In order to help a ship's sailing, that she should be lively and easy in her pitching and ascending motions, it should be contrived by the stowage, that the principal and weightiest part of the cargo or materials should lie as near the main body of the ship, and as far from the extreme ends, fore and aft, as things will admit of. For it should be considered, that the roomy part of our ships lengthwise forms as a ship or court near four times as long as they are broad; therefore those roomy parts at and above the water's edge, which are made by a full harping and a broad transom to support the ship steady and keep her from plunging into the sea, and also by the entrance and run of the ship having little or no bearing body under for the pressure of the water to support them, of course should not be stowed with heavy goods or materials, but all the necessary vacancies, broken stowage, or light goods, should be at these extreme ends fore and aft; and in proportion as they are kept lighter by the stowage, the ship will be more lively to fall and rise easy in great seas; and this will contribute greatly to her working and sailing, and to prevent her from straining and hogging; for which reason it is a wrong practice to leave such a large vacancy in the main hatchway, as is usual, to coil and work the cables, which ought to be in the fore or after hatchway, that the principal weight may be more easily stowed in the main body of the ship, above the flattest and lowest floorings, where the pressure of the water acts the more to support it.

Improved Capstan of Ships.—A capstan has been contrived by Mr Boswell, which works without requiring the messenger or cable coiled around it, to be ever surged; an operation which is necessary with common capstans, and is always attended with delay, and frequently with danger. This capstan has been approved by some gentlemen connected with the British navy. A model of this machine was presented to the Society for the Encouragement of Arts, and Mr Boswell received the gold medal of the society for his invention.

For the information of those unacquainted with maritime affairs, Mr Boswell gives an account of the manner in which cables are hauled on board of large ships. For the purpose of shewing the advantage of his improved capstan, cables, he observes, above a certain diameter are too inflexible to admit of being coiled round a capstan; in ships where cables of such large dimensions are necessary, a smaller cable is employed for this purpose, which is called the messenger, the two ends of which are made fast together so as to form an endless rope, which, as the capstan is turned about, rolls round it in unceasing succession, passing on its course to the head of the ship, and again returning to the capstan. To this returning part of the messenger, the great cable is made fast by a number of small ropes called nippers, placed at regular intervals; these nippers are applied, as the cable enters the bawse hole, and are again removed as it approaches the capstan, after which it is lowered into the cable tier.

The messenger, or any other rope coiled round the capstan, must descend a space at every revolution equal to the diameter of the rope or cable used; this circum-
stance brings the coils in a few turns to the bottom of the capstan, when it can no longer be turned round, till the coils are loosened and raised up to its other extremity, after which the motion proceeds as before. This operation of shifting the place of the coils of the messenger on the capstan is called surging the messenger. It always causes considerable delay; and when the messenger chances to slip in changing its position, which sometimes happens, no small danger is incurred by those who are employed about the capstan.

One method of preventing the necessity of surging, by placing a horizontal roller beneath the messenger when it first enters on the capstan, adds considerably to the labour in turning the capstan, and the great friction which the messenger must suffer, must occasion a very great wear and injury to the messenger.

Another method to prevent surging was, that for which Mr. Plucknett obtained a patent. In this way a number of upright rollers, placed round the capstan, were made to rise in succession as the capstan turned round by a circular inclined plane placed beneath them; a method Mr. Bowell thinks superior to the former; but still the wear of the messenger from the lateral friction in rising against the whelps of the capstan remains undiminished.

A third method proposed by Captain Hamilton, left the lateral friction, and wear of the messenger against the whelps of the capstan, as great as in the others, having also the inconvenience of causing the coils to become loose as they ascend, the upper part of the barrel being nearly one third less in the diameter than the lower part.

In Mr. Bowell's method of preventing the necessity of surging, none of the lateral friction of the messenger or cable against the whelps of the capstan, can possibly take place, and of course the wear of the messenger occasioned thereby will be entirely avoided, while it performs its purpose with a less moving power than any of them.

His method consists in the simple addition of a second smaller barrel or capstan of less dimensions to the large one; beside which it is to be placed in a similar manner, and which need not in general exceed the size of a half barrel cask. The coils of the messenger are to be passed alternately round the large capstan and this small barrel, but with their direction reversed in the different barrels, so that they may cross each other in the intervals between the barrels, in order to have the more extensive contact with, and better grip on each barrel.

To keep the coils distinct, and prevent their touching each other in passing from one barrel to the other, projecting rings are fastened round each barrel at a distance from each other equal to about two diameters of the messenger, and the thickness of the ring. Those rings should be so fixed on the two barrels that those on one barrel should be exactly opposite the middle of the intervals between those on the other barrel; the only circumstance which requires particular attention in the construction of this capstan. The rings should project about as much as the messenger from the barrels, which may be formed with whelps, and in every other respect, not before mentioned, in the usual manner for capstan barrels. The small barrel should be furnished with falling palls as well as the large one; a fixed iron spindle ascending from the deck will be the best for it, as it will take up less room. The spindle may be secured below the deck, so as to bear any strain, as the small barrel need not be much above half the height of the large barrel; the capstan bars can easily pass over it in heaving round, when it is thought fit to use capstan bars on the same dock with the small barrel. As two turns of the messenger round both barrels will be at least equivalent to three turns round the common capstan, it will scarcely ever be necessary to use more than four turns round the two barrels.

A method which prevents the lateral friction of the messenger in Mr. Bowell's double capstan is, that in each coil is kept distinct from the rest, and must pass on to the second barrel before it can gain the next elevation on the first, by which no one coil can have any influence in raising or depressing another; and what each separate coil descends in a single revolution it regains as much as is necessary in its passage between the barrels when in the air, and free from all contact with any part of the apparatus, it attains a higher elevation without a possibility of friction or wear.

It is equally applicable in large and in smaller vessels, in the former of which messengers are necessary, from the size of the cables; but in the latter also, where cables can be managed with the same ease as messengers. The same principle may be also easily applied to windlasses, by having a small horizontal barrel placed parallel to the body of the windlass, and having both fitted with rings in the same way as is proposed for the capstan. The place for the small horizontal barrel is forward, just before the windlass, and it should also be furnished with catch polls.

Besides the advantages now stated, the improved capstan is simple in its construction, can be fitted up at small expense, is easily repaired, and requires but little room.

A represents the common capstan; B, another of smaller dimensions; C, the coils of the messenger passing alternately round the large and small capstans, but with the direction reversed on the different barrels, so that they may cross each other in the intervals between them; DDDD, are projecting rings round each barrel, so fixed on the two barrels, that those on one barrel should be exactly opposite the middle of the intervals between those on the other barrel.

Machine for measuring a Ship's Way.—We have already described a variety of machines or instruments which have been proposed for this purpose under the article Log. In this place, therefore, we shall confine ourselves to the machine invented by Francis Hopkins, Esq. Judge of the Admiralty in Pennsylvania.—American Philosophical Society, afterwards shown to which the common log, and also that particular kind of instrument invented by M. Samares, are liable, he proceeds to describe his own machine as follows:

This machine, in its most simple form, is represented by fig. 5, wherein AB is a strong rod of iron moveable on the fulcrum C. D is a thin circular plate of brass rivetted to the lower extremity of the rod. E a horizontal arm connected at one end with the top of the rod AB by a moveable joint F, and at the other end with the bottom of the index H, by a like moveable joint G. H is the index turning on its centre I, and travelling over the graduated arch K; and L is a strong spring, bearing against the rod AB, and constantly counteracting the pressure upon the palate D.
The rod AB should be applied close to the cut-water or stem, and should be of such a length that the palate D may be no higher above the keel than is necessary to secure it from injury when the vessel is aground, or sails in shoal water. As the bow of the ship curves inward towards the keel M, the palate D will be thrown to a distance from the bottom of the vessel, although the perpendicular rod to which it is annexed lies close to the bow above; and therefore the palate will be more fairly acted upon. The arm E should enter the bow somewhere near the breast hole, and lead to any convenient place in the forecastle, where a smooth board or plate may be fixed, having the index H, and graduated arch K, upon it.

It is evident from the figure, that as the ship is urged forward by the wind, the palate D will be pressed upon by the resisting medium, with a greater or less force, according to the progressive motion of the ship; and this will operate upon the levers so as to immediately affect the index, making the least increase or diminution of the ship's way visible on the graduated arch; the spring L always counteracting the pressure upon the palate, and bringing back the index, on any relaxation of the force impressed.

This machine is advantageously placed at the bow of the ship, where the current first begins, and acts fairly upon the palate, in preference to the stern, where the tumultuous closing of the water causes a wake, visible to a great distance. The palate D is sunk nearly as low as the keel, that it may not be influenced by the heaping up of the water, and the dashing of the waves at and near the water line. The arch K is to ascertain how many knots or miles she would run in one hour at her then rate of sailing. But the graduations on this arch must be unequal; because the resistance of the spring L will increase as it becomes more bent, so that the index will travel over a greater space from one to five miles than from five to twelve. Lastly, the palate, rod, spring, and all the metallic parts of the instrument, should be covered with a strong varnish, to prevent rust from the corrosive quality of the salt water and sea-air.

This machine may be considerably improved as follows: Let the rod or spear AB (fig. 5) be a round rod of iron or steel, and instead of moving on the fulcrum or joint, as at C, let it pass through and turn freely in a socket, to which socket the moveable joint must be annexed, as represented in fig. 6. The rod must have a shoulder to bear on the upper edge of the socket, to prevent its slipping quite down. The rod must also pass through a like socket at F, fig. 5. The joint of the lower socket must be fixed to the bow of the ship, and the upper joint or socket must be connected with the horizontal arm E. On the top of the uppermost socket let there be a small circular plate, bearing the 32 points of the mariner's compass; and let the top of the rod AB come through the centre of this plate, so as to carry a small index upon it, as is represented in fig. 7. This small index must be fixed to the top of the rod on a square, so that by turning the index round the plate, the rod may also turn in the sockets, and of course carry the palate D round with it; the little index always pointing in a direction with the face of the palate. The small compass plate should not be fastened to the top of the socket, but only fitted slightly on, that it may be moveable at pleasure. Suppose then the intended port to bear S. W. from the place of departure, the palate must be turned on the socket till the south-west point therein looks directly to the ship's bow; so that the south-west and north-east line on the compass plate may be precisely parallel with the ship's keel, and in this position the plate must remain during the whole voyage. Suppose, then, the ship to be sailing in the direct course of her intended voyage, with her bowsprit pointing south-west. Let the little index be brought to the south-west point on the compass plate, and the palate D will necessarily present its broad face towards the north of destination; and this it must always be made to do, be the ship's course what it may. If, on account of unfavourable winds, the ship is obliged to deviate from her intended course, the little index must be moved so many points from the south-west line of the compass plate as the compass in the binnacle shall show that she deviates from her true course; so that in whatever direction the ship shall sail, the palate D will always look full to the south-west point of the horizon, or towards the port of destination, and consequently will present only an oblique surface to the resisting medium, more or less oblique as the ship deviates more or less from the true course of her voyage.

As, therefore, the resistance of the water will operate less upon the palate in an oblique than in a direct position, in exact proportion to its obliquity, the index H will not show how many knots the vessel runs in her then course, but will indicate how many she gains in the direct line of her intended voyage. Thus, in fig. 9, if the ship's course lies in the direction of the line AB, but she can sail by the wind no nearer than AC; suppose, then, her progressive motion such as to perform AC equal to five knots or miles in an hour, yet the index H will only point to four knots on the graduated arch, because she gains no more than at that rate on the true line of her voyage, viz. from A to B. Thus will the difference between her real motion and that pointed out by the index be always in proportion to her deviation from her intended port, until she sails in a line at right angles therewith, as AD; in which case the palate would present only a thin sharp edge to the resisting medium, the pressure of which should not be sufficient to overcome the friction of the machine and the bearing of the spring L. So that at whatever rate the ship may sail on that line, yet the index will not be affected, showing that she gains nothing on her true course. In this case, and also when the vessel is not under way, the action of the spring L should cause the index to point at O, as represented by the dotted lines in figs. 5 and 8.

As the truth of this instrument must depend on the equal pressure of the resisting medium upon the palate D, according to the ship's velocity, and the proportionable action of the spring L, there should be a pin or screw at the joints C and F, so that the rod may be readily unshipped and taken in, in order to clean the palate from any fouling it may contract, which would greatly increase its operation on the index H, and thereby render the graduated arch false and uncertain.

Further, the spring L may be exposed too much to injury from the salt water, if fixed on the outside of the ship's bow. To remedy this, it may be brought under cover, by constructing the machine as represented by fig. 8, where AB is the rod, C the fulcrum or centre.
of its motion, D the palate, E the horizontal arm leading through a small hole into the forecastle; M is a strong chain fastened at one end to the arm E, and at the other to a rim or barrel on the wheel G, which by means of its teeth gives motion to the semicircle I and index H. The spring L is spiral, and enclosed in a box or barrel, like the main-spring of a watch. A small chain is fixed to, and passing round the barrel, is fastened by the other end to the fusee W. This fusee is connected by its teeth with the wheel G, and countersets the motion of the palate D. N, N, are the two buckets through which the rod AB passes, and in which it is turned round by means of the little index R. S is the small compass plate, moveable on the top of the upper socket N. The plate S hath an upright rim round its edge, cut into teeth or notches, so that when the index R is a little raised up, in order to bring it round to any intended point, it may fall into one of these notches, and be detained there; otherwise the pressure of the water will force the palate D from its oblique position, and turn the rod and index round to the direction in which the ship shall be then sailing.—Should it be apprehended that the palate D, being placed so far forward, may affect the ship's steerage, or obstruct her rate of sailing, it should be considered that a very small plate will be sufficient to work the machine, as one or three or four inches in diameter would probably be sufficient, and yet not large enough to have any sensible effect on the helm or ship's way.

The greatest difficulty, perhaps, will be in graduating the arch K, (if the machine is constructed as in fig. 5); the unequal divisions of which can only be ascertained by actual experiment on board of each ship respectively, inasmuch as the accuracy of these graduations will depend on three circumstances, viz. the position of the fulcrum C with respect to the length of the rod, the size of the palate D, and the strength or bearing of the spring L. When these graduations however, are once ascertained for the machine on board of any one vessel, they will not want any future alterations, provided the palate D be kept clean, and the spring L retains its elasticity.

But the unequal divisions of the graduated arch will be unnecessary, if the machine is constructed as in fig. 8; for as the chain goes round the barrel L, and then winds through the spiral channel of the fusee W, the force of the main spring must operate equally, or nearly so, in all positions of the index, and consequently the divisions of the arch K may in each case be equal.

After all, it is not expected that a ship's longitude can be determined to a mathematical certainty by this instrument. The irregular motions and impulses to which a ship is continually exposed, make such an accuracy unattainable perhaps by any machinery; But if it should be found, as we flatter ourselves it will on fair experiment, that it answers the purpose much better than the common log, it may be considered as an acquisition to the art of navigation.

It should be observed, that in ascertaining a ship's longitude by a time-piece, this great inconvenience occurs, that a small and trifling mistake in the time makes a very great and dangerous error in the distance run. Whereas the errors of this machine will operate no farther than their real amount; which can never be great

VOL. XIX. PART L.
four lines in diameter, and his success was equally flattering as before. These experiments were repeated by order of government at La Fère, four times with an eight-inch mortar, and three times with one of twelve inches, all of which happily succeeded. The same author goes on to observe;

"It ought to be remembered, that a vessel is never cast away, or perishes on the coast, but because it is driven thither against the will of the captain, and by the violence of the waves and the wind, which almost always blows from the sea towards the shore, without which there would be no danger to be apprehended: consequently in these circumstances, the wind comes always from the sea, either directly or obliquely, and blows towards the shore.

"1st. A common paper kite, therefore, launched from the vessel and driven by the wind to the shore, would be sufficient to save a crew of 1500 seamen, if such were the number of a ship of war. This kite would convey to the shore a strong packthread, to the end of which might be affixed a cord, to be drawn on board by means of the string of the kite; and with this cord a rope, or as many as should be necessary, might be conveyed to the ship.

"2d. A small balloon, of six or seven feet in diameter, and raised by rarefied air, would also be an excellent means for the like purpose. Being driven by the wind from the vessel to the shore, it would carry thither a string capable of drawing a cord with which several ropes might be afterwards conveyed to the vessel. Had not the discovery of Montgolfier produced any other benefit, it would be entitled on this account to be considered as of great importance.

"3dly. A sky-rocket, of a large diameter, would be of equal service. It would also carry, from the vessel to the shore a string capable of drawing a rope after it.

"Lastly. A fourth plan for saving the crew of a shipwrecked vessel, is that of throwing from the vessel into the sea an empty cask with a cord attached to it. The wind and the waves would drive the cask to the shore, and afford the means of establishing that rope of communication already mentioned."

The author just quoted says, that he announced his discovery in a French journal in January 1794. It is, however, to be observed, that the method he proposes of conveying a rope to the shore, by fastening it to a bullet or bomb, to be afterwards fired from a cannon or mortar, was proposed some years ago by a seargent or officer of artillery at Woolwich, and it is said, similar experiments were made at Portsmouth and succeeded. *

SHIRAUX, See SHIRAS.

SHIRE, is a Saxen word signifying a division; but a county, comitatus, of the same import, is plainly derived from comes, "the count of the Franks;" that is, the earl or alderman (as the Saxons called him) of the shire, to whom the government of it was entrusted. This he usually exercised by his deputy, still called in Latin vicomites, and in English the sheriff, shrieve, or shire-reeve, signifying the "officer of the shire;" upon whom, in process of time, the civil administration of it totally devolved. In some counties there is an intermediate division between the shire and the hundred; as lathes in Kent and rapes in Sussex, each of them containing about three or four hundred a-piece. These had formerly their lath-reeves and rape-reeves, acting in subordinate
then washing it in an instrument, prepared for that purpose, and called a warming shoe, they find the earthy matter washed away, and of the remainder, the stony or gravelly matter lies behind, and the metallic matter at the point of the shoe. If the person who performs this operation has any judgment, he easily discovers not only what the metal is that is contained in the shoe, but also will make a very probable guess at what quantity the mine is likely to yield of it in proportion to the ore.

SHOAL, in the sea language, denotes a place where the water is shallow; and likewise a great quantity of fishes, such as a shoal of herring.

SHOCK, in Electricity. The effect of the explosion of a charged body, that is, the discharge of its electricity on any other body, is called the electric shock.

SHOE, a covering for the foot, usually of leather.

Shoes, among the Jews, were made of leather, linen, rush, or wood; those of soldiers were sometimes of brass or iron. They were tied with thongs which passed under the soles of the feet. To put on their shoes was an act of veneration; it was also a sign of mourning and humiliation: to bear one’s shoes, or to untie the latches of them, was considered as the meanest service.

Among the Greeks shoes of various kinds were used. Sandals were worn by women of distinction. The Lacedemonians wore red shoes. The Grecian shoes generally reached to the middle of the leg. The Romans used two kinds of shoes; the calceus, which covered the whole foot somewhat like our shoes, and was tied above with latches or strings; and the solea or slipper, which covered only the sole of the foot, and was fastened with leather thongs. The calceus was always worn along with the toga when a person went abroad: slippers were put on during a journey and at feasts, but it was reckoned effeminate to appear in public with them. Black shoes were worn by the citizens of ordinary rank, and white ones by the women. Red shoes were sometimes worn by the ladies, and purple ones by the concubines of the other sex. Red shoes were put on by the chief magistrates of Rome on days of ceremony and triumphs. The shoes of senators, patricians, and their children, had a crescent upon them which served for a buckle; these were called calcei lunati. Slaves wore no shoes; hence they were called cretats from their dusty feet. Phocion also and Cato Uticensis went without shoes. The toes of the Roman shoes were turned up in the point; hence they were called calcei rostrati, repandi, &c.

In the 9th and 10th centuries the greatest princes of Europe wore wooden shoes, or the upper part of leather and the sole of wood. In the reign of William Rufus, a great beat, Robert, surnamed the horned, used shoes with long sharp points, stuffed with tow, and twisted like a ram’s horn. It is said, the clergy, being highly offended, declaimed against the long-pointed shoes with great vehemence. The points, however, continued to increase till, in the reign of Richard II. they were of so enormous a length that they were tied to the knees with chains, sometimes of gold, sometimes of silver. The upper parts of the shoes in Chaucer’s time were cut out in imitation of the church mitre. The long-pointed shoes were called crackouses, and continued in fashion for three centuries in spite of the bulls of popes, the decrees of councils, and the declamations of the clergy. At length the parliament of England interposed by an act A. D. 1463, prohibiting the use of shoes or boots with pikes exceeding two inches in length, and prohibiting all shoemakers from making shoes or boots with longer pikes under severe penalties. But even this was not sufficient: it was necessary to denounce the dreadful sentence of excommunication against all who wore shoes or boots with points longer than two inches. The present fashion of shoes was introduced in 1633, but the buckle was not used till 1670.

In Norway they use shoes of a particular construction, consisting of two pieces, and without heels; in which the upper leather sits close to the foot, the sole being joined to it by many plaits or folds.

The shoes or slippers of the Japanese, as we are informed by Professor Thanberg, are made of rice-straw woven, but sometimes for people of distinction of fine slips of rattan. The shoe consists of a sole, without upper leather or hind-piece; forwards it is crossed by a strap, of the thickness of one’s finger, which is lined with linen; from the tip of the shoe to the strap a cylindrical string is carried, which passes between the great and second toe, and keeps the shoe fast on the foot. As these shoes have no hind-piece, they make a noise when people walk in them like slippers. When the Japanese travel, their shoes are furnished with three strings made of twisted straw, with which they are tied to the legs and feet, to prevent them from falling off. Some people carry one or more pairs of shoes with them on their journeys, in order to put on new, when the old ones are worn out. When it rains, or the roads are very dirty, these shoes are soon wetted through, and one continually sees a great number of worn-out shoes lying on the roads, especially near the brooks, where travelers have changed their shoes after washing their feet. Instead of these, in rainy or dirty weather they wear high wooden clogs, which underneath are hollowed out in the middle, and at top have a band across like a stirrup, and a string for the great toe; so that they can walk without soiling their feet. Some of them have their straw shoes fastened to these wooden clogs. The Japanese never enter their houses with their shoes on; but leave them in the entry, or place them on the bench near the door, and thus are always barefooted in their houses, so as not to dirty their neat mats. During the time that the Dutch live at Japan, when they are sometimes under an obligation of paying visits at the houses of the Japanese, their own rooms at the factory being likewise covered with mats of this kind, they wear, instead of the usual shoes, red, green, or black slippers, which, on entering the house, they pull off: however, they have stockings on, and shoes made of cotton stuff with buckles in them, which shoes are made at Japan, and can be washed whenever they are dirty. Some have them of black satin, in order to avoid washing them.

Shoe of an Anchor, a small block of wood, convex on the back, and having a small hole, sufficient to contain the point of the anchor fluke, on the foreside. It is used to prevent the anchor from tearing or wounding the planks on the ship’s bow, when ascending or descending for which purpose the shoe is fixed on and down along the bow between the fluke of the anchor and the planks, as being pressed close to the latter by the weight of the former.

To Shoe an Anchor, is to cover the flukes with a broad
SHOE [ 316 ]

SHOEMAKERS' MACHINE for working at in a standing posture. A machine for this purpose was invented by Mr. Thomas Parker, who on the 22d of November, 1834, attended a committee appointed by the Society of Arts, and informed them that he had made use of this apparatus for twelve months, and found it very useful. He observed that all the work of shoe-making may be done with it standing; but that in some parts thereof he found an advantage in using along with it a high stool; and that prior to the use of this machine, he never saw or heard of a similar invention; and that he found it of great service to his health.

He estimated the cost of such a machine at two guineas.

Plate CCCXCVI. fig. 1. T, a bench standing on four legs, about four feet from the ground.

V. A circular cushion affixed to the bench, in the centre of which cushion is an open space quite through the bench, through which hole a leather strap U is brought up from below. This strap holds the work and last firm upon the cushion in any position required, by means of the workman's foot placed upon the treadle W.

X. Shews the last upon the cushion, with the strap holding it firm.

Y. An implement used in closing boots.

Z. A small flat leather cushion, useful in adjusting the last and strap.

L. The shoe last shewn separate from the cushion. The round cushion is formed of a circular piece of wood, covered with leather or stuffed with wool or hair to give it some elasticity.

Another machine for the same purpose has been invented by Mr. Holden of Fletworth in Sussex, and the following account of it was presented to the Society of Arts. He observes that the sitting posture had so greatly injured his health, as to render it necessary to give up his business, and in this difficulty he invented the machine which he found to answer the purpose fully, as it enabled him to resume his work with the recovery of his health. He recommends it as the quickest way of closing all the thread work, and he adds, that he has made 1800 or 2000 pairs of shoes with the machine, and still continues to employ it. The following is a description of the machinery.

Fig. 2. A, the bed for the closing block, and to lay the shoe in, whilst sewing.

B. The closing block.

C. A loose bed to lay the shoe in whilst stitching; the lower part of which is here exhibited reversed, to shew how it is placed in the other bed A.

D. The hollow or upper part of the loose bed C, in which the shoe is laid whilst stitching.

E. A table on which the tools wanted are to be laid.

F. An iron semicircle, fixed to each end of the bed A, to allow the bed to be raised or depressed. This half circle moves in the block G.

H. Another iron semicircle, with notches, which catch upon a tooth in the centre of the block, to hold the bed in any angle required. This semicircle moves sideways on two blocks in staples at each end of the bed.

I. The tail or stem of the bed A, moving in a cylin-

drical hole in the pillar, enabling the bed to be turned in any required direction, and which, with the movement F, enables the operator to place the shoe in any position necessary.

K. The pillar, formed like the pillar of a claw-table, excepting the two side legs being in a direct line, and the other leg at a right angle with them.

L. The semicircle H, shewn separately, to explain how it is connected with the staples, and how the notches are formed.

M. The tail or stem of the bed A, and the lower part of the bed N, shewn separately, to explain how the upper part of the bed is raised or depressed occasionally.

Horse-Shoe. See Farriery, No. 191.

SHOOTING, in the military art. See ARTILLERY, GUNNERY, and Projectiles.

SHOOTING, in sportmanship, the killing of game by shooting in the gun, with or without the help of dogs.

Under this article we shall lay down all the rules which are necessary to be observed in order to render one accomplished and successful in the art of shooting.

The first thing which the sportsman ought to attend to is the choice of his fowling-piece. Convenience requires that the barrel be as light as possible, at the same time it ought to possess that degree of strength which will make it not liable to burst. Experience has proved, that a thin and light barrel, which is of equal thickness in every part of its circumference, is much less liable to burst than one which is considerably thicker and heavier, but which, from being badly filed or bored, is of unequal strength in different places.

It is also of importance to determine what length the barrel ought to be, in order to acquire that range which the sportsman has occasion for. On this subject we have received the following information from an experienced sportsman. We have, at different times, compared barrels of all the intermediate lengths between 28 and 40 inches, and of nearly the same caliber, that is to say, from 32 to 26; and these trials were made both by firing the pieces from the shoulder, and from a firm block, at an equal distance, and with equal weights of the same powder and of the same shot.

To avoid every possibility of error, the quires of paper at which we fired were fixed against planks instead of being placed against the wall. From these trials frequently repeated, we found that the shot pierced an equal number of sheets, whether it was fired from a barrel of 28, 30, 32, 34, 36, 38, or 40, inches in length. Nay more, we have compared two barrels of the same caliber, but one of them 33, and the other 66 inches long, by repeatedly firing them in the same manner as the others, at different distances from 45 to 100 paces, and the results have always been the same, i.e. the barrel of 33 inches drove its shot through as many sheets of paper as that of 66 did. The conclusion from all this is, that the difference of 10 inches in the length of the barrel, which seems to be most in the length of steel upon among sportsmen, produces no sensible difference in the range of the piece; and therefore, that every one may please himself in the length of his barrel, without either detriment or advantage to the range.

It may appear as an objection to this, that a duck-gun which is five or six feet long kills at a greater distance than.
than a fowling-piece; but this is not owing to its length, but to its greater weight and thickness, which give it such additional strength, that the shot may be increased, and the charge of powder doubled, trebled, and even quadrupled. But a barrel of five or six feet length would be very inconvenient for fowling. Those who consult the appearance of the piece, lightness, and the ease with which it is managed, will find that a barrel from 32 to 38 inches will answer best.

The next thing to be considered is, of what dimensions the caliber or bore of a fowling-piece ought to be. This matter has been subjected to experiment, and it has been found, that a barrel of 22 or 24, which is the largest caliber usually employed in fowling-pieces, throws its shot as closely as one of the smallest caliber, viz. of 30 or 32 (A).

As to the length and form of the stock, it may be laid down as a principle, that a long stock is preferable to a short one, and at the same time rather more bent than usual; for a long stock sits firmer to the shoulder than a short one, and particularly so when the shooter is accustomed to place his left hand, which principally supports the piece, near to the entrance of the ramrod into the stock.

It is certain, however, that the stock may be so formed as to be better suited to one man than another. For a tall, long-armed man, the stock of a gun should be longer than for one of a less stature and shorter arm. That a straight stock is proper for him who has high shoulders and a short neck; for, if it be much bent, it would be very difficult for him, especially in the quick motion required in shooting at a flying or running object, to place the butt of the gun-stock firmly to the shoulder, the upper part alone would in general be fixed; which would not only raise the muzzle, and consequently shoot high, but make the recoil much more sensibly felt, than if the whole end of the stock were firmly placed on his shoulder. Besides, supposing the shooter to bring the butt home to his shoulder, he would scarcely be able to level his piece at the object. On the contrary, a man with low shoulders, and a long neck, requires a stock much bent; for if it is straight, he will, in the act of lowering his head to that place of the stock at which his cheek should rest in taking aim, feel a constraint which he never experiences, when by the effect of the proper degree of bent, the stock lends him some assistance, and as it were, meets his aim half way.

Having now described the fowling-piece which has been found to answer best, it will next be proper to give some instructions for the choice of gunpowder, shot, and wadding.

The various kinds of gunpowders are well known; but, in the opinion of some experienced sportsmen, Harvey’s battle-powder is the best. Those who wish to examine the strength of powder, may determine it by drying some of it very well, and then trying how many sheets of paper it will drive the shot through, at the distance of 10 or 15 yards. In this trial we should be careful to employ the same sized shot in each experiment, the quantity both of the shot and the powder being regulated by exact weight; otherwise we cannot, even in this experiment, arrive at any certainty in comparing the strength of different powders, or of the same powder at different times.

Powder ought to be kept very dry, for every degree to be kept of moisture injures it; and if considerable, the saltpetre is dissolved, and the intimate combination of the several ingredients is entirely destroyed. It is observed, that after firing with damp powder the piece becomes very foul, which seems to arise from the diminution of the activity of the fire in the explosion. Flasks of copper or tin are much better for keeping powder in than those made of leather, or than small casks. Their necks ought to be small and well stopped with cork.

The patent milled shot is now very generally used, size of and is reckoned superior to any other. The size of the shot must vary according to the particular species of game which is the object of the sportsman’s pursuit, as well as be adapted to the season. In the first month of partridge shooting, No. 1. is most proper; for since at this time the birds spring near at hand, and we seldom fire at more than the distance of 40 paces, if the shooter takes his aim but tolerably well, it is almost impossible for a bird at this distance to escape in the circle which the shot forms.

As hares sit closer, and are thinly covered with fur at this season, they may easily be killed with this shot at 30 or 35 paces. No. 5. is equally proper for shooting snipes or quails. About the beginning of October, when the partridges are stronger, No. 3. is the most proper shot to be used. Many sportsmen use no other during the whole season. The directions which have now been given refer only to the patent shot.

We shall now subjoin a table, which will shew at one view the number of pellets composing an ounce weight of each sort of shot, the patent and the common, beginning with the smallest size.

For a fowling-piece of a common caliber, which is Properties from 24 to 30 balls to the pound weight, a dram and a of powder and shot in quarter the charge.

(A) In speaking of the size of the caliber, we mean by 22 or 24, that so many balls exactly fitting it weigh just one pound; and every caliber is marked in the same way.

(b) The reader will observe that the patent shot has no No. 6, the (b) being substituted in its place, and that the numbers do not follow each other in the order of progression: the reason of this we cannot assign.
Shooting.

Quarter, or at most a dram and a half, of good powder; and an ounce, or an ounce and a quarter of shot, is sufficient. But when shot of a larger size is used, such as No. 5, the charge of shot may be increased one-fourth, for the purpose of counteringbalancing in some degree what the size of the shot loses in the number of pellets, and also to enable it to garnish the more. For this purpose the sportsman will find a measure marked with the proper gauges very convenient to him. An instrument of this nature has been made by an ingenious artist of London, Egg of the Haymarket.

A consequence of overloading with shot, is the powder has not sufficient strength to throw it to its proper distance; for if the object fired at is distant, one-half of the pellets composing the charge, by their too great quantity and weight, will strike against each other, and fall by the way; and those which reach the mark will have small force, and will produce but little or no effect.

The use of the wadding is to carry the shot in a body to a certain distance from the muzzle of the piece. It ought to be of soft and pliable materials. The best kind of wadding, in the opinion of an experienced fowler, is a piece of an old hat; but this cannot be obtained in sufficient quantity. Next to it nothing is better than soft brown paper, which combines suppleness with consistence, moulds itself to the barrel, and never fails to the ground within 12 or 15 paces from the muzzle of the piece. Tow answers very well, and cork has been extolled for possessing the peculiar virtue of increasing the range and closeness of the shot.

The wadding ought to be quite close in the barrel, but not rammed too hard; for if it be rammed too close, or be of a rigid substance, the piece will recoil, and the shot will spread too much. On the other hand, if the wadding be very loose, or is composed of too soft materials, such as wool or cotton, the discharge will not possess proper force.

In loading a piece, the powder ought to be slightly rammed down by only pressing the ramrod two or three times on the wadding, and not by drawing up the ramrod and then returning it into the barrel with a jerk of the arm several times. For when the powder is violently compressed, some of the grains must be bruised, which will prevent the explosion from being quick, and will spread the shot too wide. In pouring the powder into the barrel, the measure ought to be held so as that the powder may fall most readily to the bottom. That no grains may adhere to the sides of the barrel, the butt-end of the piece may be struck against the ground. The shot ought never to be rammed down with force: it is sufficient to strike the butt-end of the gun against the ground as before. Then the wadding is to be put down gently. A sportsman ought never to carry his gun under his arm with the muzzle inclined downwards, for this practice loosens the wadding and charge too much.

Immediately after the piece is fired it ought to be reloaded; for while the barrel is still warm, there is no danger of any moisture lodging in it to hinder the powder from falling to the bottom. As it is found that the coldness of the barrel, and perhaps the moisture condensed in it, diminishes the force of the powder in the first shot; it is proper to fire off a little powder before the piece is loaded. Some prime before loading, but this is not proper unless the touch-hole be very large. After every discharge the touch-hole ought to be picked, or a small feather may be inserted to clear away any humidity or foulness, that has been contracted.

The sportsman having loaded his piece, must next prepare to fire. For this purpose he ought to place his hand near the entrance of the ramrod, and at the same time grasps the barrel firmly. The muzzle should be a little elevated, for it is more usual to shoot low than high. This direction ought particularly to be attended to when the object is a little distant; because shot as well as ball only moves a certain distance point blank, when it begins to describe the curve of the parabola.

Practice soon teaches the sportsman the proper distance at which he should shoot. The distance at which he ought infallibly to kill any kind of game with patent shot, No. 3, provided the aim be well taken, is from 25 to 35 paces for the footed, and from 40 to 45 paces for the winged, game. Beyond this distance even to 30 or 55 paces, both partridges and hares are sometimes killed; but in general the hares are only slightly wounded, and carry away the shot; and the partridges at this distance present so small a surface, that they frequently escape untouched between the spaces of the circle. Yet it does not follow that a partridge may not be killed with No. 3, patent shot at 60 and even 70 paces distance, but then these shots are very rare.

In shooting at a bird flying, or a hare running across, it is necessary to take aim before the object in proportion to its distance at the time of firing. If a partridge flies across at the distance of 30 or 35 paces, it will be sufficient to aim at the head, or at most, a small space before it. If it be 50, 60, or 70 paces distant, it is then requisite to aim at least half a foot before the head. The same practice ought to be observed in shooting at a hare, rabbit, or fox, when running in a cross direction; at the same time making due allowance for the distance and swiftness of the pace. Another thing to be attended to is, that the shooter ought not involuntarily to stop the motion of the arms at the moment of pulling the trigger; for the instant the hand stops in order to fire, however inconsiderable the time be, the bird gets beyond the line of aim, and the shot will miss it. A sportsman ought therefore to accustom his hand while he is taking aim to follow the object. When a hare runs in a straight line from the shooter, he should take his aim between the ears, otherwise he will run the hazard either of missing, or at least not of killing dead, or as it is sometimes called clean.

A bowling-piece should not be fired more than 20 or 25 times without being washed; a barrel when foul neither shoots so ready, nor carries the shot so far as when it is kept clean. The flint, pan, and hammer, should be well clean and wiped after each shot; this contributes greatly to make the piece go off quick; but then it should be done with such expedition, that the barrel may be reloaded whilst warm, for the reasons we have before advanced. The flint should be frequently changed, without waiting until it misses fire before a new one is put in. Fifteen or eighteen shots, therefore, should only be fired with the same flint; the expence is too trifling to be regarded, and by changing it thus often much vexation will be prevented.
A gun also should never be fired with the prime of the preceding day; it may happen that an old priming will sometimes go off well, but it will more frequently contract moisture and fuse in the firing; then the object will most probably be missed, and that because the piece was not fresh primed.

For the information of the young sportsman we shall add a few more general directions. In warm weather he ought to seek for game in plains and open grounds, and in cold weather he may search little hills exposed to the sun, along hedges, among heath, in stubbles, and in pastures where there is much fence and fern. This morning is the best time of the day, before the dew is exhaled, and before the game has been disturbed. The colour of the shooters dress ought to be the same with that of the fields and trees; in summer it ought to be green, in winter a dark gray. He ought to hunt as much as possible with the wind, not only to prevent the game from perceiving the approach of him and his dog, but also to enable the dog to scent the game at a greater distance.

He should never be discouraged from hunting and ranging the same ground over and over again, especially in places covered with heath, brambles, high grass, or young coppice wood. A hare or rabbit will frequently suffer him to pass several times within a few yards of its form without getting up. He should be still more patient when he has marked partridges into such places, for it often happens, that after the birds have been sprung many times, they lie so dead that they will suffer him almost to tread upon them before they will rise. Pheasants, quails, and woodcocks, do the same.

He ought to look carefully about him, never passing a bush or tuft of grass without examination; but he ought never to strike them with the muzzle of his gun, for it will loosen his wadding. He who patiently beats and ranges his ground over again, without being discouraged, will always kill the greatest quantity of game; and if he is shooting in company, he will find game where others have passed without discovering any.

When he has fired he should called in his dog, that he may not have the mortification to see game rise which he cannot shoot. When he has killed a bird, instead of being anxious about picking it up, he ought to follow the rest of the covey with his eye till he see them settle.

Three species of dogs are capable of receiving the proper instruction, and of being trained. These are the smooth pointer, the spaniel, and the rough pointer. The last is a dog with long curled hair, and seems to be a mixed breed of the water-dog and the spaniel. The smooth pointer is active and lively enough in his range, but in general is proper only for an open country.

The greatest part of these dogs are afraid of water, brambles, and thickets; but the spaniel and the rough pointer are easily taught to take the water, even in cold weather, and to range the woods and rough places as well as the plain. Greater dependence may therefore be had on these two last species of dogs than on the smooth pointer.

The education of a pointer may commence when he is only five or six months old. The only lessons which he can be taught at this time are to fetch and carry any thing when desired; to come in when he runs far off, and to go behind when he returns; using, in the one case, the words here, come in, and in the other back or behind. It is also necessary at this period to accustom him to be tied up in the kennel or stable; but he ought not at first to be tied too long. He should be let loose in the morning, and fastened again in the evening. When a dog is not early accustomed to be chained, he disturbs every person in the neighbourhood by howling. It is also of importance that the person who is to train him should give him his food regularly.

When the dog has attained the age of 10 or 12 months, he may be carried into the field to be regularly trained. At first he may be allowed to follow his own inclination, and to run after every animal he sees. His indiscriminating eagerness will soon abate, and he will pursue only partridges and hares. He will soon become tired of following partridges in vain, and will content himself after having flushed them to follow them with his eyes. It will be more difficult to prevent him from following hares.

All young dogs are apt to rake; that is, to hunt with their noses close to the ground, to follow birds rather by the track than by the wind. But partridges is much better to dogs that wind them, than to those that follow them by the track. The dog that winds the scent approaches the birds by degrees and without disturbing them; but they are immediately alarmed when they see a dog tracing their footsteps. When you perceive that your dog is committing this fault, call to him in an angry tone hold up; he will then grow uneasy and agitated, going first to the one side and then to the other, until the wind brings him the scent of the birds. After finding the game four or five times in this way, he will take the wind of himself, and hunt with his nose high. If it be difficult to correct this fault, it will be necessary to put the puzzle peg upon him. This is of very simple construction, consisting only of a piece of oak or deal inch board, one foot in length, and an inch and a half in breadth, tapering a little to one end; at the broader end are two holes running longitudinally, through which the collar of the dog is put, and the whole is buckled round his neck; the piece of wood being projected beyond his nose, is then fastened with a piece of leather thong to his under jaw. By this means the peg advancing seven or eight inches beyond his snout, the dog is prevented from putting his nose to the ground and raking.

As soon as the young dog knows his game, you must bring him under complete subjection. If he is tractable, this will be easy; but if he is stubborn, it will be necessary to use the trust cord, which is a rope or cord of 20 or 25 fathoms in length fastened to his collar. If he refuses to come back when called upon, you must check him smartly with the cord, which will often bring him upon his haunches. But be sure you never call to him except when you are within reach of the cord. After repeating these several times he will not fail to come back when called; he ought then to be caressed, and a bit of bread should be given him. He ought now constantly to be tied up, and never unchained, except when you give him his food, and even then only when he has done something to deserve it.

The next step will be to throw down a piece of bread on the ground, at the same moment taking hold of
of the dog by the collar, calling out to him, "take heed, softly." After having held him in this manner for some space of time, say to him, "seize—lay hold." If he is impatient to lay hold of the piece of bread before the signal is given, correct him gently with a small whip. Repeat this lesson until he "takes heed" well, and no longer requires to be held fast to prevent him from laying hold of the bread. When he is well accustomed to this manage, turn the bread with a stick; holding it in the manner you do a fowling-piece, and having done so, cry "seize." Never suffer the dog to eat either in the house or field without having first made him take heed in this manner.

Then, in order to apply this lesson to the game, fry small pieces of bread in hot ghee, with the dung of partridge; take these in a linen bag into the fields, stubbles, ploughed grounds, and pastures, and there put the pieces in several different places, marking the spots with little cleft pickets of wood, which will be rendered more distinguishable by putting pieces of card in the sacks. This being done, cast off the dog and conduct him to these places, always hunting in the wind. After he has caught the scent of the bread, if he approaches too near, and seems eager to fall upon it, cry to him a menacing tone, "take heed!" and if he does not stop immediately, correct him with the whip. He will soon comprehend what is required of him, and will stand.

At the next lesson, take your gun charged only with powder, walk gently round the piece of bread once or twice, and fire instead of crying "seize." The next time of practising this lesson, walk round the bread four or five times, but in a greater circle than before, and continue to do this until the dog is conquered of his impatience, and will stand without moving until the signal is given him. When he keeps his point well, and stands steady in this lesson, you may carry him to the birds; if he runs in upon them, or backs when they spring up, you must correct him; and if he continue to do so, you must return to the fried bread; but this is seldom necessary.

When the dog has learned by this use of the bread to take heed, he may be carried to the fields with the trash-cord dragging on the ground. When he springs birds for the first time, if he runs after them or back, check him by calling out to him, "take heed." If he points properly, caress him; but you ought never to hunt without the cord until he point staunch.

If the dog runs after sheep, and it be difficult to cure him, couple him with a ram, and then whip the dog as long as you can follow him. His cries will at first alarm the ram; he will run with all his speed, and drag the dog along with him; but he will at length take courage, turn upon the dog, and butt him severely with his horns. When you think the dog is sufficiently chastised, unite him: he will never run at sheep again.

Having now given a few general instructions concerning the best method of training pointers, we shall subjoin a few observations respecting the most common species of game, the partridge, pheasant, grouse, woodcock, snipe, and wild duck.

Partridges pair in the spring, and lay their eggs (generally from 15 to 20) during May and part of June. The young begin to fly about the end of June, and their plumage is complete in the beginning of October. The male has a conspicuous horse shoe upon his breast, an obtuse spur on the hinder part of the leg, which distinguishes him from the female. He is also rather larger.

When a sportsman is shooting in a country where the birds are thin, and he no longer chooses to range the field for the bare chance of meeting with them, the following method will show him where to find them on another day. In the evening, from sunset to nightfall, he should post himself in a field, at the foot of a tree or bush, and there wait until the partridges begin to call or juck, which they always do at that time; not only for the purpose of drawing together when separated, but also when the birds composing the covey are not dispersed. After calling in this manner for some little space of time, the partridges will take to flight; then, if he mark the place where they alight, he may be assured they will lie there the whole night, unless disturbed. Let him return to the same post the next morning by break of day, and there watch a while; being careful to keep his dog in a string, if he is not under perfect command.

As soon as the dawn begins to peep, the partridges will begin to call, and soon afterwards will perform the same manoeuvre as on the preceding evening; that is, after having called a while, they will take their flight, and will most commonly settle at a little distance. There in a few minutes they will call again, and sometimes take a second flight, but that will be to no great distance. Then as soon as the sun is risen, and the sportsman can see to shoot, he may cast off his dog and pursue them.

The pheasant is of the size of a common dunghill pheasant, and lays its eggs generally in the woods, the number of which is 10 or 12.

Pheasants are accounted stupid birds; for when they are surprised they will frequently squat down like a rabbit, supposing themselves to be in safety so soon as their heads are concealed; and in this way they will sometimes suffer themselves to be killed with a stick. They love low and moist places, and haunt the edges of those pools which are found in woods, as well as the highest grass of marshes that are near at hand; and above all, places where there are clumps of alders.

Grouse, or moor-game, are found in Wales, in the Grous, northern counties of England, and in great abundance in Scotland. They chiefly inhabit those mountains and moors which are covered with heath, and seldom descend to the low grounds. They fly in companies of four or five brace, and love to frequent mossy places, particularly in the middle of the day or when the weather is warm. In pursuing this game, when the pointer sets, and the sportsman perceives the birds running with their heads erect, he must run after them as fast as he can, in the hope that he may get near enough to shoot when they rise upon the wing; for he may be pretty certain they will not lie well that day. As these birds are apt to grow soon putrid, they ought to be drawn carefully: the instant they are shot and stuffed with any breed, and if the feathers happen to be wetted they must be wiped dry.

The woodcock is a bird of passage; it commonly arrives about the end of October, and remains until the middle of March. Woodcocks are fattest in December and January, but from the end of February they are lean. At their arrival they drop anywhere; but after-
are in company, they should divide; two should go in
the boat, whilst the others spread themselves about the
edge of the pool, in order to shoot the ducks in their
flight. In pools which will not admit a tow, water-
spaniels are absolutely necessary for this sport.

In winter they may be found on the margins of little
pools; and when pools and rivers are frozen up, they
must be watched for in places where there are springs
and waters which do not freeze. The sport is then
much more certain, because the ducks are confined to
these places in order to procure aquatic herbs, which
are almost their only food at this period.

SHOP-rousers, are those that steal goods privately
out of shops; which, being to the value of £5, though
no person be in the shop, is felony without the benefit
of clergy by the 10 and 11 W. III. c. 23.

SHORE, a place washed by the sea, or by some
large river.

Count Marsigli divides the sea shore into three por-
tions: the first of which is that tract of land which the
sea just reaches in storms and high tides, but which it
never covers; the second part of the shore is that which
is covered in high tides and storms, but is dry at other
times; and the third is the descent from this, which is
always covered with water.

The first part is only a continuation of the continent,
and suffers no alteration from the neighbourhood of the
sea, except that it is rendered fit for the growth of some
plants, and wholly unfit for that of others, by the saline
steams and impregnations; and it is scarce to be con-
ceived by any, but those who have observed it, how far
on land the effects of the sea reach, so as to make the
earth proper for plants which will not grow without
this influence; there being several plants frequently
found on high hills and dry places, at three, four, and
more miles from the sea, which yet would not grow un-
less in the neighbourhood of it, nor will ever be found
elsewhere.

The second part or portion of the shore is much
more affected by the sea than the former, being fre-
cently washed and beaten by it. Its productions are
rendered salt by the water, and it is covered with sand,
or with the fragments of shells in form of sand, and in
some places with a tartarous matter deposited from the
water; the colour of this whole extent of ground is
usually dusky and dull, especially where there are rocks
and stones, and these covered with a slimy matter.

The third part of the shore is more affected by the
sea than either of the others; and is covered with an
uniform crust of the true nature of the bottom of the
sea, except that plants and animals have their residence
in it, and the decayed parts of these alter it a little.

Stone, Jane, the celebrated concubine of the licen-
tious King Edward IV. was the wife of Mr. Matthew
Shore, a goldsmith in Lombard-street, London. Kings
are seldom unsuccessful in their amorous pursuits; there-
fore there was nothing wonderful in Mrs. Shore's remov-
ing from Lombard-street to shine at court as the royal
favourite. Historians represent her as extremely beau-
tiful, remarkably cheerful, and of most uncommon ge-
nerosity. The king, it is said, was no less captivated
with her temper than with her person: she never made
use of her influence over him to the prejudice of any
person; and if ever she imparted him, it was in fa-
avour of the unfortunate. After the death of Edward,

Sho
she attached herself to the lord Hastings; and when Richard III. cut off that nobleman as an obstacle to his ambitious schemes, Jane Shore was arrested as an accomplice, on the ridiculous accusation of witchcraft. This, however, terminated only in a public penance; excepting that Richard rilled her of all her little property: but whatever severity might have been exercised towards her, it appears that she was alive, though sufficiently wretched, under the reign of Henry VIII. when Sir Thomas More saw her poor, old, and shrivelled, without the least trace of her former beauty. Mr Rowe, in his tragedy of Jane Shore, has adopted the popular story related in the old historical ballad, of her perishing by hunger in a ditch where Shoreditch now stands. But Stow assures us that street was so named before her time.

SHORL. See SCHORL, MINERALOGY Index.

SHORLING and MORTHING, are words to distinguish fells of sheep shorling being the fells after the fleeces are shorn off the sheep's back; and morthing the fells shed off after they die or are killed. In some parts of England, they understand by a shorling, a sheep whose face is shorn off; and by a morthling, a sheep that dies.

SHORT, James, an eminent optician, was born in Edinburgh on the 10th of June O. S. in the year 1710. At ten years of age, having lost his father and mother, and being left in a state of indigence, he was received into Heriot's hospital, (see EDINBURGH, Public Buildings, No. 16.) where he soon displayed his mechanical genius, in constructing for himself, little chests, book-cases, and other conveniences, with such tools as fell in his way. At the age of twelve he was removed from the Hospital to the High School, where he showed a considerable taste for classical literature, and generally kept at the head of his forms. In the year 1726 he was entered into the university, where he passed through the usual course of education, and took his master's degree with great applause.

By his friends he was intended for the church; but after attending a course of theological lectures, his mind revolted from a profession which he thought little suited to his talents; and he devoted his whole time to mathematical and mechanical pursuits. He had been fortunate enough to have the celebrated M'Cul Aurin for his preceptor; who having soon discovered the bent of his genius, and made a proper estimate of the extent of his capacity, encouraged him to prosecute those studies in which nature had qualified him to make the greatest figure. Under the eye of that eminent master, he began in 1732 to construct Gregorian telescopes; and, as the professor observed in a letter to Dr Jurin, "by taking care of the figure of his specula, he was enabled to give them larger apertures, and to carry them to greater perfection than had ever been done before them." (See OPTICS, No. 89.)

In the year 1736 Mr. Short was called to London, at the desire of Queen Caroline, to give instructions in mathematics to William duke of Cumberland; and immediately on his appointment to that very honourable office he was elected a fellow of the royal society, and patronized by the earls of Morton and Maclesfield. In the year 1739 he accompanied the former of those noble lords to the Orkney isles, where he was employed in adjusting the geography of that part of Scotland: and happy it was for him that he was so employed, as he might otherwise have been involved in a scuffle which took place between the retainers of Sir James Stewart of Barra and the attendants of the earl, in which some of the latter were dangerously wounded.

Mr Short having returned to London, and finally established himself there in the line of his profession was in 1742 employed by Lord Thomas Spencer to make for him a reflector of 12 feet focus, for which he received 600 guineas. He made several other telescopes of the same focal distance with greater improvements and higher magnifiers; and in 1752 finished one for the king of Spain, for which, with its whole apparatus, he received 1200l. This was the noblest instrument of the kind that had then been constructed, and perhaps it has never yet been surpassed except by the astonishing reflectors of Herschel. See TELESCOPE.

Mr Short used to visit the place of his nativity once every two or three years during his residence in London, and in 1766 he visited it for the last time. On the 15th of June 1768 he died, after a very short illness, at Newington Butts, near London, of a mortification in his bowels, and was buried on the 22d of the same month, having completed, within a few days, his fifty-eighth year. He left a fortune of about 20,000l. of which 15,000l. was bequeathed to two nephews, and the rest in legacies to his friends. In gratitude for the steady patronage of the earl of Morton, he left to his daughter the lady Mary Douglas, afterwards countess of Aboyne, 1000l. and the reversion of his fortune, should his nephews die without issue; but this reversionary legacy the lady, at the desire of her father, generously relinquished by a deed in favour of Mr Short's brother Mr Thomas Short and his children. Mr Short's eminence as an artist is universally known, and we have often heard him spoken of by those who were acquainted with him from his youth, as a man of virtue and of very amiable manners.

Short-Hand Writing. See STENOGRAPHY.

Short-Jointed, in the Manage. A horse is said to be short-jointed that has a short pastern; when this joint, or the pastern is too short, the horse is subject to have his fore legs from the knee downwards turn in a straight line. Commonly your short-jointed horses do not manage so well as the long-jointed; but out of the manage the short-jointed are the best for travel or fatigue.

Short-Sightedness, a certain defect in vision by which objects cannot be distinctly seen, unless they are very near the eye. See OPTICS, No. 142.

SHORTFORD, q. d. fore-close, an ancient custom in the city of Exeter, when the lord of the fee cannot be answered rent due to him out of his tenement, and no distress can be levied for the same. The lord is then to come to the tenement, and there take a stone, or some other dead thing off the tenement, and bring it before the mayor and bailiff, and thus he must do seven quarter days successively; and if on the seventh quarter-day the lord is not satisfied of his rent and arrears, then the tenement shall be adjudged to the lord to hold the same a year and a day; and forthwith proclamation is to be made in the court, that if any man claims any title to the same tenement, he must appear within the year and day next following, and satisfy the lord of the said rent and arrears; but if no appearance be made, and the rent not paid, the lord comes again to the court,
SHOT, a denomination given to all sorts of balls for fire-arms: those for cannon being of iron, and those for guns, pistols, &c. of lead. See SHOOTING.

Case Shot formerly consisted of all kinds of old iron, nails, musket-balls, stones, &c. used as above.

Shot of a Cable, on ship-board, is the splicing of two cables together, that a ship may ride safe in deep waters and in great roads. If a ship will ride easier by one shot of a cable, than by three short cables out ahead.

Grape-Shot. See Grape-Shot.

Patent-milled Shot is made thus: Sheets of lead, whose thickness corresponds with the size of the shot required, are cut into small pieces, or cubes, of the form of a die. A great quantity of these little cubes are put into a large hollow iron cylinder, which is mounted horizontally and turned by a winch; when by their friction against one another and against the sides of the cylinder, they are rendered perfectly round and very smooth. The other patent shot is cast in moulds, in the same way as bullets are.

Shot Flaggon, a sort of flaggon somewhat bigger than ordinary, which in some counties, particularly Derbyshire, it is the custom for the host to serve his guests in, after they have drank above a shilling.

Small Shot, or that used for fowling, should be well sized, and of a moderate bigness: for should it be too great, then it flies thin, and scatters too much; or if too small, then it hath not weight and strength to penetrate far, and the bird is apt to fly away with it. In order, therefore, to have it suitable to the occasion, it not being always to be had in every place fit for the purpose, we shall set down the true method of making all sorts and sizes under the name of mould-shot. Its principal good properties are to be round and solid.

Take any quantity of lead you think fit, and melt it down in an iron vessel; and as it melts keep it stirring with an iron ladle, skimming off all impurities whatsoever that may arise at the top: when it begins to look of a greenish colour, strew on it as much auripigmentum or yellow orpiment, finely powdered, as will lie on a shilling, to every 12 or 14 pound of lead; then stirring them together, the orpiment will flame.

The ladle should have a notch on one side of the brim, for more easily pouring out the lead; the ladle must remain in the melted lead, that its heat may be the same with that of the lead, to prevent inconveniences which otherwise might happen by its being either too hot or too cold: then, to try your lead, drop a little of it into water, and if the drops prove round, then the lead is of a proper heat; if otherwise, and the shot have tails, then add more orpiment to increase the heat, till it be found sufficient.

Then take a plate of copper, about the bigness of a trencher, which must be made with a hollowness in the middle, about three inches compass, within which must be bored about 40 holes according to the size of the shot which you intend to cast: the hollow bottom should be thin; but the thicker the brim, the better it will retain the heat. Place this plate on a frame of iron, over a tub or vessel of water, about four inches from the water, and spread burning coals on the plate, to keep the lead melted upon it: then take some lead and pour it gently on the coals on the plate, and it will make its way through the holes into the water, and form itself into shot; do this till all your lead be run through the holes of the plate, taking care, by keeping your coals alive, that the lead do not cool, and so stop up the holes.

While you are casting in this manner, another person with another ladle may catch some of the shot, placing the ladle four or five inches underneath the plate in the water, by which means you will see if they are defective, and rectify them.

Your chief care is to keep the lead in a just degree of heat, that it be not so cold as to stop up the holes in your plate, nor so hot as to cause the shot to crack: to remedy the heat, you must refrain working till it is of a proper coolness; and to remedy the coolness of your lead and plate, you must blow your fire; observing, that the cooler your lead is, the larger will be your shot; as the hotter it is, the smaller they will be.

After you have done casting, take them out of the water, and dry them over the fire with a gentle heat, stirring them continually that they do not melt; when dry, you are to separate the great shot from the small, by the help of a sieve made for that purpose, according to their several sizes. But those who would have very large shot, make the lead trickle with a stick out of the ladle into the water, without the plate.

If it stop on the plate, and yet the plate be not too cool, give but the plate a little knock, and it will run again; care must be had that none of your implements be greasy, oily, or the like; and when the shot, being separated, are found too large or too small for your purpose, or otherwise imperfect, they will serve again at the next operation.

The sizes of common shot for fowling are from No. 1 to 6, and smaller, which is called mustard seed, or dust shot; but No. 5 is small enough for any shooting whatsoever. The No. 1 may be used for wild geese; the No. 2 for ducks, widgeons, and other water-fowl; the No. 3 for pheasants, partridges after the first month, and all the fen-fowl; the No. 4 for partridges, woodcocks, &c.; and the No. 5 for snipes and all the smaller birds.

Tin-Case Shot, in artillery, is formed by putting a great quantity of small iron shot into a cylindrical tin-box called a canister, that just fits the bore of the gun. Leaden bullets are sometimes used in the same manner; and it must be observed, that whatever number or sizes of the shots are used, they must weigh with their cases nearly as much as the shot of the piece.

SHOVEL, SIR CLOUDESLEY, a distinguished British admiral, was born about the year 1650, of parents in the lower rank of life. He was put apprentice to a shoemaker; but disliking this profession, he abandoned it a few years after, and went to sea. He was at first a cabin boy with Sir Christopher Mynnns, but applying to the study of navigation with indefatigable industry, his skill as a seaman soon raised him above that station.

The corsairs of Tripoli having committed great outrages on the English in the Mediterranean, Sir John Narborough was sent in 1674 to reduce them to reason. As he had received orders to try the effects of negotiation before he proceeded to hostilities, he sent Mr Shovel.
Shovel, who was at that time a lieutenant in his fleet, to demand satisfaction. The Dey treated him with a great deal of disrespect, and sent him back without an answer. Sir John dispatched him a second time, with orders to remark particularly the situation of things on shore. The behaviour of the Dey was worse than ever. Upon Mr Shovel's return, he informed Sir John that it would be possible, notwithstanding their fortifications, to burn all the ships in the harbour. The boats were accordingly manned, and the command of them given to Lieut. Shovel, who seized the guardship, and burnt four others, without losing a man. This action so terrified the Tripolins, that they sued for peace. Sir John Narborough gave so favourable an account of this exploit, that Mr Shovel was soon after made captain of the Sapphire, a fifth rate ship.

In the battle of Bantry-Bay, after the Revolution, he commanded the Edgar, and, for his gallant behaviour in that action, was soon after knighted by King William. Next year he was employed in transporting an army into Ireland; a service which he performed with so much diligence and dexterity, that the king raised him to the rank of rear-admiral of the blue, and delivered his commission with his own hands. Soon after he was made rear-admiral of the red, and shared the glory of the victory at La Hogue. In 1694, he bombarded Dunkirk. In 1703, he commanded the grand fleet in the Mediterranean, and did every thing in his power to assist the Protestants who were in arms in the Cevennes.

Soon after the battle of Malaga, he was presented by Prince George to Queen Anne, who received him graciously, and next year employed him as commander in chief.

In 1705 he commanded the fleet, together with the earl of Peterborough and Monmouth, which was sent into the Mediterranean; and it was owing to him chiefly that Barcelona was taken. After an unsuccessful attempt upon Toulon, he sailed for Gibraltar, and thence homeward with a part of the fleet. On the 22d of October, at night, his ship, with three others, was cast away on the rocks of Scilly. All on board perished. His body was found by some fishermen on the island of Scilly, who stripped it of a valuable ring, and afterwards buried it. Mr Paxton, the purser of the Arundel, hearing of this, found out the fellows, and obliged them to discover where they had buried the body. He carried it on board his own ship to Portsmouth, from whence it was conveyed to London, and interred with great solemnity in Westminster Abbey. A monument was afterwards erected to his memory by the direction of the queen. He married the widow of his patron, Sir John Narborough, by whom he left two daughters, co-heiresses.

SHOVELER, a species of Anas. See Anas, Ornithology Index.

SHOULDER-BLADE, a bone of the shoulder, of a triangular figure, covering the hind part of the ribs, called by anatomists the scapula and omoplate. See Anatomy.

SHOUT, in antiquity, was frequently used on ecclesiastical, civil, and military occasions, as a sign of approbation, and sometimes of indignation. Thus as Cicero, in an assembly of the people, was exposing the arrogance of L. Antony, who had had the impudence to cause himself to be inscribed the patron of the Romans, the people on hearing this raised a shout to show their indignation. In the ancient military discipline, shouts were used, "Upon occasion of the general's making a speech or harangue to the army from his tribunal. They did in token of their approbation what had been proposed. 2. Before an engagement, in order to encourage and spirit their own men, and fill the enemy with dread. This is a practice of great antiquity; besides which, it wants not the authority of reason to support it; for as mankind are endowed with two senses, hearing and seeing, by which fear is raised in the mind, it may be proper to make use of the ear as well as the eye for that purpose. Shouts were also raised in the ancient theatre, when what was acted pleased the spectators. It was usual for those present at the burning of the dead to raise a great shout, and call the dead person by his name before they set fire to the pile.

SHOWER, in Meteorology, a cloud condensed into Rain.

SHREWMOUSE. See Sorex, Mammalia Index.

SHREWSBURY, the capital of Shropshire in England. This town, the metropolis of the county, grew up out of the ruins of Uriconium, an ancient city, now a village called Ironbridge, about four miles from it. The Saxons called it Scrobbes Berg, from the shrubs that grew about it; and from thence the present name of Shrewsbury is supposed to have been formed. It is pleasantly situated upon a hill near the Severn, over which there are two handsome bridges. It was a place of note in the Saxon times; after which it was granted by William the Conqueror, together with the title of earl and most of the county, to Roger de Montgomery, who built a castle upon the north side of it, where the Severn that encompasses it on all other sides, leaves an opening. His son Robert built also a wall across this neck of land, when he revolted from Henry I. We learn from Doomsday-book, that at that time, when a widow of this town married, she paid 20 shillings to the king, and a virgin 10. The above-mentioned Roger founded also, and endowed here, a Benedictine monastery and a collegiate church. When old age came upon him, he quit the world, and spent the rest of his days as a monk in the abbey, and when he died was interred in its church. From the history of this church and monastery, it appears that ecclesiastical benefices about that time were hereditary. The abbey became so rich afterwards, that the abbot was mitred, and sat in parliament. Besides this abbey, in after times there were three others, viz. a Franciscan, Dominican, and Augustin; and likewise two collegiate churches, one dedicated to St Chad and the other to St Mary. In the contest between the empress Maud and Stephen, this town and its governor William Fitz-Allen sided with the empress. In Henry's III.'s time, a part of it was burnt down by the Welsh; and in Richard II.'s reign a parliament was held in it. At a place called Battlefield, near this town, Henry Percy the younger, surnamed Hotspur, was killed in an engagement with Henry IV. against whom he had rebelled. The king afterwards built a chapel upon the spot, and endowed it for the support of two priests to pray for the souls of the slain. Two of Edward IV.'s sons were born here; namely,
necessarily, Richard, duke of York, whom Perkin Warbeck afterwards personated, and who was murdered in the Tower; and George Plantagenet, who died before his brothers. Here first broke out the sweating sickness, which carried off great numbers so suddenly, that those who were seized with it either died or recovered in the space of 24 hours. In the beginning of the civil wars, King Charles I. came hither, and formed an army, with which he marched towards London; but was met by the parliament’s forces at Edgehill. He continued here from the 25th of September to the 12th of October, during which time he was joined by Prince Rupert, and many of the gentry and nobility of these parts. This town anciently gave title of earl to the Montgomeries, and afterwards to the Talbots, by whom it is still retained. Here is a free grammar-school, with three masters and several ushers, well endowed by Edward VI. and Queen Elizabeth, and not inferior to many colleges in the universities. It has a good library and chapel, and there are several scholarships appropriated to it in the university of Cambridge. Here are also several hospitals, alms-houses, and charity-schools. This town is one of the most flourishing in England, having two great weekly markets for corn, cattle, and provisions; and another for Welch cottons and flannels, of which great quantities are sold. A great trade is carried on with the Welch, who bring their commodities hither, as to the common mart of both nations. The town is large and well-built, and the situation extremely pleasant. There is a very beautiful walk called the quarry, between the town walls and the Severn, delightfully shaded with rows of lime-trees, so that it is not inferior to the Mall in St James’s Park. The town is also noted for its gallantry and politeness, being full of gentry, for whom there are always balls and assemblies once a-week all the year round.—Here is a fine house and gardens, which belonged to the earl of Bradford; and in the neighbourhood, at Wroxeter, the Roman highway, called Waling street, may be seen for several miles, where Roman coins are frequently found. In Shrewsbury are 12 incorporated trading companies; and the corporation has a power to try even criminal causes of itself, except high treason. Shrewsbury contained 14,739 inhabitants in 1801, and 16,656 in 1811.

SHRIKE. See Lanius, Ornithology Index.
SHRIMP. See Cancer, Entomology Index.
SHRINE, in Ecclesiastical History, a case or box to hold the relics of some saint.

SHROPSHIRE, a county of England, bounded on the south by Worcestershire, Herefordshire, and Radnorshire; on the north, by Cheshire; on the east, by Staffordshire; on the west, by Montgomeryshire and Denbighshire, in Wales. Its length is between 49 and 50 miles, its breadth about 38, and its circumference about 210. It is an inland county, containing 900,000 acres, and 15 hundreds, in which are 170 parishes, and 15 market towns; and the number of inhabitants in 1811 was 194,259. It makes a part of three bishoprics, viz. Hereford, Coventry and Lichfield, and St Asaph. Some part of it lies on the north, and some on the south side of the Severn. Besides the Severn, it is also watered by the Tern or Telford, which flows from the mountains of Radnorshire; and by the Tern, which has its rise and name from one of those pools called teurres, in Staffordshire. All these abound with fish, especially
trouts, pikes, lampreys, graylings, carp, and eels. The Shropshire air, especially upon the hills, with which the county abounds, is very wholesome. There is as great a diversity of soil as in most other counties. On the hills, where it is poor, is very good pasture for sheep; and in the low grounds, where it is very rich, along the Severn in particular, there is plenty of grass for bay and black cattle, with all sorts of corn. This county is abundantly provided with fuel, having in it many extensive mines of coal; it has also mines of lead and iron. Over most of the coal pits in this county lies a stratum or layer of blackish porous rock, of which, by grinding and boiling, they make pitch and tar, which are rather better than the common sort for caulking ships, as they do not crack, but always continue close and smooth. Quarries of limestone and iron-stone are common in the county, and the soil in many places is a reddish clay. The abundance of coal and iron-stone in this county has given rise to numerous manufactories.

As it lies upon the borders of Wales, it was anciently full of castles and walled towns. On the side next that country there was an almost continued line of castles, to guard the county against the inroads and depredations of the Welch. The borders here, as those between England and Scotland, were called marches, and there were certain noblemen entitled barones marchiae, marchiones de marchia Wallia, “lords of the marches, or marquises of the marches of Wales,” who were vested with a sort of palatine jurisdiction, held courts of justice to determine controversies, and enjoyed many privileges and immunities, the better to enable and encourage them to protect the county against the incursions of the Welch, and to maintain order amongst the borderers; but they often abused their power, and were the greatest of tyrants.

As to the ecclesiastical government of the county, the far greater part, belonging to the bishoprics of Hereford, and of Litchfield and Coventry, is under the jurisdiction and visitation of the archdeacon of Shrewsbury, or Salop, and is divided into several deaneries.

The Oxford circuit includes in it this county, which sends 12 members to parliament, viz. two for the shire, and two for each of the following towns, Shrewsbury, Ludlow, Wenlock, and Bishop’s Castle. See Shropshire, Supplement.

SHROVE-TUESDAY, is the Tuesday after the Quinquagesima Sunday, or the day immediately preceding the first of Lent; being so called from the Saxon word shrive, which signifies “to confess.” Hence Shrove-Tuesday signifies Confession-Tuesday; on which day all the people in every parish throughout England (during the Roman times) were obliged to confess their sins, one by one, to their own parish priests, in their own parish-churches; and, that this might be done the more regularly, the great bell in every parish was rung at ten o’clock (or perhaps sooner), that it might be heard by all, and that they might attend, according to the custom then in use. And though the Roman religion has now given way to the Protestant religion, the custom of ringing the great bell in our ancient parish-churches, at least in some of them, still remains, and obtains in and about London the name of Pancake bell; perhaps, because after the confession it was customary for the several persons to dine on pancakes or fritters. Most churches,
churches, indeed, have rejected that custom of ringing
the bell on Shrove-Tuesday; but the usage of dining
on pancakes or fritters, and such like provision, still
continues.

SHROUDS (scruad Sax.), a range of large ropes ex-
tending from the mast-heads to the right and left side of
the ship, to support the masts, and enable them to carry
sail, &c.

The shrouds as well as the sails are denominated from
the masts to which they belong. Thus there are the
main, fore, and mizen shrouds; the main-top-mast, fore-
top-mast, or mizen-top-mast shrouds; and the main-top-
gallant, fore-top-gallant, or mizen-top-gallant shrouds.
The number of shrouds by which a mast is sustained, as
well as the size of rope of which they are formed, is al-
ways in proportion to the size of the mast and the weight
of the sail it is intended to carry.

Bowsprit shrouds are those which support the bowsprit.
Bumkin shrouds are those which support the bumkins.
Futtock shrouds are shrouds which connect the efforts
of the topmast shrouds to the lower shrouds. Bentick
shrouds are additional shrouds to support the masts in
heavy gales. Preventer shrouds are similar to bentick
shrouds, and are used in bad weather to ease the lower
rigging. See Mast and Sail.

SHRUB, frutex, a little, low, dwarf tree, or a woody
vegetable, of a size less than a tree; and which, instead
of one single stem, frequently from the same root puts
forth several sets or stems. See Plant and Tree. Such
are privet, phillyrea, holly, box, honey-suckle, &c.
Shrubs and trees put forth in autumn a kind of buttons,
or gems, in the axis of the leaves; these buttons are as
so many little ova, which, coming to expand by the
warmth of the following spring, open into leaves and
flowers. By this, together with the height, some distin-
guish shrubs from suffrutes, or under shrubs, which
are low bushes, that do not put forth any of these but-
tons, as sage, thyme, &c.

The two hardest shrubs we are possessed of are the
ivy and box; these stand the severity of our sharpest
winters unharmed, while other shrubs perish, and trees
have their solid bodies split and torn to pieces. In the
hard winter of the year 1693, these two shrubs suffered
no injury anywhere; though the yews and hollies,
which are generally supposed very hardy, were that
winter in some places killed, and in others stripped of
their leaves, and damaged in their bark. Furse-bushes
were found to be somewhat harder than these, but they
sometimes perished, at least down to the root. The
broom seemed to occupy the next step of hardiness be-
yond these. This lived where the others died, and
where even this died, the juniper shrubs were sometimes
found unhurt. This last is the only shrub that ap-
proaches to the hardiness of the box and ivy, but even
it does not quite come up to them; for while they suffer
nothing in whatever manner they are exposed, the ju-
niper, though it bears cold well under the shelter of
other trees, yet cannot bear the vicissitudes of heat and
cold; insomuch that some juniper shrubs were found half
dead and half vigorous; that side which faced the
mid-day sun having perished by the successive thawings
and freezings of its sap; while that which was not ex-
posed to the vicissitudes of heat bore the cold per-
fectly well. Such shrubs as are not hardy enough to de-
fy the winter, but appear half dead in the spring, may
often be recovered by Mr. Evelyn's method of beating
their branches with a slender hazel-wand, to strike off
the withered leaves and buds, and give a free passage
to the air to the internal parts. Where this fails, the me-
Method to cut them down to the quick, and if no part of
the trunk appears in a growing condition, they must be
taken off down to the level of the ground. Philosophi-
cal Transactions, N° 165.

SHUTTLE, in the manufactures, an instrument used
by the weavers, which guides the thread it contains, ei-
ther of woolen, silk, flax, or other matter, so as to make
it form the woofs of stuffs, clothes, linens, ribbands, &c.,
by throwing the shuttle alternately from left to right,
and from right to left, across between the threads of
the warp, which are stretched out lengthwise on the loom.

In the middle of the shuttle is a kind of cavity, called
the eye or chamber of the shuttle; wherein is inclosed
the spool, which is a part of the thread destined for the
woof; and this is wound on a little tube of paper, rush,
or other matter.

The ribband-weaver's shuttle is very different from
that of most other weavers, though it serves for the
same purpose: it is of box, six or seven inches long,
one broad, and as much deep; shod with iron at both
ends, which terminate in points, and are a little crook-
ed, the one towards the right, and the other towards the
left, representing the figure of an 8 horizontally placed.
See Weaving.

SIALOGOGUES, medicines which promote the sa-
 livary discharge.

SIAM PROPER, by some called Upper, (to distinguish
it from the Lower Siam, under which are often inclu-
ded Laos, Cambodia, and Malacca), is bounded on
the north by the kingdoms of Pegu and Laos; on the east
by Cambodia and Cochin-China; on the south by Mal-
acca and the bay of Siam; and on the west by the
ocean. But as the opinions of geographers are extreme-
ly various concerning the situation and extent of most of
the inland countries of Asia and Africa, neither the ex-
tent nor boundaries of Siam are yet accurately known.
By some it is supposed to extend 550 miles in length, and
250 miles in breadth; in some places it is not above
50 miles broad. The winds blow here from the south upon the coast. Weather of Siam, in March, April, and May; in April the rains begin, in May and June they fall almost without ceas-
ing. In July, August, and September, the winds blow
from the west, and the rains continuing, the rivers over-
flow their banks nine or ten miles on each sides, and for
more than 150 miles up the stream. At this time, and
more particularly in July, the tides are very strong as
to come up the river Menan as far as the city of
Siam, which is situated 60 miles from its mouth; and
sometimes as far as Louvo, which is 50 miles higher.
The winds blow from the west and north in October,
when the rain ceases. In November and December the
winds blow dry from the north, and the waters being
in a few days reduced to their ancient channels, the
Tides become so insensible, that the water is fresh at the
mouth of the river. At Siam there is never more than
one flood and one ebb in the space of twenty-four hours. In
January the wind blows from the east, and in February
from the east and south. When the wind is at east,
the current sets to the west; and, on the contrary, when the wind is at west, the currents run to the eastward.

As this country is situated near the tropic, it must necessarily be very hot; but yet, as in other places nearly of the same latitude, when the sun is vertical and shines with a most intense heat, the inhabitants are so skreened by the clouds, and the air is so refreshed by a deluge of rain that overflows the plains which the people chiefly inhabit, that the heat is very supportable. The coolest wind blows in December and January.

The vegetable produce of this country is chiefly rice and wheat, besides tropical and a few European fruits. The Siamese prepare the land for tillage as soon as the earth is sufficiently moistened by the floods. They plant their rice before the waters rise to any considerable height, and, as they rise slowly, the rice keeps pace with them, and the ear is always above the water. They reap their corn when the water retires, and sometimes go in boats to cut it while the waters are upon the ground. They also sow rice in several parts of the kingdom that are not overflowed, and this is thought better tasted, and will keep longer than the other; but they are forced to supply these fields constantly with water, while the rice is growing, from basins and ponds that lie about them.

They have no European fruits except oranges, lemons, citrons, and pomegranates. They have bananas, Indian figs, jaques, durions, mangoes, mangostans, tamarinds, ananas, and cocoa nuts; they have also abundance of pepper and sugar-canes. The mountains are covered with trees which make good mast. The vegetable of greatest use in the country is the bamboo, which grows chiefly in marshy soils, and is often found of a prodigious size. Cotton trees are found in great numbers; and others that yield cocoac, a very fine cotton wool, but so short as to be unfit for spinning, though it answers very well for stuffing mattresses and pillows.

There is no country where elephants abound more than in Siam, or where they are held in greater veneration. They have a few horses, sheep, and goats, besides oxen and buffaloes; but they have no good animal food except the flesh of hogs, their beef and mutton being of a very indifferent quality.

The Siamese are of small stature, but well proportioned; their complexions are swarthy; the faces of both the men and women are broad, and their foreheads, suddenly contracting, terminate in a point, as well as their chins. They have small black eyes, hollow jaws, large mouths, and thick pale lips. Their teeth are dyed black, their noses are short and round at the end, and they have large ears, which they think very beautiful. Their hair is thick and lank, and both sexes cut it so short that it reaches no lower than their ears; the women make it stand up on their foreheads; and the men shave their beards.

People of distinction wear a piece of calico tied about their loins, that reaches down to their knees.—The men bring up this cloth between their legs, and tuck it into their girdles, which gives it the appearance of a pair of breeches. They have also a muslin shirt without a collar, with wide sleeves, no wristbands, and the bosom open. In winter they wear a piece of stuff or painted linen over their shoulders, like a mantle, and wind it about their arms.

The king of Siam is distinguished by wearing a vest of brocaded satin, with straight sleeves that reach down to the wrist, under such a shirt as we have just described, and it is unlawful for any subject to wear this dress unless he receives it from the king. They wear slippers with piked toes turned up, but no stockings. The king sometimes presents a military vest to the generals; this is buttoned before, and reaches to the knees; but the sleeves are wide, and come no lower than the elbows. All the retinue of the king, either in war or in hunting, are clothed in red. The king wears a cap in the form of a sugar-loaf, encompassed by a coronet or circle of precious stones, and those of his officers have a circle of gold, silver, or of vermilion gilt, to distinguish their quality; and these caps are fastened with a stay under the chin; they are only worn when they are in the king's presence, or when they preside in courts of justice, and on other extraordinary occasions. They have also hats for travelling; but, in general, few people cover their heads notwithstanding the scorching heat of the sun.

The women also wrap a cloth about their middle, which hangs down to the calf of their legs. They cover their breasts with another cloth, the ends of which hang over their shoulders. But they have no garment corresponding to a shift, nor any covering for their heads but their hair. The common people are almost naked, and wear neither shoes nor slippers. The women wear as many rings on the three last fingers of each hand as they can keep on, and bracelets upon their wrists and ankles, with pendants in their ears shaped like a pear.

For an inferior to stand before a superior is deemed insolent; and therefore slaves and people of inferior rank sit upon their heels, with their heads a little inclined, and their joined hands lifted up to their foreheads. In passing by a superior they bend their bodies, joining their hands, and lifting them towards their heads in proportion to the respect they would show. When an inferior pays a visit, he enters the room stooping, prostrates himself, and then remains upon his knees, sitting upon his heels without speaking a word till he is addressed by the person whom he visits; for he that is of the highest quality must always speak first. If a person of rank visits an inferior, he walks upright, and the master of the house receives him at the door, and waits on him so far when he goes away, but never farther.

The highest part of the house is esteemed the most honourable, and no person cares to lodge under another's feet. The Siamese indeed have but one story, but the rooms rise gradually, and the innermost, which are the highest, are always the most honourable. When the Siamese ambassador came to the French court, some of his retinue were lodged in a floor over the ambassador's head; but they no sooner knew it, than they were struck with the greatest consternation, and ran down tearing their hair at the thoughts of being guilty of what they considered as so unpardonable a crime.

The Siamese never permit such familiarities as are practised by gentlemen in Europe. Easiness of access, and
and as they are considered as superior to the commoner, it is in that part of the world thought a sign of weakness, and yet they take no notice of some things which may be looked upon as ill breeding among us; such as belching in company, which no man endeavours to prevent or so much as holds his hand before his mouth. They have an extraordinary respect for the head, and it is the greatest affordment to strike or touch the head of another person; nay, their cap must not be used with too much familiarity; for when a servant carries it, it is put on a stick and held above his head; and when the master stands still the stick is set down, having a foot to stand upon. They also show their respect by lifting their hands to the head; and therefore, when they receive a letter from any one for whom they have a great respect, they immediately hold it up to their heads, and sometimes lay it upon their heads.

Genius and dispositions. They are esteemed an ingenious people, and though rather indolent than active in disposition, they are not addicted to the voluptuous vices which often accompany a state of ease, being remarkably chaste and temperate, and even holding drunkenness in abhorrence. They are, however, accounted insolent towards their inferiors, and equally obsequious to those above them; the latter of which qualities appears to be particularly inculcated from their earliest youth. In general, their behaviour is extremely modest, and they are averse to loquacity. Like the Chinese, they avoid speaking in the first person, and when they address a lady, it is always with some respectful epithet, insinuating personal accomplishments.

No man in this country learns any particular trade, but has a general knowledge of all that are commonly practised, and every one works six months for the king by rotation; at which time, if he should be found perfectly ignorant of the business he is set about, he is doomed to suffer the bastinado. The consequence of this burdensome service is, that no man endeavours to excel in his business, lest he should be obliged to practise it as long as he lives for the benefit of the crown.

The government of this country is extremely oppressive, the king being not only sovereign but proprietor of all the lands, and chief merchant likewise; by which means he monopolizes almost the whole traffic, to the great prejudice of his subjects. The crown is said to be hereditary, but it is often transferred by revolutions, on account of the exorbitant abuse of power in those who exercise the royal office. In his palace, the king is attended by women, who not only prepare his food, and wait on him at table, but even perform the part of valets, and put on all his clothes, except his cap, which is considered as too sacred to be touched by any hand but his own. He shows himself to the people only twice a year, when he distributes his alms to the talapoins or priests; and on those occasions he always appears in an elevated situation, or mounted on the back of an elephant. When he takes the diversion of hunting, he is as usual attended by his women on foot, preceded by a guard of 200 men, who drive all the people from the roads through which they are to pass; and when the king stops, all his attendants fall upon their faces on the ground.

All their proceedings in law are committed to writing, and none is suffered to exhibit a charge against another, without giving security to prosecute it, and answer the damages if he does not prove the fact against the person accused. When a person intends to prosecute another, he draws up a petition, in which he sets forth his complaint, and presents it to the near, or head of the band to which he belongs, who transmits it to the governor; and if the complaint appears frivolous, the prosecutor, according to the laws of the country, should be punished; but the magistrates generally encourage prosecutions on account of the perquisites they bring to their office.

Every thing being prepared for hearing, the parties are several days called into court, and persuaded to agree; but this appears to be only a matter of form. At length the governor appoints a day for all parties to attend; and being come into court, the clerk reads the process and opinion of his associates, and then the governor examines upon what reasons their opinions are founded; which being explained to him, he proceeds to pass judgment.

When sufficient proofs are wanting, they have recourse to ordeal. Trial by ordeal is an unusual trial, like that of our Saxon ancestors; both the plaintiff and the defendant walk upon burning coals, and he that escapes unhurt is adjudged to be in the right; sometimes the proof is made by putting their hands in boiling oil; and in both these trials, by some peculiar management, one or the other is said to remain unhurt. They have also a proof by water, in which he who remains longest under it is esteemed innocent. They have another proof, by swallowing pills, which their priests administer with severe imprecations; and the party who keeps them in his stomach without vomiting is thought to be innocent.

All these trials are made in the presence of the magistrates and people; and the king himself frequently directs them to be performed, when crimes come before him by way of appeal. Sometimes he orders both the informer and prisoner to be thrown to the tigers: and the person that escapes by his not being seized upon by those beasts, is sufficiently justified.

They maintain the doctrine of transmigration, believing in a pre-existent state, and that they shall pass into other bodies till they are sufficiently purged to be received into paradise. They believe likewise that the soul is material, but not subject to the touch; that it retains the human figure after quitting a body of that species; and that when it appears to persons with whom it was acquainted, which they suppose it to do, the wounds of one that has been murdered will then be visible. They are of opinion that no man will be eternally punished; that the good, after several transmigrations, will enjoy perpetual happiness; but that those who are not reformed will be doomed to transmigration to all eternity. They believe in the existence of a Supreme Being; but the objects of their adoration are departed saints, whom they consider as mediators or intercessors for them; and to the honour of this numerous tribe both temples and images are erected.

The men of this country are allowed a plurality of women; but excepting one, who is a wife by contract, the others are only concubines, and their children deemed incapable of any legal inheritance. Previous to every nuptial contract, an astrologer must be consulted, who calculates the nativity of the parties, and determines whether their union is likely to prove fortunate or
SIBERIA, a large country, comprehending the northerly parts of the Russian empire in Asia. It is bounded on the east by the eastern ocean; on the south by Great Tartary; on the west by Russia; and on the north by the Frozen ocean. It is about 2000 miles in length from east to west, and 750 miles in breadth from north to south.

At what time this country was first inhabited, or conquered by whom it was peopled, we are entirely ignorant; but writings have been found in it when it was discovered, which shows that it must have been early known to a civilized people. The Russians, from whom we have received our knowledge, knew nothing of it before the middle of the 16th century. In the reign of John Basilowitz I., indeed, an incursion had been made into Siberia, and some Tartar tribes subdued; but these conquests were not permanent; and we have no further communication between Russia and Siberia till the time of John Basilowitz II. It was opened again at that time by means of one Anika Strogonoff, a Russian merchant, who had established some salt-works at a town in the government of Archangel. This man carried on a trade with the inhabitants of the north-west parts of Siberia, who brought every year to the town above mentioned large quantities of the finest furs. Thus he acquired a very considerable fortune in a short time; when at last the czar, perceiving the advantages which would accrue to his subjects from having a regular intercourse with Siberia, determined to enlarge the communication which was already opened. With this view he sent into Siberia a body of troops, which crossed the Yugorian mountains, that form part of the north-eastern boundary of Europe. They seem, however, not to have passed the Irtish, or to have penetrated farther than the western branch of the river Oby. Some Tartar tribes were laid under contribution, and a chief named Yediger consented to pay an annual tribute of 1000 sables. But this produced no lasting advantage to Russia; and soon after, Yediger was defeated and taken prisoner by Kutchum Khan, a descendant of the great Jenghiz Khan; and thus the allegiance of this country to Russia was dissolved.

For some time we hear of no further attempts made by the Russians on Siberia; but in 1577 the foundation of a permanent conquest was laid by one Yermas Temofeef, a Cossack of the Don. This man was at first the head of a party of banditti who infested the Russians in the province of Casan; but being defeated by the troops of the czar, he retired with 6000 of his followers into the interior parts of that province. Continuing his course still eastward, he came to Orel, the most easterly of all the Russian settlements. Here he took up his winter-quarters; but his restless genius did not suffer him to continue for any length of time in a state of inactivity; and from the intelligence he procured concerning the situation of the neighbouring Tartars of Siberia, he turned his arms towards that quarter.

Siberia was at that time partly divided among a number of separate princes, and partly inhabited by the various tribes of independent Tartars. Of the former Kutchum Khan was the most powerful sovereign. His dominions consisted of that tract of country which now forms the south-western part of the province of Tobolsk; and stretched from the banks of the Irtish and Oby to...
Siberia

his principal residence was at Sibir, a small fortress upon the river Irish, not far from the present town of Tobolsk, and of which some ruins are still to be seen. After a course of unremitting fatigue, and a series of victories which almost exceeded belief, but of which we have no room to give the detail, our intrepid adventurer dispossessed this prince of his dominions, and seated himself on the throne of Sibir. The number of his followers, however, being greatly reduced, and perceiving he could not depend on the affection of his new subjects, he had recourse to the czar of Muscovy, and made a tender of his new acquisitions to that monarch, upon condition of receiving immediate and effectual support. This proposal was received with the greatest satisfaction by the czar, who granted him a pardon for all former offences, and sent him the required succours. Yermak, however, being soon after drowned in an unsuccessful excursion, the Russians began to lose their footing in the country. But fresh reinforcements being reasonably sent, they not only recovered their ground, but pushed their conquests far and wide; wherever they appeared, the Tartars were either reduced or exterminated. New towns were built, and colonies were planted on all sides. Before a century had well elapsed, all that vast tract of country now called Siberia, which stretches from the confines of Europe to the Eastern ocean, and from the Frozen sea to the present frontiers of China, was annexed to the Russian dominions.

The air of Siberia is, in general, extremely piercing, the cold there being more severe than in any other part of the Russian dominions. The Siberian rivers are frozen very early, and it is late in the spring before the ice is thawed (A). If the corn does not ripen in August, there is little hope of a harvest in this country; and in the

(A) M. Gmelin, M. Muller, and two other philosophers, set out in the year 1733 to explore the dreary regions of Siberia, by desire of the empress Anne of Russia. After spending nine years and a half in observing every thing that was remarkable, they returned to Petersburg; and an account of this journey was published by M. Gmelin. In order to examine how far the frost had penetrated into the ground, M. Gmelin, on the 18th of June, at a place called Jacutia, ordered the earth to be dug in high ground; they found mould to the depth of 11 inches, under which they met with loose sand to two feet and a half further, after which it grew harder, and at half a foot deeper so hard as scarcely to give way to the tools; so that the ground still remained unthawed at not less than the depth of four feet. He made the same experiment in a lower situation; the soil was 10 inches deep, after that a loose sand for two feet and ten inches, below which all was frozen and hard. At Jacutia the inhabitants preserve in cellars several sorts of berries, which they reckon among their dainties, perfectly good and fresh the whole year, though these cellars are scarcely a fathom deep. At the fortress of Argun, in little more than 50 degrees of latitude, the inhabitants relate that the earth in many places is never thawed above a yard and a half, and that the internal cold of the earth will scarcely permit a well to be dug, of which they bring an instance that happened not long before the author's arrival at that place. They designed to sink a well near a house at some distance from the river Argun, for which purpose they thawed the earth by degrees, and dug some fathoms till they had penetrated a fathom and half below the level of the river, but found no spring. Hence perhaps we may venture to assert, that besides the great elevation of the earth in these countries, there is another cause, perhaps latent in the earth itself, of this extraordinary cold, naturally suggested to us by considering the cavity of an old silver mine at Argun, which being exhausted of its ore, now serves the inhabitants in summer time for a cellar to keep their provisions: this place is so extremely cold as to preserve flesh meats from putrefaction in the hottest summers, and to sink the mercury in De Lisle's thermometer to 146 and 147. The author travelling from Nerschoi towards Argun, to visit the works of the silver mines in that place, August 1735, came to the river Orkiya, near Solonischeia, on July the first, from whence he arrived a little before dark at the village of Sevantsua, distant from the river 27 leagues. In this journey he and his fellow travellers for more than four leagues felt it vastly cold; soon after they came into a warm air, which continued some leagues; after which the cold returned; and thus are travellers subjected to perpetual vicissitudes of warmth and cold. But it is observed in general, that the eastern parts are colder than the western, though situated in the same latitude; for as in those eastern regions some tracts of land are much colder than the rest, their effects must be felt by the neighbouring parts. And this conjecture is favoured by the thermometrical observations made with M. de Lisle's instrument in all parts of Siberia, in which the mercury was depressed to the 226th degree, even in those parts that lie very much towards the south, as in the territory of Selings, which said degree answers in Fahrenheit's thermometer about 55.5 below 0, but the same thermometer sometimes indicated a much greater cold. At the fort of Kirings, on February 10. 1738, at 8 in the morning, the mercury stood at 240, which answers nearly to 72 below 0 in Fahrenheit's. On the 23d of the same month it was a degree lower. At the same place, December 11. at three in the afternoon, it stood at 234 in De Lisle's thermometer, and very near 90 in Fahrenheit's; on December 29. at four in the afternoon, at 263; on November 27, at noon, at 270; January 9. at 275, which several depressions answer in Fahrenheit's to 99, 107, 73, and 113.5; on January 5. at five in the morning, at 263; an hour after at 281, but at eight o'clock it returned to 235, and there remained till six in the afternoon, and then rose by degrees till an hour before midnight, when it stood at 202. So that the greatest depression of the mercury answers in Fahrenheit's thermometer to 120.76 degrees below 0, which is indeed very surprising, and what nobody ever imagined before. While this cold lasted at Jenisen, the sparrows and magpies fell to the ground, struck dead, as it were, with the frost, but revived if they were soon brought into a warm room. The author was told also that numbers of wild beasts were found in the woods dead and stiff with the frost, and several travellers had their blood and viscera quite frozen in their vessels. The air itself at that time was so dismal, that you would think it changed to ice; as it was a thick fog, which was not dissipable by any exhalations, as in the spring and autumn, and the author could scarcely stand three minutes in the porch of his house for the cold.
the province of Jeniseisk, it is sometimes covered with snow before the peasants can reap it. To defend the inhabitants against this extreme severity of the climate, Providence seems more liberally to have dealt out to them wood for fuel and furs for clothing. As the winter days in the north parts of Siberia last but a few hours, and the storms and flakes of snow darken the air so much, that the inhabitants, even at noon, cannot see to do any thing without artificial lights, they sleep away the greatest part of that season.

These severe winters are rapidly succeeded by summers, in which the heat is so intense that the Tungusians, who live in the province of Jakutsk, go almost naked. Here is scarcely any night during that season; and towards the Frozen ocean the sun appears continually above the horizon. The vegetables and fruits of the earth are here extremely quick in their growth.

The whole tract of land beyond the 60th degree of north latitude is a barren waste; for the north part of Siberia yields neither corn nor fruits; though barley is known frequently to come to perfection in Jakutsk. For this reason, the inhabitants of the northern parts are obliged to live on fish and flesh, but the Russians are supplied with corn from the southern parts of Siberia, where the soil is surprisingly fertile. The countries beyond the lake of Baikal, especially towards the east, as far as the river Argun, are remarkably fruitful and pleasant; but such is the indolence of the inhabitants, that several fine tracts of land, which would make ample returns to the peasant for cultivating them, lie neglected. The pastures are excellent in this country, which abounds in fine horned cattle, horses, goats, &c. on which the Tartars chiefly depend for subsistence. However, there are several steppes, or barren wastes, and unimproved tracts in these parts; and not a single fruit tree is to be seen. There is great variety of vegetables, and in several places, particularly near Krasnoia Sloboda, the ground is in a manner overrun with asparagus of an extraordinary height and delicious flavour. The bulbs of the Turkish buns, and other sorts of lilies, are much used by the Tartars instead of bread. This want of fruit and corn is richly compensated by the great quantities of wild and tame beasts and fowls, and the infinite variety of fine fish which the country affords (a).

In that part of Siberia which lies near the Icy sea, as well as in several other places, woods are of pine, larch, and other trees; besides which, a considerable quantity of wood is thrown ashore by the waves of the Icy sea; but whence it comes is not yet ascertained.

Besides the wild fowl with which Siberia abounds, there is a prodigious number of quadrupeds, some of which are edible, and others valuable for their skins or furs.

The animals most valued for their skins are the black fox, the sable, the hyena, the ermine, the squirrel, the beaver, and the lynx. The skin of a real black fox is more esteemed than even that of a sable. In the country near the Frozen ocean are also blue and white foxes. The finest sables come from Nertshinsk and Jakutsk, the inhabitants of which places catch them in the mountains of Stannowoi Krebet. The tributary nations were formerly obliged to pay their taxes in the skins of foxes and sables only. But now the skins of squirrels, bears, rein-deer, &c. and sometimes money, are received by way of tribute; and this not only from those who live near the Lena, but also in the governments of Itil, Irkutsk, Selenginsk, and Nertshinsk. When the Tartars first became tributary to Russia, they brought their furs indiscriminately as they caught them, and among them were often sables of extraordinary value; and formerly, if any trader brought with him an iron kettle, they gave him in exchange for it as many sables as it would hold. They are now better acquainted with their value. They sell their sables to smugglers at a very high price, and pay only a ruble instead of a skin to the revenue officers, who now receive more ready money than sables by way of tribute. The subjects plead the scarcity of furs, and indeed not without some appearance of truth.

Siberia has still other and more valuable treasures than minerals, those we have yet mentioned. The silver mines of Argun are extremely rich; the silver they produce yields some gold, and both of these are found among the copper ore of Koliwan. This country is also particularly rich in copper and iron ore. The former lies even upon the surface of the earth: and considerable mines of it are found in the mountains of Pictow, Koliwan, Ploksau, Woskerensk, Kuswi, Alepalei, and several others, and in the government of Krasnoiaarsk (c). Iron is still more plentiful in all these places, and very good; but that of Kamesnik is reckoned the best. Several hundred thousand puds of these metals are annually exported from the smelting houses, which belong partly to the crown, and partly to private persons. Most of them lie in the government of Catharinenburg. The Tartars also extract a great quantity of iron from the ore.

The topazes of Siberia have a fine lustre; and in precious open sandy places, near the river Argun, as well as on stones, the banks of other rivers and lakes, are found single small pieces of agate. Here are also cornelians and green jasper with red veins. The latter is chiefly met with in the deserts of Gobiokoi.

The famous marquinglas, or lapis specularis, is numerous in quantities.

(a) The oak, though frequent in Russia, it is said, is not to be found through this vast region nearer than the banks of the Argun and Amur, in the dominions of China. The white poplar, the aspen, the black poplar, the common sallow, and several species of the willow, are very common. The Norway and silver fir form great forests; but the former does not grow beyond the 60th degree of north latitude, and the latter not beyond 78 degrees. To this dreary region of Siberia, Europe is indebted for that excellent species of oats called Avena Siberica; and our gardens are enlivened with the gay and brilliant flowers brought from the same country.

(c) The copper mines of Koliwan, from which gold and silver are extracted, employ about 40,000 people. The silver mines of Nertshinsk, beyond Lake Baikal, employ above 14,000. The whole revenue arising from these mines, according to Mr Coxe, is not less than 679,182l.
quantities of which are dug up in Siberia, is by some called Muscovy or Russian glass. It is a particular species of transparent stone, lying in strata like so many sheets of paper. The matrix or stone in which it is found, is partly a light yellow quartz, or moraccass, and partly a brown indurated fluid; and this stone contains in it all the species of the marniglas. To render the marniglas fit for use, it is split with a thin two-edged knife; but care is taken that the lamina be not too thin. It is used for windows and lanterns all over Siberia, and indeed in every part of the Russian empire, and looks very beautiful; it is strong and clearness surpassing that of the finest glass, to which it is particularly preferable for windows and lanterns of ships, as it will stand the explosion of cannon. It is found in the greatest plenty near the river Witim.

Siberia affords magnets of an extraordinary size, and even whole mountains of loadstone. Pit-coal is also dug up in the northern parts of this country. The kamennoe masha, a yellowish kind of alum, unctuous and smooth to the touch, like soap, is found in the mountains of Krasnoiarst, Ural, Altaish, Jenisea, Baikal, Barygosik, Lena, and several others in Siberia.

In this country are not only a great number of fresh water lakes, but likewise several whose waters are salt; and these reciprocally change their nature, the salt sometimes becoming fresh, and the fresh changing into saline. Some lakes also dry up, and others appear where none were ever seen before. The salt lake of Yamushka, in the province of Tobolsk, is the most remarkable of all, for it contains a salt as white as snow, consisting entirely of cubic crystals. One finds also in Siberia saline springs, salt water brooks, and a hill of salt.

Siberia affords many other things which deserve notice. That useful root called rhubarb grows in vast quantities near the city of Seleginsirk. The curious mammoth's bones and horns, as they are called, which are found along the banks of the Oby, Jenisei, Lena, and Irtysh, are unquestionably the teeth and bones of elephants. But whether these elephants teeth and bones were conveyed to these different regions by the general deluge, or by any other inundation, and were by degrees covered with earth, is a point which might lead us into long and very fruitless disquisitions; we shall therefore only observe, that such bones have likewise been found in Russia, and even in several parts of Germany. A kind of bones of a still larger size than these have also been dug up in Siberia, and seem to have belonged to an animal of the ox kind. The horn of the whale called narwhal has been found in the earth near the river Indigirka and Anadiri; and the teeth of another species of whales, called drozd, are about Anadirskoi. The latter are larger than the common sort, which are brought from Greenland, Archangel, and Kola.

The chain of Siberian mountains reaches from that of Werchoturie towards the south as far as the neighbourhood of the city of Orenburg, in a continued ridge, under the name of the Uralian mountains; but from thence it alters its direction westward. These mountains are a kind of boundary between Russia Proper and Siberia. Another chain of hills divides Siberia from the country of the Calkmucks and Mongolian.—These mountains, between the rivers Irtysh and Oby, are called the Altaic or Golden Mountains, which name they afterwards lose, particularly between the river Jenesei and the Baikal lake, where they are called the Sayanian mountains.

The inhabitants of Siberia consist of the aborigines or ancient inhabitants, the Tartars, and Russians, and of state criminals.

Some of these nations have no other religion but that of nature; others are Pagans or Mahometans, and some of them have been converted to Christianity, or rather only baptised by the Russian missionaries.

SIBTHORPIA, a genus of plants belonging to the class of didynamia, and to the order of angiosperma; and in the natural system placed with those the order of which is doubtful. See BOTANY INDEX.

SIBYLS, in pagan antiquity, certain women said to have been endowed with a prophetic spirit, and to have delivered oracles, showing the fates and revolutions of kingdoms. Their number is unknown. Plato speaks of one, others of two, Pliny of three, Ælian of four, and Varro of ten; an opinion which is universally adopted by the learned. These ten Sibyls generally resided in the following places, Persia, Libya, Delphi, Cumae in Italy, Erythraea, Samos, Cumae in Eolia, Marpesia on the Hellespont, Anencya in Phrygia, and Tiburis. The most celebrated of the Sibyls is that of Cumae in Italy, whom some have called by the different names of Amalthia, Demophile, Hecrops, Daphne, Manto, Phemonoe, and Deiphoboe. It is said, that Apollo became enamoured of her, and that to make her sensible of his passion he offered to give her whatever she should ask. The Sibyl demanded to live as many years as she had grains of sand in her hand, but unfortunately forgot to ask for the enjoyment of the health, vigour, and bloom, of which she was then in possession. The god granted her request, but she refused to gratify the passion of her lover though he offered her perpetual youth and beauty. Some time after she became old and decrepit, her form decayed, melancholy paleness and haggard looks succeeded to bloom and cheerfulness. She had already lived about 700 years when Æneas came to Italy, and as some have imagined, she had three centuries more to live before her years were as numerous as the grains of sand which she had in her hand. She gave Æneas instructions how to find his father in the infernal regions, and even conducted him to the entrance of hell. It was usual for the Sibyl to write her prophecies on leaves, which she placed at the entrance of her cave; and it required particular care in such as consulted her to take up these leaves before they were dispersed by the wind, as their meaning then became incomprehensible. According to the most authentic historians of the Roman republic, one of the Sibyls came to the palace of Tarquin the Second, with nine volumes, which she offered to sell for a very high price. The monarch disregarded her, and she immediately disappeared, and soon after returned, when she had burned three of the volumes. She asked the same price for the remaining six books; and when Tarquin refused to buy them, she burned three more, and still persisted in demanding the same sum of money for the three that were left.—This extraordinary behaviour astonished Tarquin; he bought the books, and the Sibyl instantly vanished, and never after appeared. These books were preserved with great care by the monarch, and called the Sibylline verses. A college of priests was appointed to have the care of them; and such reverence did the Romans
Romans entertain for these prophetic books, that they were consulted with the greatest solemnity, and only when the state seemed to be in danger. When the capitol was burnt in the troubles of Sylla, the Sibylline verses which were deposited there perished in the conflagration; and to repair the loss which the republic seemed to have sustained, commissioners were immediately sent to different parts of Greece to collect whatever verses could be found of the inspired writings of the Sibyls. The fate of these Sibylline verses which were collected after the conflagration of the capitol is unknown. There are now many Sibylline verses extant, but they are reckoned universally spurious; and it is evident that they were composed in the second century by some of the followers of Christianity, who wished to convince the heathens of their error, by assisting the cause of truth with the arms of pious artifice.

SICERA, a name given to any inebriating liquor by the Hellenistic Jews. St. Chrysostom, Theodore, and Theophilus of Antioch, who were Syrians, and who therefore ought to know the signification and nature of "sicera," assure us, that it properly signifies palm-wine. Pliny acknowledges, that the wine of the palm-tree was very well known through all the east, and that it was made by taking a bushel of the dates of the palm-tree, and throwing them into three gallons of water; then squeezing out the juice, it would intoxicate like wine. The wine of the palm-tree is white: when it is drunk now, it has the taste of the cocoa, and is sweet as honey. When it is kept longer, it grows stronger, and intoxicates. After long keeping, it becomes vinegar.

SICILIAN, in Music, denotes a kind of gay, sprightly air, or dance, probably invented in Sicily, somewhat of the nature of an English jig; usually marked with the characters 6 8 and 12 8. It consists of two strains; the first of four, and the second of eight, bars or measures.

SICILY, is a large island in the Mediterranean sea, adjoining to the southern extremity of Italy, and extends from latitude 36° 25' to latitude 38° 25', and from longitude 12° 50' to longitude 16° 5' east from London. Its greatest length 210 miles, breadth 133, circumference 600; its form triangular, the three angles being the promontories of Pelorum, Pachynum, and Lillybæum, or, as they are now called, the Faro, Capo Passaro, and Capo Boco. It is divided from Italy by the straits of Messana, reaching from the tower of Faro, which is the most northerly part of the island, to the Capo dell'Armi, or the Cape of Arms, the most southern part of Calabria. These straits, by the Latina called Fretum Siculum, by the Italians Il Faro di Messina, and by us the Faro di Messina, are between 12 and 15 miles over in the broadest places, and in the narrowest about a mile and a half; insomuch that when Messina was taken by the Carthaginians, many of the inhabitants are said to have saved themselves by swimming to the opposite coast of Italy. Hence has arisen an opinion that the island of Sicily was originally joined to the continent, but afterwards separated by an earthquake or some other natural cause. This separation, however, is reckoned by the most judicious among the ancients to be fabulous; and they content themselves with speaking of it as a thing said to have happened.

Anciently this island was called Sicenion, Sicilia, and Trinacria or Trigeta; the two former it had from the Sicanii and Siculi, who peopled a considerable part of the country; the two latter from its triangular figure. Its first inhabitants, according to the most respectable ancient authors, were the Cyclopae and Læstrigones, who are said to have settled in the countries adjoining to Mount Etna; but of their origin we know nothing, except what is related by the poets. After them came the Sicanii, who called themselves the original inhabitants of the country; but several ancient historians informs us that they came from a country in Spain watered by the river Sicion. Diodorus, however, is of opinion, that the Sicanii were the most ancient inhabitants of this island. He tells us that they were in possession of the whole, and applied themselves to cultivate and improve the ground in the neighbourhood of Etna, which was the most fruitful part of the island: they built several small towns and villages on the hills to secure themselves against thieves and robbers: and were governed, not by one prince, but each city and district by its own king. Thus they lived till Etna began to throw out flames, and forced them to retire to the western parts of the island, which they continued to inhabit in the time of Thucydides. Some Trojans, after the destruction of their city, landed in the island, settled among the Sicanii, and built the cities of Eryx and Egesta, uniting themselves with them, and taking the general name of Elymi or Elymii. They were afterwards joined by some Phocenses, who settled here on their return from the siege of Troy.

After the Sicanii had for many ages enjoyed an undisturbed possession of the whole of Sicily, or such parts of it as they chose to inhabit, they were visited by the Siculi, who were the ancient inhabitants of Ausonia properly so called; but being driven out from thence by the Opici, they took refuge in the island of Sicily. Not being contented with the narrow bounds allowed them by the Sicanii, they began to encroach upon their neighbours; upon which a war ensuing, the Sicanii were utterly defeated, and confined to a corner of the island, the name of which was now changed from Sicenion into that of Sicilia.

About 350 years after the arrival of the Siculi, the island first began to be known to the Greeks, who established various colonies, and built many cities in different parts of the island; and it is only from the time of their arrival that we have any history of the island. The first of the Greeks that came into Sicily were the Chalcidians of Euoboea, under the conduct of Thucles, who built Naxus, and a famous altar of Apollo, which, as Thucydides tells us, was still standing in his time without the city. The year after which was, according to Dionysius Halicarnassensis, the third of the 17th Olympiad, Archias the Corinthian, one of the Heraclids, laid the foundations of Syracuse. Seven years after, a new colony of Chalcidians founded Leontini, and Catana, after having driven out the Siculi, who inhabited that tract. About the same time Lamis, with a colony from Megara, a city of Achaia, settled on the river Pantacius, at a place called Troilium, where his adventurers lived some time in common with the Chalcidians of Leontini; but being driven from thence by the Leontines, he built the city of Thapsus, where he died. Upon his death, the colony left Thapsus; and, under the conduct of Hyblon king of the Siculi, founded Megara Hyblae, where they resided 245 years, till...
sic

they were driven out by Gelon tyrant of Syracuse. During their abode at Megara, they sent one Pamphilus, who was come from Megara in Achaia, their original city, to build Selinus. This city was founded about 100 years after the foundation of Megara. Antipheus and Entimus, the former a Rhodian, the other a Cretan, led each a colony of their countrymen, and jointly built the city of Gela on a river of the same name, establishing in their new settlement the Doric customs, about 45 years after the founding of Syracuse. The inhabitants of Gela founded Agrigentum 108 years after their arrival in Sicily, and introduced the same customs there. A few years after, Zancle was built by the pirates of Cumae in Italy; but chiefly peopled by the Chalcidians, Samians, and Ionians, who chose rather to seek new settlements than live under the Persian yoke. Some time after, Anaxales, tyrant of Rhegium, drove out the ancient proprietors; and, dividing his lands amongst his followers, called the city Messana or Messene, which was the name of his native city in Peloponnesus. The city of Himera was founded by the Zancleans under the direction of Eucleides, Simus, and Sacca; but peopled by the Chalcidians and some Syracusan exiles, who had been driven out by the contrary faction.

The Syracusans built Acra, Chamaene, and Camarina; the first 70 years, the second 90, and the third 133, after the foundation of their own city. This is the account which Thucydides, a most judicious and exact writer, gives us of the various nations, whether Greeks or Barbarians, who settled in Sicily. Strabo counts among the ancient inhabitants of Sicily the Morges, who being driven out of Italy by the Oenotrians, settled in that part of the island where the ancient city of Morgantum stood. The Campani, who assumed the name of Mamertini, that is, invincible warriors, and the Carthaginians, who settled very early in Sicily, ought likewise to be counted among the ancient inhabitants of the island.

Before this period the history of Sicily is blended with fables, like the early history of almost every other country. After the settlement of the Greeks in the island, its various revolutions have been traced from their several sources by many writers; but by none with greater accuracy than Mr Swinburne. From his account of his Travels in the Two Sicilies, we have therefore taken the following concise history of this kingdom, which will at once gratify such of our readers as are interested in themselves in the fate of a generous people who long struggled in vain for freedom; and at the same time afford them a specimen of the entertainment they may receive from the very elegant work of the author.

Aristocracy prevailed at first in the Greek settlements, but soon made way for tyranny; which in its turn was expelled by democracy. One of the earliest destroyers of common liberty was Phalaris of Agrigentum, who reigned 620 years before Christ: his example was contagious; a legion of tyrants sprang up, and not a commonwealth in the island escaped the lash of an usurper. Syracuse was most oppressed and torn to pieces by dissension; as its wealth and preponderance in the general scale held out a greater temptation than other cities to the ambition of wicked men. It requires the combined testimony of historians to enforce our belief of its wonderful prosperity, and the no less extraordinary tyranny of some of its sovereigns. These Grecian colonies attained to such excellence in arts and sciences as emboldened them frequently to vie with the learned and ingenious in the mother country; nay, often enabled them to bear away the palm of victory: these needs no stronger proof of their literary merits than a bare recital of the names of Archimedes, Theocritus, Gorgias, and Charondas.

But the Sicilian Greeks were not destined to enjoy their sweets of their situation without molestation. Very soon after their arrival, the inhabitants of the meagre great portion of the island, and about 500 years before the Christian era had made themselves masters of all the western parts of it. The Siculi retained possession of the midland country, and the southern and eastern coasts were inhabited by the Greeks.

About that time Gelo was chosen prince of Syracusans on account of his virtues, which grew still more conspicuous after his exaltation: these were followed by his successors, the advantages of freedom would never have been known or wished for by the Syracusans. The Carthaginians found in him a vigorous opponent to their project of enlisting Sicily, a project in vain pursued but never accomplished. He succeeded his brother Gelo, and, contrary to the usual progression, began his reign by a display of bad qualities. Sensible of his error, and improved by experience, he afterwards adopted more equitable measures. At his death the Syracusans threw off the yoke, and for sixty years revelled in all the joys of freedom. Their peace was, however, disturbed by the Athenians and the Carthaginians. The latter plundered Agrigentum, and threatened ruin to the rest of the Grecian states; but a treaty of peace averted that storm. The Athenians, under pretence of supporting their allies the people of Segesta, but in reality from a thirst of dominion, invested Syracuse with a formidable land and naval armament under the command of Nicias; in consequence of a rash indigestible plan, ill conducted attacks, and inadequate supplies, their whole host was cut to pieces or led away into captivity.

Syracuse had scarcely time to breathe after her victory ere intestine wars broke out, and raised Dionysius the elder to supreme command. Avarice, despotism, and cruelty, marked every day of his reign; but his military enterprises were crowned with constant success. He died in peace, and bequeathed a powerful sovereignty to a son of his name tinctured with the same and worse vices, but not endowed with equal capacity and martial ability; in such hands the rod of tyranny ceased to be formidable, and the tyrant was driven out of Sicily by the patriotic party; but matters were not sufficiently settled for popular government, and Dionysius resumed the sceptre for a while, till Timoleon forced him into perpetual exile.

Liberty seemed now to be established on a permanent basis; but in Syracuse such prospects always proved illusory. Agathocles, a tyrant more inhuman than any preceding usurper, seized the throne, and deluged the country with blood. He was involved in a perilous contest with the Carthaginians, who obtained many advantages
His grandson Hieronymus, forsaking this happy line of politics, and contracting an alliance with Carthage, fell an early victim to the troubles which his own folly had excited. Once more, and for the last time, the Syracusans found themselves in possession of their independence: but the times were no longer suited to such a system; dissensions gained head, and distracted the public councils. Carthage could not support them, or prevent Marcus from undertaking the siege of Syracuse, immortalized by the mechanical efforts of Archimedes, and the immensity of the plunder. See SYRACUSE.

The Sicilians after this relinquished all martial ideas, Sicily continued plundered by the Saracens, and agriculture. Their position in the centre of the Roman empire preserved them both from civil and foreign by the Nor- manes, except in two instances of a servile war. The capacity of their governors was a more constant and insupportable evil. In this state of apathy and opulence Sicily remained down to the 7th century of our era, when the Saracens began to disturb its tranquillity. The barbarous nations of the north had before ravaged and ravaged its coasts, but had not long kept possession. The Saracens were more fortunate. In 827 they availed themselves of quarrels among the Sicilians to subdue the country. Palermo was chosen for their capital, and the standard of Mahomet triumphed about 200 years. In 1038 George Maniaces was sent by the Greek emperor with a great army to attack Sicily. He made good his landing, and pushed his conquests with vigour; his success arose from the employment of some Norman troops, which were at that time unemployed and ready to sell their services to the best bidder. Maniaces repaid them with ingratitude; and by his absurd conduct gave the Mussulmans time to breathe, and the Normans a pretext and opportunity of invading the Imperial dominions in Italy. Robert and Roger of Hauteville afterwards conquered Sicily on their own account, not as mercenaries; for having substantially settled their power on the continent, they turned their arms against this island in obedience to the dictates of zeal and ambition. After ten years struggle, the Saracens yielded up the rich prize, and Robert ceded it to his brother Roger, who assumed the title of Great Earl of Sicily, ruled the state with wisdom, and ranks deservedly among the greatest characters in history. He raised himself from the humble station of a poor younger son of a private gentleman, to the exalted dignity of a powerful monarch, by the sole force of his own genius and courage; he governed a nation of strangers with vigour and justice, and transmitted his possessions undisputed to his posterity. Such an assemblage of great qualities is well intituled to our admiration.

He was succeeded by his son Simon, whose reign was short, and made way for a second son called Roger. In dominion 1127 this prince joined to his Sicilian possessions the whole inheritance of Robert Guiscard. (see NAPLES, N° 23.), and assumed the regal style... The greatest part of his reign was taken up in quelling revolts in Italy, but Sicily enjoyed profound peace. In 1154 his son William ascended the throne, and passed his life in war and confusion. William II. succeeded his father, and died without issue. Tancred, though basely born, was elected his successor, and after him his son William III. who was vanquished by Henry of Swabia. During...
the troubles that agitated the reign of his son the emperor Frederic, peace appears to have been the lot of Sicily. A short-lived sedition, and a revolt of the Saracens, are the only commotions of which we read. For greater security, the Saracens were removed to Puglia 400 years after the conquest of Sicily by their ancestors. Under Conrad and Manfred Sicily remained quiet; and from that time the history of Sicily is related under the article Naples, N° 20, &c.

15

At the death of Charles II. of Spain, his spoils became an object of furious contention; and at the peace of Utrecht, Sicily was ceded to Victor duke of Savoy, who, not many years after, was forced by the emperor Charles VI. to relinquish that fine island, and take Sardinia as an equivalent. But as the Spaniards had no concern in these bargains, they made a sudden attempt to recover Sicily, in which they failed through the vigilance of the English admiral Byng. He destroyed their fleet in 1718, and compelled them to drop theirscheme for a time. In 1734 the Spanish court resumed their design with success. The infant Don Carlos drove the Germans out, and was crowned king of the two Sicilies at Palermo. When he passed into Spain to take possession of that crown, he transferred the Sicilian diadem to his son Ferdinand III. of Sicily, and IV. of Naples, and it has ever since remained in the possession of the same family.

Account of the straits of Messina

Sicily is separated, as we have already observed, from Italy by a narrow strait called the Forno of Messina. This strait is still remarkable for the rapidity of its currents and the irregular ebb and flowing of the sea, which sometimes rushes in with such violence as to endanger ships riding at anchor. Anciently it was much more remarkable for Scylla and Charybdis, the one a rock, and the other a whirlpool, between which it was very dangerous to steer, and concerning which so many fables have been related by the ancients. Scylla is a rock on the Italian side, opposite to Cape Pylorus, which runs out into the sea on the Sicilian side. Mr Brydone informs us, that the navigation of the straits is not even yet performed without danger. He also informs us, that the noise of the current which sets through the straits may be heard for several miles, like the roaring of some large impetuous river confined between narrow banks. In many places the water rose into whirlpools and eddies, which are dangerous to shipping. The current set exactly for the rock of Scylla, and would certainly have carried anything thrown into it against that point. Our author, however, is by no means of opinion that the strait is so dangerous as the ancients have represented it; though he thinks that the strait is now probably much wider than formerly, which may have diminished the danger. There are many small rocks, which show their heads near the base of the large ones. These are probably the dogs described by the ancient poets as howling round Scylla. The rock is near 200 feet high, and has a kind of a castle or fort built on its summit with a town called Scylia or Sciglio, containing 300 or 400 inhabitants on its south side, which gives the title of prince to a Calabrese family.

The following account of these rocks and whirlpools is given by the celebrated naturalist Spallanzani. He informs us, that Scylla is a lofty rock, 12 miles from Messina, rising almost perpendicular from the sea on the shore of Calabria, beyond which is the small city of the same name. Though there was scarcely any wind, Spallanzani heard, about two miles distant from the rock, a noise like a confused barking of dogs, and on a nearer approach he discovered the cause. This rock contains a number of caverns, one of the largest of which is called by the people Drogara. The waves, when in the least agitated, rushing into these caverns, break, dash, throw up frothy bubbles, and thus occasion these various and multiplied sounds. He then perceived with how much truth and resemblance of nature Homer and Virgil, in their personifications of Scylla, had portray ed this scene, by describing the monster they drew as lurking in the darkness of a vast cavern, surrounded by ravenous barking mastiffs, together with wolves, to increase the horror.

Though the tide is almost imperceptible in the open parts of the Mediterranean, it is very strong in the strait of Messina, owing to the meandering of the channel, and regulated by the periodical elevations and depressions of the water. Where the current is accompanied by a wind blowing the same way, vessels have nothing to fear, since they either do not enter the strait, both the wind and stream opposing them; or, if both are favourable, enter on full sail, and pass with such rapidity that they seem to fly over the water. When the current runs from south to north, and the north wind blows hard at the same time, the ship is resisted by the opposite current, and impelled by two forces in contrary directions, is dashed on the rock of Scylla, or driven on the neighbouring sands. The current, where it is strongest, does not extend over the whole strait, but winds through it in intricate meanders, with the course of which the sailors stationed to give strangers assistance are well acquainted, and thus able to guide the ship in such a manner as to avoid it. Should the pilot, however, confiding in his own skill, neglect such assistance, he would run the most imminent risk of being shipwrecked.

In this conflict of the waters, it is useless to throw the line to discover the depth of the bottom, the violence of the current frequently carrying the lead almost on the surface of the water. The strongest cables, though some feet in circumference, break like small cords. Every expedient afforded by the art of navigation, is useless here. The only means of avoiding being dashed against the rocks, or driven upon the sands in the midst of this perilous contest of the winds and waves, is to have recourse to the skill and courage of the Messinese seamen.

Charybdis is distant from the shore of Messina about 750 feet, and is called by the people of the country Calafaro, not from the agitation of the waves, but from Cala and Faro, beautiful tower, from the lighthouse erected near it for the guidance of vessels. When the current sets in from the north, the pilots call it the descending rema, or current; and when it runs from the south, the ascending rema. The current ascends or descends at the rising or setting of the moon, and continues for six hours. In the interval between each ascent or descent, there is a calm which lasts at least 15 minutes, but not longer than an hour. Afterwards, at the rising or setting of the moon, the current enters from the north, making various angles of incidence with the shore, and at last reaches the Calafaro. This delay sometimes...
among them. Some treatises have been written concerning this phenomenon; but nothing satisfactory has been delivered concerning its cause.

Though Sicily lies in a warm climate, the air is healthful, being refreshed with sea-breezes on every side. It has at all times been remarkably fertile; but the era, of its greatest prosperity was from the siege of Syracuse by the Athenians to the Carthaginian conquests. Then and long after it supplied with grain, in years of scarcity, all the countries upon the Mediterranean except Egypt and the coasts of Asia, and Rome and Carthage continually. Even now, under all the impediments of superstition and bad government, its productions are, in quantity and quality, the best in Europe. Of the vegetable are grain, wines, oil, fruits, tobacco, mulberry trees for the silkworm, cotton, medicinal roots, and sugar canes. The last of these flourish near Avola and Merilli. They are of an inferior quality to those of the West Indies, but their sugar is sweeter than any other. The animal productions are by no means inferior to those of Italy, but the horned cattle are a smaller breed. The coasts abound with fish, particularly with tunny and anchovies; the export of which forms a very lucrative branch of commerce. There are mines of silver, copper, and lead, but none are worked. Near Palma are beds of the best sulphur; at the mouth of the river Giarretta is found a yellow amber, preferable to that of the Baltic: and in every part of the island quarries of marbles, that have furnished materials for all the noble edifices of Sicily. The most beautiful are in the neighbourhood of Palermo, particularly the yellow, and those that resemble the verde antique, porphyry, and lapis lazuli. The population of the island in 1815, amounted to 1,655,000 souls; not as much again as the single city of Syracuse formerly contained.

Here are several rivers and good springs; but few of rivers and mountains.

If a ship be extricated from the fury of Charybdis, and carried by a strong southerly wind along the strait towards the northern entrance, it will indeed pass out safely; but should it meet with a wind in a nearly opposite direction, it would become the sport of both these winds, and unable to advance or recede, be driven in a middle course between their two directions, that is to say, full upon the rock of Scylla, if it be not immediately assisted by the pilots. It is likewise observed, that in these hurricanes a land wind frequently rises, which descends from a narrow pass in Calabria, and increases the force with which the ship is impelled towards the rock. Thus, the saying which became proverbial among the ancients—that "he who endeavours to avoid Charybdis, dashes upon Scylla," is, in a great measure, true.

In the straits, Mr Brydone informs us, a most surprising phenomenon is to be observed. In the heat of summer, after the sea and air have been much agitated, there appears in the heavens over the straits a great variety of singular forms, some at rest and others moving with great velocity. These forms, in proportion as the light increases, seem to become more aerial, till at last, some time before sunrise, they totally disappear. The Sicilians represent this as the most beautiful sight in nature. Leonti, one of the best Sicilian writers, says, that the heavens appear crowded with a variety of objects, such as palaces, woods, gardens, &c. besides the figures of men and other animals that are seen in motion.

Vol. XIX. Part I.
them from future oppression. In these disputes, the
king has the advantage at least of power, if not of right;
and several works, in which the claims of the Sicilian
barons have been asserted, were publicly burned not
many years ago.

As the sovereign holds his court at Naples, Sicily is
governed by a viceroy, who is appointed only for three
years, though at the end of that term his commission is
sometimes renewed. He lives in great state, and, as
the representative of the king, his power is very con-
siderable. He presides in all the courts and departments
of government, and is commander in chief of all the
forces: he calls or dissolves the parliament when he
pleases; and by him all orders, laws, and sentences, must
be signed; and his office is far from being desirable, as
it generally renders him the object either of the jealousy
of the court of Naples, or of the hatred of the Sicilians.
The parliament consists of the nobles, the bishops,
and abbots, and the representatives of 43 cities, which
are immediately subject to the crown. Those cities
which are subject to any of the nobles send no members
to the parliament; in these the king has not much au-
thority, and derives little advantage from them. Ac-
cording to the laws, the parliament ought to be assem-
bled at the end of every three years: but the govern-
ment pays little attention to this rule. The common
people are in general very much attached to the nobles,
and are inclined to take their part in all their differen-
ces with the court: but the magistrates and principal
inhabitants of the cities which belong to these feudal
lords, wish to get rid of their authority, and imagine
that they should be less oppressed, if immediately sub-
ject to the king; these inclinations are not disagreeable
to the court, and are encouraged by most of the law-
yers, who are of great service to government in contest-
ing the privileges of the nobles. Many of these privi-
leges are now abridged; and the power of the barons,
with respect to the administration of justice in their do-
 mains, was very properly limited by the viceroy Ca-
raccioli, in the year 1785. The government of this
nobleman was very beneficial to Sicily, as he, in a great
measure, cleared the island of the banditti that used to
infest it, and made several excellent regulations for the
establishment of social order and personal security. He
deserves the thanks of every well-wisher to mankind for
having abolished the court of inquisition, which had
been established in this country by Ferdinand the Cat-
tholic, and made dependent on the authority of the
grand inquisitor of Spain. Its last auto da fe was held
in the year 1724, when two persons were burned. At
length Charles III. rendered it independent of the Spa-
nish inquisitor, and abrogated its power, by forbidding it
to make use of the torture, and to inflict public punis-
ments. The Marchese Squillace, and his successor the
Marchese Tanucci, were both enemies to the hierarchy
and, during their vicerealties, took care to appoint sen-
sible and liberal men to the office of inquisitor: the last
of whom was Ventimiglia, a man of a most humane and
amiable character, who heartily wished for the abolition
of this diabolical court, and readily contributed toward
it. While he held the office of inquisitor, he always
deavored to procure the acquittal of the accused; and
when he could succeed no other way, would pretend
some informality in the trial. The total annihilation of
this instrument of the worst of tyranny was reserved for
Caraccioli. A priest being accused to the inquisition,
was dragged out of his house and thrown into the du-
gon. He was condemned; but, on account of inform-
ality, and a violation of justice in the trial, he appeal-
 ed to the viceroy, who appointed a committee of juris-
to examine the process. The inquisitor refused to ac-
knowledge the authority of this commission; pretending
that to expose the secrets of the holy office, and to sub-
mit its decisions to the examination of lay judges, would
be so inconsistent with his duty, that he would see the
inquisition abolished rather than consent to it. Carac-
cioli took him at his word, and procured a royal mandate
by which the holy office was at once annihilated. He
assembled all the nobility, judges, and bishops, on the
27th of March 1782, in the palace of the inquisition,
and commanded the king’s order to be read; after
which he took possession of the archives, and caused all
the prisons to be set open: in these were at that time
only two prisoners, who had been condemned to per-
petual confinement for witchcraft. The papers relat-
ing to the finances were preserved; but all the rest
were publicly burned. The possessions of the holy office
were assigned to the use of churches and charitable in-
stitutions: but the officers then belonging to it retained
their salaries during their lives. The palace itself is
converted into a customhouse, and the place where he-
retics were formerly roasted alive for the honour of the
Catholic faith, is now changed into a public garden.
The cognizance of offences against orthodoxy is com-
mited to the bishops: but they cannot cite any one
to appear before them without permission from the vice-
roy; neither can they confine any person to a solitary
prison, nor deny him the privilege of writing to his
friends, and conversing freely with his advocate. The
nobility are so numerous in this island, that Labat says
it is paved with noblemen. The general assembly of
parliament is composed of 66 archbishops, bishops, ab-
bots, and priors, which form the Braccio ecclesiastic.
Fifty-eight princes, 27 dukes, 37 marquises, 27 counts,
one viscount, and 79 barons, form the military; and
the demesne comprises 43 representatives of free towns.
Out of each braccio four deputies are chosen to con-
duct public business. The government was new-model-
led while the British forces occupied the island; but
the alterations introduced have since fallen to the
ground. The government has resumed its old course,
and the noblemen who supported the reform have been
banished. See Russell’s Tour, 1817.

SICINIUS DENTATUS, a tribune of the people,
lived a little after the expulsion of the kings from Rome.
He was in 120 battles and skirmishes, besides single com-
bats, in all of which he came off conqueror. He served
under nine generals, all of whom triumphed by his
means. In these battles he received 45 wounds in the
forepart of his body, and not one in his back. The se-
nate made him great presents, and he was honoured with
the name of the Roman Achilles.

SICYOS, a genus of plants belonging to the class of
monocotyledons, and to the order of syngenesia; and in the
natural system arranged under the 34th order, Cucur-
biteris. See Botany Index.

SIDA, Yellow or Indian MALLOW, a genus of plants
belonging to the class of monadophia, and to the order
of polyandra; and in the natural system ranging under
the 37th order, Cuminum ferum. See Botany Index.

SIDDEE,
SIDEE, or Sedee, an Arabic title, by which the Abyssinians or Habashys are always distinguished in the courts of Hindostan; where, being in great repute for firmness and fidelity, they are generally employed as commanders of forts or in posts of great trust.

SIDERAL YEAR. See Astronomy Index.

SIDERIA, in Natural History, the old name of a genus of crystals, used to express those altered in their figure by particles of iron. These are of a rhomboidal figure, and composed only of six planes. Of this genus there are four known species. 1. A colourless, pellucid, and thin one; found in considerable quantities among the iron ores of the forest of Dean, in Gloucestershire, and in several other places. 2. A dull, thick, and brown one; not uncommon in the same places with the former. And, 3. A black and very glossy kind, a fossil of great beauty; found in the same place with the others, as also in Leicestershire and Sussex.

SIDERITE, a substance supposed by Meyer to be a new metal; but according to Bergman and Kirwan it is nothing else than a natural combination of phosphoric acid with iron.

SIDERITIS, Iron-wort; a genus of plants belonging to the class of didynamia, and to the order of gymnospernia; and in the natural system ranging under the 42d order, Verticillata. See Botany Index.

SIDEROXYLON, Iron-wood; a genus of plants belonging to the class of pentandria, and to the order of monogyenia; and in the natural system ranging under the 53d order, Dusome. See Botany Index.

SIDNEY, Sir Philip, was born, as is supposed, at Penshurst in Kent in the year 1554: His father was Sir Henry Sidney, an Irish gentleman, and his mother Mary the eldest daughter of John Dudley, Duke of Northumberland. He was sent when very young to Christchurch college at Oxford, but left the university at 17 to set out on his travels. After visiting France, Germany, Hungary, and Italy, he returned to England in 1575, and was next year sent by Queen Elizabeth as her ambassador to Rudolph emperor of Germany. In his return he visited Don John of Austria, governor of the Netherlands by whom he was received with great respect. In 1579, when Queen Elizabeth seemed on the point of concluding her long projected marriage with the duke of Anjou, Sir Philip wrote her a letter, in which he dissuaded her from the match with unusual elegance of expression, as well as force of reasoning. About this time a quarrel with the earl of Oxford occasioned his withdrawing from court; during which retirement he is supposed to have written his celebrated romance called Arcadia.

In 1585, after the queen's treaty with the United States, he was made governor of Flushing and master of the horse. Here he distinguished himself so much both by his courage and conduct, that his reputation rose to the highest pitch. He was named, it is pretended, by the republic of Poland as one of the competitors for that crown, and might even have been elected had it not been for the interference of the queen. But his illustrious career was soon terminated; for in 1586 he was wounded at the battle of Zutphen, and carried to Arnhem, where he soon after died. His body was brought to London, and buried in St Paul's cathedral. He is described by the writers of that age as the most perfect model of an accomplished gentleman that could be formed even by the wanton imagination of poetry or fiction. Virtuous conduct, polite conversation, heroic valour, and elegant erudition, all concurred to render him the ornament and delight of the English court: and as the credit which he enjoyed with the queen and the earl of Leicester was wholly employed in the encouragement of genius and literature, his praises have been transmitted with advantage to posterity. No person was so low as not to become an object of his humanity. After the battle of Zutphen, while he was lying on the field mangled with wounds, a bottle of water was brought him to relieve his thirst; but observing a soldier near him in a like miserable condition, he said, This man's necessity is still greater than mine; and resigned to him the bottle of water. Besides his Arcadia, he wrote several smaller pieces both in prose and verse, which have been published.

Sidney, Algernon, was the second son of Robert Earl of Leicester, and of Dorothy eldest daughter of the Earl of Northumberland. He was born about the year 1617. During the civil wars he took part against the king, and distinguished himself as a colonel in the army of the parliament. He was afterwards appointed one of King Charles's judges, and declined appearing in that court. During the usurpation of Cromwell, Sidney, who was a violent republican, retired to the country, and spent his time in writing those discourses on government which have been so deservedly celebrated. After the death of the Protector, he again took part in the public transactions of his country, and was abroad on an embassy to Denmark when King Charles was restored. Upon this he retired to Hamburgh, and afterwards to Francfort, where he resided till 1677, when he returned to England and obtained from the king a pardon. It has been affirmed, but the story deserves no credit, that during his residence abroad King Charles hired ruffians to assassinate him. After his return he made repeated attempts to procure a seat in parliament, but all of them proved unsuccessful. After the intention of the commons to exclude the duke of York from the throne had been defeated by the sudden dissolution of parliament, Sidney joined with eagerness the councils of Russell, Essex, and Monmouth, who had resolved to oppose the duke's succession by force of arms. Frequent meetings were held at London; while, at the same time, a set of subordinate conspirators, who were not, however, admitted into their confidence, met and embraced the most desperate resolutions. Keithing, one of these men, discovered the whole conspiracy; and Algernon Sidney, together with his noble associates, was immediately thrown into prison, and no art was left unattempted in order to involve them in the guilt of the meager conspirators.

Howard, an abandoned nobleman, without a single spark of virtue or honour, was the only witness against Sidney; but as the law required two, his discourses on government, found unpublished in his closet, were construed into treason, and declared equivalent to another witness. It was in vain for Sidney to plead that papers were no legal evidence; that it could not be proved they were written by him; and that if they were, they contained nothing treasonable. The defence was overruled; he was declared guilty, condemned, and executed! His attainder was reversed in the first year of King William.
S I D O N

He was a man of extraordinary courage; steady even to obstinacy; of a sincere but rough and boisterous temper. Though he professed his belief in the Christian religion, he was an enemy to an established church, and even, according to Burnet, to every kind of public worship. In his principles he was a zealous republican: government was always his favourite study; and his essays on that subject are a proof of the progress which he made.

SIDON, in Ancient Geography, a city of Phoenicia in Asia, famous in Scripture for its riches, arising from the extensive commerce carried on by its inhabitants. Heavy judgments were denounced against the Sidonians on account of their wickedness, which were accomplished in the time of Ochos king of Persia: for that monarch having come against them with an army on account of their rebellion, the city was betrayed by its king; upon which the wretched inhabitants were seized with despair; they set fire to their houses, and 40,000 with their wives and children, perished in the flames.

This city is now called Saïde, and, according to Mr Bruce's account, not only its harbour is filled up with sand, but the pavement of the ancient city stood 7½ feet lower than the ground on which the present city stands. Volney describes it as an ill-built dirty city. Its length along the sea-shore is about 600 paces, and its breadth 150. At the north-west side of the town is the castle, which is built in the sea itself, 80 paces from the main land, to which it is joined by arches. To the west of this castle is a shoal 15 feet high above the sea, and about 200 paces long. The space between this shoal and the castle forms the road, but vessels are not safe there in bad weather. The shoal, which extends along the town, has a basin inclosed by a decayed pier. This was the ancient port; but it is so choked up by sand, that boats alone can enter its mouth near the castle. Fakr-el-din, emir of the Druses, destroyed all these little ports from Bairout to Acre, by sinking boats and stones to prevent the Turkish ships from entering them. The basin of Saïde, if it were emptied, might contain 20 or 25 small vessels. On the side of the sea, the town is inclosed within the sea wall; and that which incloses it on the land side is no better than a prison-wall. The whole artillery does not exceed six cannons, and these are without carriages and gunners. The garrison scarcely amounts to 100 men. The water comes from the river Aoula, through open canals, from which it is fetched by the women. These canals serve also to water the orchards of mulberry and lemon trees.

Saïde is a considerable trading town, and is the chief emporium of Damascus and the interior country. The French, who are the only Europeans to be found there, have a consul, and five or six commercial houses. Their exports consist in silks, and particularly in raw and spun cottons. The manufacture of this cotton is the principal art of the inhabitants, the number of whom may be estimated at about 5000. It is 4½ miles west from Damascus.

E. Long. 36. 5. N. Lat. 37.

S I D U S G E R O M I U M, in Astronomy, a new primary planet, discovered by Dr Herschel in the year 1781. By most foreign, and even by some British philosophers, it is known by the name of Herschel, in honour of the discoverer. As the other planets are distinguished by marks or characters, the planet Herschel is distinguish-
ed by an H, the initial letter of the discoverer's name, and a cross to show that it is a Christian planet. See Astronomy Index.

S I E G E, in the art of war, is to surround a fortified place with an army, and approach it by passages made in the ground, so as to be covered against the fire of the place.

SIEGEN, a town of Germany in Wetteravia, with a castle and the title of a principality, which it gives to a branch of the house of Nassau. It is seated on a river of the same name, in E. Long. 8. 5. N. Lat. 50. 53.

SIENNA, a large, ancient, and celebrated city of Tuscany in Italy; capital of the Sienese, with an archbishop's see, a famous university, and a citadel. It is about four miles in circumference, and surrounded with an old wall. The metropolitan church is much esteemed by travellers; and though it is a Gothic structure, the architecture is admirable. It is built with black and white marble, and the pavement is of mosaic work. The town is adorned with a great number of palaces, fountains, and superb churches, as also a magnificent hospital. The great area is round, and the houses about it are of the same height, supported by piazzas, under which people may walk in hot or rainy weather; in the middle is a basin, which can be filled with water at any time, to represent a sea fight with small vessels. The Italian language is taught here with such purity, that a great many foreigners frequent it on that account. It is seated on three eminences, in a fertile soil, in E. Long. 11. 11. N. Lat. 43. 10.

SIENNESE, a duchy in Italy; bounded on the north by the Florentino, on the south by the Mediterranean sea and the duchy of Castro, on the east by the Perugino and Orvietano, and on the west by the Florentino and the Tuscan sea; being about 55 miles in length, and as much in breadth. The soil is pretty fertile, especially in mulberry trees, which feed a great number of silk-worms; and there are several mineral springs. Sienna is the capital town.

SIERRA LEONA, a large country on the west coast of Africa, which some extend from the Grain Coast only as far as Cape Verge or Cape Grafton in the north-west, i.e. between 9° and 10° N. Lat. Others, however, confine the country between Cape Verge and Cape Tagrin. There runs through it a great river of the same name, of which the source is unknown but the mouth is in longitude 12° 30. west, lat. 8. 5. north, and is nine miles wide. The climate and soil of this tract of country appear to be, on both sides of the river, among the best in Africa, or at least the most favourable to European constitutions. The heat is much the same as that of the West Indies; but on the higher grounds there is a cool sea breeze, and in the mountainous parts the air is very temperate. According to Lieutenant Matthew, "Sierra Leona, if properly cleared and cultivated, would be equal in salubrity and superior in produce to any of the islands in the West Indies;" and others have affirmed, that "the air is better for a man's health than in many places of Europe." These advantages of climate induced the English to establish a factory at Sierra Leona; but they chose not the most healthful situation. For the benefit of a spring of good water they fixed their residence in a low valley, which is often overspread with mists and noisome vapours, while the
S I E

air is clear and serene on the summits of the hills, to
which water from the well might easily be carried.

Within the district occupied by this colony are the
Foulahs, who are in general of a tawney complexion,
though many of them are entirely black. They lead a
wandering life, and roam about the country with large
droves of cows, sheep, goats, and horses. They are
much praised by travellers for their hospitality; but
more regard is shown by them for their freedom than
for the comfort of their guests; and when one of their
countrymen has fallen into misfortune, the rest
join stock to redeem him. Elephants are so numerous in
the country of the Foulahs, that they are frequently seen in
droves of 200 together. The people are very dexterous
at hunting them, and other wild beasts; from which they derive their
principal articles of trade.

The animal productions of Sierra Leone are lions,
from which it has its name; leopards, hyenas, musk
cats, and many kinds of weasels; the japanned or chim-pa-
zee, a species of simia, which has a still more stri-
king resemblance to the human figure than even the
erican outang; porcupines, wild dogs, squirrels, and
antelopes. Besides these, which are natives of the
country, oxen thrive in it, and even grow fat. Cattle
are employed in labour, and do not suffer by the
climate; but sheep suffer much from the heat, change
their wool into hair, grow lean and increase very little:
while the hardy goat is here as prolific and large as in
any other country. Of the birds which frequent the
woods of Sierra Leone we can give no perfect account.
A species of crane is mentioned as easily tamed;
common poultry multiply fast; ducks thrive well, but geese
and turkeys seem not to agree with the climate.
Turtles of all kinds are very common, and sometimes of a
large size. Crocodiles or alligators of a non-descript
species have been found ten or twelve feet in length,
and lizards of six different species. Snakes, which are almost
innumerable, haunt the houses in the night in
search of poultry; and one was observed which measured
18 feet, but was happily found not to be venomous.
Fish are in great variety both in the sea and in
the rivers. Besides the whale, the shark, stingy, ray,
and porpoise, there are eels, horse-mackarel, tarpons,
cavillos, mullets, snappers, yellow-tails, old-maides,
ten-pounders, and some other fishes; all of which, except
the eels and ten-pounders, are esteemed fine eating. Oys-
ters are found in great abundance, and another shell-
fish, which the natives eat. Among the zoophytes,
none is more worthy of notice than the common sponge,
which covers all the sandy beaches of the river, particu-
larly on the Bullom shore, and would fetch a high
price in Great Britain.

Of the numerous vegetable productions of Sierra
Leona, our limits will permit us only to mention the
following. Rice, which is the plant chiefly cultivated,
as the natives subsist almost entirely upon it, grows both
in the high and low grounds. It prospers indeed best
in swamps, though the grain is better in a drier soil.
Next to rice the cassava constitutes the chief food of
the inhabitants, and is cultivated with great care. The
country is also the source of various kinds of pota-
toes, adzules, or the arum esculentum. Oil-palm, plan-
tains, and bananas; papaw, guava, oranges and limes;
poonions, melons, and cucumbers; pine-apples, pigeon-
peas, which dressed like English peas are a good pulse,
mercantile factory, but that, to introduce civilization, cultivation, and a safe trade, the company must provide for the security of the persons and property of the colonists. The directors therefore resolved, that three or four vessels should sail at once, with such a number of people as would be able to protect and assist each other; with goods both for trade and for the supply of the colony. Accordingly several vessels sailed, having on board a council for the government of the colony and the management of the company's affairs; a number of artificers and other servants of the company; some soldiers, and a very few English settlers. The directors were laudably cautious in the choice of colonists. They admitted into the society no white man of bad character, or who was not a declared enemy to the slave-trade; and as the chief object of their enterprise was the civilization of the natives, it was with great propriety that they chose more than three-fourths of their settlers from the free negroes in Nova Scotia, who had borne arms for the British government during the American war. The superintendent and council were particularly instructed to secure to all blacks and people of colour, at Sierra Leone, equal rights and equal treatment, in all respects, with whites. They were to be tried by jury, as well as others; and the council was desired to allot to the blacks employments suited to their present abilities, and to afford them every opportunity of cultivating their talents. All practicable means of maintaining subordination were directed to be used; and the council was especially instructed to promote religion and morals, by supporting public worship and the due observance of the Sabbath, and by the instruction of the people, and the education of children. But no person was to be prevented from performing or attending religious worship in whatever place, time, or manner, he might think fit, or from peaceably inculcating his own religious opinions. Orders were given in choosing the site of a town, to consider health as the first object; and the first town was directed to be called Free Town. Articles for building and cultivation were sent out, besides the cargoes for prosecuting the company's commerce; and schools for reading, writing, and accounts, were ordered to be set up for the purpose of instructing the children of such natives as should be willing to put them under the company's care.

The leading object of the company was to substitute, for that disgraceful traffic which has too long subsisted, a fair commerce with Africa, and all the blessings which might be expected to attend it. Considerable advantage appeared thereby likely to result to Great Britain, not only from our obtaining several commodities cheaper, but also for opening a market for British manufactures, to the increasing demands of which it is difficult to assign a limit. From this connection, Africa was likely to derive the still more important benefits of religion, morality, and civilization. To accomplish these purposes, it was necessary for the company to possess a tract of land, as a repository for their goods, and which the Africans might cultivate in peace, secure from the ravages of the slave-trade. It had been ascertained, beyond a doubt, that the climate and soil of Africa were admirably suited to the growth of sugar, spices, coffee, cotton, indigo, rice, and every other species of tropical produce. The company proposed to instruct the natives to raise these articles, and to set them the example, by a spirited cultivation, on its own account. Directions were given to the company's commercial agent to push forward a trade, in a mode prescribed, in the present produce of Africa. Measures were taken for cultivating, on the company's account, the most profitable tropical produce; and in particular, a person of long experience in the West Indies was ordered to begin a sugar plantation. A mineralogist and botanist were likewise engaged to go out and explore the country for new articles of commerce.

Everything being thus settled upon the most equitable and benevolent principles, the ships sailed with the British colonists, to whom, in March 1792, were added 1131 Blacks from Nova Scotia. The native chiefs being reconciled to the plan, and made to understand its beneficial tendency towards their people, the colony proceeded to build Free-Town, on a dry and rather elevated spot on the south side of the river. It occupied between 70 and 80 acres, its length being about one-third of a mile, and its breadth nearly the same; and it contained near 400 houses, each having one-twelfth of an acre annexed, on which a few vegetables were raised. There were nine streets running from north-west to south-east, and three cross streets, all 80 feet wide, except one of 160 feet, in the middle of which were all the public buildings. These consisted of a governor's house and offices; a large store-house; a large hospital; six or eight other houses, offices, and shops, occupied by the company's servants; and a church capable of containing 800 people. The colonists at first suffered much from the rainy season, against which it was not in their power to provide sufficient protection; but at the end of it they recovered in a great measure their health and spirits, and proceeded with alacrity to execute the various purposes of their settlement. To excite emulation in culture, the government gave premiums to those colonists who raised the greatest quantities of rice, yams, eddoes, cabbages, Indian corn, and cotton, respectively. To limit the excesses of the slave-trade, and gain the favour of the neighbouring chiefs, the directors instructed the governor and council to inform them how native from the neighbourhood, who should be unjustly sold either to or by a British subject. The servants of the company conducted themselves with the utmost propriety, being sober, moral, and exemplary; and from the labours of the clergymen were derived services highly important in every point of view. Before the end of two years from the institution of the colony, order and industry had begun to show their effects in an increasing prosperity. The woods had been cut down to the distance of about three English miles all round the town. By these means the climate had become healthier, and sickness had diminished. The fame of the colony spread not only along the whole western coast of Africa, but also to parts far distant from the coast; embassies had been received of the most friendly nature from kings and princes several hundred miles distant; and the native chiefs had begun to send their children to the colony, with full confidence, to be taught reading, writing, and accounts, and to be brought up in the Christian religion. In a word, it was not without grounds that the directors looked forward to that joyful period when, by the influence of the company's measures, the continent of Africa should be rescued from her present state of darkness and misery, and exhibit a delightful scene of light and
and knowledge of civilization and order, of peaceful industry and domestic comfort. On their benevolent exertions they hoped with confidence for the blessing of Providence; they were countrerased and supported by the British government; and upon the breaking out of the present war, the French Convention authorised one of their agents to write to the directors, requesting a full account of the design of the institution, and the names of the ships employed in their service, and assuring them of the good wishes of the French government to so noble an undertaking. How completely that government fulfilled its promise is very generally known. Having vindicated the rights of man in Europe by the violation of every principle of truth and justice, they determined by the same means to give light and liberty to the Africans; and that they have fully carried their determination into effect will be seen by the following extract of a letter from Mr Azzellius, the company’s botanist, dated Sierra Leona, 15th November 1794. “The French have been here and have ruined us. They arrived on the 28th of September last, early in the morning, with a fleet consisting of one large ship, two frigates, two armed brigs, and one cutter, together with two large armed merchant ships, taken by them at the Isles de Louis, an English slave factory to the north of our colony, and which they have also destroyed and burnt. So well had they concealed their nation, that we took them at first for English. They had English-built vessels, which were rigged in the English way. They showed the English flag, and had their sailors, at least those we saw on deck, dressed like English. In short, we did not perceive our mistake till we observed them pointing their guns. We had not strength sufficient to resist, and therefore our governor gave orders, that as soon as they should begin to fire, the British flag should bestruck, and a flag of truce hoisted. Accordingly this was done, but still they continued firing, and did much damage, both within and without the town. They killed two people and wounded three or four. But as we did not understand the meaning of this proceeding, we asked them for an explanation; and they answered us, that we should display the flag of liberty, as a proof of our submission. We assured them that it should already have been done, if we had had any, which terminated the hostilities from the ships. In the mean time, most of the inhabitants had fled from the town, having taken with them as much of their property as they conveniently could in such a hurry. I was with the governor, together with a number of others; but as soon as I was certain they were enemies, I went towards my own house with a view to save as much as possible of my property and natural collections; but was received in such a manner, that I could not venture to proceed. My house was situated near the shore, and unfortunately just opposite the frigate which fired. I saw the balls passing through the house, and heard them whizzing about my ears. I saw that I should lose all my property; but life was dearer to me, and I hastened to the woods. “In the afternoon the enemy landed, finding the town almost destitute of people, but rich in provision, clothing and other stores. They began immediately to break open the houses and to plunder. What they did not want, they destroyed, burnt, or threw into the river. They killed all the cattle and animals they found in the fields or streets, yards or elsewhere, not sparing even asses, dogs, and cats. These proceedings they continued the whole succeeding week, till they had entirely ruined our beautiful and prospering colony; and when they found nothing more worth plundering, they set fire to the public buildings and all the houses belonging to the Europeans; and burnt, as they said, by mistake nine or ten houses of the colonists. In the mean time, they were not less active on the water. They sent three of their vessels to Bance island, an English slave factory higher up the river, which they plundered and burnt, together with some slave ships lying there. They took besides about 10 or 12 prizes, including the company’s vessels. Most of these they unloaded and burnt. They took along with them also two of our armed vessels, one of which was a large ship, laden with provisions, and which had been long expected; but she unfortunately arrived a few days too soon, and was taken with her whole cargo. We expected at least, to receive our private letters, but even this was refused, and they were thrown overboard. At last, after inflicting on us every hardship we could suffer, only sparing our lives and the houses of the colonists, they sailed on the 13th of October last, at noon, proceeding downwards to the Gold Coast, and left us in the most dreadful situation, without provisions, medicines, clothes, houses, or furniture, &c. &c. and I fear much, that most of us should have perished, had not our friends in the neighbourhood, both native and Europeans, who were so happy as to escape the enemy, been so kind as to send us what they could spare. In the mean time, most of us have either been, or still are, very sick, and many have died for want of proper food and medicine. The worst, however, is now past. At least we are not in any want of provision, although of the coarsest kind, but are destitute of the most necessary articles and utensils for the house, the table, and the kitchen. “It was thus that the Convention executed their purpose of spreading light and liberty through the world. The Sierra Leona colony was established for no other end than to abolish the slave-trade, to enlighten the Africans, and to render them virtuous, rational, free, and happy; and those powerful patrons of the rights of man destroyed that colony with many circumstances of the most wanton cruelty. Though Mr Azzellius is a Swede, and ought therefore to have been protected by the laws of neutrality, they burnt his house with the rest; deprived him of his trunks, his clothes, and his bed; destroyed the natural curiosities which he had collected at the hazard of his life; and carried away the instruments by means of which only he could collect more. “In 1798, Free-Town consisted of about 300 houses, and a number of public buildings, together with three wharfs. The government-house, so situated as to command the town and harbour, was protected by a palisade, and six pieces of cannon. The inhabitants of this colony were then computed at 1200, of whom 15 were shopkeepers, 25 fishermen, 10 trading shipmasters, owners of small vessels, 15 seamen, 20 labourers, sailors, servants of the company, 4 schoolmasters; about one half of the whole population petty farmers, and the rest mechanics. The number of Europeans resident at that time in the colony was
Sierra Leone was about 30, and nearly 400 free natives brought as labourers for wages, on the farms in the colony.

A charter of justice was obtained in 1800, to control the turbulence of the blacks from Nova Scotia, and a small military force from Goree was stationed at Sierra Leone. Parliament allowed the company 70,000l. for the purpose of erecting a fort, with a promise of 8000l. more for the same undertaking. The company also received 10,000l. for their expense in settling the blacks from Nova Scotia, and a vote of parliament agreed to pay 4000l. for supporting the civil government of the colony.

The Maroons arrived in Sierra Leone in the month of October 1800, and greatly assisted in suppressing an insurrection of the Nova Scotia blacks, who had attempted to seize on the government of the colony. A body of natives of the Timmaney, headed by two of the fugitive blacks, made an attack on the unfinished fort on the 18th of November, about day-break, but they were repulsed with loss. A truce was concluded; but it was supposed that the Timmanee chiefs would make use of this interval to form alliances with the natives against the British, in order to exterminate them from this part of Africa. Soldiers to the amount of 65 were brought from Goree, and a ship of war was stationed in the river, to defend the settlement.

In 1802, parliament again voted 10,000l. to the company, for the annual expense of the settlement; and in February 1803, the directors were informed by Lord Hobart, that it would be for the interest of the colony to transfer the civil and military power from the company to the British government.

When Captain Hallowell arrived at Sierra Leone on the 12th of January 1803, he found the colony in a wretched condition, reporting to government on his return, that the Maroons were not satisfied with their condition, regarding it as one in which they could not find subsistence; that provisions of every description were both scarce and dear; that its inhabitants lived in hourly danger from the natives; and that the whole colony lived in a state of despondency. Government, however, were not satisfied, from the explanation of the directors and their servants, that the account of Captain Hallowell was by much too unfavourable. Expectations are indulged that, since the entire abolition of the slave-trade, the colony will soon obtain a flourishing trade with the natives, in the exchange of British manufactures for the raw produce of the interior parts of Africa.

A committee of the house of commons has had a most satisfactory proof of the progressive improvement of the internal administration of the colony, arising from the additional powers conferred on the company by the charter of justice, and the increased vigilance and exertion of the Company's servants. The Maroons have, in a great measure, abandoned some pernicious habits they had long indulged, and by their attachment to the colony, and peaceable demeanour, have merited the approbation of government. The progress made in the erection of works has been considerable, and the colony may be regarded in a state of sufficient security against the attack of any native power. A body of volunteers has been raised within the colony, whose fidelity and attachment have been tried by experience. The sickness and mortality which for some time existed, have in a great degree subsided; and there is reason to believe, that it rather originated with the troops when they entered the colony, and their habits of intemperance, than from any disorder connected with their residence in that situation. The number of births, which has for some time exceeded that of the deaths in the colony, is a satisfactory proof that it is not unfriendly to population.

Sierra Leone is already rendered secure against the only enemies whose hostilities it has immediately to apprehend; its resources are increased; its cultivation reviving; and it is in the possession of every advantage that can arise from the enjoyment of internal tranquillity and order. It is sufficiently manifest, from the inconveniences already experienced in the colony, that during its continuance, it will be essentially necessary to support a local government capable of maintaining order among its inhabitants, and affording them protection. The expense of the civil establishment for some years to come cannot be estimated at less than 10,000l. per annum; that of completing the proposed works has been estimated at 8000l. It also appears that the defence of the colony will require the present volunteer force to be permanently kept up, the expense of which has been estimated at 4000l. per annum; or if the establishment should be discontinued, a regular garrison must be maintained at the constant establishment of 17,000l.

Of 100 effective men, exclusive of about 20 artillery men, which, considering the numerous casualties in that climate, and great expense of supporting them, would exceed the sum already mentioned.

SIERRA MORENA, a considerable ridge of mountains of Andalusia in Spain. See SPAIN.

SIEUR, a title of respect among the French, like that of master among us. It is much used by lawyers, as also by superiors in their letters to inferiors.

SIFANTO, or SIFANTO, an island of the Archipelago, to the west of Paros, to the north-east of Milo, and to the south-west of Serphanto. The air is so good here, that many of the inhabitants live to the age of 120; and their water, fruits, wild fowl, and poultry, are excellent, but more especially the grapes. It abounds with marble and granite, and is one of the most fertile and best cultivated of these islands. The inhabitants employ themselves in cultivating olive-trees and capers; and they have very good silk. They trade in figs, onions, wax, honey, and straw-hats; and may be about 8000 in all. E. Long. 25. 15. N. Lat. 37° 9'.

SI-FANS, or TOU-FANS, a people inhabiting the country on the west of China. Their country is only a continued ridge of mountains, inclosed by the rivers Hoang-lo on the north, Ya-long on the west, and Yang-tze-kiang on the east, between the 30th and 33rd degrees of north latitude.

The Si-fans are divided into two kinds of people; the one are called by the Chinese Black Si-fans, the other Yellow; names which are given them from the different colours of their tents. The black are the most clownish and wretched; they live in small bodies, and are governed by petty chiefs, who all depend upon a greater.

The yellow Si-fans are subject to families, the oldest of which becomes a lama, and assumes the yellow dress. These lama princes, who command in their respective districts, have the power of trying causes, and punish
Imperfection of Sight with regard to Colours. Under the article Colours is given an instance of a strange deficiency of sight in some people, who could not distinguish between the different colours. In the Phil. Trans. vol. lxviii. p. 611, we have an account of a gentleman who could not distinguish a clear colour from black. These imperfections are totally unaccountable from anything we yet know concerning the nature of this sense.

SIGN, in general, the mark or character of something absent or invisible. See Character.

Among physicians, the term sign denotes some appearance in the human body which serves to indicate or point out the condition of the patient with regard to health or disease.

SIGN, in Algebra. See Algebra.

SIGN, in Astronomy, a constellation containing a 12th part of the zodiac. See Astronomy Index.

NAVAL SIGNALS. When we read at our fireside the account of an engagement, or other interesting operation of an army, our attention is generally so much engaged by the results, that we give but little to the movements which led to them, and produced them; and we seldom form to ourselves any distinct notion of the conduct of the day. But a professional man, or one accustomed to reflection, and who is not satisfied with the mere indulgence of eager curiosity, follows every regiment in its movements, endeavours to see their connection, and the influence which they have had on the fate of the day, and even to form to himself a general notion of the whole scene of action, at its different interesting periods. He looks with the eye of the general, and sees his orders succeed or fail.

But few trouble themselves farther about the narration. The movement is ordered; it is performed; and the fortune of the day is determined. Few think how all this is brought about; and when they are told that during the whole of the battle of Custon, Frederic the Great was in the upper room of a country inn, from whence he could view the whole field, while his aids de camp, on horseback, waited his orders in the yard below, they are struck with wonder, and can hardly conceive how it can be done: but, on reflection, they see the possibility of the thing. Their imagination accompanies the messenger from the inn yard to the scene of action; they hear the general's orders delivered, and they expect its execution.

But when we think for a moment on the situation of the commander of a fleet, confined on board one ship, and this ship as much, or more closely, engaged, than any other of the fleet; and when we reflect that here are no messengers ready to carry his orders to ships of the squadron at the distance of miles from him, and to deliver them with precision and distinctness, and that even if this were possible by sending small ships or boats, the vicissitudes of wind and weather may render the communication so tedious that the favourite moment may be irretrievably lost before the order can be conveyed.—When we think of all these circumstances, our thoughts are bewildered, and we are ready to imagine that a sea battle is nothing but the unconnected struggle of individual ships; and that when the admiral has once "cried havoc, and let slip the dogs of war,"
The naval occurrences of modern Europe, mention is frequently made of signals. Indeed, as we have already observed, it seems impossible for a number of ships to act in any kind of concert, without some method of communication. Numberless situations must occur, when it would be impossible to convey orders or information by messengers from one ship to another, and coast and alarm signals had long been practised by every nation. The idea, therefore, was familiar. We find, in particular, that Queen Elizabeth, on occasion of the expedition to Cadiz, ordered her secretaries to draw up instructions, which were to be communicated to the admiral, the general, and the five counsellors of war, and by them to be copied and transmitted to the several ships of the navy, not to be opened till they should arrive in a certain latitude. It was on this occasion (says our historian Guthrie), “that we meet with the first regular sets of signals and orders to the commanders of the English fleet.” But till the movements of a fleet have attained some sort of uniformity, regulated and connected by some principles of propriety, and agreed on by persons in the habit of directing a number of ships, we may with confidence affirm that signals would be nothing but a parcel of arbitrary marks, appropriated to particular pieces of naval service, such as attacking the enemy, landing the soldiers, &c.; and that they would be considered merely as referring to the final result, but by no means pointing out the mode of execution, or directing the movements which were necessary for performing it.

It was James II., when duke of York, who first considered this practice as capable of being reduced into a system, and who saw the importance of such a composition. He, as well as the king his brother, had always showed a great predilection for the sea service; and when appointed admiral of England, he turned his whole attention to its improvement. He had studied the art of war under Turenne, not as a pastime, but as a science, and was a favourite pupil of that most accomplished general. Turenne one day pointed him out, saying, “Behold one who will be one of the first princes and greatest generals of Europe.” When admiral of England, he endeavoured to introduce into the maritime service all those principles of concert and arrangement which made a number of individual regiments and squadrons compose a great army. When he commanded in the Dutch war, he found a fleet to be little better than a collection of ships, on board of each of which the commander and his ship’s company did their best to annoy the enemy, but with very little dependence on each other, or on the orders of the general; and in the different actions which the English fleet had with the Dutch, every thing was confusion as soon as the battle began. It is remarkable that the famous pensionary De Witt, who from a statesman became a navigator and a great sea commander in a few weeks, made the same representation to the States General on his return from his first campaign.

In the memoirs of James II., written by himself, we have the following passage: “1665. On the 15th of March, the duke of York went to Yarmouth, the general rendezvous of the fleet, and hastened their equipment. He ordered all the flag officers on board with him every morning, to agree on the order of battle and rank. In former battles, no order was kept, and this
under the duke of York, was the first in which fighting in a line and regular form of a battle was observed.

This must be considered as full authority for giving the duke of York the honour of the invention. For whatever faults may be laid to the charge of this unfortunate prince, his word and honour stand unimpeachable. And we are anxious to vindicate his claim to it, because our neighbours the French, as usual, would take the merit of this invention, and of the whole of naval tactics, to themselves. True it is, that Colbert, the great and justly celebrated minister of Louis XIV. created a navy for his ambitious and vain-glorious master, and gave it a constitution which may be a model for other nations to copy. By his encouragement, men of the greatest scientific eminence were engaged to contribute to its improvement; and they gave us the first treatises of naval evolutions. But it must ever be remembered, that our accomplished, though misguided sovereign, was then residing at the court of Louis; that he had formerly acted in concert with the French as a commander and flag officer, and was at this very time aiding them with his knowledge of sea affairs. In the memorable day at La Hogue, the gallant Russel, observing one of Tournville's movements, exclaimed, 'There! they have got Pepys among them.' This anecdote we give on the authority of a friend, who heard an old and respectable officer (Admiral Clinton) say, that he had it from a gentleman who was in the action, and heard the words spoken; and we trust that our readers will not be displeased at having this matter of general opinion established on some good grounds.

It was on this occasion, then, that the duke of York made the evolutions of a fleet the object of his particular study, reduced them to a system, and composed that 'System of Sailing and Fighting Instructions,' which has ever since been considered as the code of discipline for the British navy, and which has been adopted by our rivals and neighbours as the foundation of their naval tactics. It does great honour to its author, although its merit will not appear very eminent to a careless surveyor, on account of that very simplicity which constitutes its chief excellence. It is unquestionably the result of much sagacious reflection and painful combination of innumerable circumstances, all of which have their influence; and it is remarkable, that although succeeding commanders have improved the subject by several subordinate additions, no change has to this day been made in its general principles or maxims of evolution.

Till some such code be established, it is evident that signals can be nothing but arbitrary and disconnected hieroglyphics, to be learned by rote, and retained by memory, without any exercise of the judgment; and the acquisition of this branch of nautical skill must be a more irksome task than that of learning the Chinese writing. But such a code being once settled, the character in which it may be expressed becomes a matter of rational discussion.

Accordingly, the sailing and fighting instructions of the duke of York were accompanied by a set of signals for directing the chief or most frequent movements of the fleet. These also were contrived with due judgment, and such attention to distinctness, simplicity, and propriety, that there has hardly been any change found necessary; and they are still retained in the British navy as the usual signals in all cases when we are not anxious to conceal our movements from an enemy.

Notwithstanding this acknowledged merit of the duke of York's signals, it must be admitted that great improvements have been made on this subject, considered as an art. The art military has, in the course of a century past, become almost an appropriate calling, and has therefore been made the peculiar study of its professors. Our rivals the French were sooner and more formally placed in this situation; and the ministers of Louis XIV. took infinite and most judicious pains to make their military men superior to all others by their academical education. A more scientific turn was given to their education, and the assistance of scientific men was liberally given them; and all the nations of Europe must acknowledge some obligations to them for information on every thing connected with the art of war. They have attended very much to this subject, have greatly improved it, and have even introduced a new principle into the art; and by this means have reduced it to the most simple form of reference to the code of sailing and fighting instructions, by making the signals immediately expressive, not of orders, but of simple numbers. These numbers being prefixed to the various articles of the code of instructions, the officer who sees a signal thrown out by the admiral reads the number, and reports it to his captain, perhaps without knowing to what it relates. Thus simplicity and secrecy, with an unlimited power of variation, are combined. We believe that M. de la Bourdonnais, a brave and intelligent officer, during the war 1758, was the author of this ingenious thought.

We do not propose to give a system of British signals. This would evidently be improper. But we shall show our readers the practicability of this curious language, the extent to which it may be carried, and the methods which may be practised in accomplishing this purpose. This may make it an object of attention to scientific men, who can improve it; and the young officer will not only be able to read the orders of the commander in chief, but will not be at a loss, should circumstances place him in a situation where he must issue orders to others.

Signals may be divided into,

I. Day Signals.

II. Night Signals; and,

III. Signals in a Fog.

They must also be distinguished into, 1. Signals of Evolution, addressed to the whole fleet, or to squadrons of the fleet, or to divisions of these squadrons. 2. Signals of Movements to be made by particular ships; and, 3. Signals of Service, which may be either general or particular.

The great extent of a large fleet, the smoke in time during a battle, and the situation of the commander in chief, engage the attention of the officers of distant ships to perceive his signals with the greatest distinctness. Frigates, therefore, are stationed out of the line, to windward or to leeward, whose sole office it is to observe the admiral's signals constantly to repeat them. The eyes of all the signal officers in the private ships of war are directed to the repeating frigates, as well as to the admiral; and the officers of the repeating frigate, having no other duty, observe the admiral incessantly.
The following Signals usually signify

Before we proceed to the description of the signals by means of colours, such as flags, banners (or triangular flags), pendants of vanes, we must take notice of the ostensible distinctions of the various divisions and subdivisions of a fleet, so that we may understand how the same signal may be addressed to a squadron, division, or single ship or ships. We suppose it known that a fleet of ships of war is distributed into three grand divisions (which we shall term squadrons), called the van, centre, and rear. These denominations have not always a relation to the one being more advanced than the other, either towards the enemy, or in the direction of their course.

In a land army, the position of every part is conceived from its reference to the enemy; and the reader, of the terms conceiving himself as facing the enemy, easily understands the terms van, centre, and rear in the line of wing, &c. But the movements of a sea army having battle at a necessary dependence on the wind, they cannot be considered unless expressed in a language which keeps this circumstance continually in view. The simplest and most easily conceived disposition of a fleet, is that in which it is almost indispensably obliged to form in order to engage an enemy. This is a straight line, each ship directly ahead of its neighbour, and close hauled. This is therefore called the line of battle. In this position, the two extremities of the fleet correspond to the right and left wings of an army. Suppose this line to be in the direction east and west, the wind blowing from the north-north-west, and therefore the fleet on the starboard tack; the ships heads are to the west, and the westermost division is undoubtedly the van of the fleet, and the eastermost division is the rear. And it is in conformity to this arrangement and situation that the list of the fleet is drawn up. But the ships may be on the same east and west line, close hauled, with their heads to the west, but the wind blowing from the south-south west. They must therefore be on the larboard tack. The same ships, and the same division, are still, in fact, the van of the fleet. But suppose the ships heads to be to the eastward, and that they are close hauled,

I. OF DAY SIGNALS.

These are made by means of the ship’s sails, or by colours of various kinds.

Those made with sails are but few in number, and are almost necessarily limited to the situation of a fleet at anchor. Thus,
hauled, having the wind from the south-south-east or the north-north-east, the ships which were the real van on both tacks in the former situation are now, in fact, the rear on both tacks; yet they retain the denomination of the van squadron of this fleet, and are under the immediate direction of the officer of the second rank, while the other extremity is under the direction of the third officer. This subdivision therefore is rather an arrangement of rank and precedence than of evolution. It is, however, considered as the natural order to which the general signals must be accommodated. For this reason, the division which is denominated van in the list of this fleet, is generally made to lead the fleet when in the line of battle on the starboard tack, and to form the weathermost column in the order of sailing in columns; and, in general, it occupies that station from which it can most easily pass into the place of the leading division on the starboard line of battle ahead. Although this is a technical nicety of language, and may frequently puzzle a landsman in reading an account of naval operations, the reflecting and intelligent reader will see the propriety of retaining this mode of conceiving the subordinate arrangement of a fleet, and will comprehend the employment of the signals which are necessary for re-establishing this arrangement, or directing the movements while another arrangement is retained.

This being understood, it is easy to contrive various methods of distinguishing every ship by the place which she occupies in the fleet, both with respect to the whole line, with respect to the particular squadron, the particular division of that squadron, and the particular place in that division. This may be done by a combination of the position and colour of the pendants and vanes of each ship. Thus the colour of the pendants may indicate the squadron, their position or mast on which they are hoisted may mark the division of that squadron, and a distinguishing vane may mark the place of the private ship in her own division. The advantages attending this method are many. In a large fleet it would hardly be possible for the commander in chief to find a sufficient variety of single signals to mark the ship to which an order is addressed, by hoisting it along with the signal appropriated to the intended movement. But by this contrivance one-third of these signals of address is sufficient. It also enables the commander in chief to order a general change of position by a single signal, which otherwise would require several. Thus, suppose that the fore, main, and mizen masts, are appropriated (with the proper modifications) for exhibiting the signals addressed to the van, the centre, and the rear squadrons of the fleet, and that a red, a white, and a blue flag, are chosen for the distinguishing flags of the officers commanding these squadrons; then, if the commander in chief shall hoist a red flag at his mizen topgallant mast head, it must direct the van squadron to take the position then occupied by the rear squadron, the evolution necessary for accomplishing this being supposed known by the commander of the squadron, who will immediately make the necessary signal to the squadron under his particular direction. In the same manner, the distinguishing signal for the leading ship of a squadron being hoisted along with the signal of address to the whole fleet, and the signal for any particular service, will cause the three or the nine leading ships to execute that order, &c. &c.

All that has been said hitherto may be considered as so many preparations for the real issuing of orders by the commander in chief. The most difficult part of the language remains, viz. to invent a number of signals which shall correspond to that almost infinite variety of movements and services which must be performed.

Distinctness, simplicity, and propriety, are the three essential qualities of all signals. A signal must be some object easily seen, strongly marked, so that it may be distinctly understood, with little risk of its being mistaken for another. When made by flags, banners, or pendants, they must be of the fullest colours, and strongest contrasts. The ships are frequently at a very great distance, so that the intervening air occasions a great degradation of colour. They are seen between the eye and a very variable sky; and in this situation, especially in the morning or evening, or a dark day, it is not easy to distinguish one full colour from another, all of them approaching to the appearance of a black. At the distance of a very few miles hardly any full colours can be distinguished but a scarlet and a blue. Red, blue, yellow, and white, are the colours which can be distinguished at greater distances than any others, and are therefore the only colours admitted as signals. Even these are sometimes distinguished with difficulty. A yellow is often confounded with a dirty white, and a blue with a red. All other dark colours are found totally unfit. But as these afford but a small variety, we must combine them in one flag, by making it striped, spotted, or chequered, taking care that the opposition of colour may be as great as possible, and that the pieces of which the flags are made up may not be too minute. Red must never be striped nor spotted with blue; and the stripes, spots, or chequers, should never be less than one third of the breadth of the flag. Pl. CCCXCVL is a selection by an officer of experience, as a set very easily recognised, and little liable to be confounded. Their colours are represented by hatching, in the same manner as in heraldry (see HERALDRY).

Difference of shape, as flags, banners, or pendants, is another distinction by which the expression may be varied. And in doing this, we must recollect, that in light winds it may be difficult to distinguish a flag from a banner, as neither are fully displayed for want of wind to detach the fly from the staff. And, lastly, signals may be varied by their position, which may be on any lofty and well detached part of the masts, yards, or rigging.

Simplicity is an eminent property in all signals. They simplicity, are addressed to persons not much accustomed to combinations, and who are probably much occupied by other pressing duties. It were to be wished that every piece of service could be indicated by a single flag. This is peculiarly desirable with respect to the signals used in time of battle. The rapid succession of events on this occasion call for a multitude of orders from the commander in chief, and his ship is frequently clad over with flags and pendants, so that it is exceedingly difficult for the signal officer of a private ship to distinguish the different groups, each of which make a particular signal.
These considerations are the foundation of a certain propriety in signals, which directs us to a choice among marks which appear altogether arbitrary. Signals which run any risk of being confounded, on account of some resemblance, or because their position hinders us from immediately perceiving their difference, should be appropriated to pieces of service which are hardly possible to be executed, or can hardly be wanted, in the same situation. No bad consequence could easily result though the signal for coming to closer action should resemble that for unmooring, because the present situation of the ships makes the last operation impossible or absurd. Such considerations direct us to select for battle signals, those which are of easiest exhibition, are the most simple, and have the least dependence on the circumstance of position; so that their signification may not be affected by the damages sustained in the masts or rigging of the flag ship. Such signals as are less easily seen at a distance, should be appropriated to orders which can occur only in the middle of the fleet, &c. &c. Signals which are made to the admiral by private ships may be the same with signals of command from the flag ship, which will considerably diminish the number of signals perfectly different from each other.

By what means signals are distinctly conveyed.

What avails that courage which we would willingly arrogate to ourselves, if we cannot come to action with our enemy, or must do it in a situation in which it is almost impossible to succeed, and which needlessly throws away the lives of our gallant crews? Yet this must happen, if our admirals do not make evolutions their careful study, and our captains do not habituate themselves, from the first hoisting a pendant, to consider their own ship as connected with the most remote ship in the line. We cannot think that this view of their situation would in the least lessen the character which they have so justly acquired, of fighting their ship with a courage and firmness unequalled by those of any other nation. And we may add, that it is only by such a rational study of their profession, that the gentleman can be distinguished from the mercenary commander of a privateer.

II. Night Signals.

It is evident, that the communication of orders by night must be more difficult and more imperfect than by day. We must, in general, content ourselves with such orders as are necessary for keeping the fleet together, by directing the more general movements and evolutions which any change of circumstances may render necessary. And here the division and subordinate arrangement of the fleet is of indispensable necessity, it being hardly possible to particularise every ship by a signal of address, or to see her situation. The orders are therefore addressed to the commanders of the different divisions, each of whom is distinguished by his poop and top-lights, and is in the midst of, and not very remote from, the ships under his more particular charge. Yet even in this unfavourable situation, it is frequently necessary to order the movements of particular ships. Actions during the night are not uncommon. Pursuits and rallying is still often carried on at this time. The common dangers of the sea are as frequent and more disastrous. The system of signals is therefore very incomplete till this part be accomplished.

Night signals must be made by guns, or by lights, or by both combined.

Gun-signals are susceptible of variety both in number and in disposition. The only distinct variation which can be made in this disposition, is by means of the time elapsed between the discharges. This will easily admit of three varieties, slow, moderate, and quick.—Half-minute guns are as slow as can easily be listened to as appertaining to one signal. Quarter-minute guns are much better, and admit of two very distinct subdivisions. When the gunners, therefore, are well trained to this service (especially since the employment of forelocks for cannon), intervals of 15 or 12 seconds may be taken for slow firing, 8 or 10 seconds for moderate, and 4 or 5 seconds for quick firing. If these could be reduced one half, and made with certainty and precision, the expression would be incomparably more distinct. A very small number of firings varied in this way will give a considerable number of signals. Thus five guns, with the variety of only quick and moderate, will give 20 very distinguishable signals. The same principle must be attended to here as in the flag signals. The most simple must be appropriated to the most important orders, such as occur in the worst weather, or such as are most
most liable to be mistaken. Quick firing should not
make part of a signal to a very distant ship, because
the noise of a gun at a great distance is a lengthened
sound, and two of them, with a very short interval, are
apt to coalesce into one long-continued sound. The
mode of varying gun-signals by the time must therefore
be employed with great caution, and we must be very
certain of the steady performance of the gunners.

Note, that a preparatory signal or advertisement that
an effective signal is to be made, is a very necessary
circumstance. It is usual (at least in hard weather)
to make this by a double discharge, with an interval of
half a second, or at most a second.

Gun-signals are seldom made alone, except in ordina-
tory situations and moderate weather; because accident
may derange them, and inattention may cause them to
escape notice, and, once made, they are over, and their
repetition would change their meaning. They are also
improper on an enemy's coast, or where an enemy's
cruisers or fleets may be expected.

Signals by lights are either made with LIGHTS simply
so called, i.e. lanthorns shown in different parts of
the ship, or by rockets. Lights may differ by number,
and by position, and also by figure. For the flag ship
always carrying poop or top-lights, or both, presents an
object in the darkest night, so that we can tell whether
the additional lights are exhibited about the mainmast,
the foremast, the mizen-mast, &c. And if the lights
shown from any of these situations are arranged in cer-
tain distinguishable situations in respect to each other,
the number of signals may be greatly increased. Thus
three lights may be in a vertical line, or in a horizontal
line, or in a triangle; and the point of this triangle may
be up, or down, or forward, or aft, and thus may have
many significations.

Lights are also exhibited by false fires or rockets:
These can be varied by number, and by such differences
of appearance as to make them very distinguishable.
Rockets may be with stars, with rain fire, or simple
squibs.

By varying and combining these, a very great num-
ber of signals may be produced, fully sufficient to direct
every general movement or evacuation, or any ordinary
and important service. The Chevalier de Morogues
has given a specimen of such a system of night signals,
into which he has even introduced signals of address or
direction to every ship of a large fleet; and has also
given signals of number, by which depths of soundings,
points of the compass, and other things of this kind,
may be expressed both easily and distinctly. He has
made the signals by rockets perfectly similar in point of
number to those by lanthorns, so that the commander
can take either; a choice which may have its use, be-
cause the signals by rockets may cause the presence of
a fleet to be more extensively known than may be con-
vincient.

The commander in chief will inform the fleet by sig-
als, that guns, or perhaps rockets, are not to be used
concerning that night. This signal, at the same time, directs the
fleet to close the line or columns, that the light signals
may be better observed.

It is indeed a general rule to show as few lights as
possible; and the commander frequently puts out his
open poop and top-lights, only showing them from time
to time, that his ships may keep around him.

The signal lanthorns on board the flag ship, and a
lanthorn kept in readiness on board of every private
ship, to answer or acknowledge signals from the com-
mander in chief, are all kept in bags, to conceal their
light till the moment they are fixed in their places, and
the preparatory or advertising signal has been made.

The commander in chief sometimes orders by signal
every ship to show a light for a minute or two, that he
may judge of the position of the fleet; and the admiral's
signal must always be acknowledged by those to whom it
is addressed.

It is of particular importance that the fleet be kept
together. Therefore the leading ships of the fleet, on
either tack, are enjoined to acknowledge the signals of
the commander in chief by a signal peculiar to their
station. Thus the commander in chief learns the posi-
tion of the extremities of his fleet.

In framing a set of night signals, great attention must
be given to their position, that they be not obscured by
the sails. The nature of the order to be given will fre-
quently determine this. Thus, an order for the rear
ships to make more sail, will naturally direct us to
exhibit the signal at the mizen-peak; and so of other
pieces of service. Lanthorns exposed in groups, such
as triangles, lozenges, &c. are commonly suspended at
the corners of large frames of laths, at the distance of a
fathom at least from each other. Attempts have been
made to show lights of different colours; but the risk of
mistake or failure in the composition at the laboratory,
makes this rather hazardous. Coloured lanthorns are
more certain; but when the glasses are made of a colour
sufficiently intense, the vivacity of the light (which
at no time is very great) is too much diminished.

Besides, the very distance changes the colour exceedingly
and unaccountably.

III. Of Signals in a Fog.

These can be made only by noises, such as the firing
of cannon and muskets, the beating of drums and ring-
ing of bells, &c. Fog signals are the most difficult to
contrive of any, and are susceptible of the least variety.
The commander in chief is principally concerned to
keep his fleet together; and unless something very ur-
genent requires it, he will make no change in his course
or rate of sailing. But a shift of wind or other causes
may make this necessary. The changes which he will
order, it will be prudent to regulate by some fixed rule,
which is in general convenient. Thus, when a fleet is
in the order of sailing upon a wind, and a fog comes on,
the fleet will hold on the same course. If the wind
should come a little more on the beam, the fleet will
still keep close to the wind. Certain general rules of By obser-
this kind being agreed on, no signals are necessary for keeping
certain
certain general signal.

The commander of divisions fire guns,
with some distinction from those of the commander in
chief. This both informs the commander in chief of the
position of his squadrons, and enables the private
ships of each division to keep in the neighbour-

hood of their own flag ship. On board of every private
ship the drum is beaten, or the bell is chimed, every
quarter.
Naval Signals.

quarter of an hour, according as the ship is on the starboard or larboard tack. By such contrivances, it is never difficult to keep a fleet in very good order when sailing on a wind. The wind is almost always moderate, and the ships keep under a very easy sail. It is much more difficult when going large, and separation can be prevented only by the most unwearied attention. The greatest risk is the falling in with strange ships steering another course.

But evolutions and other movements are frequently indispensable. The course must be changed by tacking or wearing, and other services must be performed. None, however, are admitted but the most probable, the most simple, and the most necessary.

The commander in chief first informs the fleet by the preparatory fog signal, that he is about order an evolution, and that he is to direct it by fog signals. This precaution is indispensable to prevent mistakes. Along with this advertising signal he makes the signal of the movement intended. This not only calls the attention of the fleet, but makes the ships prepare for the precise execution of that movement. The commanders of divisions repeat the advertising signal, which informs their ships of their situation, and the private ships beat their drums or chime their bells. Thus the whole ships of the fleet close a little, and become a little better acquainted with their mutual position. It is now understood that a movement is to be made precisely a quarter of an hour after the advertisement. At the expiration of this time, the effective signal for this movement is made by the commander in chief, and must be instantly repeated by the commanders of divisions, and then the movement must be made by each ship, according to the sailing and fighting instructions. This must be done with the utmost attention and precision, because it produces a prodigious change in the relative position of the ships; and even although the good sense of the commander in chief will select such movements for accomplishing his purpose as produce the smallest alterations, and the least risk of separation or running foul of each other; it is still extremely difficult to avoid these misfortunes. To prevent this as much as possible, each ship which has executed the movement, or which has come on a course thwarting that of the fleet, intimates this by a signal properly adapted, often adding the signal of the tack on which it is now standing, and even its particular signal of recognizance. This is particularly incumbent on the flag ships and the leading ships of each division.

After a reasonable interval, the commander in chief will make proper signals for bringing the fleet to a knowledge of their reunion in this new position. This must serve for a general account of the circumstances which must be attended to in framing a code of signals. The arbitrary characters in which the language is written must be left to the sagacity of the gentlemen of the profession. It must be observed, that the stratagems of war make secrecy very necessary. It may be of immense hazard if the enemy should understand our signals. In time of battle it might frequently frustrate our attempts to destroy them, and at all times would enable them to escape, or to throw us into disorder. Every commander of a squadron, therefore, issues private signals, suited to his particular destination; and therefore it is necessary that our code of signals be susceptible of endless variations. This is exceedingly easy, without any increase of their number. The commander needs only intimate that such and such a signal is so and so changed in its meaning during his command.

We cannot leave this article without returning to an observation which we made almost in the beginning, viz. that the system of signals, or, to speak more properly, the manner of framing this system, has received much improvement from the gentlemen of the French navy, and particularly from the most ingenious thought of M. de la Bourdonnais, of making the signals the immediate expressions of numbers only, which numbers may be afterwards used to indicate any order whatever. We shall present our readers with a scheme or two of the manner in which this may be done for all signals, both day, night, and fog. This alone may be considered as a system of signals, and is equally applicable to every kind of information at a distance. Without detracting in the smallest degree from the praise due to M. de la Bourdonnais, we must observe, that this principle of notation is of much older date. Bishop Wilkins, in his Secret and Swift Messenger, expressly recommends it, and gives specimens of the manner of execution; so does Dr. Hooke in some of his proposals to the Royal Society. Gaspar Schottius also mentions it in his Technica Curiosa; and Kircher, among others of his Curious Projects.

M. de la Bourdonnais's method is as follows:

He chooses pendants for his effective signals, because they are the most easily displayed in the proper order. Several pendants, making part of one signal, may be hoisted by one halyard, being stopped on it at the distance of four or six feet from each other. If it be found proper to throw out another signal at the same time and place, they are separated by a red pendant without a point. His colours are chosen with judgment, being very distinctly recognised, and not liable to be confounded with the addressing signals appropriated to the different ships of the fleet. They are,

For No. 1. Red. For No. 6. Red, with blue tail.
2. White. 7. White, with blue tail.
5. Red, with 10. Yellow, with blue tail.
white tail.

Three sets of such pendants will express every letter under a thousand, by hoisting one above the other, and reckoning the uppermost hundreds, the next below it, and the lowest units. Thus the number 643 will be expressed by a pendant red with blue tail, a yellow pendant below it, and a blue one below the last.

This method has great advantages. The signals may be hoisted in any place where best seen, and therefore the signification is not affected by the derangement of the flag-ship's masts and rigging. And by appropriating the smaller numbers to the battle signals, they are more simple, requiring fewer pendants.

As this method requires a particular set of colours, might be it its inconveniences. An admiral is often obliged to shift his flag, even in time of action. He cannot take the colours along with him. It is therefore better to make use of such colours as every private ship is provided with. One set of 11 will do, with the addition
division of three, at most of four pendants, of singular make, to mark 100, 200, 300, 400. Two of these flags, one above the other, will express any number under 100, by using the 11th as a substitute for any flag that should be repeated. Thus the 11th flag, along with the flag for eight or for six, will express the number 88 or 68, &c. Thus we are able to express every number below 500, and this is sufficient for a very large code of signals.

And in order to diminish as much as possible the number of these compound signals, it will be proper that a number of single flag signals be preserved, and even varied by circumstances of position, for orders which are of very frequent occurrence, and which can hardly occur in situations where any obstructions are occasioned by loss of mast, &c. And farther, to avoid all chance of mistake, a particular signal can be added, intimating that the signals now exhibited are numerary signals; or, which is still better, all signals may be considered as numerary signals; and associated with which we have just now called single flag signals may be set down opposite to, or as expressing, the largest numbers of the code.

This method requires the signal of advertisement, the annulling signal, the signal of address to the particular ship, or division, the signals of acknowledgment, the signal of indistinctness, of distress, of danger, and one or two more which, in every method must be employed.

Another method of expressing numbers with fewer colours is as follows: Let the flags be A, B, C, D, E, F, and arrange them as follows:

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
<th>E</th>
<th>F</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>3</td>
<td>4</td>
<td>5</td>
<td>6</td>
</tr>
<tr>
<td>A</td>
<td>7</td>
<td>8</td>
<td>9</td>
<td>10</td>
<td>11</td>
</tr>
<tr>
<td>B</td>
<td>13</td>
<td>14</td>
<td>15</td>
<td>16</td>
<td>17</td>
</tr>
<tr>
<td>C</td>
<td>19</td>
<td>20</td>
<td>21</td>
<td>22</td>
<td>23</td>
</tr>
<tr>
<td>D</td>
<td>25</td>
<td>26</td>
<td>27</td>
<td>28</td>
<td>29</td>
</tr>
<tr>
<td>E</td>
<td>31</td>
<td>32</td>
<td>33</td>
<td>34</td>
<td>35</td>
</tr>
<tr>
<td>F</td>
<td>37</td>
<td>38</td>
<td>39</td>
<td>40</td>
<td>41</td>
</tr>
</tbody>
</table>

The number expressed by any pair of flags is found in the intersection of the horizontal and perpendicular columns. Thus the flag D, hoisted along with and above the flag F, expresses the number 40, &c. In order to express a greater number (but not exceeding 84) suppose 75, hoist the flag E, which expresses 33, or 75 wanting 42, and above them a flag or signal G, which alone expresses 42.

This method may be still farther improved by arranging the flags thus:

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
<th>E</th>
<th>F</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>3</td>
<td>4</td>
<td>5</td>
<td>6</td>
</tr>
<tr>
<td>A</td>
<td>7</td>
<td>8</td>
<td>9</td>
<td>10</td>
<td>11</td>
</tr>
<tr>
<td>B</td>
<td>—</td>
<td>13</td>
<td>14</td>
<td>15</td>
<td>16</td>
</tr>
<tr>
<td>C</td>
<td>—</td>
<td>—</td>
<td>18</td>
<td>19</td>
<td>20</td>
</tr>
<tr>
<td>D</td>
<td>—</td>
<td>—</td>
<td>—</td>
<td>22</td>
<td>23</td>
</tr>
<tr>
<td>E</td>
<td>—</td>
<td>—</td>
<td>—</td>
<td>—</td>
<td>25</td>
</tr>
<tr>
<td>F</td>
<td>—</td>
<td>—</td>
<td>—</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

In this last method the signification of the signal is totally independent of the position of the flags. In whatever parts of the ship the flags D and E are seen, they express the number 23. This would suit battle signals.

Another method still may be taken. Flags hoisted anywhere on the foremost may be accounted units, those on the mainmast tens, and those on the mizenmast hundreds. Thus numeral signals may be made by a ship dismantled, or having only poles in their place.

Many other ways may be contrived for expressing numbers by colours, and there is great room for exercising the judgment of the contriver. For it must always be remembered, that these signals must be accompanied with a signal by which it is addressed to some particular ship or division of the fleet, and it may be difficult to connect the one with the other, which is perhaps shown in another place, and along with other executive signals.

One great advantage of these numeral signals is, that Advantages they may be changed in their signification at pleasure, of numeral Thus, in the first method, it can be settled, that one signal. Sundays the colours A, B, C, D, &c. express the cyphers 1, 2, 3, 4, &c. but that on Mondays they express the cyphers 0, 1, 2, 3, &c. and on Tuesdays the cyphers 9, 0, 1, 2, &c.; and so on through all the days of the week. This mean of secrecy is mentioned by Dr. Hooke for the coast and alarm signals, where, by the by, he shews a method for conveying intelligence over land very similar to what is now practised by the French with their telegraph.

It is equally easy to express numbers by night signals. Thus, M. de la Bourdonnais proposes that one may be also discharged of a great gun shall express 7, and that 1, 2, expressed by night, 3, 4, 5, 6, shall be expressed by lights. Therefore to express 24, we must fire three guns, and show three lights. This is the most perfect of all forms of night and fog signals. For both the manner of firing guns and of exhibiting lights may be varied to a sufficient extent with very few guns or lights, and with great distinctness.

Thus, for guns. Let F mark the firing of a single gun at moderate intervals, and ff a double gun, that is, two discharged at the interval of a second. We may express numbers thus:

| 1 | F |
| 2 | F, F |
| 3 | F, F, F |
| 4 | F, F, F, F |
| 5 | F, ff |
| 6 | F, F, ff |
| 7 | F, F, F, F |
| 8 | F, F, F, F, F |
| 9 | F, F, F, F, F |
| 10 | ff, ff |

It might be done with fewer guns if the ff were admitted as the first firing. But it seems better to begin always with the single gun, and thus the double gun beginning a signal distinguishes the tens, &c.

In like manner, a small number of lights will admit of a great variety of very distinct positions, which may serve for all signals to ships not very remote from the commander in chief. For orders to be understood at a very great distance, it will be proper to appropriate the numbers which are indicated by signals made with y rockets.
rockets. These can be varied in number and kind to a sufficient extent, so as to be very easily distinguished and understood. It is sufficient to have shown how the whole, or nearly the whole, notation of signals may be limited to the expression of numbers.

We have taken little notice of the signals made by private ships to the commander in chief. This is a very easy business, because there is little risk of confounding them with other signals. Nor have we spoken of signals from the flag ships whose ultimate interpretation is number, as when ships are directed to change their course so many points. Those also are easily contrived in any of the methods already described: also when a private ship wishes to inform the commander in chief that soundings are found at so many fathoms. In like manner, by numbering the points of the compass, the admiral can direct to change to any one of them, or may be informed of strange ships being seen in any quarter, and what is their number.

Signals by the Drum, made use of, in the exercise of the army, instead of the word of command, viz.

**Signals.**

- **A short roll.**
- **A long roll.**
- **A drum roll.**
- **The march.**
- **The quick march.**
- **The point of war.**
- **The retreat.**
- **Drum ceasing.**
- **Two short rolls.**
- **The dragon march.**
- **The grenadier march.**
- **The troop.**
- **The long roll.**
- **The grenadier march.**
- **The preparations.**
- **The general.**
- **Two long rolls.**

**Operations.**

- To caution.
- To perform any distinct thing.
- To form the line or battalion.
- To advance, except when intended for a salute.
- To advance quick.
- To march and charge.
- To retreat.
- To halt.
- To perform the flank firing.
- To open the battalion.
- To form the column.
- To form the square.
- To reduce the square to the column.
- To make ready and fire.
- To cease firing.
- To bring or lodge the colours.

**SIGNET,** one of the king's seals, made use of in sealing his private letters, and all grants that pass by bill signed under his majesty's hand: it is always in the custody of the secretaries of state.

**SIGNET, in Scots Law.** See Law, Part III. § 17.

**SILENE,** CATCHFLY, or _Viscum Campion_, a genus of plants belonging to the class _decandria_, and order _trigynia_; and in the natural system arranged under the 22d order, _Caryophyllaceae_. See Botany Index.

**SILESIA,** a duchy of Germany, bounded on the east by Poland; on the west, by Bohemia and Lower Lusatia; on the south, by a chain of mountains, and a thicket of considerable extent which separates it from Hungary; and to the north by the marquisate of Brandenburg and Poland. From northwest to southeast it is about 274 miles, and about 100 miles broad; but it is much contracted at both ends. Upon the frontiers of this country, to the west and south, are very high mountains, and some likewise in other parts of it. One of the ridges upon the frontiers is styled the _Riphean Mountains_, another the _Moravian_, another the _Bohemian_, and another the _Hungarian_, _Crapack_, or _Carpathan_. A branch of the Bohemian is called the _Giant Mountains_. The winter on these hilly tracts is more severe, sets in sooner, and lasts longer than in the low lands. The inhabitants use a kind of skates when the snow is deep, as they do in Carniola. Little or no grain is raised in the mountains and some sandy tracts; but the rest of the country is abundantly fruitful, not only in grain, but fruits, roots, pasture, flax, hops, madder, tobacco, and hemp, yielding also some wine, with considerable quantities of silk and honey. In many places are great woods of pines, fir, beech, larch, and other trees, affording tar, pitch, rosin, turpentine, lampblack, and timber for all uses. In this country also is found marble of several sorts, some precious stones, limestone, millstone, pitch, coal, turf, vitriol, some silver ore, copper, lead, iron, and mineral springs. Great numbers
bers of black cattle and horses are brought hither from Poland and Hungary for sale, those bred in the country not being sufficient; but of sheep, goats, game, and venison, they have great plenty. As for wild beasts, here are lynxes, foxes, weasels, otters, and beavers. The rivers, lakes, and ponds, yield fish of several sorts, particularly sturgeons several ells in length, and salmon. Besides a number of smaller streams to water this country, there is the Oder, which traverses it almost from one end to the other; and the Vistula, which after a pretty long course through it enters Poland. The inhabitants are a mixture of Germans, Poles, and Moravians. The language generally spoken is German; but in some places the vulgar tongue is a dialect of the Slavonic. The states consist of the princes and dukes, and those called state-lords, with the nobility, who are immediately subject to the sovereign, and the representatives of the chief cities; but since the country fell under the dominion of the king of Prussia, no diets have been held. The king, however, when he took possession of the country, confirmed all the other privileges of the inhabitants. With respect to religion, not only Protestants, but Papists, Jews, and Greeks, enjoy full liberty of conscience. The greatest part of Silesia lies in the diocese of Breslaw, but some part of it in the Polish dioceses of Posen and Cracow. The bishop of Breslaw stands immediately under the pope with regard to spirituals; but all ecclesiastical bencches, not excepting the see of Breslaw, are in the king's gift. Besides Latin schools, colleges, and seminaries, at Breslaw is an university, and at Lignitz an academy for martial exercises. The principal manufactures here are woollens, linens, and cottons of several sorts, with hats, glass-ware, gunpowder, and iron manufactures. Of these there is a considerable exportation. Accounts are generally kept in rix-dollars, silver groschen, and ducats. With respect to its revolutions and present government, it was long a part of the kingdom of Poland; afterwards it had several dukes and petty princes for its sovereigns, who by degrees became subject to the kings of Bohemia, until at last King Charles IV. incorporated the whole duchy with Bohemia; and thus it continued in the possession of the house of Austria, until the king of Prussia in 1742, taking advantage of the troubles that ensued upon the death of the emperor Charles VI. and pretending a kind of claim, wrested a great part of it, together with the county of Glatz, from his daughter and heiress Maria Theresa, the late empress dowager; so that now only a small part of it is possessed by the house of Austria, and connected with the empire, the rest being governed by the king of Prussia, without acknowledging any sort of dependence on the crown of Bohemia or the empire. For the administration of justice in all civil, criminal, and feudal cases, and such as relate to the revenue, the king of Prussia has established three supreme judicatories, to which an appeal lies from all the inferior ones, and from which, when the sum exceeds 500 rix-dollars, causes may be moved to Berlin. The Lutheran churches, and schools, are under the inspection of the upper consistories, and those of the Papists under the right of the bishop's court at Breslaw; but from both an appeal lies to the tribunal at Berlin. As to the revenue, the excise here is levied only in the walled towns, being on the same footing as in the marquisate of Brandenburg; but in the rest of the country the contributions are fixed, and the same both in peace and war. The several branches of the revenue are under the management of the war and domain offices of Breslaw and Glogau. The whole revenue arising to the king of Prussia from Silesia and the county of Glatz amounts to about 134 millions of florins per annum.

Silesia is divided into Upper and Lower, and each of these again into principalties and lordships; of some of which both the property and jurisdiction belong immediately to the sovereign, but of others to his subjects and vassals. Silesia is the most industrious province in the Prussian dominions, and the seat of the principal manufactures. Its exports in 1804 amounted to 21 millions of florins. It is rich in mines, and furnishes annually 405,000 centners of iron. Its population in 1818 amounted to 2,017,058, and has doubled itself since the year 1746. In short, Silesia may now be considered the most valuable province belonging to the Prussian monarchy.

SILESIAN EARTH, in the Materia Medica, a fine astringent bole. It is very heavy, of a firm compact texture, and in colour of a brownish yellow. It breaks easily between the fingers, and does not stain the hands; is naturally of a smooth surface, is readily diffusible in water, and melts freely into a butter-like substance in the mouth. It leaves no grittiness between the teeth, and does not ferment with acids. It is found in the perpendicular fissures of rocks near the gold mines in Hungary.

SILICERNIUM, among the Romans, was a feast of a private nature, provided for the dead some time after the funeral. It consisted of beans, lettuces, bread, eggs, &c. These were laid upon the tomb, and they foolishly believed that the dead would come out for the repast. What was left was generally burnt on the stone. The word silicenium is derived from silex and ceca, i.e. "a supper upon a stone." Eating what had thus been provided for the dead, was esteemed a mark of the most miserable poverty. A similar entertainment was made by the Greeks at the tombs of the deceased; but it was usual among them to treat the ghosts with the fragments from the feast of the living. See Funeral and Inferiæ.

SILEX. See Flint.

SILICEOUS EARTHS. See Silica, Chemistry Index.

SILIUS ITALICUS, Catus, an ancient Roman poet, and author of an epic poem in 17 books, which contains an history of the second Punic war, so famous for having decided the empire of the world in favour of the Romans. He was born in the reign of Tiberius, and is supposed to have derived the name of Italicus from the place of his birth; but whether he was born at Italia in Spain, or at Corinum in Italy, which, according to Strabo, had the name of Italia given it during the Social war, is a point which cannot be known: though, if his birth had happened at either of these places, the grammarians would tell us, that he should have been called Italicensis, and not Italicus. When he came to Rome, he applied himself to the bar; and, by a close imitation of Cicero, succeeded so well, that he became a celebrated advocate and most accomplished orator. His merit and character recommended him to the highest offices in the republic, even to the consulship, of
which he was possessed when Nero died. He is said to
have been aiding and assisting in accusing persons of
high rank and fortune, whom that wicked emperor had
devoted to destruction: but he retrieved his character
afterwards by a long and uniform course of virtuous be-

Vespasian sent him as proconsul into Asia,
where he behaved with clean hands and unblemished re-
putation. After having thus spent the best part of his
life in the service of his country, he bade adieu to pub-
lic affaires, resolving to consecrate the remainder to po-
lite retirement and the muses. He had several fine villas
in the country on the coast, celebrated for having
been Cicero's; and a farm near Naples, said to have
been Virgil's, at which was his tomb, which Silius often
visited. Thus Martial compliments him on both these
accounts:

_Silv. hae magni celebrat monumenta Maronis,
Jugeru facundi qui Ciceronis habet._
_Herred. Dominatiae sui tumultuque larisque
Non atum mallet nec Maro nec Cico._

Epigr. 49. lib. xi.

Of Tully's seat my Silius is possess'd,
And his the tomb where Virgil's ashes rest.
Could those great shades return to choose their heir,
The present owner they would both prefer.

In these retirements he applied himself to poetry: led
not so much by any great force of genius, which would
certainly not have suffered him to stay till life was in
the wane and his imagination growing cold, as by his
exceeding great love of Virgil, to whose memory he
paid the highest veneration. He has imitated him
in his poem; and though he falls infinitely short of him,
yet he has discovered a great and universal genius, which
would have enabled him to succeed in some degree in
whatever he undertook.

Having been for some time afflicted with an impostu-
hume, which was deemed incurable, he grew weary of
life, to which, in the language of Pliny, he put an end
with determined courage.

There have been many editions of _Silv. Italicius._ A
next and correct one was published at Leipsic in 1696,
in 8vo, with short and useful notes by Cellarius: but the
best is that of _cum notis integris variis et Arnoldi Dra-
kenburch._ Traiect. ad Rhen. 1717, in 4to.

_SILK, a very soft, fine, bright thread, the work of
an insect called bombyx, or the silk worm._

As the silk worm is a native of China, the culture of
silk in ancient times was entirely confined to that coun-
try. We are told, that the empresses, surrounded by
their women, spent their leisure hours in hatching and
rearing silk worms, and in weaving tissues and silk veils.
That this example was soon imitated by persons of all
ranks, we have reason to conclude; for we are informed
that the Chinese, who were formerly clothed in skins,
in a short time after were dressed in vestments of silk.
Till the reign of Justinian, the silk worm was unknown
beyond the territories of China, but silk was introduced
into Persia long before that period. After the conquest
of the Persian empire by Alexander the Great, this va-
ducible commodity was brought into Greece, and thence
conveyed to Rome. The first of the Roman writers
extant by whom silk is mentioned, are Virgil and Ho-

R _Opinions of the ancients concerning the nature
of silk._

3

produced. By some of the ancients it was supposed to
be a fine down adhering to the leaves of certain trees or
flowers. Others imagined it to be a delicate species of
wool or cotton; and even those who had learned that
it was the work of an insect, show by their descriptions
that they had no distinct idea of the manner in which it
was formed. Among the Romans, silk was deemed a
dress too expensive and too delicate for men, and was
appropriated wholly to women of eminent rank and op-
pulence. Elagabalus is said to have been the first man
among the Romans who wore a garment of fine silk; a
story which is accordingly related by the Latin historians.

For several centuries the Persians supplied the Roman Brought
empire with the silks of China. Caravans traversed the from China
whole latitude of Asia, in 243 days, from the Chinese
by the Pers-

3

rian till the

The Persians, with the usual rapacity of mon-
oplists, raised the price of silk to such an exorbitant
height, that Justinian eager not only to obtain a full
supply of silk, and certain supply of a commodity which was become
of indispensable use, but solicitous to deliver the com-
merce of his subjects from the exactions of his enemies,
endeavoured, by means of his ally, the Christian
monarch of Abyssinias, to wrest some portion of the silk
trade from the Persians. In this attempt he failed; but
when he least expected it, he, by an unforeseen event,
attained, in some measure, the object which he had in
view. Two Persian monks having been employed as Silk worms
missionaries in some of the Christian churches, which
were introduced into Europe (as we are informed by Cosmas) in dif-
fervent parts of India, had penetrated into the country of the
Seres, or China. There they observed the labour

S
in the nature of the commercial intercourse between Europe and India.

As silk is the production of a worm, it will be first necessary to give a description of its nature and mode of manufacturing. But before we give any account of the most approved methods of managing silk worms in Europe, it will be proper to present a short description of the methods practised in China, the original country of the silk worm. These are two: they either permit them to remain at liberty on mulberry trees, or keep them in rooms. As the finest silk is produced by worms confined in rooms, and as the first method is very simple, it will suffice to describe the second.

To begin with the eggs, which are laid on large sheets of paper, to which they firmly adhere. The sheets are hung up on a beam of the room, with the eggs inward, and the windows are opened in the front to admit the wind; but no hempen ropes must ever come near the worms or their eggs. After some days the sheets are taken down, rolled up loosely with the eggs inward, and then hung up again, during the summer and autumn. At the end of December, or the beginning of January, the eggs are put into cold water, with a little salt dissolved in it. Two days after they take them out, hang them up again, and when dry roll them a little tighter, and enclose each separately, standing on one end in an earthen vessel. Some put them into a lye made of mulberry tree ashes, and then lay them some moments in snow-water, or else hang them up three nights on a mulberry tree to receive the snow or rain, if not too violent. The time of hatching them is when the leaves of the mulberry trees begin to open, for they are hastened or impeded according to the different degrees of heat or cold to which they are exposed. When they are ready to come forth, the eggs swell, and become a little pointed.

The third day before they are hatched, the rolls of paper are taken out of the vessel, stretched out, and hung up with their backs toward the sun, till they receive a kindly warmth, and then being rolled up, they are set upright in a vessel in a warm place. This is repeated the next day, and the eggs change to an oah-gray. Then they put two sheets together, and rolling them close tie the ends.

The third day, towards night, the sheets are unrolled and stretched on a fine mat, when the eggs appear blackish. They then roll three sheets together, and carry them into a pretty warm place, sheltered from the south wind. The next day the people taking out the rolls, and opening them, find them full of worms like small black ants.

The apartment chosen for silk worms is on a dry ground, in a pure air, and free from noise. The rooms are square, and very close, for the sake of warmth; the door faces the south, and is covered with a double mat, to keep out the cold; yet there should be a window on every side, that when it is thought necessary the air may have a free passage. In opening a window to let in a refreshing breeze, care must be taken to keep out the gnats and flies. The room must be furnished with nine or ten rows of frames, about nine inches one above the other. On these they place rush hurdles, upon which the worms are fed till they are ready to spin; and, to preserve a regular heat, stove fires are placed at the corners of the room, or else a warming pan is carried up and down it; but it must not have the least flame or smoke. Cow-dung dried in the sun is esteemed the most proper fuel.

The worms eat equally day and night. The Chinese give them on the first day forty-eight meals, that is, one every half hour; the next thirty; the third day they have still less. As cloudy and rainy weather takes away their stomach, just before their repast a wisp of very dry straw, the flame of which must be all alike, is held over the worms to free them from the cold and moisture that benumbs them, or else the blinds are taken from the windows to let in the full day-light.

Eating so often hastens their growth, on which the chief profit of the silk worm depends. If they come to maturity in 23 or 25 days, a large sheet of paper covered with worms, which at their first coming from the eggs weigh little more than a drachm, will produce 25 ounces of silk; but if not till 28 days, they then yield only 20 ounces; and if they are a month or 40 days in growing, they then produce but ten.

They are kept extremely clean, and are often removed; and when they are pretty well grown, the worms belonging to one hurdle are divided into three, afterwards they are placed on six, and so on to the number of 20 or more; for being full of humours, they must be kept at a due distance from each other. The critical moment for removing them is when they are of a bright yellow and ready to spin; they must be surrounded with mats at a small distance, which must cover the top of the place to keep off the outward air; and because they love to work in the dark. However, after the third day's labour, the mats are taken away from one o'clock till three, but the rays of the sun must not shine upon them. They are at this time covered with the sheets of paper that were used on the hurdles.

The cocoons are completed in seven days, after which the worm is metamorphosed into a chrysalis; the cocoons are then gathered, and laid in heaps, having first set apart those designed for propagation upon a hurdle, a cool airy place. The next care is to kill the moths in those cocoons which are not to be bored. The best way of doing it is to fill large earthen vessels with cocoons in layers of ten pounds each, throwing in four ounces of salt with every layer, and covering it with large dry leaves like those of the water-lily, and closely stopping the mouth of the vessels. But in laying the cocoons into the vessels, they separate the long, white, and glittering ones, which yield a very fine silk, from those that are thick, dark, and of the colour of the skin of an onion, which produce a coarser silk.

The silk worm is a species of caterpillar, which, like all others of the same class, undergoes a variety of and history changes, that, to persons who are not acquainted with the silk objects of this kind, will appear to be not a little surprising.

It is produced from a yellowish-coloured egg, about the size of a small pin head, which has been laid by a The Div species of grayish-coloured moth, which the vulgar con-No. 71. found with the butterfly.

These eggs, in the temperature of this climate, if kept beyond the reach of the fire and sunshine, may be preserved during the whole of the winter and spring months without danger of hatching; and even in summer they may easily be prevented from hatching if they be kept in a cool place; but in warmer climates it is scarcely
Silk. Scarcely possible to preserve them from hatching, even for a few days, or from drying so much as to destroy them. Hence it is easy for a native of Britain to keep the eggs till the food on which the worm is to feed be ready for that purpose. When this food is in perfection, the eggs need only be exposed to the sun for a day or two, when they will be hatched with great facility.

When the animal is first protruded from the egg, it is a small black worm, which is active, and naturally ascends to the top of the heap in search of food. At this stage of his growth the silk worm requires to be fed with the youngest and most tender leaves. On these leaves, if good, he will feed very freely for about eight days, during which period he increases in size to about a quarter of an inch in length. He is then attacked with his first sickness, which consists in a kind of lethargic sleep for about three days duration; during which time he refuses to eat and changes his skin, preserving the same bulk. This sleep being over, he begins to eat again, during five days, at which term he is grown to the size of full half an inch in length; after which follows a second sickness, in every respect like the former.

He then feeds for other five days; during which time he will have increased to about three quarters of an inch in length, when he is attacked with his third sickness. This being over, he begins to eat again, and continues to do so for five days more, when he is attacked by his fourth sickness, at which time he is arrived at his full growth. When he recovers this sickness, he feeds once more during five days with a most voracious appetite; after which he disdains his food, becomes transparent, a little on the yellowish cast, and leaves his silky traces on the leaves where he passes. These signs denote that he is ready to begin his cocoon, and will eat no more.

Thus it appears that the whole duration of the life of the worm, in this state of its existence, in our climate, is usually about 46 days; 28 of which days he takes food, and remains in his sick or torpid state; 18; but it is to be observed, that during warm weather the periods of sickness are shortened, and in cold weather lengthened, above the terms here specified. In very hot climates it may be said to live faster, and sooner to attain maturity, than in those that are colder. Dr Anderson informs us, that at Madras the worm undergoes its whole evolutions in the space of 22 days. It appears, however, that it feeds fully as many days in India as in Europe, the difference being entirely occasioned by shortening the period of sickness. The longest sickness he had seen them experience there did not exceed two days; and during summer it only lasts a few hours.

When the worm has attained its full growth, it searches about for a convenient place for forming its cocoon, and mounts upon any branches or twigs that are put in its way for that purpose. After about two days spent in this manner, it settles in its place, and forms the cocoon, by winding the silk which it draws from its bowels round itself into an oblong roundish ball.

During this operation it gradually loses the appearance of a worm; its length is much contracted, and its thickness augmented. By the time the web is finished, it is found to be transformed into an oblong roundish ball, covered with a smooth shelly skin, and appears to be perfectly dead. In this state of existence it is called an auterio. Many animals in this state may be often seen sticking on the walls of out-houses, somewhat resembling a small beam.

In this state it remains for several days entirely motionless in the heart of the cocoon, after which it bursts like an egg hatching, and from that comes forth a heavy dull-looking moth with wings; but these wings it never uses for flying; it only crawls slowly about in the place it has been hatched. This creature forces its way through the silk covering which the worm had woven, goes immediately in quest of its mate, after which the female lays her eggs; and both male and female, without tasting food in this stage of their existence, die in a very short time.

The silk worm, when at its full size, is from an inch and a quarter to an inch and a half in length, and about half an inch in circumference. He is either of a milk or pearl colour, or blackish; these last are esteemed the best. His body is divided into seven rings, to each of which are joined two very short feet. He has a small point like a horn exactly above the anus. The substance which forms the silk is in his stomach, which is very long, wound up, as it were, upon two spindles, as some say, and surrounded with a gum, commonly yellowish, sometimes white, but seldom greenish. When the worm spins his cocoon, he winds off a thread from each of his spindles, and joins them afterwards by means of two hooks which are placed in his mouth, so that the cocoon is formed of a double thread. Having opened a silk worm, you may take out the spindles, which are folded up in three plaits, and, on stretching them out, and drawing each extremity, you may extend them to near two ells in length. If you then scrape the thread so stretched out with your nail, you scrape off the gum, which is very like bees wax, and performs the same office to the silk it covers as gold leaf does to the ingot of silver it surrounds, when drawn out by the wire drawer. This thread which is extremely strong and even, is about the thickness of a middling pin.

Of silk worms, as of most other animals, there is a considerable variety of breeds, some of which are much more hardy, and possess qualities considerably different from others. This is a particular of much importance to be adverted to at the time of beginning to breed these creatures in any place; for it will make a great difference in the profit on the whole to the undertaker if he rears a good or a bad sort (A). This is a department in respect to the economy of animals that has been in every

---

(A) As the success of the silk manufacture must depend on the breed of worms, it is of great consequence to bring them from those countries where they are reckoned best.

Mr Andrew Wright, an ingenious silk manufacturer of Paisley, has given the following directions for conveying the eggs of the silk worm from distant countries by sea: As soon as the moth has laid her eggs, dry them immediately, and put them into glass phials; seal them so close that damp air or water will not penetrate into them. Put these phials that contain the eggs into earthen pots filled with cold water; and as often as the water becomes warm...
every case much less adverted to than it deserves; and in particular with regard to the silk worm it has been almost entirely overlooked. A few eggs of the silk worm can be easily transported by post in a letter from any part of Europe to another, especially during the winter season. It would therefore be an easy matter for any patriotic society, such as the Society of Arts in London, to obtain a specimen of the eggs from every country in which silk is now reared, to put these under the care of a person who could be depended upon, and who understood the management of them, with orders to keep each kind distinct from another, and advert to every particular that occurred in their management, so as to make a fair estimate of their respective merits. By these means the best might be selected, and those of inferior value rejected. Forty or fifty of each sort might be enough for the experiment; but it ought to be repeated several times before conclusions could be drawn from it that might be altogether relied upon; for it is well known that a variation of circumstances will make a change in the result; and it is by no means certain that the same particular would affect those of one breed exactly in the same manner as it would do those of a different breed. One may be more hardy with regard to cold, another more delicate in respect to food, and so on. It is experience alone that can ascertain the circumstances here inquired for.

From the above-mentioned particulars, it is evident, that the management of silk worms must be very different in hot climates from what is required in those that are colder. At Madras, it appears from Dr Anderson's experiments that it is very difficult to prevent the eggs from hatching for a very few days, so that many generations of them must be propagated in one year. "In this hottest season," says he, in a letter to Sir Joseph Banks, dated July 6, 1791, "the shortest time I have been able to remark for the whole evolutions of the silk worm is 40 days; that is to say, six days an egg, 22 a worm, 8 a grub in the cocoon, and one a moth or butterfly." Fortunately, where the climate forces forward their production so rapidly, nature hath been equally provident of food for their subsistence; for in these regions the mulberry continues to grow and push out leaves throughout the whole year.

Though the silk worm be a native of China, there is no doubt but it might easily be propagated perhaps in most parts of the temperate zones. The eggs of this insect, indeed, require a considerable degree of warmth to hatch them, but they can also endure a severe frost. No less than 5400 lbs. of silk were raised in 1789 in the cold, sandy territories of Prussia. In the province of Pekin, in China, where great quantities of silk are fabricated, the winter is much colder than even in Scotland. From the information of some Russians who were sent thither to learn the Chinese language, we find that Reaumur's thermometer was observed from 10 to 15, and even 20 degrees below the freezing point. Nor is it difficult to rear the food of the silk worm in a temperate clime. The mulberry-tree is a hardy vegetable, which bears, without injury, the winters of Sweden, and even of Siberia. Of the seven species of the mulberry (see Morus) enumerated by Linneus, four of these (viz. the white, red, black, and Tartarian), there is every reason to believe could be reared both in Britain and Ireland. The white grows in Sweden; the red is abundant round Quebec; the black delights in bleak situations, exposed to wind, on the sea shore; and the Tartarian mulberry is represented as growing in the chilly regions of Siberia.

As to the superior qualities of the different species, whether probably there is very little to be pointed out among these species, the four just mentioned with regard to nourishment, except what may be drawn from the following fact: that if the first three are laid down together, the silk worm of the others will first eat the white, then the red, and last the black, in the order of the tenderness of the leaves. The Tartarian seems to hold as high a place in its esteem as either the red or black; but all must yield to the white, which seems to be its natural food.

In Calabria the red mulberry is used; in Valencia the white; and in Granada, where excellent silk is produced, the mulberries are all black. The white seems to prosper very well in a moist soil: the black agrees well with a dry, sandy, or gravelly soil; and the white is most luxuriant in a moist rich loam.

It may justly be asserted, that Britain possesses some advantage in the raising of raw silk which are not enjoyed by warmer countries. Even in the south of France, Mr Arthur Young informs us, the mulberry trees in countries over which the leaves are often nipped by frost in the bud; and this is for raising scarcely ever the case with us. It is well known that silk thunder and lightning are hurtful to the silk worm. Now our climate can boast that it is almost wholly exempt from those dreadful storms of thunder and lightning which prevail so much in hot climates. Nature has then furnished us with every thing requisite for the silk manufacture; it remains only for us to improve the advantages which we possess. Let mulberry tree be planted by proprietors of lands, and let a few persons of skill and attention devote their time to the raising of silk worms. This is an employment that will not interfere with any manufacture already established; on the contrary, it would afford a respectable, a lucrative, and agreeable employment to ladies, or to females in general, who have at present too few professions to which they can apply. The society instituted at London for the encouragement of arts, manufactures, and commerce, much to their honour, have offered premiums to those who shall plant a certain number of mulberry trees.

The following method of raising mulberry trees Method of from seed is practised in the south of France, and has been repeated with success in the East Indies by Dr Anderson. Populare a son of Madras. "Take the ripe berries of the mulberry south of it when it is full of juice and of seeds. Next take a France. rough horse-hair or rope, such as we dry linen on, Letters on and with a good handful of ripe mulberries run your hand along the line, brushing the berries and mashing the silk on the Coast of Coromandel."

warm renew it. Place the earthen vessels in the coldest place of the ship, and let them remain until the end of the voyage. It must be observed, that the ship chosen for this purpose ought to be one that would arrive in Britain in the months of June or July.
them as much as possible as your hand runs along, so that the pulp and seeds of the berries may adhere in great abundance to the rope or hair line. Next dig a trench in the ground where you wish to plant them, much like what is practised in kitchen gardens in England for crops of various kinds. Next cut the rope or hair line into lengths according to the length of the trench you think fit to make, and plunge the line full of mashed berries into the trench, and then cover it over with well with earth, always remembering afterwards to water it well, which is essential to the success. The seeds of the berries thus sown will grow, and soon shoot out young suckers, which will bear young leaves, which are the best food for the silk worm.

"The facility and rapidity with which young leaves may be produced is evident, for as many rows of trenches may thus be filled as can be wished; and it can never be necessary to have mulberry trees higher than our raspberries, currants, or gooseberry bushes. Whenever they get beyond that, they lose their value; and if these trenches succeed, you may have a supply coming fresh up day after day, or any quantity you please." Thus abundance of these trees might be reared. But as mulberry trees are not yet found in abundance in this country, it was to be wished that some other food could be substituted in their place: attempts have accordingly been made by those who have reared silk worms, and it has been found possible to support the silk worm upon lettuce (8).

Miss Henrietta Rhodes, a lady who has made some successful experiments on raising silk worms in England, had found that the silk worm could with safety be kept on lettuce for some time. This is pretty generally known by ladies who have turned their attention to this subject; but she found that in general they could not with safety be kept upon that food above three weeks. If longer fed upon that plant, the worms for the most part die without spinning a web at all. She found, however, that they did not always die, but that in some cases they produced very good cocoons, even when fed entirely on lettuce. She therefore with reason suspected that the death of the animal must be occasioned by some extraneous circumstance, and not from the poisonous quality of the food itself: the circumstance she suspected, from some incidental observations, was the coldness of that food; and therefore she thought it was not impossible, but if they were kept in a very warm place, while fed on lettuce, they might attain, in all cases, a due perfection. General Mordaunt having been informed of this conjecture, resolved to try the experiment. He got some silk worm eggs, had them hatched in his hot-house, and caused them to be all fed upon lettuce and nothing else. They prospered as well as any worms could do, few or none of them died; and they afforded silk cocoons, as if they had been fed upon mulberry leaves. As far as one experiment can go, this affords a very exhilarating prospect in many points of view. If one kind of fresh has been toxicous, merely on account of an improper temperature, others may be found which have been hurtful only from a similar cause; so that it is not impossible but we may at last find that this delicate creature may be supported by a variety of kinds of food. Few, however, could be more easily obtained than lettuce; and this plant, when cabbaged (the cos or ice lettuce especially), would possess one quality that the mulberry leaf never can possess, from the want of which many millions of worms die in those countries where silk is now reared; for it is observed, that when the leaves are gathered wet, it is scarcely possible to preserve the worms alive for any length of time; so that during a continuance of rainy weather many of them are unavoidably cut off; but a lettuce, when cabbaged, resists moisture. If gathered, even during rain, the heart of it is dry; so that if the outer leaves be thrown aside at that time, the worms would be continued in perfect health. The expense, too, of cultivating and gathering lettuce, would be so much less than that of gathering mulberry leaves, as to occasion a saving that would be much more than sufficient to counterbalance the expense of heating the conservatory, as a little reflection will show.

But the great point to be now ascertained is, whether it is a fact that worms feed on lettuce, if kept in a due temperature, will continue in good health, in general, till they shall have perfected their cocoon? One experiment is too little to establish this fact with perfect certainty. It would therefore be necessary that more experiments should be made on this subject.

It is said that Dr Lodovico Bellardi, a learned and ingenious botanist of Turin, has, after a number of experiments, discovered a new method of feeding silk worms, when they are hatched before the mulberry trees have produced leaves, or when it happens that the frost destroys the tender branches. This new method consists in giving the worms dried leaves of the mulberry-tree. One would think that this dry nourishment would not be much relished by these insects; but repeated experiments made by our author, prove that they prefer it to any other, and eat it with the greatest avidity. The mulberry leaves must be gathered about the end of autumn, before the frosts commence, in dry weather, and at times when the heat is greatest. They must be dried afterwards in the sun, by spreading them upon large cloths, and laid up in a dry place after they have been reduced to powder. When it is necessary to give this powder to the worms, it should be gently moistened with a little water, and a thin coat of it must be placed around the young worms, which will immediately begin to feed upon it.

We have mentioned all the different kinds of food, Proper ex which, as far as we have heard, have been tried with.periments to any success to nourish the silk worm; not, however, in a very various way made on with great confidence, but as experiments which it might be worth while carefully to consider and perform. We must not omit to mention that one person, who has had much

(n) It is not improbable, says Dr Anderson, to whose valuable work entitled the Bcr, we have been much indebted in drawing up this article, that other kinds of food may be found which will answer the same purpose. The chichorium intybus and common endive might be tried, as they have the same lettuce-like quality with the lettuce.
such experience in the managing of silk worms, assures us, that the silk produced from any other food than mulberry leaves is of inferior quality, and that the worms are sickly. We think, however, that there is reason to suspect that the experiment has not been skilfully performed; and therefore, before every other food except mulberry leaves is discarded, the experiment ought to be performed with more attention and care. We know that many animals in a domestic state can live upon food very different from that which supports them when running wild in the fields. Certain it is, however, that every animal, in its state of nature, partakes of a food peculiar to itself, which is rejected by other animals as if it were of a poisonous quality; and it may be mentioned as a curious fact, as well as an admirable instance of the care of that Being who feeds the fowls of heaven, that notwithstanding the numberless insects that prey upon animals and vegetables, the mulberry tree is left untouched by them all, as the exclusive property of the silk worm, the chief of the insect tribe, which toils and spins for the use of man.

Having now considered the food proper for the silk worm, we shall next consider what situation is most favourable to them. In the opinion of some persons in this country who have been in the practice of rearing silk worms, they ought always to be kept in a dry place, well sheltered, and possessing a considerable degree of warmth, and which is not exposed to sudden transitions from heat to cold. If the weather be too cool, a small fire must be made; this is of most importance when the worms are nearly for spinning. A southern exposure is therefore preferable. Some think light is of great utility to silk worms, others think that they thrive better in the dark. As to what apartments are best accommodated for promoting the health of silk worms, and most convenient for those who have the care of them, they may be various according to the extent of the manufacture or the wealth of the proprietors. Silk worms may be kept in boxes or in shelves. When shelves are to be used, they may be constructed in the following manner: The shelves may be of wicker, ranged at the distance of a foot and a half, and fixed in the middle of the room: their breadth ought to be such, that any person can easily reach to the middle from either side. This is perhaps the simplest and cheapest apparatus for rearing silk worms; but there is another apparatus which may be recommended to those who are anxious to unite some degree of elegance with convenience. This apparatus is the invention of the Rev. George Swaine of Picklechurch, a gentleman who has studied this subject much, in order to find out the way for promoting the culture of silk among the poor. This apparatus, with the description of it, may be found in the Transactions of the Society for encouraging Arts, Manufactures, and Commerce, vol. vii. p. 148. The apparatus consists of a wooden frame four feet two inches high, each side 16 inches and a half wide, divided into eight partitions by small pieces of wood which form grooves, into which the slides run, and are thus easily thrust into or drawn out of the frame. The upper slide in the model sent to the Society by Mr Swaine is of paper only, and designed to receive the worms as soon as hitched; the two next are of catgut, the threads about one-tenth of an inch distant from each other: these are for the insects when a little advanced in size: the five lower ones are of wicker work; but, as Mr Swaine afterwards found, netting may be substituted with advantage instead of wicker bottoms. Under each of these, as well as under those of catgut, are sliders made of paper, to prevent the dung of the worms from falling on those feeding below them.

The management of silk worms is next to be attended to. The proper time for hatching them is when the forage leaves of the mulberry are fully grown, or nearly so; and the worms that as soon as these insects are capable of receiving food they may obtain it in abundance. To attempt to hatch them sooner would be hurtful, as the weather would not be sufficiently warm. Besides, as leaves are necessary to the life of a vegetable, if the young leaves of the mulberry tree are cropped as soon as they are unfolded, the tree will be so much weakened as to be incapable of producing so many leaves as it would otherwise have done; and if this practice be frequently repeated, will inevitably be destroyed.

When the proper season is arrived, the eggs may be hung either by the heat of the sun, when it happens ought to be strong enough, or by placing them in a small room moderately heated by a stove or fire; and after being exposed for six or seven days to a gentle heat, the silk worm issues from the egg in the form of a black hairy caterpillar. When Mr Swaine's apparatus is used, the worms are to be kept on the drawers with paper bottoms till they are grown so large as not readily to creep through the gauze-bottomed drawers: they are then to be placed on those drawers, where they are to remain till their excrements are so large as not readily to fall through; when this is the case they must be removed to the drawers with the wicker or netting bottoms, and fed thereon, till they show symptoms of being about to spin. It is scarcely necessary to mention, that the paper slides beneath the gauze and wicker drawers are intended to receive the dung, which should be emptied as often as the worms are fed, at least once a-day; or to direct, that when the worms are fed, the slides are to be first drawn out a considerable way, and the drawers to rest upon them.

It has been already mentioned, that wet or damp food is exceedingly prejudicial to those insects. It promotes contagious and fatal diseases. To prevent the production of these diseases, it is necessary to give them either wet or damp food, attention ought to be paid to the weather, so that when there is an immediate prospect of rain, a sufficient quantity of leaves may be gathered to serve the worms two or three days. In this country, the leaves of the black or red mulberry tree may be preserved good for food, although kept four or five days, by the following method: When new gathered, lay them loosely in glazed earthen vessels, place these in a cold place, well aired, not exposed to drought.

The utmost attention must be paid to preserve the place where the silk worms are kept as clean as possible: be kept as the house or room must be well ventilated, that no noxious vapours be accumulated. By some experiments of M. Faujas de St Fond, which are recorded in his history of Languedoc, it appears that the silk worm is much injured by foul air. All decayed leaves must be removed from them, as it is now well known that they emit bad air in great abundance.
One of the most difficult branches of the management of silk worms has hitherto been the cleaning without bruising them. To avoid this inconvenience, the peasants in France and Italy frequently allow the whole litter to remain without ever cleaning them, which is the cause of that unwholesome stench that has been so often remarked by those who visit the places for rearing silk worms in these countries. This difficulty may be effectually removed by providing a net, or, what would be still better, a wire-bottomed frame, wrought into large meshes like a riddle. Have that made of a size exactly sufficient to cover the wooden box in which the worms are kept. When you mean to shift them, spread fresh leaves into the wire basket; and let it down gently over the worms till it comes within their reach. They no sooner perceive the fresh food than they abandon the rubbish below, and creep through the leaves, so as to fix themselves upon the leaves; then by gently raising the fresh basket, and drawing out the board below (which ought to be made to slip out like the lip-bottom of a bird's cage), you get off all the excrement and decayed leaves, without incommoding the worms in the smallest degree; and along with the litter you will draw off an inch or two in depth of the foulest mephitic vapours. To get entirely rid of these, the board, when thus taken out, should be carried without doors, and there cleaned; and the slip-board immediately replaced to receive all the excrements and offals. After it is replaced, the wire frame that had been elevated a little may be allowed to descend to a convenient distance above the board without touching it. Thus will there be left a vacant space for the mephitic air to fall below the worms, so as to allow them to inhabit a wholesome region of the atmosphere.

When a fresh supply of food is to be given before cleaning, the wire frame ought to be let down as close to the board as can be safely done, and another wire-bottomed frame put over it, with fresh leaves, as before described. When the worms have abandoned that in their turn, let the slip-board, together with the lower wire frame, be drawn out and removed, and so on as often as necessary. To admit of this alternate change, every table, consisting of one slip-board, ought to have two sets of wire-bottomed frames of the same size; the slip-board to be always put into its place immediately after it is cleaned, and the wire frames reserved to be afterwards placed over the other. By this mode of management, it is probable that the worms would be saved from the diseases engendered by the mephitic air, and the numerous deaths that are the consequence of it avoided.

Dr Anderson, to whom we have already acknowledged quicklime's obligation, and to whom this country has been much indebted for valuable works on agriculture, the fisheries, &c. advises those who have the management of silk worms to strew a thin stratum of fresh slaked round quicklime upon the slip-board each time it is cleaned, immediately before it is put into its place. This would absorb the mephitic gas, for as soon as it is generated it would descend upon the surface of the quicklime. Thus would the worms be kept continually in an atmosphere of pure air (c). Were the walls of the apartments to be frequently washed with quicklime and water, it would tend much to promote cleanliness at a small expense, and augment the healthiness of the worms as well as that of the persons who attend them.

When the silk worm refuses its food, and leaves silksy Mr Swayne's traces on the leaves over which it passes, it is a proof that it is ready to begin its cocoon. It is now necessary for the try to form a new receptacle, which is commonly done worms, by pinning together papers in the shape of inverted cones when go with broad bases. This method (says Mr Swayne), is not to spin.

Transactions, of the Society for besides, as the silk worm always weaves an outer covering of Peru, or oval ball, I apprehended that it caused a needless waste of silk in forming the broad web at the top. The method I make use of is, to roll a small piece of paper (an unc octavo leaf, such as that of an old magazine, is sufficient for three), round my forefinger, and to give it a twist at the bottom; which is done with the utmost expedition, and gives no occasion for the use of pins. These rolled paper-cases being likewise of a form more nearly resembling that of a cocoon, with a much narrower opening on the top than the others, takes away the necessity of wasting much silk in the outer web, and consequently leaves more to be employed in forming the ball. The silk is readily taken out of these cases by untwisting the bottom; and if this be done with moderate care, and the papers are preserved, they will serve several times for the like purpose."

Others recommend to spin, little bushes of heath, broom, or twigs, should bushes of be health.

(c) To put this question beyond a doubt, Mr Blancard made the following comparative experiments, which were several times repeated. "I procured (says he) four glass jars nine inches high and five in diameter, closing the mouth with cork stoppers. After which I placed in each of them, in their second life (so may be translated, which means the stage between the different sicknesses), twelve silk worms, which were fed four times a day; and which I confined in this kind of prison all their life, without taking away either their dead companions or their ordures or litter. I sprinkled with chalk the worms of only two of these jars, and kept the two others to compare with them.

"In those without lime, I never obtained either more or less than three small and imperfect cocoons (chiques ou bonnifard), and in the two that were sprinkled with lime, I had very often twelve, and never less than nine fine full-sized firm cocoons."

This experiment affords the most satisfactory proof of the utility of this process. From a number of trials be found, that even when the worms were covered with a large proportion of lime, they never were in any way incommode by it.
be stuck upright next the shelf or box in which they are inclosed: the worms mount these, and attach their web to them.

When the worms are ready to mount, in order to spin, if the weather be hot, attended with thunder, you will see them in a languishing condition; your care must then be to revive them, which is effected thus: Take a few eggs and onions, and fry them in a pan with some stale hog's lard, the saltier the better, and make pancakes; which done, carry it smoking hot into the room where they are kept, and go round the chamber with it. You will be surprised to see how the smell revives them, excites those to eat who have not done feeding, and makes the others that are ready to spin climb up the twigs.

In about ten or twelve days, according to the accounts we have received from Mr Andrew Wright of Paisley, it may be safely concluded, that if the worms have finished their work, the cocoons may be collected.

We shall now distinguish the cocoons from one another according to their value or their use, and consider the method of managing each. They may be distinguished into the good and the bad. The good cocoons may be known by these marks: they are little, strong, and firm; have a fine grain, both ends are round, and they are free from spots. Among the good cocoons also may be arranged those which are called calcined cocoons, in which the worm, in consequence of sickness, is petrified or reduced to a fine powder. These cocoons produce more silk than others, and are sold in Piedmont at half as much again; because the contexture of the dupion being stronger than that of the other cocoons, it is consequently less easy to be penetrated by the heat. You must observe to take it from the middle of the basket, because in that part the heat is least perceptible. After you have drawn your baskets from the oven, you must first cover each of them with a woollen blanket or rug, leaving the wrapper besides, and then you pile them above one another. If your baking has succeeded, your woollen cover will be all over wet with a kind of dew, the thickness of your little finger. If there be less, it is a sign your cocoons have been too much or too little baked. If too much baked, the worm, being over-dried, cannot transpire a humour he no longer contains, and your cocoon is then burnt. If not enough baked, the worm has not been sufficiently penetrated by the heat to distil the liquor he contains, and in that case is not dead.

You must let your baskets stand thus covered five or six hours if possible, in order to keep in the heat, as this makes an end of stifling those worms which might have avoided the first impression of the fire. You are likewise to take great care to let your cocoons stand in the oven the time that is necessary; for if they do not stand long enough, your worms are only stunned for a time, and will afterwards be revivified. If, on the other hand, you leave them too long in the oven, you burn them: many instances of these two cases are frequently to be met with. It is a good sign when you see some of the butterflies spring out from the cocoons which have been baked, because you may be certain they are not burnt. For if you would kill them all to the last worm, you would burn many cocoons which might be more exposed to the heat than that particular worm.

The next operation is the winding of the silk.
fore you begin to wind, you must prepare your cocoons as follows:

1. In stripping them of that waste silk that surrounds them, and which served to fasten them to the twigs. This burr is proper to stuff quilts, or other such uses; you may likewise spin it to make stockings, but they will be coarser and ordinary.

2. You must sort your cocoons, separating them into different classes in order to wind them apart. These classes are, the good white cocoons; the good cocoons of all the other colours; the dupions; the cocoons, among which are included the weak cocoons; the good choquette; and, lastly, the bad choquette.

In sorting the cocoons, you will always find some perforated cocoons amongst them, whose worm is already born; those you must set apart for fleurét. You will likewise find some soufflons, but very few; for which reason you may put them among the bad choquette, and they run up into waste.

The good cocoons, as well white as yellow, are the easiest to wind; those which require the greatest care and pains are the cocoons; you must wind them in cooler water than the others, and if you take care to give them to a good windster, you will have as good silk from them as the rest. You must likewise have careful windsters for the dupions and choquettes. These two species require hotter water than the common cocoons.

The good cocoons are to be wound in the following manner: First, choose an open convenient place for your filature, the better the better, if you intend to have many furnaces and coppers. The building should be high and open on one side, and walled on the other, as well to screen you from the cold winds and receive the sun, as to give a free passage to the steam of your basons or coppers.

These coppers or basons are to be disposed (when the building will admit of it) in a row on each side of the filature, as being the most convenient method of placing them, for by that means in walking up and down you see what every one is about. And these basons should be two and two together, with a chimney between every couple.

Having prepared your reels (which are turned by hand, and require a quick eye), and your fire being a light one under every basin, your windster must stay till the water is as hot as it can be without boiling. When every thing is ready, you throw into your basons two or three handfuls of cocoons, which you gently brush over with a wisk about six inches long, cut stumply like a broom worn out: by these means the threads of the cocoons stick to the wisk. You must disengage these threads from the wisk, and purge them by drawing these ends with your fingers till they come off entirely clean. This operation is called Battue.

When the threads are quite clear, you must pass four of them (if you will wind fine silk) through each of the holes in a thin iron bar, that is placed horizontally at the edge of your basin; afterwards you twist the two ends (which consist of four cocoons each) twenty or twenty-five times, that the four ends in each thread may the better join together in crossing each other, and that your silk may be plump, which otherwise would be flat.

Your windster must always have a bowl of cold water by her, to dip her fingers in, and to sprinkle very often the said bar, that the heat may not burn the thread.

Your threads, when thus twisted, go upon two iron hooks called rimpins, which are placed higher, and from thence they go upon the reel. At one end of the axis of the reel is a cog-wheel, which catching in the teeth of the post-rimpin, moves it from the right to the left, and consequently the thread that is upon it; so that your silk is wound on the reel crossways, and your threads form two hanks of about four fingers broad.

As often as the cocoons you wind are done, or break or diminish only, you must join fresh ones to keep up the number requisite, or the proportion; because, as the cocoons wind off, the thread being finer, you must join two cocoons half wound to replace a new one: Thus you may wind three new ones and two half wound, and your silk is from four to five cocoons.

When you would join a fresh thread, you must lay one end on your finger, which you throw lightly on the other threads that are winding, and it joins them immediately, and continues to go up with the rest. You must not wind off your cocoons too bare or to the last, because when they are near at an end, the burr, that is, the husk, joins in with the other threads, and makes the silk foul and gouty.

When you have finished your first parcel, you must clean your basons; taking out all the striped worms, as well as the cocoons, on which there is a little silk, which you first open and take out the worm, and then throw them into a basket by you, into which you likewise cast the loose silk that comes off in making the battue.

You then proceed as before with other two or three handfuls of cocoons; you make a new battue; you purge them, and continue to wind the same number of cocoons or their equivalent, and so to the end.

As was already mentioned, the windster must always have a bowl of cold water by her, to sprinkle the bar, to cool her fingers every time she dips them in the hot water, and to pour into her basin when necessary, that is, when her water begins to boil. You must be very careful to twist your threads a sufficient number of times, about 25; otherwise your silk remains flat, instead of being round and full; besides, when the silk is not well crossed, it never can be clean, because a good or nub that comes from a cocoons will pass through a small number of these twists, though a greater will stop it. Your thread then breaks, and you pass what foulness there may be in the middle of your reel between the two hanks, which serves for a head-band to tie them.

You must observe that your water be just in a proper degree of heat. When it is too cold, the thread is dead, and has no body; when it is too hot, the ends which form the thread do not join well, and form a harsh ill-qualified silk.

You must change the water in your basin four times a day for your dupions and choquette, and twice only for good cocoons when you wind fine silk; but if you wind coarse silk, it is necessary to change it three or four times. For if you were not to change the water, the silk would not be so bright and glossy, because the worm contained
contained in the cocoons foul it very considerably.
You must endeavour to wind as much as possible with
clear water, for if there are too many worms in it, your
silk is covered with a kind of dust which attracts the
moth, and destroys your silk.
You may wind your silk of whatever size you please,
from one cocoon to 1000; but it is difficult to wind more
than 30 in a thread. The sticky, and that in which
consists the greatest difficulty, is to wind even; because
as the cocoon winds off the end is finer, and you must
then join other cocoons up to keep the same size. This
difficulty of keeping the silk always even is so great,
that (excepting a thread of two cocoons, which we call
such) we do not say a silk of three, of four, or six
cocoons; but a silk of three to four, of four to five, of six
to seven cocoons. If you proceed to a coarser silk,
you cannot calculate so nicely as to one cocoon more or
less. We say, for example, from 12 to 15, from 15 to
20, and so on.

What number of worms are necessary to produce a
certain quantity of silk has not been ascertained. And
as different persons who wished to determine this point
have had different results, the truth seems to be, that
from various circumstances the same number of worms
may produce more silk at one time than at another.
It is related in the second volume of the Transactions of the
Society for encouraging Arts, &c. that Mrs. Will-
iams obtained nearly an ounce and a half of silk from
244 cocoons. Mr. Swyys from 70 cocoons procured
100 grains. Miss Rhodes obtained from 250 of the
largest cocoons, three quarters of an ounce and a dram.
From a paper in the second volume of the American
Transactions, which we have before referred to in
the course of this article, we are informed that 150
ounces of good cocoons yield about 11 ounces of silk from five
to six cocoons: if you wind coarser, something more.
But what appears astonishing, Mr. Salvatore Bertezens,
Italian, to whom the Society for encouraging Arts,
&c. adjudged their gold medal, raised five pounds of
excellent silk from 12,000 cocoons.

The cocoons produce a thread of very unequal
length; you may meet with some that yield 1200 ells,
whilst others will scarcely afford 200 ells. In general,
you may calculate the production of a cocoon from 500
to 600 ells in length.

**SILK-LOOM.** See WEAVING.
**SILK-WORM.** See SILK.

**SILLA,** a large town on the Niger, by which the
travels of Mr. Park were bounded towards the east. He
gives no particular description of the place, which his
health and spirits permitted him not to survey, but as-
signs the reasons by which he was induced to proceed
no farther. On his arrival, he was allowed to remain un-
der a tree, till it was quite dark, surrounded by hun-
dreds of people. But their language was extremely dif-
ferent from the other parts of Bambarra; and he was
given to understand, that in his progress eastward, the
Bambarra tongue was very little understood; and that,
on his reaching Jenné, he would find the greater part of
the inhabitants accustomed to speak a different language.
He had now become the prey of sickness, exhausted
with hunger and fatigue, half naked, and without any
article of value, to procure for himself provisions,
clothes, or lodging, on which account he resolved to re-
turn, finding that to prosecute his journey further in
that direction was wholly impracticable. Silla, accord-
ing to the latest map of Africa, is in 14° 49' N. Lat.
1 2° 46' W. Long.

**SILPHA,** CARRION-BEETLE, a genus of insects
belonging to the order Coleoptera. See ENTOMOLOGY
Index.

**SILPHIUM,** a genus of plants belonging to the
class of synogenesis, and to the order of polygamae necessariae;
and in the natural system arranged under the 49th or-
der, Composite. See BOTANY Index.

**SILVER,** a well known metallic substance. For an
account of its properties, see CHEMISTRY Index.

**SILVER, Ores of.** See MINERALOGY Index.

**Shell-Silver,** is prepared of the shreds of silver leaf,
or of the leaves themselves, for the use of painters, after
the same manner as shell-gold. See SHELL-GOLD.

**SILVERING,** the covering of any thing with silver.
It is usual to silver metals, wood, paper, &c. which is
performed either with fire, oil, or size. Metal-gilders
silver by the fire; painter gilders all the other ways.
See GILDING.

To silver copper or brass. 1. Cleanse the metal with
aqua-fortis, by washing it lightly, and immediately
throwing it into pure water; or by heating it red hot,
and scouring it with salt and tartar, and pure water,
with a small wire brush. 2. Dissolve some silver in
aqua-fortis, in a broad-bottomed glass vessel, or of gla-
zed earth; then evaporate away the aqua-fortis over a
shewing dish of coals. 3. Put five or six times its
quantity of water, or as much as is necessary to
dissolve it perfectly, on the remaining dry calx; evap-
orate this water with the like heat; then put more fresh
water, and evaporate again; and, if need be, the third
time, making the fire towards the latter end so strong as
to leave the calx perfectly dry, which, if your silver is
good, will be of a pure white. 4. Take of this calx,
common salt, crystals of tartar, of each a like quantity
or bulk, and mixing well the whole composition, put
the metal into pure water, and take of the said powder
with your wet fingers, and rub it well on, till you find
every little cavity of the metal sufficiently silvered
over. 5. If you would have it richly done, you must
rub on more of the powder; and, in the last place, wash
the silvered metal in pure water, and rub it hard with a
dry cloth.

**SILVERING of Glasses.** See FOLLIATING of Looking-
glasses.

**SILLURIS,** a genus of fishes belonging to the order
abdominales. See Ichthyology Index.

**SIMANCAS,** a village on the eastern boundary of
the kingdom of Leon in Spain, six miles below Vallad-
dolid, on the river Guinerga. Dr. Robertson, in the intro-
duction to his History of America, makes mention of
it, and it is remarkable for the archives of the kingdoms
of Leon and Castile, kept in this castle. This collec-
tion was begun when the kings often resided at Valla-
dolid, in which city is still the civil and military tribu-
nal for almost the whole of Spain to the north of the
Tagus. It was thought proper to have those papers
kept in the vicinity of that court, for which purpose this
castle was peculiarly fitted, being entirely erected of
stone. At one period there were two large halls in this
office filled with papers respecting the first settlement of
the Spaniards in South America. There was likewise
in the room called the ancient royal patronage, a box
containing:
containing treatises with England, in which are many
letters and treaties between the Kings of England and
Spain, from the year 1400 to 1600. There was also a
strong box in the same archives, with five locks, which,
we are told, has not been opened since the time of Phi-
lip II. and it is supposed that it contains the process a-
gainst Philip's son Prince Charles. But it appears that
some of the state papers have been removed to Madrid.

SIMONE of DURHAM, the contemporary of William
of Malmsbury, took great pains in collecting the mon-
uments of our history, especially in the north of Eng-
land, after they had been scattered by the Danes. From
these he composed a history of the kings of England,
from A.D. 616 to 1130; with some smaller historical
pieces. Simeon both studied and taught the sciences,
and particularly the mathematics at Oxford; and be-
came preacher of the church at Durham, where he
died, probably soon after the conclusion of his history,
which was continued by John, prior of Hexham, to
A.D. 1156.

SIMIA, the Monkey, a genus of quadrupeds be-
longing to the class of mammals, and order of primates,
in the Linnaean system, but by Mr. Pennant arranged
under the digitated quadrupeds. See Mammalia In-
der.

SIMILE, or SIMILITUDE, in Rhetoric, a com-
parison of two things, which though different in other
respects, yet agree in some one. The difference be-
tween a simile and comparison is said to consist in this,
that the simile properly belongs to whatever we call
the quality of a thing, and the comparison to the quan-
tity. See Comparison; and Oratory, No. 118.

SIMILOR, a name given to an alloy of red cop-
er and zinc, made in the best proportions, to imitate
silver and gold.

SIMON MACCABEUS, a celebrated leader and high-
priest of the Jews, who, after rendering the most im-
portant services to his country, was at last treacherous-
ly slain by his son-in-law. See the History of the
Jews, No. 15.

SIMON MAGUS, or the Sorcerer, was a native of Git-
tio, a village of Samaria. According to the usual prac-
tice of the Asiaots of that age, he visited Egypt, and
there probably became acquainted with the sublime
mysteries taught in the Alexandrian school, and learned
those theurgic or magical operations, by means of which
it was believed that men might be delivered from the
power of evil demons. Upon his return into his own
country, the author of the Clementine Recognitions
relates, that he imposed upon his countrymen by high
pretensions to supernatural powers. And St. Luke at-
tests, that this artful fanatic, using sorcery, had be-
witched the people of Samaria, giving out that he was
some great one; and that he obtained such general at-
tention and reverence in Samaria, that the people all
gave heed to him from the least to the greatest, saying
"This man is the great power of God."

By the preaching of Philip the Deacon, he was with,
other Samaritans converted to the Christian faith, and
admitted into the infant church by the ordinance of
baptism. His conversion, however, seems not to have
been real; for, upon seeing the miraculous effects of
the laying on of the apostle's hands, he offered them mo-
ney, saying, "Give me also this power, that on whom-
soever I lay hands he may receive the Holy Ghost."

He probably thought Peter and John magicians like
himself, but better skilled in the art of deceiving the
multitude.

Being sharply reproved for this impiety, he seems
by his answer to have been made sensible of his sin; but
his repentance, if sincere, was of short duration. Re-
turning to his former practices of imposture, he travel-
ed through various provinces of the empire, opposing
the progress of the gospel; and arriving at Rome, he
led astray vast numbers of people by his pretended mir-
acles. How long he lived in that metropolis of the
world, or in what manner he died, we have no accounts
that can be fully depended on. The Christian writers
tell us, that being raised in the air by two demons, he
was deprived of their support by the prayers of St. Pe-
ter and St. Paul, and falling, broke his legs. By some
he is thought to have been the person mentioned by
Suetonius, who, undertaking to fly in the presence of
Nero, fell to the ground with such violence, that his
blood spurted up to the gallery where the emperor was
sitting.

The sum of this impostor's doctrine, divested of
legory, was, that from the Divine Being, as a fountain
of light, flow various orders of seats, or eternal na-
tures, subsisting within the plenitude of the divine es-
ence; that beyond these, in the order of emanation,
are different classes of intelligences, among the lowest
of which are human souls; that matter is the most re-
more production of the emanative power, which, on ac-
count of its infinite distance from the Fountain of
Light, possesses sluggish and malignant qualities, which
oppose the divine operations, and are the cause of evil;
that it is the great design of philosophy to deliver
the soul from its imprisonment in matter, and restore it to
that divine light from which it was derived: and that
for this purpose God had sent him one of the first mens
among men. To his wife Helena he also ascribed a si-
milar kind of divine nature, pretending that a female
man inhabited the body of this woman, to whom he
gave the name of Emuna, Wisdom; whence some Chris-
tian fathers have said, that he called her the Holy Spi-
rit. He also taught the transmigration of souls, and
denied the resurrection of the body.

SIMON, Richard, was born at Dieppe the 15th May
1638. He began his studies among the priests of the
Oratory in that city, but quitted their society in a short
time. From Dieppe he went to Paris, where he
made great progress in the study of the oriental lan-
guages. Some time afterwards he joined the society
of the Oratory again, and became a priest of it in
1660. In 1670 he published some pieces of a smaller
kind. In 1678 his Critical History of the Old Testa-
ment appeared, but was immediately suppressed by the
intrigues of Messieurs du Port Royal. It was reprint-
ed the year after, and its excellence soon drew the at-
tention of foreigners; an edition of it was accordingly
published at Amsterdam in Latin, and at London in
English.

He died at Dieppe in 1712, at the age of 74.

He certainly possessed a vast deal of learning; his
criticism is exact, but not always moderate; and there
reigns in his writings a spirit of novelty and singularity
which raised him a great many adversaries. The most
celebrated of these were Le Clerc, Vossius, Jurieu, Du
Pin, and Bossuet. Simon wrote an answer to most of
the
the books that were published against him, and displays a pride and obstinacy in his controversial writings which do him little honour.

He was the author of a great many books. The following are the principal: 1. The Ceremonies of the Jews, translated from the Italian of Leo of Modena, with a supplement concerning the sects of the Carraoites and Samaritans. 2. L' Histoire Critique du Vieux Testament, "The Critical History of the Old Testament." This is a very important work, and deserves the attention of every clergyman. He sometimes, however, deviates from the road of integrity, to serve the cause of the church of Rome, particularly in his endeavours to prove the uncertainty of the Hebrew language. These passages have been very justly exposed and confuted by Dr Campbell, in his ingenious Preliminary Dissertations to his new Translation of the Gospels. 3. Critical History of the Text of the New Testament. 4. Critical History of the Versions of the New Testament. 5. Critical History of the principal Commentators on the New Testament. 6. Inspiration of the Sacred Books. 7. A translation of the New Testament. This book was censured by Cardinal Noailles and Bosquet. 8. The History of the rise and progress of Ecclesiastical Revenues, which is commended by Voltaire, as is his Critical History of the Old Testament. It resulted from a quarrel with a community of Benedictines. 9. A new select Library, which points out the good books in various kinds of literature, and the use to be made of them. 10. Critical History of the Belief and Customs of the Nations on the Levant. 11. Critical Letters, &c.

SIMONICAL, is applied to any person guilty of simony. See Simony.

SIMONIDES, the name of several poets celebrated in antiquity; but by the Marbles it appears that the eldest and most illustrious of them was born in the 55th Olympiad, 538 years B. C. and that he died in his 90th year; which nearly agrees with the chronology of Eusebius. He was a native of Ceos, one of the Cyclades, in the neighbourhood of Attica, and the preceptor of Pindar. Both Plato and Cicero give him the character not only of a good poet and musician, but speak of him as a person of great virtue and wisdom. Such longevity gave him an opportunity of knowing a great number of the first characters in antiquity with whom he was in some measure connected. It appears in Fabricius, from ancient authority, that Simonides was contemporary and in friendship with Pitanus of Mitylene, Hipparchus tyrant of Athens, Pausanias king of Sparta, Hiero tyrant of Syracuse, with Themistocles, and with Alesander king of Thessaly. He is mentioned by Herodotus; and Xenophon, in his Dialogue upon Tyranny, makes him one of the interlocutors with Hiero king of Syracuse. Cicero alleges, what has often been quoted in proof of the modesty and wisdom of Simonides, that when Hiero asked him for a definition of God, the poet required a whole day to meditate on so important a question: at the end of which, upon the prince putting the same question to him a second time, he asked two days respite; and in this manner always doubled the delay each time he was required to answer it; till at length, to avoiding offending his patron by more disappointments, he frankly confessed that he found the question so difficult, that the more he meditated upon it, the less was his hope of being able to solve it.

In his old age, perhaps from seeing the respect which money procured to such as had lost the charms of youth and the power of attaching mankind by other means, he became somewhat mercenary and avaricious. He was frequently employed by the victors at the games to write panegyrics and odes in their praise, before his pupil Pindar had exercised his talents in their behalf: but Simonides would never gratify their vanity in this particular, till he had first tied them down to a stipulated sum for his trouble; and upon being un búsqueda of his meanness, he said, that he had two coffers, in one of which he had for many years put his pecuniary rewards; the other was for honours, verbal thanks, and promises; that the first was pretty well filled, but the last remained always empty. And he made no scruple to confess in his old age, that of all the enjoyments of life, the love of money was the only one of which time had not deprived him.

He was frequently reproached for his vice; however, he always defended himself with good humour. Upon being asked by Hiero's queen, Whether it was most desirable to be learned or rich? he answered, that it was far better to be rich; for the learned were always dependent on the rich, and waiting at their doors; whereas, he never saw rich men at the doors of the learned. When he was accused of being so sordid as to sell part of the provisions with which his table was furnished by Hiero, he said he had done it in order to display to the world the magnificence of that prince and his own frugality. To others he said, that his reason for amassing wealth was, that he would rather leave money to his enemies after death, than be troublesome to his friends while living.

He obtained the prize in poetry at the public games when he was fourscore years of age. According to Suidas, he added four letters to the Greek alphabet; and Pliny assigns to him the eighth string of the lyre; but these claims are disputed by the learned.

His poetry was so tender and plaintive, that he acquired the cognomen of Melicertes, 'sweet as honey;' and the tearful eye of his muse was proverbial. Dionysius places him among those polished writers who excel in a smooth volubility, and flow on like plentiful and perennial rivers, in a course of even and uninterrupted harmony.

It is to Dionysius that we are indebted for the preservation of the following fragment of this poet. Danae being by her merciless father inclosed in a chest, and thrown into the sea with her child, when night comes on, and a storm arises which threatens to overset the chest, she, weeping and embracing the young Perseus, cries out:

"Sweet child! what anguish does thy mother know, Ere cruel grief has taught thy tears to flow! Amidst the roaring wind's tremendous sound, Which threatens destruction as it howls around; In balmy sleep thou liest, as at the breast, Without one bitter thought to break thy rest— The glistening moon in pity hides her light, And shrinks with horror at the ghastly sight. Didst thou but know, sweet innocent! our woes, Not opiate's pow'r thy eyelids now could close."

Sleep.
Sleep on, sweet babe! ye waves in silence roll;
And lull, O lull, to rest my tortured soul!

There is a second great poet of the name of Simonides recorded on the Marbles, supposed to have been his grandson, and who gained, in 478 B.C., the prize in the games at Athens.

SIMONY, is the corrupt presentation of any one to an ecclesiastical benefice for money, gift, or reward. It is so called from the resemblance it is said to bear to the sin of Simon Magus; though, in the purchasing of holy orders seems to approach nearer to his offence. It was by the canon law a very grievous crime: and is so much the more odious, because, as Sir Edward Coke observes, it is ever accompanied with perjury; for the presentee is sworn to have committed no simony. However, it was not an offence punishable in a criminal way at the common law: it being thought sufficient to leave the clerk to ecclesiastical censure. But as these did not affect the simoniacal patron, nor were efficacious enough to repel the notorious practice of the thing, divers acts of parliament have been made to restrain it by means of civil forfeitures; which the modern prevailing usage, with regard to spiritual preferments, calls aloud to be put in execution. The statute 31 Eliz. c. 6. enacts, that if any patron, for money or any other corrupt consideration or promise, directly or indirectly given, shall present, admit, institute, induct, install, or collate any person to an ecclesiastical benefice or dignity, the giver and taker shall forfeit two years value of the benefice or dignity; one moiety to the king, and the other to any one who will sue for the same. If persons also corruptly resign or exchange their benefices, both the giver and taker shall in like manner forfeit double the value of the money or other corrupt consideration. And persons who shall corruptly ordain or license any minister, or procure him to be ordained or licensed (which is the true idea of simony), shall incur a like forfeiture of forty pounds; and the minister himself of ten pounds, besides an incapacity to hold any ecclesiastical preterment for seven years afterwards. Corrupt elections and resignations in colleges, hospitals, and other ecclesiastical corporations, are also punished, by the same statute, with forfeiture of the double value, vacating the place or office, and a devolution of the right of election, for that term, to the crown.

SIMOOM, a hot wind which blows occasionally in the deserts of Africa, and probably in other widely extended countries parched in the same manner by a vertical sun. Its effects on the human body are dreadful. If inhaled in any quantity, it produces instant suffocation, or at least leaves the unhappy sufferer oppressed with asthma and lowness of spirits. The approach of this awful scourge of God is indicated by a redness in the air, well understood by those who are accustomed to journey through the desert; and the only refuge which they have from it, is to fall down with their faces close to the ground, and to continue as long as possible without drawing in their breath.

Mr Bruce, who, in his journey through the desert, suffered from the simoom, gives of it the following graphical description: "At eleven o'clock, while we contemplated with great pleasure the rugged top of Chigge, to which we were fast approaching, and where we were to solace ourselves with plenty of good water,
One of the greatest critics in antiquity, himself conspicuous in the sublime and simple manner, hath borne this testimony to the writings of Moses and St Paul; and by parity of reason we must conclude, that had he been conversant with the other sacred writers, his taste and candour would have allowed them the same encomium.

It hath been often observed, even by writers of no mean rank, that the "Scriptures suffer in their credit by the disadvantage of a literal version, while other ancient writings enjoy the advantage of a free and embellished translation." But in reality these gentlemen's concern is ill placed and groundless: for the truth is, "that most other writings are impaired by a literal translation; whereas giving only a due regard to the idiom of different languages, the sacred writings, when literally translated, are then in their full perfection."

Now this is an internal proof, that in all other writings there is a mixture of local, relative, exterior ornament, which is often lost in the translation from one language to another. But the internal beauties, which depend not on the particular construction of tongues, no change of tongue can destroy. Hence the Bible preserves its native beauty and strength alike in every language, by the sole energy of unadorned phrase, natural images, weight of sentiment, and great simplicity.

It is in this respect like a rich vein of gold, which, under the severest trials of heat, cold, and moisture, retains its original weight and splendour, without either loss or alloy; while laser metals are corrupted by earth, air, water, fire, and assimilated to the various elements through which they pass.

This circumstance, then, may be justly regarded as sufficient to vindicate the composition of the sacred Scriptures, as it is at once their chief excellence and greatest security. It is their excellence, as it renders them intelligible and useful to all; it is their security, as it prevents their being disguised by the false and explicative ornaments of vain or weak translators. We may safely appeal to experience and fact for the confirmation of these remarks on the superior simplicity, utility, and excellence, of the style of the Holy Scripture. Is there any book in the world so perfectly adapted to all capacities? that contains such sublime and exalted precepts, conveyed in such an artless and intelligible strain, that can be read with such pleasure and advantage by the lettered sage and the unlettered peasant?

SIMPLOCE. See Oratory, No. 72.

SIMPSON, THOMAS, professor of mathematics at the royal academy at Woolwich, fellow of the Royal Society, and member of the Royal Academy at Stockholm, was born at Market Bosworth in Leicestershire in 1710. His father, a stuff-weaver, taught him only to read English, and brought him up to his own business; but meeting with a scientific pedlar, who likewise practised fortune-telling, young Simpson by his assistance and advice left off weaving, and professed astrology. As he improved in knowledge, however, he grew disgusted with this pretended art; and renouncing it, was driven to such difficulties for the subsistence of his family, that he came up to London, where he worked as a weaver, and taught mathematics at his spare hours.

VOL. XIX. Part I.
in any of his studies. He became, at a very early period, an adept in the philosophy and theology of the schools, was able to supply the place of a sick relation in the class of oriental languages, was noted for historical knowledge, and one of the most knowing botanists of his time.

It was during his theological studies, as preparatory for his entering into orders, that mathematics took hold of his fancy. He used to tell in his convivial moments how he amused himself when preparing his exercises for the divinity hall. When tired with vague speculation, in which he did not meet with certainty to reward his labours, he turned up a book of oriental philology, in which he found something which he could discover to be true or to be false, without going out of the line of study which was to be of ultimate use to him. Sometimes even this could not relieve his fatigue. He then had recourse to mathematics, which never failed to satisfy and refresh him. For a long while he restricted himself to a very moderate use of the cordial, fearing that he would soon exhaust the small stock which so limited and abstract a science could yield; till at last he found, that the more he learned, a wider field opened to his view, and scenes that were inexhaustible. Becoming acquainted with subjects far beyond the elements of the science, and with numbers of names celebrated during that period of ardent research all over Europe, he found it to be a manly and important study, by which he was as likely to acquire reputation as by any other. About this time, too, a prospect began to open of making mathematics his profession for life. He then gave himself up to it without reserve.

His original incitement to this study as a treat, as something to please and refresh his mind in the midst of severer tasks, gave a particular turn to his mathematical studies, from which he never could afterwards deviate. Perspicuity and elegance are more attainable, and more discernible, in pure geometry, than in any other parts of the science of measure. To this therefore he chiefly devoted himself. For the same reason he preferred the ancient method of studying pure geometry, and even felt a dislike to the Cartesian method of substituting symbols for operations of the mind, and still more was he disgusted with the substitution of symbols for the very objects of discussion, for lines, surfaces, solids, and their affections. He was rather disposed in the solution of an algebraical problem, where quantity alone was considered, to substitute figure and its affections for the algebraical symbols, and to convert the algebraic formula into an analogous geometrical theorem. And he came at last to consider algebraic analysis as little better than a kind of mechanical knack, in which we proceed without ideas of any kind, and obtain a result without meaning, and without being conscious of any process of reasoning, and therefore without any conviction of its truth. And there is no denying, that if genuine unsophisticated taste alone is to be consulted, Dr Simson was in the right: for though it must also be acknowledged, that the reasoning in algebra is as strict as in the purest geometry of Euclid or Apollonius, the expert analyst has little perception of it as he goes on, and his final equation is not felt by himself as the result of ratiocination, any more than if he had obtained it by Pascal’s arithmetical mill. This does not in the least diminish our admiration of the algebraic analysis; for its almost boundless grasp, its rapid and certain procedure, and the delicate metaphysics and great address which may be displayed in conducting it. Such, however, was the ground of the strong bias of Dr Simson’s mind to the analysis of the ancient geometers. It increased as he went forward; and his veneration (we may call it his love or affection) for the ancient geometry was carried to a degree of idolatry. His chief labours were exerted in efforts to restore the works of the ancient geometers; and he has nowhere bestowed much pains in advancing the modern discoveries in mathematics. The noble inventions, for example, of fluxions and of logarithms, by which our progress in mathematical knowledge, and in the useful application of this knowledge, is so much promoted, attracted the notice of Dr Simson; but he has contented himself with demonstrating their truth on the genuine principles of the ancient geometry. Yet was he very thoroughly acquainted with all the modern discoveries; and there are to be seen among his papers discussions and investigations in the Cartesian method, which show him thoroughly acquainted with all the principles, and even expert in the tours de main, of the most refined symbolic analysis (A).

About the age of 25 Dr Simson was chosen professor of mathematics in the university of Glasgow. He went to London immediately after his appointment, and there formed an acquaintance with the most eminent men of that bright era of British science. Among these he always mentioned Captain Halley (the celebrated Dr Edmund Halley) with particular respect; saying, that he had the most acute penetration, and the most just taste in that science, of any man he had ever known. And, indeed, Dr Halley has strongly exemplified both of these in his divination of the work of Apollonius de Sectione Spatii, and the 8th book of his Conics, and in some of the most beautiful theorems in Sir Isaac Newton’s Principia. Dr Simson also admired the wide and masterly steps which Newton was accustomed to take in his investigations, and his manner of substituting geometrical figures for the quantities which are observed in the phenomena of nature. It was from Dr Simson that the writer of this article had the remark which has been oftener than once repeated in the course of this Work, “That the 39th proposition of the first book of the Principia was the most important proposition

(A) In 1752 the writer of this article being then his scholar, requested him to examine an account which he gave him of what he thought a new curve (a conchoid having a circle for its base). Dr Simson returned it next day with a regular list of its leading properties, and the investigation of such as he thought his scholar would not so easily trace. In this hasty scrawl the lines related to the circle were familiarly considered as arithmetical fractions of the radius considered as unity. This was before Euler published his Arithmetic of the Sines and Tangents, now in universal use.
position that had ever been exhibited to the physico-mathematical philosopher; and he used always to illustrate to his more advanced scholars the superiority of the geometrical over the algebraic analysis, by comparing the solution given by Newton of the inverse problem of centripetal forces, in the 42d proposition of that book, with the one given by John Bernoulli in the Memoirs of the Academy of Sciences at Paris for 1713. We have heard him say, that to his own knowledge Newton frequently investigated his propositions in the symbolical way, and that it was owing chiefly to Dr Halley that they did not finally appear in that dress. But if Dr Simson was well informed, we think it a great argument in favour of the symbolic analysis, when this most successful practical artist (for so we must call Newton when engaged in a task of discovery) found it conducive either to dispatch or perhaps to his very progress.

Returning to his academical chair, Dr Simson discharged the duties of a professor for more than 52 years with great honour to the university and to himself. It is almost needless to say, that in his prelections he followed strictly the Euclidian method in elementary geometry. He made use of Theodorus as an introduction to spherical trigonometry. In the higher geometry he proceeded from his own Conics; and he gave a small specimen of the linear problems of the ancients, by explaining the properties, sometimes of the conchoid, sometimes of the cissoid, with their application to the solution of such problems. In the more advanced class he was accustomed to give Napier's mode of conceiving logarithms, i.e. quantities as generated by motion; and Mr Cotes's view of them, as the sums of ratiocinulae; and to demonstrate Newton's lemmas concerning the limits of ratios; and then to give the elements of the fluxional calculus; and to finish his course with a select set of propositions in optics, gnomonics, and central forces. His method of teaching was simple and perspicuous, his elocution clear, and his manner easy and impressive. He had the respect, and still more the affection, of his scholars.

With respect to his studies, we have already informed the reader that they got an early bias to pure geometry, and to the elegant and scrupulous methods of the ancients.

We have heard Dr Simson say, that it was in a great measure owing to Dr Halley that he so early directed his efforts to the restoration of the ancient geometers. He had recommended this to him, as the most certain way for him, then a very young man, both to acquire reputation, and to improve his own knowledge and taste; and he presented him with a copy of Pappus's Mathematical Collections, enriched with some of his own notes. The perspicuity of the ancient geometrical analysis, and a certain elegance in the nature of the solutions which it affords, especially by means of the local theorems, soon took firm hold of his fancy, and made him, with the sanguine expectation of a young man, direct his very first efforts to the recovery of this in toto; and the restoration of Euclid's Porisms was the first task which he set himself. The accomplished geometer knows what a desperate task this was, from the scanty and mutilated account which we have of this work in a single passage of Pappus. It was an ambition which nothing but success could justify in so young an adventurer. He succeeded; and so early as 1718 seemed to have been in complete possession of this method of investigation, which was considered by the eminent geometers of antiquity as their surest guide through the labyrinths of the higher geometry. Dr Simson gave a specimen of his discovery in 1723 in the Philosophical Transactions. And after this time he ceased not from his endeavours to recover that choice collection of Porisms which Euclid had collected, as of the most general use in the solution of difficult questions. What some of these must have been pointed out to Dr Simson by the very nature of the general proposition of Pappus, which he has restored. Others were pointed out by the lemmas which Pappus has given as helps to the young mathematician towards their demonstration. And, being thus in possession of a considerable number, their mutual relations pointed out a sort of system, of which these made a part, and of which the blanks now remained to be filled up.

Dr Simson, having thus gained his favourite point, had leisure to turn his attention to the other works of the ancient geometers; and the porisms of Euclid now had only an occasional share. The loci plani of Apollonius was another task which he very early engaged in, and completed about the year 1738. But, after it was printed, he imagined that he had not given the ipseisimae propositiones of Apollonius, and in the precise spirit and order of that author. The impression lay by him for some years; and it was with great reluctance that he yielded to the entreaties of his mathematical friends, and published the work, in 1746, with some emendations, where he thought he had deviated farthest from his author. He quickly repeated of this scanty concession, and recalled what he could of the small number of copies which he had given to the booksellers, and the impression again lay by him for years. He afterwards recorrected the work, and still with some reluctance allowed it to come abroad as the Restitution of Apollonius. The public, however, had not been so fastidious as Dr Simson, and the work had acquired great celebrity, and he was now considered as one of the first and the most elegant geometers of the age: for, in the mean time, he had published his Conic Sections, a work of uncommon merit, whether we consider it as equivalent to a complete restitution of the celebrated work of Apollonius Pergaeus, or as an excellent system of this important part of mathematics. It is marked with the same features as the loci plani, the most anxious solicitude to exhibit the very text of Apollonius, even in the propositions belonging to the books which had been completely lost. Three could be recovered in no other way but by a thorough knowledge of the precise plan proposed by the author, and by taking it for granted that the author had accurately accomplished this plan. In this manner did Viviani proceed in the first attempt which was made to restore the conics of Apollonius; and he has given us a detail of the process of his conjectures, by which we may form an opinion of its justness, and of the probability how far he has attained the desired object. Dr Simson's view in his performance was something different, deviating a little in this one case from his general track. He was not altogether pleased with the work of Viviani, even as augmented by the eighth book added by Halley, and his wish was to restore the ancient original. But, in the mean time, an academical
Simson’s academical text book for conic sections was much wanted. He was much dissatisfied with those in common use; and he was not insensible of the advantage resulting from the consideration of these sections, independent of the cone first introduced by Dr Wallis. He therefore composed this excellent treatise as an elementary book, not to supersede, but to prepare for the study of Apollonius; and accordingly accommodates it to this purpose, and gives several important propositions in their proper places, expressus as restitutiones of Apollonius, whom he keeps constantly in view through the whole work.

Much about this time Dr Simson seriously began to prepare a perfect edition of Euclid’s Elements. The intimate acquaintance which he had by this time acquired with all the original works of the ancient geometers, and their ancient commentators and critics, encouraged him to hope that he could restore to his original lustre this leader in mathematical science; and the errors which had crept into this celebrated work, and which still remained in it, appeared of magnitude sufficient to merit the most careful efforts for their removal. The data also, which were in like manner the introduction to the whole art of geometrical investigation, seemed to call more loudly for his amending hand. For it appears that the Saracens, who have preserved to us the writings of the ancients, have contended themselves with admiring these celebrated works, and have availed themselves of the knowledge which they contain; but they have shown no inclination to add to the stock, or to promote the sciences which they had received. They could not do any thing without the synthetical books of the geometers; but, not meaning to go beyond the discoveries which they had made, they neglected all the books which related to the analytic art alone, and the greatest part of them (about 25 out of 30) have irrecoverably perished. The data of Euclid have fortunately been preserved, but the book was neglected, and the only ancient copies, which are but three or four, are miserably erroneous and mutilated. Fortunately, it is no very arduous matter to reinstate this work in its original perfection. The plan is precise, both in its extent and its method. It had been restored, therefore, with success by more than one author. But Dr Simson’s comprehensive view of the whole analytical system pointed out to him many occasions for amendment. He therefore made its restitution a joint task with that of the elements. All the lovers of true geometry will acknowledge their obligations to him for the edition of the Elements and Data which he published about 1758. The text is corrected with the most judicious and scrupulous care, and the notes are inestimable, both for their information, and for the tendency which they must have to form the mind of the student to a true judgment and taste in mathematical subjects. The more accomplished reader will perhaps be sometimes disposed to smile at the axiom which seems to pervade the notes, “that a work of Euclid must be supposed without error or defect.” If this was not the case, Euclid has been obliged to his editor in more instances than one. Nor should his greatest admirers think it impossible that in the progress of human improvement, a geometrical truth should occur to one of the latter days, which escaped the notice of even the Lincean Euclid. Such merit, however, Dr Simson nowhere claims; but lays every blame of error, omission, or obscurity, to the charge of Proclus, Theon, and other editors and commentators of the renowned Grecian.

There is another work of Apollonius on which Dr Simson has bestowed great pains, and has restored, as we imagine, omnibus numeris perfectum, viz. the Sectio Determinata; one of those performances which are of indispensable use in the application of the ancient analysis. This also seems to have been an early task, though we do not know the date of his labours on it. It did not appear till after his death, being then published along with the great work, the Porsims of Euclid, at the expense of the late Earl Stanhope, a nobleman intimately conversant with the ancient geometry, and zealous for its reception among the mathematicians of the present age. He had kept up a constant correspondence with Dr Simson on mathematical subjects; and at his death in 1768, engaged Mr Clow professor of logic in the university of Glasgow, to whose care the Doctor had left all his valuable papers, to make a selection of such as would serve to support and increase his well-earned reputation as the RESTORER OF ANCIENT GEOMETRY.

We have been thus particular in our account of Dr Simson’s labours in these works, because his manner of execution, while it does honour to his inventive powers, and shows his just taste in mathematical composition, also confirms our former assertion, that he carried his respect for the ancient geometers to a degree of superstitious idolatry, and that his fancy, unchecked, viewed them as incapable of error or imperfection. This is distinctly to be seen in the emendations which he has given of the texts, particularly in his editions of Euclid. Not only every imperfection of the reading is ascribed to the ignorance of copyists, and every indiscernitiveness in the conception, inconclusiveness in the reasoning, and defect in the method, is ascribed to the ignorance or mistake of the commentators; but it is all along assumed that the work was perfect in its kind; and that by exhibiting a perfect work, we restore the genuine original. This is surely gratious; and it is very possible that it has, in some instances, made Dr Simson fail of his anxious purpose, and give us even a better than the original. It has undoubtedly made him fail in what should have been his great purpose, viz. to give the world a connected system of the ancient geometrical analysis; such as would, in the first place, exhibit it in its most engaging form, elegant, perspicuous, and comprehensive; and, in the next place, such as should engage the mathematicians of the present age to adopt it as the most certain and successful conductor in those laborious and difficult researches in which the demands of modern science continually engage them. And this might have been expected, in the province of speculative geometry at least, from a person of such extensive knowledge of the properties of figure, and who had so eminently succeeded in the many trials which he had made of its powers. We might have expected that he would at least have exhibited in one systematic point of view, what the ancients had done in several detached branches of the science, and how far they had proceeded in the solution of the several successive classes of problems; and we might have hoped, that he would have instructed us in what manner we should apply that method to the solution of problems of a more elevated kind, daily prese
sent to us in the questions of physico-mathematical science. By this he would have acquired distinguished honour, and science would have received the most valuable improvement. But Dr Simson has done little of all this; and we cannot say that great helps have been derived from his labours by the eminent mathematicians of this age, who are successfully occupied in advancing our knowledge of nature, or in improving the arts of life. He has indeed contributed greatly to the entertainment of the speculative mathematician, who is more delighted with the conscious exercise of his own reasoning powers, than with the final result of his researches. Yet we are not even certain that Dr Simson has done this to the extent he wished and hoped. He has not engaged the liking of mathematicians to this analysis, by presenting it in the most agreeable form. His own extreme anxiety to tread in the very footsteps of the original authors, has, in a thousand instances, precluded him from using his own extensive knowledge, that he might not employ principles which were not of a class inferior to that of the question in hand. Thus, of necessity, did the method appear tampered with. We are deterred from employing a process which appears to restrain us in the application of the knowledge which we have already acquired, and, disgusted with the tedious, and perhaps indirect path, by which we must arrive at an object which we see clearly over the hedge, and which we could reach by a few steps, of the security of which we are otherwise perfectly assured. These prepossessions are indeed founded on a mistake; but the mistake is such, that all fall into it, till experience has enlarged their views. This circumstance alone has hitherto prevented mathematicians from acquiring that knowledge of the ancient analysis which would enable them to proceed in their researches with certainty, dispatch, and delight. It is therefore deeply to be regretted, that this eminent genius has occupied, in this superstitious paleology, a long and busy life, which might have been employed in original works of infinite advantage to the world, and honour to himself.

Our readers will, it is hoped, consider these observations as of general scientific importance, and as intimately connected with the history of mathematics; and therefore as not improperly introduced in the biographical account of one of the most eminent writers on this science. Dr Simson claimed our notice as a mathematician; and his affectionate admiration of the ancient analysis is the prominent feature of his literary character. By this he is known all over Europe; and his name is never mentioned by any foreign author without some very honourable allusion to his distinguished geometrical elegance and skill. Dr James Moor, professor of Greek in the university of Glasgow, no less eminent for his knowledge in ancient geometry than for his professional talents, put the following appendage inscription below a portrait of Dr Simson:

GEOMETRIAM, sub TYRANNO BARBARO SEVA
SERVITUTE DIU SQUALENTEM, IN LIBERTATEM
ET DECUS ANTIQUUM VINDICAVIT
UNUS.

Yet it must not be understood that Dr Simson’s predilection for the geometrical analysis of the ancients did so far mislead him as to make him neglect the symbo- lical analysis of the present times; on the contrary, he was completely master of it, as has been already observed, and frequently employed it. In his academical lectures to the students of his upper classes, he used to point out its proper province (which he by no means limited by a scanty boundary), and in what cases it might be applied with safety and advantage even to questions of pure geometry. He once honoured the writer of this article with the sight of a very short dissertation on this subject (perhaps the one referred to in the preface to his Conic Sections). In this piece he was perhaps more liberal than the most zealous partizans of the symbolical analysis could desire, admitting as a sufficient equation of the Conic Sections \( \frac{p^2 - c^2}{a^2} \), where \( L \) is the lotus rectum, \( a \) is the distance of any point on the curve from the focus, \( p \) is the perpendicular drawn from the focus to the tangent in the given point, and \( c \) is the chord of the equiangular circle drawn through the focus. Unfortunately this dissertation was not found among his papers. He spoke in high terms of the Analytical Works of Mr Cotes, and of the two Bernoullis. He was consulted by Mr Mc Laurin during the progress of his inestimable Treatise of Fluxions, and contributed not a little to the reputation of that work. The spirit of that most ingenious algebraic demonstration of the fluxions of a rectangle, and the very process of the argument, is the same with Dr Simson’s in his dissertation on the limits of quantities. It was therefore from a thorough acquaintance with the subject, and by a just taste, that he was induced to prefer his favourite analysis, or, to speak more properly, to exhort mathematicians to employ it in its own sphere, and not to become ignorant of geometry, while he successfully employed the symbolical analysis in cases which did not require it, and which suffered by its admission. It must be acknowledged, however, that in his later years, the disgust which he felt at the artificial and slovenly employment on subjects of pure geometry, sometimes hindered him from even looking at the most refined and ingenious improvements of the algebraic analysis which occur in the writings of Euler, D’Alembert, and other eminent masters. But, when properly informed of them, he never failed to give them their due praise; and we remember him speaking, in terms of great satisfaction, of an improvement of the infinitesimal calculus, by D’Alembert and De la Grange, in their researches concerning the propagation of sound, and the vibration of musical cords.

And that Dr Simson not only was master of this calculus and the symbolical calculus in general, but held them in proper esteem, appears from two valuable dissertations to be found in his posthumous works; the one on logarithms, and the other on the limits of ratios. The last, in particular, shows how completely he was satisfied with respect to the solid foundation of the method of fluxions; and it contains an elegant and strict demonstration of all the applications which have been made of the method by its illustrious author to the objects of pure geometry.

We hoped to have given a much more complete and instructive account of this eminent geometer and his works, by the aid of a person fully acquainted with both, and able to appreciate their value; but an accident has deprived us of this assistance, when it was too late to procure an equivalent; and we must request our readers to accept of this very imperfect account, since we cannot do justice to Dr Simson’s merit, unless almost equally
But we ask the reader’s pardon for this digression: it is not however useless, since it takes the man as much as any recital of his studies; and to his acquaintances we are certain that it will be an acceptable memorandum. To them it was often matter of regret, that a person of such eminent talents, which should have made him shine equally in any line of life, should have allowed himself to be so completely devoted to a study which abstracted him from the ordinary pursuits of men, unfitted him for the active enjoyment of life, and kept him out of those walks which they frequented, and where they would have rejoiced to meet him.

Dr Simson was of an advantageous stature, with a fine countenance; and even in his old age had a graceful carriage and manner, and always, except when in mourning, dressed in white cloth. He was of a cheerful disposition; and though he did not make the first advances to acquaintance, had the most affable manner, and strangers were at perfect ease in his company. He enjoyed a long course of uninterrupted health; but towards the close of life suffered from an acute disease, and was obliged to employ an assistant in his professional labours for a few years preceding his death, which happened in 1768, at the age of 81. He left to the university his valuable library, which is now arranged apart from the rest of the books, and the public use of it is limited by particular rules. It is considered as the most choice collection of mathematical books and manuscripts in the kingdom, and many of them are rendered doubly valuable by Dr Simson’s notes.

SIN, a breach or transgression of some divine law or command.

SINAI, or SINA, a famous mountain of Arabia Petraea, upon which God gave the law to Moses. It stands in a kind of peninsula, formed by the two arms of the Red sea, one of which stretches out towards the north, and is called the gulf of Kolsam; the other extends towards the east, and is called the gulf of Elan, or the Elanitish sea. At this day the Arabsians call Mount Sinai by the name of Tor, that is, the mountain, by way of excellence; or Jibol or Jibul Musa, the mountain of Moses. It is 250 miles from Cairo, and generally it requires a journey of ten days to travel thither. The wilderness of Sinai, where the Israelites continued encamped for almost a year, and where Moses erected the tabernacle of the covenant, is considerably elevated above the rest of the country; and the ascent to it is by a very craggy way, the greatest part of which is cut out of the rock; then one comes to a large space of ground, which is a plain surrounded on all sides by rocks and eminences, whose length is nearly 12 miles. Towards the extremity of this plain, on the north side, two high mountains show themselves, the highest of which is called Sinait and the other Horœb. The tops of Horœb and Sinai have a very steep ascent, and do not stand upon much ground, in comparison to their extraordinary height: that of Sinai is at least one-third part higher than the other, and its ascent is more upright and difficult.

Two German miles and a half up the mountain stands Michel's the convent of St Catharine. The body of this monastery is a building 120 feet in length and almost as many in breadth. Before it stands another small building, in which is the only gate of the convent, which remains always shut, except when the bishop is here.
here. At other times, whatever is introduced within
the convect, whether men or provisions, is drawn up by
the roof in a basket, and with a cord and a pulley. The
whole building is of hewn stone; which, in such a de-
sert, must have cost prodigious expense and pains. Near
this chapel issues a fountain of very good fresh water;
it is looked upon as miraculous by some who cannot con-
ceive how water can flow from the brow of so high and
barren a mountain. Five or six pace from it they
show a stone, the height of which is four or five feet, and
breadth about three, which, they say, is the very stone
 whence Moses caused the water to gush out. Its col-
our is of a spotted gray, and it is, as it were, set in a
kind of earth where no other rock appears. This stone
has twelve holes or channels, which are about a foot
wide, whence it is thought the water came forth for
the Israelites to drink.

Much has been said of the writings to be seen at Si-
na, and in the plain about it; and such were the hopes
of discoveries respecting the wanderings of the Israelites
from these writings, that Dr. Clayton, bishop of Clogher,
offered 500l. sterling to defray the expenses of journey
 to any man of letters who would undertake to copy
them. No man, he believed, undertook this task:
and the accurate Danish traveller Niebuhr found no writings
there, but the names of persons who had visited the
place from curiosity, and of Egyptians who had chosen
to be buried in that region.

SINAPIS, MUSK, a genus of plants belonging
to the class tetradyminae, and to the order silicouos; and
in the natural system ranged under the 35th order, Sili-
quose. See Botany Index.

SINAPISM, in Pharmacy, an external medicine, in
form of a cataplasmin, composed chiefly of mustard seed
powdered, and other ingredients mentioned in the pre-
ceding article.

SINCERITY, honesty of intention, freedom from
hypocrisy. See Moral Philosophy, No. 157.

SINCIPUT, in Anatomy, the forntpart of the head,
reaching from the forehead to the coronal suture.
SINDY, a province of Hindostan Proper, bounded on
the west by Makran, a province of Persia; on the
north by the territories of the king of Candahar; on
the north-east by those of the Seiks; on the east by a
sandy desert; and on the south-east by Cutch. It ex-
tends along the course of the river Sinde or Indus from
its mouth to Behber or Bhakor, on the frontiers of
Moultan. Reckoned that way, it is 300 miles long;
and its breadth, in its widest part, is about 150. In
many particulars of soil and climate, and in the general
appearance of the surface, Sindy resembles Egypt; the
lower part of it being composed of rich vegetable mould,
and extended into a wide dell; while the upper part of
it is a narrow strip of country, confined on one side by
a ridge of mountains, and on the other by a sandy desert,
the river Indus, equal at least to the Nile, winding
through the midst of this level valley, and annually
overflowing it. During great part of the south-west
monsoon, or at least in the months of July, August,
and part of September, which is the rainy season in most
other parts of India, the atmosphere is here generally
clouded; but no rain falls except very near the sea. In-
deed, very few showers fall during the whole year;
owing to which, and the neighbourhood of the sandy
deserts, which bound it on the east and on the north-

west, the heats are so violent, and the winds from those
quarters so pernicious, that the houses are contrived so
as to be occasionally ventilated by means of apertures
on the tops of them, resembling the funnels of small
chimneys. When the hot winds prevail, the windows
are closely shut; and the lower part of the current
of air, which is always the hottest; being thus exclu-
sed, a cooler, because more elevated part, descends in-
to the house through the funnels. By this contrivance
also vast clouds of dust are excluded: the entrance of
which would alone be sufficient to render the houses un-
inhabitable. The roofs are composed of thick layers
of earth instead of terraces. Few countries are more
unwholesome to European constitutions, particularly
the lower part of the Delta. The prince of this pro-
vince is a Mahometan, tributary to the king of Can-
dahar. He resides at Hyderabad, although Tatta is the
capital. The Hindoos, who were the original inhabi-
tants of Sindy, are by their Mahometan governors treat-
ed with great rigour, and denied the public exercise of
their religion; and this severity drives vast numbers of
them into other countries. The inland parts of Sindy
produce saltpetre, sal-ammoniac, borax, bezor, lapis la-
zuli, and raw silk. They have also manufactories of
cotton and silk of various kinds; and they make fine
hotels, inlaid with ivory, and finely lacquered. They
also export great quantities of butter, clarified and wrapt
up in duppas, made of the hides of cattle. The ladies
wear hoops of ivory on both their arms and legs, which
when they die are burnt with them. They have large
black cattle, excellent mutton, and small hardy horses.
Their wild game are deer, hares, antelopes, and foxes,
which they hunt with dogs, leopards, and a small fierce
creature called a shiahgush.

SINE, or Right Sine of an Arch, in Trigonometry,
is a right line drawn from one end of that arch, perpen-
dicular to the radius drawn to the other end of the arch;
being always equal to half the cord of twice the arch.
See Trigonometry and Geometry.

SINECURE, a nominal office, which has a revenue
without any employment.

SINews, a tendon, that which unites the muscles to
the bones.

Singing, the action of making divers inflections of
the voice, agreeable to the ear, and correspondent
to the notes of a song or piece of melody. See Mel-
dory.

The first thing to be done in learning to sing, is to
raise a scale of notes by tones and semitones to an octave,
and descend by the same notes; and then to rise and
fall by greater intervals, as a third, fourth, fifth, &c.
and to do all this by notes of different pitch. Then
these notes are represented by lines and spaces, to which
the syllables fit, sol, la, mi, are applied, and the pupil
taught to name each line and space thereby; whence
this practice is called solfaing, the nature, reason, ef-
fects, &c. whereof, see under the article SOLFAING.

Singing of Birds. It is worthy of observation, that
the female of no species of birds ever sings: with birds
it is the reverse of what occurs in human kind. Among
the feathered tribe, all the cares of life fall to the lot of
the tender sex; theirs is the fatigue of incubation; and
the principal share in nursing the helpless brood: to al-
leviate these fatigues, and to support her under them,
nature hath given to the male the song, with all the
little blandishments and soothing arts; these he fondly
exacts (even after courtship) on some spray contiguous
to the nest, during the time his mate is performing her
parental duties. But that she should be silent is also
another wise provision of nature, for her song would
discover her nest; as would a gaudiness of plumage,
which, for the same reason, seems to have been denied
her.

On the song of birds several curious experiments and
observations have been made by the Hon. Daines Bar-
rington. See Phil. Trans. vol. liii.

SINGULAR NUMBER, in Grammar, that number of
nouns and verbs which stands opposed to plural. See
GRAMMAR, No. 14.

SINISTER, something on or towards the left hand.
Hence some derive the word sinister à sinistro; because
the gods, by such auguries, permit us to proceed in our
designs.

SINISTER, is ordinarily used among us for unlucky;
though, in the sacred rites of divinity, the Romans
used it in an opposite sense. Thus avis sinister, or a bird
on the left hand, was esteemed a happy omen: whence,
in the law of the 12 tables, Ave sinistra populis magister
est.

SINISTER, in Heraldry. The sinister side of an es-
cutcheon is the left-hand side; the sinister chief, the left
angle of the chief; the sinister base, the left-hand part
of the base.

SINISTER Aspect, among astrologers, is an appear-
ance of two planets happening according to the succes-
sion of the signs; as Saturn in Aries, and Mars in the
same degree of Gemini.

SINISTRI, a set of ancient heretics, thus called
because they held the left hand in abhorrence, and
made it a point of religion not to receive any thing
therewith.

SINKING FUND, a provision made by parliament,
consisting of the surplusage of other funds, intended to
be appropriated to the payment of the national debt; on
the credit of which very large sums have been borrowed
for public uses.

As the funding system had been adopted in other
countries long before it was resorted to in Great Brit-
ain, a provision of this kind had appeared necessary at
a much earlier period, and had been established in Hol-
lund in 1655, and in the Ecclesiastical States in 1685.
These funds were both formed by the reduction of the
interest on the public debts, and by appropriating the
annual sum thus saved to the gradual discharge of the
principal.

In the reign of King William, when the mode of pro-
viding for extraordinary expences was first adopted in
this country, the particular tax on which money was
borrowed, generally produced much more than was suf-
icient to pay the annual interest, and the surplus was
applied in sinking the principal, which was generally
effectually in a few years. Had this plan been pursued,
there never could have been any great accumulation of
public debts; but, as the expenditure increased, and the
necessity of loans of still greater amount became more
frequent, it was found difficult to provide for the annual
interest of the sums thus borrowed; and the repayment
of the principal was either put off to a distant period,
or left without any provision to the chance of more fou-
ishing times.

Some of the effects of an accumulating public debt
soon became evident in the discount at which all govern-
ment securities sold, and in the difficulties experienced
in providing for the annual expenditure; the propriety
of reducing, and even of wholly discharging, the debt,
was generally acknowledged; and the plan of a sinking
fund was recommended in a pamphlet published in 1701.
In 1713 Mr Archibald Hutchison presented to George I.
a plan for payment of the public debts. In 1715 dif-
f erent projects for this purpose were published by Ed-
ward Leigh, Mr Asgill, and others. And in 1717 a
plan for the gradual discharge of the debt was actually
adopted, which was afterwards generally known by the
name of the sinking fund.

For a few years the fund was strictly applied to the
purposes for which it was established; and so well was
its nature and importance then understood, that money
was at the same time borrowed for extraordinary ex-
penses. In 1724, the sum of 1,144,198. was taken
from the fund, to make good the loss to the treasury
from the reduction of the value of gold coin; and within
12 years from its establishment it was charged with the
interest of new loans. In 1733, the gross sum of half
a million was taken from it towards the supplies, at
which time the medium annual produce of the fund
for five years had been 1,212,000. This amount would
have fully discharged the debt which then existed, but
the alienation of it was continued.

This was succeeded by the consolidated fund, one ob-
ject of which was, to lay the foundation of a new sink-
ing fund, and consisting, like the old one, in the appli-
cation of the principle of compound interest. On this
occasion Mr Pitt consulted the late Dr Price, who con-
ominated three plans, one of which was afterwards
adopted, but with such alterations as greatly affected its
efficacy, and which it had been since found necessary to
correct. By the act passed for carrying this scheme in
execution, the annual sum of 1,000,000. was placed
in the hands of commissioners, to be issued in four equal
quarterly payments, and to be applied either in paying
off such redeemable annuities as were at or above par,
or in the purchase of annuities below par, at the market-
price.

On the 17th of February, 1792, Mr Pitt proposed
that the sum of 400,000. should be issued in addition
to the million, for the purpose of accelerating the op-
eration of the fund: and stated that it might be expect-
ed that 25 millions of 3 per cents would be paid off
by the year 1803; and that in the year 1808, the fund
would amount to 4,000,000. per annum, the sum to
which it was then restricted. The injudicious restric-
tion of the fund to 4,000,000. per annum, was done
away by an act passed in 1802, which directed that the
produce of the two funds should continue to accumulate,
without any limitation as to its amount, and be from
time to time applied, according to the former provi-
sions, in the redemption or purchase of stock, until the
whole of the perpetual redeemable annuities, existing at
the time of passing the act, shall have been completely
paid off. At the same time, the annual grant of 200,000.
in aid of the fund, was made a permanent charge, to
be issued in quarterly payments from the consolidated
fund, in the same manner as the original million per
annum. In consequence of these improvements, the in-
crease of the fund has been much greater than it was
originally
and other parts, the entrance whereof is very narrow, and the bottom wider and more spacious.

**SINUS, in Surgery**, a little cavity or sacculus, frequently formed by a wound or ulcer, wherein pus is collected.

**SIPHON.** See HYDRODYNAMICS.

**SIPHONANTHUS**, a genus of plants belonging to the class of tetrandria and order of monogynia. See BOTANY Index.

**SIPONUM, SEPUNTUM, or SIRUS**, in Ancient Geography, a town of Apulia, so denominated (according to Strabo) from the great quantity of sereus or cuttlefish that are thrown upon the coast. Diomedes is supposed by the same author to have been the founder of this place; which appears from Livy to have become a colony of Roman citizens. In the early ages of Christian hierarchy, a bishop was fixed in this church; but, under the Lombards, his see was united to that of Beneventum. Being again separated, Sipontum became an archiepiscopal see in 1094, about which time it was so ill treated by the Barbarians, that it never recovered its splendour, but sunk into such misery, that in 1261 it was a mere desert, from the want of inhabitants, the decay of commerce, and the insalubrity of the air. Manfred having taken these circumstances into consideration, began in 1261 to build a new city on the seaside, to which he removed the few remaining Sipontines. (See the article MANFREDONIA.) Sipontum was situated at the distance of a mile from the shore. Excepting a part of its Gothic cathedral, scarce one stone of the ancient city now remains upon another.

**SIPUNCULUS**, in Natural History, a genus of the class of vermes, and order intestina. See HELMINTHOLOGY Index.

**SIR**, the title of a knight or baronet, which, for distinction’s sake, as it is now given indiscriminately to all men, is always prefixed to the knight’s Christian name, either in speaking or writing to them.

**SIRCAR, any office under the government in Hindostan.** It is sometimes used for the state of government itself. Likewise a province, or any number of pergunnahs placed under one head in the government books, for conveniency in keeping accounts. In common usage in Bengal, the under-banyans of European gentlemen are called sircars.

**SIRE, a title of honour formerly given to the king of France as a mark of sovereignty.**

**Sire**, was likewise anciently used in the same sense with sicut and seigneur, and applied to barons, gentlemen, and citizens.

**SIRENS,** in fabulous history, certain celebrated song-stresses who were ranked among the demigods of antiquity. Hyacinthus places their birth among the consequences of the rape of Proserpine. Others make them daughters of the river Acheoos and one of the muses. *Ovid Met.*

The number of the Sirens was three, and their names were Parthenope, Lygsea, and Leucosia. Some make them half women and half fish; others half women and half birds. There are antique representations of them still subsisting under both these forms. Pausanias tells us, that the Sirens, by the persuasion of Juno, challenged the Muses to a trial of skill in singing; and these having vanquished them, plucked the golden feathers from the wings of the Sirens, and formed them into...
SIREX, a genus of insects belonging to the order of hymenoptera. See Entomology Index.

SIRIUM, a genus of plants belonging to the class of tetrandra and order of monogynia. See Botany Index.

SIRIUS, in Astronomy, a bright star in the constellation Canis. See Astronomy, No. 403, &c.

SIRLET, Flavius, an eminent Roman engraver on precious stones: his Laocoon, and representations in miniature of antique statues at Rome, are very valuable and scarce. He died in 1737.

SIROCCO, a periodical wind which generally blows in Italy and Dalmatia every year about Easter. It blows from the south-east by south: it is attended with heat, but not rain; its ordinary period is twenty days, and it usually ceases at sunset. When the sirocco does not blow in this manner, the summer is almost free from westerly winds, whirlwinds, and storms. This wind is prejudicial to plants, drying and burning up the buds; though it hurts not men any otherwise than by causing an extraordinary weakness and lassitude; inconveniences that are fully compensated by a plentiful fishing, and a good crop of corn on the mountains. In the summer time, when the westerly wind ceases for a day, it is a sign that the sirocco will blow the day following, which usually begins with a sort of whirlwind.

SISKIN. See Fringilla, Ornithology Index.

SISON, BASTARD STONE PARSLEY, a genus of plants belonging to the class of pentandria, and to the order of digynia; and in the natural system arranged under the 43d order, Umbellata. See Botany Index.

SISTRUM, or CISTRUM, a kind of ancient musical instrument used by the priests of Isis and Osiris. It is described by Spous as of an oval form, in manner of a rattle, with three sticks traversing it breadthwise; which playing freely by the agitation of the whole instrument, yielded a kind of sound which to them seemed melodious. Mr Malcolm takes the sistrum to be no better than a kind of rattle. Osceius observes, that the sistrum is found represented on several medals, and on talismans.

SISYMBRIUM, WATER-CRESSES, a genus of plants belonging to the class of tetrachymenia, and to the order of siligiosa; and in the natural system ranged under the 39th order, Siligiosa. See Botany Index.

SISYPHUS, in fabulous history, one of the descendants of Eolus, married Merope, one of the Pleiades, who bore him Glaucus. He resided at Ephyra in Peloponnesus, and was a very crafty man. Others say, that he was a Trojan secretary, who was punished for discovering...
SIWA, or SIWAE, a town in Egypt to the westward of Alexandria, built on a small fertile spot, surrounded on all sides by desert land. A considerable portion of this space is filled with date trees, but there are also plantains, pomegranates, figs, apricots, and olives; and the gardens are in a very flourishing condition. The people cultivate rice, which is of a reddish colour, and different from that of the Delta. The rest of the land furnishes abundance of wheat for the consumption of the inhabitants.

The greatest curiosity about Siwa is a ruin of undoubted antiquity, measuring 52 feet in length, 18 in height, and 15 in breadth, which does not appear ever to have been much larger. Mr Horneman estimates the dimensions of it at 36 feet long, 24 feet wide, and 27 high, which agrees with no other traveller whatever; and indeed Mr Horneman himself allows that the jealousy of the natives prevented him from pursuing any plan of accurate examination or admeasurement. The people of Siwa have no tradition respecting this edifice, nor attribute any quality to it, but that of concealing treasures, and as the haunt of demons. It has, however, been supposed, that Siwa is the Siropus of Pliny, and that this building was coeval with the temple of Jupiter Ammon, and a dependency on it; yet neither the natives of Siwa, nor the various tribes of Arabs who frequent that place, know any thing of the ruins of that temple, about which Mr Browne made every possible enquiry.

The complexion of the people of Siwa is generally darker than that of the Egyptians, and their dialect is also different. They do not habitually make use of snuff or tobacco. Their sect is that of Malik. The dress of the lower class is very simple, as they are almost naked; among those whose costume was discernible, it approaches nearer to that of the Arabs of the desert than the Egyptians or Moors. Their clothing consists of a shirt of white cotton, with large sleeves reaching to the feet, a red cap without a turban, and shoes of the same colour. Some earthen ware is made by themselves, and a few mats, form the chief part of their household furniture, none but the higher ranks being possessed of copper utensils. They sometimes purchase a few slaves from the Mouroozok caravan. The rest of their wants are supplied from Cairo or Alexandria, whither their dates are transported, both in a dry state, and beaten into mash, which, when good, greatly resembles a sweet meat. They do not eat large quantities of animal food, and bread known to us is uncommon. They drink plentifully of the liquor extracted from the date tree, which they call date-tree water, though it has frequently the power of inebriating in the state in which they drink it. Their animals are the hairy sheep and goat of Egypt, the ass, and a very small number of oxen and camels. The women wear veils as in Egypt. After the rains, the ground in the vicinity of Siwa is covered with salt for many weeks.

Siwa has sometimes been compared to a bee hive, which it very much resembles, whether in respect to the general appearance of the eminence covered with buildings, the swarm of its people crowded together, or the confused noise, or hum and buzz from its narrow passages and streets, and which reach the ear at a considerable distance. North-west of the town there is a stratum of salt extending a full mile, and near it salt is found on
the surface. There are numerous springs, and frequently a spring of water perfectly sweet is found within a few pieces of one that is salt. The people, according to Horneman, are obstructive and thievish. Siwa is situated in 20° 12' N. Lat. and 44° 54' E. Long.

SIX CLERKS, officers in chancery of great account, next in degree below the twelve masters, whose business it is to enrol commissions, pardons, patents, warrants, &c. which pass the great seal, and to transact and file all proceedings by bill, answer, &c. They were anciently clerici, and forfeited their places, if they married; but when the constitution of the court began to alter, a law was made to permit them to marry, Stat. 14 and 15 Hen. VIII. cap. 8. They are also solicitors for parties in suits depending in the court of chancery. Under them are six deputies and 60 clerks, who, with the under clerks, do the business of the office.

Six Nations. See Niagara.

SIXTH, in Music, one of the simple original concords, or harmonical intervals. See Interval.

SIXTHS V. Pope, was born the 13th December, 1521, in La Marca, a village in the seigniory of Montalto. His father, Francis Peretti, was a gardener, and his mother a servant maid. He was their eldest child, and was called Felix. At the age of nine he was hired out to an inhabitant of the village to keep sheep; but disobliging his master, he was soon after degraded to be keeper of the hogs. He was engaged in this employment when Father Michael Angelo Selleri, a Franciscan friar, asked the road to Ascoli, where he was going to preach. Young Felix conducted him thither, and struck the father so much with his conversation and eagerness for knowledge, that he recommended him to the fraternity to which he had come. Accordingly he was received among them, invested with the habit of a lay brother, and placed under the sacristan, to assist in sweeping the church, lighting the candles, and other offices of that nature; for which he was to be taught the responses, and the rudiments of grammar. His progress in learning was so surprising, that at the age of 14 he was thought qualified to begin his noviciature, and was admitted the year following to make his profession.

He pursued his studies with such unwearied assiduity, that he was soon reckoned equal to the best disputants. He was ordained priest in 1545, when he assumed the name of Father Montalto; soon after he took his doctor's degree, and was appointed professor of theology at Sienna. It was then that he so effectually recommended himself to Cardinal di Carpi, and his secretary Bossius, that they ever remained his steady friends. Meanwhile the severity and obstinacy of his temper incessantly engaged him in disputes with his monastic brethren. His reputation for eloquence, which was now spread over Italy, about this time gained him some new friends. Among these were the Colonna family, and Father Ghislieri, by whose recommenda-

Sixtus was treated with great respect, and liberal offers were made him to induce him to continue in Spain, which, however, he could not prevail on to accept.

In the mean time, news were brought to Madrid that Pius IV. was dead, and that Father Ghislieri, who had been made Cardinal Alexandrino by Paul IV. had succeeded him under the name of Pius V. These tidings filled Montalto with joy, and not without reason, for he was immediately invested by the pontiff with new dignities. He was made general of his order, bishop of St Agatha, was soon after raised to the dignity of cardinal, and received a pension. About this time he was employed by the pope to draw up the bill of excommunication against Queen Elizabeth.

He began now to cast his eyes upon the papacy; and, in order to obtain it, formed and executed a plan of hypocrisy with unparalleled constancy and success. He became humble, patient, and affable. He changed his dress, his air, his words, and his actions, so completely, that his most intimate friends declared him a new man. Never was there such an absolute victory gained over the passions; never was a fictitious character so long maintained, nor the foibles of human nature so artfully concealed. He courted the ambassadors of every foreign power, but attached himself to the interests of none; nor did he accept a single favour that would have laid him under any peculiar obligation. He had formerly treated his relations with the greatest tenderness, but he now changed his behaviour altogether. When his brother Anthony came to visit him, he lodged him in an inn, and sent him home next day, charging him to inform his family that he was now dead to his relations and the world.

When Pius V. died in 1572, he entered the conclave with the other cardinals, but seemed altogether indifferent about the election, and never left his apartment except to his devotion. When solicited to join any party, he declined it, declaring that he was of no consequence, and that he would leave the choice of a pope entirely to persons of greater knowledge and experience. When Cardinal Buon Compagnon, who assumed the name of Gregory XIII., was elected, Montalto assured him that he never wished for anything so much in his life, and that he would always remember his goodness, and the favours he had conferred on him in Spain. But the new pope treated him with the greatest contempt, and deprived him of his pension. The cardinals also, deceived by his artifices, paid him no greater respect, and used to call him, by way of ridicule, the Roman beast; the ass of La Marca.

He now assumed all the infirmities of old age; his head hung down upon his shoulders; he tottered as he walked, and supported himself on a staff. His voice became feeble, and was often interrupted by a cough so exceedingly severe, that it seemed every moment to threaten his dissolution. He interfered in no public transactions, but spent his whole time in acts of devotion and benevolence. Mean time he constantly employed the ablest spies, who brought him intelligence of every particular.

When Gregory XIII. died in 1585, he entered the conclave with the greatest reluctance, and immediately shut himself up in his chamber, and was no more thought of than if he had not existed. When he went
to mass, for which purpose alone he left his apartment, he appeared perfectly indifferent about the event of the election. He joined no party, yet flattered all.

He knew early that there would be great divisions in the conclave, and he was aware that when the leaders of the different parties were disappointed in their own views, they all frequently agreed in the election of some old and infirm cardinal, the length of whose life would merely enable them to prepare themselves sufficiently for the next vacancy. These views directed his conduct, nor was he mistaken in his hopes of success.

Three cardinals, the leaders of opposite factions, being unable to procure the election which each of them wished, unanimously agreed to make choice of Montalto. When they came to acquaint him with their intention, he fell into such a violent fit of coughing that every person thought he would expire on the spot. He told them that his reign would last but a few days; that, besides a continual difficulty of breathing, he wanted strength to support such a weight, and that his small experience rendered him very unfit for so important a charge. He conjured them all three not to abandon him, but to take the whole weight of affairs upon their own shoulders; and declared that he would never accept the mitre upon any other terms: "If you are resolved," added he, "to make me pope, it will only be placing yourselves on the throne. For my part, I shall be satisfied with the bare title. Let the world call me pope, and I make you heartily welcome to the power and authority." The cardinals swallowed the bait, and exerted themselves so effectually that Montalto was elected. He now pulled off the mask which he had worn for 14 years. No sooner was his election secured, than he started from his seat, flung down his staff in the middle of the hall, and appeared almost a foot taller than he had done for several years.

When he was asked, according to custom, if he would accept of the papacy, he replied, "It is trilling to ask whether I will accept what I have already accepted. However, to satisfy every scruple that may arise, I will say that I accept it with great joy, and would accept another if I could get it; for I find myself able, by the Divine assistance, to manage two papacies." His former complaisance and humility disappeared, together with his infirmities, and he now treated all around him with reserve and haughtiness. The first care of Sixtus V. the name which Montalto assumed, was to correct the abuses, and put a stop to the enormities, which were daily committed in every part of the ecclesiastical state. The lenity of Gregory's government had introduced a general licentiousness of manners, which burst forth with great violence, after that pontiff's death. It had been usual with former popes to release delinquents on the day of their coronation, who were therefore accustomed to surrender themselves voluntary prisoners immediately after the election of the pope. At present, however, they were fatally disappointed.

When the governor of Rome and the keeper of St Angelo waited on his Holiness, to know his intention in this particular, he replied, "What have you to do with pardons, and releasing of prisoners? Is it not sufficient that our predecessor has suffered the judges to remain unemployed these 13 years? Shall we also stain our pontificate with the same neglect of justice? We have too long seen, with inexpressible concern, the prodigious degree of wickedness that reigns in the state, to think of granting pardons. Let the prisoners be brought to a speedy trial, and punished as they deserve, to show the world that Divine Providence has called us to the chair of St Peter, to reward the good, and chastise the wicked: that we bear not the sword in vain, but are the ministers of God, and a revenger to execute wrath on them that do evil."

He appointed commissioners to inspect the conduct of the judges, displaced those who were inclined to lenity, and put others of severe dispositions in their room. He offered rewards to any person who could convict them of corruption or partiality. He ordered the synods of all the towns and signories to make out a complete list of the disorderly persons within their districts, and threatened the strappado for the smallest omission. In consequence of this edict, the synod of Albino was scourged in the market-place, because he had left his nephew, an incorrigible libertine, out of his list.

He made very severe laws against robbers and assassins. Adulterers, when discovered, suffered death; and they who willingly submitted to the prostitution of their wives, a custom then common in Rome, received the same punishment. He was particularly careful of the purity of the female sex, and never forgave those who attempted to debauch them.

His execution of justice was as prompt as his edicts were rigorous. A Swiss happening to give a Spanish gentleman a blow with his halberd, was struck by him so rudely with a pilgrim's staff that he expired on the spot. Sixtus informed the governor of Rome that he was to dine early, and that justice must be executed on the criminal before he sat down to table. The Spanish ambassador and four cardinals intreated him not to disgrace the gentleman by suffering him to die on a gibbet, but to order him to be beheaded. "He shall be hanged (replied Sixtus), but I will alleviate his disgrace by doing him the honour to assist personally at his death." He ordered a gibbet to be erected before his own windows, where he continued sitting during the whole execution. He then called to his servants to bring in dinner, declaring that the act of justice which he had just seen had increased his appetite. When he rose from table, he exclaimed, "God be praised for the good appetite with which I have dined!"

When Sixtus ascended the throne, the whole ecclesiastical state was infested with bands of robbers, who, from their numbers and outrages, were exceedingly formidable; by his prudent and vigorous conduct, however, he was in a short time extirpated the whole of these banditti.

Nor was the vigour of his conduct less conspicuous in his transactions with foreign nations. Before he had been pope two months he quarrelled with Philip II. of Spain, Henry III. of France, and Henry king of Navarre. His intrigues indeed in some measure influenced all the councils of Europe.

After his accession to the pontificate he sent for his family to Rome, with express orders that they should appear in a decent and modest manner. Accordingly, his sister Camilla came thither, accompanied by her daughter and two grandchildren. Some cardinals, in order to pay court to the pope, went out to meet her, and introduced her in a very magnificent dress. Sixtus pretended not to know her, and asked two or three times.
SIX

Sixties.

time who she was: Upon this one of the cardinals said,
"It is your sister, holy father." "I have but one
sister (replied Sixtus with a frown), and she is a poor
woman at Le Grotte; if you have introduced her in
disguise, I declare I do not know her; yet I think
I would know her again, if I saw her in the clothes she
used to wear."

Her conductors at last found it necessary to carry
her to an inn, and strip her of her finery. When Ca-
milla was introduced a second time, Sixtus embraced
her tenderly, and said, "Now we know indeed that it
is our sister; nobody shall make a princess of you but
ourselves." He stipulated with his sister, that she
should neither ask any favour in matters of govern-
ment, nor intercede for criminals, nor interfere in the
administration of justice; declaring that every request
of that kind would meet with a certain refusal. These
terms being agreed to, and punctually observed, he made
the most ample provision not only for Camilla but for
his whole relations.

This great man was also an encourager of learning.
He caused an Italian translation of the Bible to be pub-
lished, which raised a good deal of discontent among
the Catholics. When some cardinals reproached him
for his conduct in this respect, he replied, "It was pub-
lished for the benefit of you cardinals who cannot read
Latin."

Sixtus died in 1590, after having reigned little more
than five years. His death was ascribed to poison, said
to have been administered by the Spaniards; but the
story seems rather improbable.

It was to the indulgence of a disposition naturally
formed for severity, that all the defects of this wonder-
ful man are to be ascribed. Clemency was a stranger
to his bosom; his punishments were often too cruel, and
seemed sometimes to border on revenge. Pasquin was
dressed one morning in a very nasty shirt, and being
asked by Marforio why he wore such dirty linen? re-
plied, that he could get no other, for the pope had made
his washerwoman a princess, alluding to Camilla, who
had formerly been a laundress. The pope ordered strict
search to be made for the author of this lampoon, and
offered him his life and a thousand pistoles if he would
discover himself. The author was simple enough to
make his appearance and claim the reward. "It is
true (said the pope) we made such a promise, and we
shall keep it; your life shall be spared, and you shall re-
ceive the money presently: but we have reserved to
ourselves the power of cutting off your hands and bo-
rting your tongue through, to prevent your being so
witty for the future." It is needless to add, that the
sentence was immediately executed. This, however,
is the only instance of his resenting the many severe
satires that were published against him.

But though the conduct of Sixtus seldom excites
love, it generally commands our esteem, and sometimes
our admiration. He strenuously defended the cause of
the poor, the widow, and the orphan: he never refused
audience to the injured, however wretched or forlorn
their appearance was. He never forgave those magis-
trates who were capable of partiality or corruption;
nor suffered crimes to pass unpunished, whether commit-
ted by the rich or the poor. He was frugal, temper-
ate, sober, and never neglected to reward the smallest
favour which had been conferred on him before his ex-
altation.

When he mounted the throne, the treasury was not
only exhausted, but in debt; at his death it contained
five millions of gold.

Rome was indebted to him for several of her greatest
embellishments, particularly the Vatican library; it was
by him, too, that trade was first introduced into the Ec-
clesiastical State.

SIXA-GUSH, the carnage of Buffon, an animal of
the cat kind. See Felis, Mammalia Index.

SIZAR, or SIZER, in Latin Sizarior, an appellation
by which the lowest order of students in the universities
of Cambridge and Dublin are distinguished, is derived
from the word sise, which in Cambridge, and probably
in Dublin likewise, has a peculiar meaning. To sise,
in the language of the university, is to get any sort of
victuals from the kitchens, which the students may want
in their own rooms, or in addition to their commons in
the hall, and for which they pay the cooks or butchers
at the end of each quarter. A size of any thing is the
smallest quantity of that thing which can be thus
bought; two sizes, or a part of beef, being nearly equal
to what a young person will eat of that dish to his din-
ner; and a size of ale or beer being equal to half an
English pint.

The sizars are divided into two classes, viz. sub-
sizatours or sizars, and sizatours or proper sizars. The
former of these are supplied with commons from the
table of the fellows and fellow commones; and in for-
mer times, when these were more scanty than they are
now, they were obliged to supply the deficiency by siz-
ing, as is sometimes the case still. The proper sizars
had formerly no commons at all, and were therefore
obliged to size the whole. In St John's college they
have now some commons allowed them for dinner,
from a benefaction, but they are still obliged to size
their suppers: in the other colleges they are allowed a
part of the fellow-commons, but must size the rest;
and from being thus obliged to size the whole or part
of their victuals, the whole order derived the name of
sizars.

In Oxford, the order similar to that of sizar is deno-
minated servitor, a name evidently derived from the
menial duties which they perform. In both universi-
ties these orders were formerly distinguished by round
caps and gowns of different materials from those of the
pensioners or commoners, the order immediately above
them. But about 30 years ago the round cap was en-
tirely abolished in both seminaries. There is still,
however, in Oxford, a distinction in the gowns, and there is also a trifling difference in some of the
small colleges in Cambridge; but in the largest
colleges the dress of the pensioners and sizars is entirely
the same.

In Oxford, the servitors are still obliged to wait at
the table on the fellows and gentlemen-commoners; but
much to the credit of the university of Cambridge, this
most degrading and disgraceful custom was entirely
abolished about 10 or 12 years ago, and of course the
sizars of Cambridge are now on a much more respect-
able footing than the servitors of Oxford.

The sizars are not upon the foundation, and there-
fore while they continue sizars are not capable of being
elected.
SIZE, the name of an instrument used for finding the
bigness of fine round pearls. It consists of thin pieces
or leaves, about two inches long, and half an inch
broad, fastened together at one end by a rivet. In each
of these are round holes drilled of different diameters.
Those in the first leaf serve for measuring pearls from
half a grain to seven grains; those of the second, for
pearls from eight grains or two carats to five carats, &c.;
and those of the third, for pearls from six carats and a
half to eight carats and a half.

SKATE, or also a sort of paint, varnish, or glue, used
by painters, &c.

The shreds and parings of leather, parchment, or
vellum, being boiled in water and strained, make size.
This substance is much used in many trades.—The
manner of using size is to melt some of it over a gentle
fire; and scraping as much whitening into it as will just
colour it, let them be well incorporated together; after
which you may whiten frames, &c. with it. After it
dries, melt the size again, and put more whitening and
whiten the frames, &c. seven or eight times, letting it
dry between each: but before it is quite dry, be-
tween each washing with size, you must smooth and wet
it over with a clean brush-pencil in fair water.

To make gold-size. Take gum-anime and asphaltum,
of each one ounce; minimum, 1/2 an ounce of, gold, and
amber, of each half an ounce: reduce all into a very fine
powder, and add to them four ounces of linseed oil, and
eight ounces of drying oil: digest them over a gentle
fire that does not flame, so that the mixture may only
smoulder, but not boil; lest it should run over and set the
house on fire, stir it constantly with a stick till all the
ingredients are dissolved and incorporated, and do not
leave off stirring till it becomes thick andropy; after
being sufficiently boiled, let it stand till it is almost cold,
and then strain it through a coarse linen cloth, and keep
it for use.—To prepare it for working, put what quantity
you please in a horse-muscle shell, adding as much
oil of turpentine as will dissolve it; and making it as
thin as the bottom of your seed-lac varnish, hold it over
a candle, and then strain it through a linen-rag into an-
other shell; add to these as much vermilion as will make
it of a darkish red; if it is too thick for drawing, you
may thin it with some oil of turpentine. The chief use
of this size is for laying on medals.

The best gold size for furnishing is made as follows:
Take fine bole, what quantity you please; grind it finely
on a piece of marble, then put it into a little hot
suet; grind all well together; after which mix in a
small proportion of parchment size, with a double pro-
portion of water, and it is done.

To make silver-size. Take tobacco-pipe clay in fine
powder, into which scrape some black-lead and a little
Genoa soap, and grind them all together with parch-
ment size as already directed.

SKATING, an exercise on ice, both graceful and
healthy. Although the ancients were remarkable for
their dexterity in most of the athletic sports, yet ska-
ting seems to have been unknown to them. It may
therefore be considered as a modern invention; and pro-
bably it derived its origin in Holland, where it was
practised, not only as a graceful and elegant amusement,
but as an expeditious mode of travelling when the lakes
and canals were frozen up during winter. In Holland
long journeys are made upon skates with ease and expedi-
tion; but in general less attention is there paid to
graceful and elegant movements, than to the expedi-
cion and celerity of what is called journey skating. It
is only in those countries where it is considered as an
amusement, that its graceful attitudes and movements
are studied; and there is no exercise whatever better
calculated to set off the human figure to advantage.
The acquirement of most exercises may be attained at
an advanced period of life; but to become an expert
skater, it is necessary to begin the practice of the art at
a very early age. It is difficult to reduce the art of
skating to a system. It is principally by the imitation
of a good skater that a young practitioner can form his
own practice. The English, though often remarkable
for seats of agility upon skates, are very deficient in
gracefulness; which is partly owing to the construction
of the skates. They are too much curved in the sur-
face which embraces the ice, consequently they invol-
untarily bring the users of them round on the outside upon
a quick and small circle; whereas the skater, by using
skates of a different construction, less curved, has the
command of his stroke, and can enlarge or diminish the
circle according to his own wish and desire. The me-
tropolis of Scotland has produced more instances of ele-
gant skaters than perhaps any other country whatever;
and the institution of a skating club about 30 years ago,
has contributed not a little to the improvement of this
elegant amusement. We are indebted for this article
to a gentleman of that club, who has made the practice
and improvement of skating his particular study; and as
the nature of our work will not permit the insertion of
a full treatise on skating, we shall present our readers
with a few instructions.

Those who wish to be proficient should begin at an
early period of life; and should first endeavour to throw
off the fear which always attends the commencement of
an apparently hazardous amusement. They will soon
acquire a facility of moving on the inside: when they
have done this, they must endeavour to acquire the
movement on the outside of the skates; which is nothing
more than throwing themselves upon the outer edge of
the skate, and making the balance of their body tend
towards...
towards that side which will necessarily enable them to form a semicircle. In this, much assistance may be derived from placing a bag of lead-shot in the pocket next to the foot employed in making the outside stroke, which will produce an artificial point of the body, which afterwards will become natural by practice. At the commencement of the outside stroke, the knee of the employed limb should be a little bended, and gradually brought to a rectilinear position when the stroke is completed. When the practitioner becomes expert in forming the semicircle with both feet, he is then to join them together, and proceed progressively and alternately with both feet, which will carry him forward with a graceful movement. Care should be taken to use very little muscular exertion, for the impelling motion should proceed from the mechanical impulse of the body thrown into such a position as to regulate the stroke. At taking the outside stroke, the body ought to be thrown forward easily, the unemployed limb kept in a direct line with the body, and the face and eyes directly looking forward: the unemployed foot ought to be stretched towards the ice, with the toes in a direct line with the leg. In the time of making the curve, the body must be gradually, and almost imperceptibly, raised, and the unemployed limb brought in the same manner forward; so that, at finishing the curve, the body will bend a small degree backward, and the unemployed foot will be about two inches before the other, ready to embrace the ice and form a correspondent curve. The muscular movement of the whole body must correspond with the movement of the skate, and should be regulated so as to be almost imperceptible to the spectators. Particular attention should be paid in carrying round the head and eyes with a regular and imperceptible motion; for nothing so much diminishes the grace and elegance of skating as sudden jerks and exertions, which are too frequently used by the generality of skaters. The management of the arms likewise deserves attention. There is no mode of disposing of them more gracefully in skating outside, than folding the hands in to each other, or using a muff.

There are various feats of activity and manoeuvres used upon skates; but they are so various that we cannot pretend to detail them. Moving on the outside is the primary object for a skater to attain; and when he becomes an adept in that, he will easily acquire a facility in executing other branches of the art. There are few exercises but will afford him hints of elegant and graceful attitudes. For example, nothing can be more beautiful than the attitude of drawing the bow and arrow whilst the skater is making a large circle on the outside: the manual exercise and military salutes have likewise a pretty effect when used by an expert skater.

SKELETON, in Anatomy, the dried bones of any animal joined together by wires, or by the natural ligament dried, in such a manner as to show their position when the creature was alive.

We have, in the Philosophical Transactions, an account of a human skeleton, all the bones of which were so united, as to make but one articulation from the back to the os sacrum, and downwards a little way. On sawing some of them, where they were unnaturally joined, they were found not to cohere throughout their whole substance, but only about a sixth of an inch deep all round. The figure of the trunk was crooked, the spine making the convex, and the inside of the vertebrae the concave part of the segment. The whole had been found in a charnel-house, and was of the size of a full grown person.

SKIDS, or Skeeds, in sea-language, are long compassing pieces of timber, notched below so as to fit closely upon the wales, extending from the main-wale to the top of the side, and retained in this position by bolts or spike-nails. They are intended for preserving the planks of the side, when any heavy body is hoisted or lowered.

SKIE, ISLE OF. See SKYE.

SKIFF, a small boat resembling a yawl, usually employed for passing rivers.

SKIMMER, BLACK. See RHYNCHOPS, ORNITHOLOGY Index.

SKIMMIA, a genus of plants belonging to the tetrandra class; and in the natural method ranking under the 40th order, Peronateae. See BOTANY Index.

SKIN, in Anatomy, the general covering of the body of any animal. See ANATOMY, No. 74.

SKIN, in Commerce, is particularly used for the membrane stripped off the animal to be prepared by the tanner, skinner, parchment-maker, &c. and converted into leather, &c. See TANNING.

SKINNER, Stephen, an English antiquarian, was born in 1622. He travelled, and studied in several foreign universities during the civil wars; and in 1654, returned and settled at Lincoln, where he practised physic with success until the year 1667, when he died of a malignant fever. His works were collected in folio in 1671, by Mr Henshaw, under the title of Etymologiae Linguae Anglicae, &c.

SKIPPER, or SAURY, a species of fish. See ESOX, ICHTHYOLOGY Index.

SKIRMISH, in War, a slight engagement between small parties, without any regular order; and is therefore easily distinguished from a battle, which is a general engagement between two armies continued for some time.

SKIRMISH BOY, the name given by Lieutenant Broughton to a bay in an island which was discovered by him in latitude 43° 49′ south, and in longitude 183° east. The Chatham armed tender worked up into the bay, and came to anchor about a mile from the shore. When the captain and some of the people landed, they found the natives so extremely inhospitable, that self-preservation made it necessary to fire upon them. The land is of considerable magnitude, whether island or continent, and what they saw of it extended nearly 40 miles from east to west, and the appearance of the country they regarded as very promising. The natives resembled those of New Zealand, from which they are distant about 100 leagues; but their skins were destitute of any marks, and they seemed to be cleanly in their persons. Their dresses were of seal skin, while some had fine mats fastened round the waist. Mr Broughton says, "on our first landing, their surprise and exclamations can hardly be imagined; they pointed to the sun, and then to us, as if to ask whether we had come from thence?" The arms they made use of were clubs, spears, and a small weapon resembling the pateau of New Zealand.

SKULL, in Anatomy, the bony case in which the brain is enclosed. See ANATOMY, No. 41, &c.
SKY-CAp. See Scutellaria; Botany Index.
SKY, the blue expanse of air or atmosphere. For the reason of its blue colour and concave figure, see Optics, No. 223.

SKYE, one of the greatest of the Western islands of Scotland, so called from Skintarach, which in the Erse dialect signifies winged, because the two promontories of Valerness and Toternish, by which it is bounded on the north-west and north-east, are supposed to resemble wings. The island lies between the shire of Ross and the western part of Lewis. According to the computation of Mr. Pennant, Dr. Johnson, and Dr. Campbell, it is 63 miles in length, and nearly the same in width where broadest; according to others it is 50 miles in length, and in some places 30 broad. The island of Skye was formerly divided between two proprietors; the southern part belonged to the laird of Macleod, said to be lineally descended from Leod son to the black prince of Man, but part of this division has fallen into other hands; the northern district is the property of Lord Macdonald, whose ancestor was Donald, king or lord of the isles, and chief of the numerous clan of Macdonalds, who are counted the most warlike of all the Highlanders. Skye is part of the shire of Inverness, and formerly belonged to the diocese of the Isles; on the south it is parted from the main land by a channel three leagues in breadth; though, at the ferry of Glencoe, it is so narrow that a man may be heard calling for the boat from one side to the other. Skye is well provided with a variety of excellent bays and harbours.

The face of the country is roughened with mountains, some of which are so high as to be covered with snow on the top at midsummer; in general, their sides are clothed with heath and grass, which afford good pasturage for sheep and black cattle. Between the mountains there are some fertile valleys, and the greater part of the land towards the sea-coast is plain and arable. The island is well watered with a great number of rivers, above 30 of which afford salmon; and some of them produce black muscles in which pearls are bred, particularly the rivers of Kilmarin and Ord: Martin was assured by the proprietor of the former, that a pearl hath been found in it valued at 20l. sterling. Here is also a considerable number of fresh-water lakes well stored with trout and eels. The largest of these lakes takes its denomination from St. Columba, to whom is dedicated a chapel that stands upon a small isle in the middle of the lake. Skye likewise affords several cataracts, that roar down the rocks with great impetuosity. That the island has been formerly covered with woods, appears from the large trunks of fir and other trees daily dug out of the bogs and peat-marshes in every part of the country.

From the height of the hills, and proximity of the sea, the air seldom continues long of the same temperature; sometimes it is dry, oftener moist, and in the latter end of winter and beginning of spring cold and piercing; at an average, three days in twelve throughout the year; scarcely free from rain, far less from clouds. These, attracted by the hills, sometimes break in useful and refreshing showers; at other times suddenly bursting, pour down their contents with tremendous noise, in impetuous torrents that deluge the plains below, and render the smallest rivulet impassable; which, together with the stormy winds so common in this country in the months of August and September, frequently blast the hopes, and disappoint the expectations, of the husbandman. Snow has been often known to lie on the ground for three or seven weeks; and on the highest hills, even in the middle of June, some spots of it are to be seen. To this various temperature of the air, and uncertainty of weather, the fevers and agues, head-aches, rheumatisms, colds, and dysenteries, which are the prevailing distempers, may be ascribed. That it is far, however, from being unwholesome, is sufficiently evinced by experience; for the inhabitants are, in general, as strong and healthy, and arrive at as advanced an age, as those who live in milder climates, and under a serener sky. The gout is scarcely known in this island.

The soil is generally black, though it likewise affords clay of different colours; such as white, red, and blue, and in some places fuller's earth. It is, however, much less adapted for agriculture than for pasture, and seldom, unless, in very good years, supplies itself with a sufficiency of provisions. Yet, though the soil is not very fertile or rich, it might with proper management be made to produce more plentiful crops. But the generality of the farmers are so prejudiced in favour of old customs, and indeed so little inclined to industry, that they will not easily be prevailed on to change them for better; especially if the alteration or amendment proposed be attended with expense. Therefore, with respect to improvements in agriculture, they are still much in the same state as they were 20 or 30 years ago. Ploughs, on a new and improved model, that in comparison to the advantages derived from them might be had at a moderate expense, have lately been introduced into several districts around, where their good effects are manifest in improving the crops and diminishing the labour of man and beast; but the laird of Rassay and one other gentleman are the only persons in Portree that have used them. The coarsoins, a crooked kind of spade, is almost the only instrument for labouring the ground used among the ordinary class of tenants. The average crops of corn are 8,000 boors.

When Mr. Knox visited this island in 1786, the number of inhabitants amounted to 15,000; but between 1790-98, according to the Statistical History of Scotland, the population is only 14,470.

Various minerals are found in Skye, but none have been wrought to any advantage. Near the village of Sartle, the natives find black and white marcasites, and variegated pebbles. The Applesglen, in the neighbourhood of Lochfallait, produces beautiful agates of different colours: stones of a purple hue are, after great rains, found in the rivulets; crystal, of different colours and forms, abounds in several parts of the island, as well as black and white marble, free-stone, lime-stone, and tallow: small red and white coal is found on the southern and western coasts in great abundance. The fuel consists chiefly of peat and turf, which are impregnated with iron ore; and coal has been discovered in several districts; but it does not appear to be worth working.

The wild birds of all sorts most common in the country, are, solan gaeze, gulls, cormorants, cranes, wild geese, and wild ducks; eagles, crows, ravens, rooks, cuckoos, rails, woodcocks, moor-fowl, partridges, plover, wild pigeons, and blackbirds, owls, hawks, snipes, and
SKY

a variety of small birds. In mild seasons, the cuckoo and rail appear in the latter end of April; the former disappears always before the end of June; the latter sometimes not till September. The woodcock comes in October, and frequently remains till March. The tame sorts of fowl are geese, ducks, turkeys, cocks, pullets, and tame pigeons.

The black cattle are here exposed to all the rigours of the severe winter, without any other provender than the tops of the heath and the algae marina; so that they appear like mere skeletons in the spring; though, as the grass grows up, they soon become plump and juicy, the beef being sweet, tender, and finely interlarded.—The amphibious animals are seals and otters. Among the reptiles may be reckoned vipers, asps, frogs, toads, and three different kinds of serpents; the first spotted black and white, and very poisonous; the second yellow, with brown spots; and the third a brown colour, the smallest and least poisonous.

Whales, and cairbans or sun-fish, come in sometimes to the sounds after their prey, but are rarely pursued with any success. The fishes commonly caught on the coast are herrings, ling, cod, skate, haddock, mackerel, lythe, syc, and dog-fish. The average price of ling at home is 13l. 13s. per ton; when sold, one by one, if fresh, the price is from 3d. to 5d.; if cured, from 5d. to 7d. The barrel of herrings seldom sells under 15s., which is owing to the great difficulty of procuring salt, even sometimes at any price; and the same cause prevents many from taking more than are sufficient for their own use.

The kyle of Scalp trembles with oysters, in such a manner, that after some spring-tides, 25 horse-loads of them are left upon the sands. Near the village of Bernstihill, the beach yields muscles sufficient to maintain 60 persons per day; this providential supply helps to support many poor families in times of scarcity.

The people are strong, robust, healthy, and prolific. They generally profess the Protestant religion; are honest, brave, innocent, and hospitable. They speak the language, wear the habit, and observe the customs that are common to all the Hebrides. The meconium in new-born infants is purged away with fresh butter; the children are bathed every morning and evening in water, and grow up so strong, that a child of 10 months is able to walk alone: they never wear shoes or stockings before the age of eight or ten, and night-caps are hardly known; they keep their feet always wet; they lie on beds of straw or heath, which last is an excellent restorative: they are quick of apprehension, ingenious, and very much addicted to music and poetry. They eat heartily of fish; but seldom regale themselves with flesh-meat: their ordinary food consists of butter, cheese, milk, potatoes, colewort, brochan, and a dish called oon, which indeed is no other than the froth of boiled milk or whey raised with a stick like that used in making chocolate.

A sort of coarse woollen cloth called cloa, or cardoes, the manufacture of their wives, made into short jackets and trousers is the common dress of the men. The philibeg is rarely worn, except in summer and on Sundays: on which days, and some other occasions, those in better circumstances appear in tartans, a bonnet, and short hose, and some in a hat, short coat, waistcoat, and breeches, of Scotch or English manufacture. The wo-

men are in general very cleanly, and so excessively fond of dress, that many maid-servants are often known to lay out their whole wages that way.

There are two fairs held annually at Portree, to which almost every part of Skye sends cattle. The first is held in the end of May, and the second in the end of July. The fair commonly continues from Wednesday till the Saturday following. The commodities which are sold in these are horses, cows, sheep, goats, hides, butter, cheese, fish, and wool. The cattle sold in these fairs form over to the main land; those a mile or half a mile of sea. Thousands of these are yearly exported, at from 2l. to 3l. each. Many of them are driven to England, where they are fattened for the market, and counted delicious eating.

In Skye appear many ruins of Danish forts, watch-towers, beacons, temples, and sepulchral monuments. All the forts are known by the term Deen; such as Dun-Skudhorg, Dun-Derig, Dun-Skariness, Dun-David, &c.

SKY-COLOUR. To give this colour to glass, set in the furnace a pot of pure metal of fritt from rochetta or brolla, but the rochetta fritt does best; as soon as the metal is well purified, take for a pot of twenty pounds of metal six ounces of brass calcined by itself; put it by degrees at two or three times into the metal, stirring and mixing it well every time, and diligently skimming the metal with a ladle: at the end of two hours the whole will be well mixed, and a proof may be taken: if the colour be found right, let the whole stand 24 hours longer in the furnace, and it will then be fit to work, and will prove of a most beautiful sky colour.

SLAB, an outside sappy plank or board, sawed off from the sides of a timber tree. The word is also used for a flat piece of marble.

SLAB-LINE, in sea-language, a small cord passing up behind a ship's main-sail, or fore-sail, and beingreeved through a block attached to the lower part of the yard, is thence transmitted in two branches to the foot of the sail, to which it is fastened. It is used to truss up the sail as occasion requires, and more particularly for the convenience of the pilot or steersman, that they may look forward beneath it as the ship advances.

SLACK-WATER, in sea-language, denotes the interval between the flux and reflux of the tide, or between the last of the ebb and the first of the flood, during which the current is interrupted, and the water apparently remains in a state of rest.

SLACKEN, in Metallurgy, a term used by miners to express a spongy and semivitrified substance which is mixed with the ores of metals, to prevent their fusion. It is the scoria or scum separated from the surface of the former fusions of metals. To this is frequently added limestone, and sometimes a kind of coarse iron ore, in the running of the poorer gold ores.

SLATE, a stone of a compact texture and laminated structure, splitting into fine plates, some varieties of which are employed for covering houses. See Clay-Steel, under Mineralogy, p. 185. See also Geology.

SLAV. See Slavery.

SLAVERY is a word, of which, though generally Slavery, is understood, it is not easy to give a proper definition. An excellent moral writer has defined it to be "an obligation to labour for the benefit of the master, without the contract or consent of the servant." But may not be
one proprietor to another, like an ox or an ass, happiness must be for ever banished. How then came a traffic so unnatural and unjust as that of slaves to be originally introduced into the world?

The common answer to this question is, that it took its rise among savages, who, in their frequent wars with each other, either massacred their captives in cold blood, or condemned them to perpetual slavery. In support of this opinion we have heard it observed, that the Latin word servus, which signifies not a hired servant, but a slave, is derived from servare, "to preserve;" and that such men were called servi, because they were captives, who, if they were preserved on the condition of their becoming the property of the victor.

That slavery had its origin from war, we think extremely probable (c), nor are we inclined to controvert slavery; this etymology of the word servus; but the traffic in men prevailed almost universally long before the Latin language or Roman name was heard of; and there is no good evidence that it began among savages. The word servus, in the Old Testament, which in our version is rendered servant, signifies literally a slave, either born in the family or bought with money, in contradistinction to servum, which denotes a hired servant; and as Noah makes use of the word servus in the curse which he denounced upon Ham and Canaan immediately after the deluge, it would appear that slavery had its origin before that event. If so, there can be little doubt but that it began among those violent persons whom our translators have called giants, though the original word גָּזֶה, literally signifies assaulsters of others. Those wretches seem first to have seized upon women, whom they forcibly compelled to minister to their pleasures; and from this kind of violence the progress was natural to that by which they enslaved their weaker brethren among the men, obliging them to labour for their benefit, without allowing them fee or reward.

After the deluge the first dealer in slaves seems to have been Nimrod. "He began, we are told, 'to be a mighty one in the earth, and was a mighty hunter before the Lord.' He could not, however, be the first hunter of wild beasts; for that species of hunting must have been practised from the beginning; nor is it probable that his dexterity in the chase, which was then the universal employment, could have been so far superior to that of all his contemporaries, as to entitle him to the appellation of 'the mighty hunter before the Lord.' Hence most commentators have concluded, that he was a hunter of men; an opinion which they think receives some countenance from the import of his name, the word Nimrod signifying a rebel. Whatever

---

(a) Aleam (quod mirere) sobirii inter seria exercent, tanta lucrandi perpendicular temeritate, ut cum omnia desecerunt, extremo ac novissimi jactu de libertate et corpore contendant. Victor voluntarium servitutem adit; quamvis junior, quamvis robustior, alligari se ac verum patitur. — Tacitus de Mor. Germ.

(b) The Roman orator's definition of slavery, Parad. V. is as accurate as any that we have seen. "Servitus est obedientia fructi animis et subjecti et arbitrio carentis suo!" whether the unhappy person fell into that state with or without his own contract or consent.

(c) In the article Society, the reader will find another account of the origin of slavery, which we think likewise probable, though we have transferred it to this place; as it would, in our opinion, be wrong to give to one writer what we know to belong to another. It may be proper, however, to observe here, that between the two articles there is no contradiction, as barbarous wars were certainly one source of slavery.
Slavery.

It be in this, there can be little doubt but that he became a mighty one by violence; for being the sixth son of his father, and apparently much younger than the other five, it is not likely that his inheritance exceeded theirs either in extent or in population. He enlarged it, however, by conquest; for it appears from Scripture, that he invaded the territories of Ashur the son of Sem, who had settled in Shinar, and obliterating him to remove into Assyria, he seized upon Babylon, and made it the capital of the first kingdom in the world. As he had great projects in view, it seems to be in a high degree probable that he made bond-servants of the captives whom he took in his wars, and employed them in building or repairing the metropolis of his kingdom; and hence we think is to be dated the origin of post-diluvial slavery.

That it began thus early can hardly be questioned; for we know that it prevailed universally in the age of Abraham, who was born within seventy years after the death of Nimrod. That patriarch had three hundred and eighteen servants or slaves, born in his own house, and trained to arms, with whom he pursued and conquered the four kings who had taken captive his brother's son. And it appears from the conversation which took place between him and the king of Sodom after the battle, that both believed the conqueror had a right to consider his prisoners as part of his spoil. “Give me (says the king) the persons, and take the goods to thyself.” It is indeed evident from numberless passages of scripture, that the domestics whom our translators call servants were in those days universally considered as the most valuable part of their master's property, and clasped with his flocks and herds. Thus when the sacred historian describes the wealth of Abraham, he says, that he had sheep and oxen, and he-asses, and men-servants, and maid-servants, and she-asses, and camels. And when Abimelech wished to make some reparation to the patriarch for the unintended injury that he had done him, “he took sheep and oxen, and men-servants, and women-servants, and gave them unto Abraham, and restored to him Sarah his wife.” The riches and power of Isaac and Jacob are estimated in the very same manner. Of the former it is said, that “the man waxed great, and went forward and grew, until he became very great: for he had possession of flocks, and possession of herds, and great store of servants, and many possessions; and the Philistines envied him.” The latter, we are told, “increased exceedingly, and had much cattle, and maidservants, and men-servants, and camels, and asses.”

That the practice of buying and selling servants thus early began among the patriarchs descended to their posterity, is known to every attentive reader of the Bible. It was expressly authorized by the Jewish law, in which are many directions how such servants were to be treated. They were to be bought only of the heathen; for if an Israelite grew poor and sold himself either to discharge a debt, or to procure the means of subsistence, he was to be treated not as a slave γυς, but as a hired servant γύς, and restored to freedom at the year of Jubilee. “Both thy bond-men and thy bond-maids (says Moses) shall be of the heathen that are round about you: of them shall ye buy bond-men and bond-maids. And ye shall take them as an inheritance for your children after you, to inherit them for a possession; they shall be your bond-men for ever.” Unlimited as the power is, thus given to the Hebrews over their bond-servants of γύς, the heathen extraction appears to have been, they were strictly prohibited from acquiring such property by any other means than fair purchase: “he that stealeth a man and sell eth him,” said their great lawgiver, “shall surely be put to death.”

While slavery, in a mild form, was permitted among the people of God, a much worse kind of it prevailed among the heathen nations of antiquity. With other abominable customs, the traffic in men quickly spread through the whole world, from Chaldea into Egypt, Arabia, and over all the east, and by degrees found its way into every known region under heaven.

Of this hateful commerce we shall not attempt to trace the progress through every age and country, but shall content ourselves with taking a transient view of it among the Greeks and Romans, and a few other nations, in whose customs and manners our readers must be interested.

One can hardly read a book of the Iliad or Odyssey without perceiving that in the age of Homer, all prisoners of war were liable to be treated as slaves, and compelled, without regard to their rank, sex, or years, to labour for their masters in offices of the vilest drudgery. So universally was this cruel treatment of captives admitted to be the right of the victor, that the poet introduces Hector in the very act of taking a tender and perhaps last farewell of his wife, when it was surely his business to afford her every consolation in his power, telling her, as a thing of course which could not be concealed, that, on the conquest of Troy, she would be compelled to bear the victor's hard commands, or bring the weight of water from Hyperia's spring.

At that early period, the Phoenicians, and probably the Greeks themselves, had such an established commerce in slaves, that, not satisfied with reducing to bondage their prisoners of war, they scrupled not to kidnap in cold

(d) If credit be due to a late account of China, the people of that vast empire have never made merchandise of men or women. The exception, however, is so singular, that we should be glad to see it better authenticated; for it is apparent from works of the most undoubtedly credit, that over all the other eastern countries with which we are acquainted, slavery has prevailed from time immemorial, and that some of the Indian nations make long journeys into Africa for the sole purpose of buying slaves.

(e) In those early times drawing water was the office of the meanest slaves. This appears from Joshua's curse over the Gibeonites who had deceived him.—“Now therefore ye are cursed, and there shall none of you be freed from being bond-men, and hewers of wood, and drawers of water, for the house of my God.” To this state of bondage Homer makes Hector say, that Andromache would necessarily be brought upon the destruction of Troy; 

and Iliad, lib. vi.
Slavery.

blood persons who had never kindled their resentment, in order to supply their foreign markets. In the 14th book of the Odyssey, Ulysses represents himself as having narrowly escaped a snare of this kind laid for him by a false Phæacian, who had doomed the hero to Libyan slavery: and as the whole narrative, in which this circumstance is told, is an artful fiction, intended to have the appearance of truth to an Ithacan peasant, the practice of kidnapping slaves could not then have appeared incredible to any inhabitant of that island.

Such were the manners of the Greeks in the heroic age; nor were they much improved in this respect at periods of greater refinement. Philip of Macedon having conquered the Thespians, not only sold their captives, but even took money for permitting the dead to be buried; and Alexander, who had more generosity than Philip, afterwards razed the city of Thebes, and sold the inhabitants, men, women, and children, for slaves. This cruel treatment of a brave people may indeed be supposed to have proceeded, in the first instance, from the avarice of the conqueror; and in the second, from the momentary resentment of a man who was savage and generous by turns, and who had no command of his passions. We shall not positively assign it to other causes; but from the manner in which the Spartans behaved to their slaves, there is little reason to imagine that had they received from the Thespians the same provocation with Alexander, they would have treated their captives with greater lenity. “At Sparta (says a humane and elegant writer) slaves were treated with a degree of rigour that is hardly conceivable; although to them, as to their husbandmen and artificers, their proud and idle masters were indebted for all the necessities of life. The Lacedemonian youth, trained up in the practice of deceiving and butcher ing those poor men, were from time to time let loose upon them, in order to show their proficiency in stratagem and massacre. And once, without any provocation, and merely for their own amusement, we are told that they murdered three thousand in one night, not only with the connivance of law, but by its avowed permission. Such, in promoting the happiness of one part of society and the virtue of another, are the effects of slavery.”

It has been said, that in Athens and Rome slaves were better treated than in Sparta; but in the former city their treatment cannot have been good, or their lives comfortable, when the Athenians relished that tragedy of Euripides in which Hecuba, the wife of Priam, is introduced as lamenting that she was chained like a dog at Agamemnon’s gate. Of the estimation in which slaves were held in Rome, we may form a tolerable notion from the well-known fact, that one of those unhappy beings was often chained at the gate of a great man’s house, to give admittance to the guests invited to a feast. In the early periods of the commonwealth it was customary, in certain sacred shrines exhibited on solemn occasions, to drag through the circus a slave, who had been scourged to death holding in his hand a fork in the form of a gibbet. But we need not multiply Cicero’s proofs of the cruelty of the Romans to their slaves. If Dion. lib. I. 18, the inhuman combats of the gladiators (see GLADIATORS) admit of any apology on account of the martial spirit with which they were thought to inspire the spectators, the conduct of Vedius Pollio must have proceeded from the most wanton and brutal cruelty. This man, who flourished not in the earliest periods of the republic, when the Romans were little better than a savage banditti, but in the polished age of Augustus, frequently threw such slaves as gave him the slightest offence into his fishponds to fatten his lampreys; and yet he was suffered to die in peace! The emperor, indeed, upon coming to the knowledge of his cruelty, ordered his lampreys to be destroyed, and his ponds to be filled up; but we do not recollect that any other punishment was inflicted on the savage master. Till the time of the same emperor the depositions of slaves were never admitted in the courts of judicature; and then they were received only when persons were accused of treasonable practices.

The origin of slavery in Rome was the same as in every other country. Prisoners of war were of course reduced to that state, as if they had been criminals. The dictator Camillus, one of the most accomplished generals of the republic, sold his Hetrurian captives to pay the Roman ladies for the jewels which they had presented to Apollo. Fabius, whose cautious conduct saved his country when Hannibal was victorious in Italy, having subdued Tarentum, reduced 30,000 of the citizens to slavery, and sold them to the highest bidder. Coriolanus, when driven from Rome, and fighting for the Volsci, scrupled not to make slaves of his own countrymen; and Julius Cæsar, among whose faults wanton cruelty has never been reckoned, sold at one time fifty-three thousand captives for slaves. Nor did the slaves in Rome consist only of foreigners taken in war. By one of the laws of the twelve tables, creditors were empowered to seize their insolvent debtors, and keep them in their houses till, by their services or labour, they had discharging the sum they owed: and in the beginning of the commonwealth they were authorised to sell such debtors, and even to put them to death. The children of slaves were the property not of the commonwealth, or of their own parents, but of their masters; and thus was slavery perpetuated in the families of such unhappy

(f) After a certain number of citations, the law granted to the debtor thirty days of grace to raise the sum for which he was accountable. The words of the law are: “Æris confessi, rebusque jure judicatis, triginti dies justi suntos. Post dein manum endojacite.—Vincentu aut nervo, aut compribus.” When the debt is confessed, and the trial passed, let there be thirty days of forbearance; afterwards lay hands on him; bind him either with a cord or fetters.” After the thirty days were expired, if the debtor had not discharged the debt, he was led to the praetor, who delivered him over to the mercy of his creditors; these bound him and kept him in chains for the space of sixty days. Afterwards, for three market-days successively, the debtor was brought to the tribunal of the praetor; then a public crier proclaimed in the forum the debt for which the prisoner was detained. It often happened, that rich persons redeemed the prisoner by paying his debts; but if nobody appeared in behalf of the debtor after the third market-day, the creditor had a right to inflict the punishments appointed by the law. “Tertiis nudinis

capite.
unhappy men as fell into that state, whether through the chance of war or the cruelty of a sourdird creditor. The consequence was, that the number of slaves belonging to the rich patricians was almost incredible. Caius Cæcilius Iulianus, who died about seven years before the Christian era, left to his heirs 4116 slaves; and if any one of those wretched creatures made an unsuccessful attempt to regain his liberty, or was even suspected of such a design, he was marked on the forehead with a red-hot iron (v). In Sicily, during the most flourishing periods of the commonwealth, it seems to have been customary for masters to mark their slaves in this manner; at least we know that such was the practice of Damophilus, who, not satisfied with this security, shut up his slaves every night in close prisons, and led them out like beasts in the morning to their daily labour in the field. Hence arose the servile war in Sicily.

Its duration.

Though many laws were enacted by Augustus and other patrician emperors to diminish the power of creditors over their insolvent debtors; though the influence of the mild spirit of Christianity tended much to mitigate the condition of slaves even under Pagan masters; and though the emperor Adrian made it capital to kill a slave without a just reason, yet this infamous commerce prevailed universally in the empire for many ages after the conversion of Constantine to the religion of Christ. It was not indeed completely abolished even in the reign of Justinian; and in many countries which had once been provinces of the empire it continued long after the empire itself had fallen to pieces.

It has already been observed, that among the ancient Germans it was not uncommon for an ardent gamaster to lose his personal liberty by a throw of the dice. This was indeed a strong proof of savage manners; but the general condition of slaves among those savage nations seems to have been much better than among the polished Greeks and Romans. In Germany the slaves were generally attached to the soil, and only employed in tending cattle, and carrying on the business of agriculture; for the menial offices of every great man's house were performed by his wife and children. Such slaves were seldom beaten, or chained, or imprisoned. Sometimes indeed they were killed by their masters in a fit of sudden passion; but none were considered as materials of commerce, except those who had originally been free men, and lost their freedom by play. These, indeed, the successful gamester was very ready to sell, both because he felt them an useless burden, and because their presence continually put him in mind of that state to which a throw of the dice might one day reduce himself.

Such is the account which Tacitus gives of slavery De Mor. among the ancient Germans. The Anglo-Saxons, hor. Germ. 14, ever, after they were settled in this island seem not to have carried on that traffic so honourably. By a statute of Alfred the Great, the purchase of a man, a woman's horse, or an ox, without a voucher to warrant the sale, was strictly forbidden. That law was, doubtless, enacted to prevent the stealing of men and cattle; but it seems to Henry I. to have been so late as the ninth or tenth century A. M., when fairly purchased, was, in England, as much the property of the buyer as the horse on which he rode, in England or the ox which dragged his plough. In the same country, now so nobly tenacious of freedom and the rights of man, a species of slavery similar to that which prevailed among the ancient Germans subsisted even to the end of the sixteenth century. This appears from a commission issued by Queen Elizabeth in 1574, for inquiring into the lands and goods of all her bond-men and bond-women in the counties of Cornwall, Devon, Somerset, and Gloucester, in order to compound with them for their manumission, that they might enjoy their lands and goods as freemen. In Scotland there certainly existed an order of slaves or bond-men, who tilled the Scottish districts, and, after the death of the proprietor, were not released. These bond-men, as they were called, obtained their freedom, seems to be unknown to every lawyer and antiquary of the present day. Coalliers and salters were, in the same country, slaves till little more than 30 years ago, that they were manumitted by an act of the British legislature, and restored to the rights of freemen and citizens. Before that period the sons of coalliers could follow no business but that of their fathers; nor were they at liberty to seek employment in any other mines than those to which they were attached by birth, without the consent of the lord of the manor, who, if he had no use for their services himself, transferred them by a written deed to some neighbouring proprietor.

That the savage nations of Africa were at any period slavery among the Carthaginians.

capite poenas data aut trans Tiberim peregred venenumduito;” that is, “Let him on the third market-day be punished with death, or sold beyond the Tiber as a slave.” If there were several creditors, they were allowed, in consequence of this severe law, to divide the body of the prisoner into several parts, and share it among them in proportion to the sum which they demanded.

(c) This is evident from the story of Appius and Virginia. See Rome, No 113.

(h) How capriciously and unjustly this infamous mark was impressed, we learn from the story of Restio. This man being proscribed, and a reward offered for his head by the triumvirs Octavianus, Antony, and Lepidus, concealed himself from the fury of the tyrants in the best way that he could. A slave whom he had marked with the hot iron having found out the place of his retreat, conducted him to a cave, and there supported him for some time with what he earned by his daily labour. At length a company of soldiers coming that way, and approaching the cave, the faithful slave, alarmed at the danger his master was in, followed them close, and falling upon a poor peasant, killed him in his presence; and cut off his head, crying out, “I am now revenged on my master for the marks with which he has branded me.” The soldiers, seeing the infamous marks on his forehead, and not doubting but he had killed Restio, snatched the head out of his hand, and returned with it in all haste to the triumvirs. They were no sooner gone, than the slave conveyed his master to the sea side, where they had the good luck to find one of Sextus Pompeius’s vessels, which transported them safe into Sicily.
of history exempted from this approbrium of our nature which spread over all the rest of the world, the enlightened reader will not suppose. It is indeed in that vast country that slavery has in every age appeared in its ugliest form. We have already observed, that about the era of the Trojan war, a commerce in slaves was carried on between Phoenicia and Libya: and the Carthaginians, who were a colony of Phoenicians, and revered the customs, manners, and religion of their parent state, undoubtedly continued the Tyrian traffic in human flesh with the interior tribes of Africa. Of this we might rest assured, although we had no other evidence of the fact than what results from the practice of human sacrifices so prevalent in the republic of Carthage. The genuine instincts of nature are often subdued by dire superstition, but they cannot be wholly eradicated; and the rich Carthaginians, when a human victim was demanded from him to the gods, would be ready to supply the place of his own child by the son of a poor stranger, perniciously purchased at whatever price. That this was, indeed, a very common practice among them, we learn from the testimony of various historians, who assure us, that when Agathocles the tyrant of Syracuse had overthrown their generals Hanno and Bomiclar, and threatened Carthage itself with a siege, the people attributed their misfortunes to the just anger of Saturn for having been worshipped, for some years, by the sacrifices of children meanly born and secretly bought, instead of those of noble extraction. These substitutions of one offering for another were considered as a profane deviation from the religion of their forefathers; and therefore to expiate the guilt of so horrid an impurity, a sacrifice of 200 children of the first rank was on that occasion made to the bloody god. As the Carthaginians were a commercial people, we cannot suppose that they purchased slaves only for sacrifices. They undoubtedly condemned many of their prisoners of war to the state of servitude, and either sold them to foreigners, or distributed them among their senators and the leaders of their armies. Hanno, who endeavoured to usurp the supreme power in Carthage whilst that republic was engaged in war with the Romans in 218 B.C., armed 20,000 of his slaves in order to carry his nefarious purpose into execution: and Hannibal, after his decisive victory at Canea, sold to the Greeks many of his prisoners whom the Roman senate refused to redeem. That illustrious commander was indeed more humane, as well as more politic, than the generality of his countrymen. Before his days it was customary with the Carthaginians either to massacre their captives in cold blood, that they might never again bear arms against them, or to offer them in sacrifice as a grateful acknowledgement to the gods by whose assistance they believed that they were vanquished; but this was not always done even by their most superstitious or most unprincipled leaders. Among other rich spoils which Agathocles, after his victory already mentioned, found in the camp of Hanno and Bomiclar, were twenty thousand pair of letters and mantles, which those generals had provided for such of the Sicilian prisoners as they intended to preserve alive and reduce to a state of slavery.

With the ancient state of the other African nations we are but very little acquainted. The Numidian, Mauretanians, Cetulins, and Garamantes, are indeed mentioned by the Roman historians, who give us ample details of the battles which they fought in attempting to preserve their national independence; but we have no particular account of their different manners and customs in that age when Rome was disputing with Carthage the sovereignty of the world. All the African states of which we know any thing, were in alliance with one or other of those rival republics; and as the people of those states appear to have been less enlightened than either the Romans or the Carthaginians, we cannot suppose that they had purer morals, or a greater regard for the sacred rights of man, than the powerful nations by whom they were either protected or oppressed. They would, indeed, insensibly adopt their customs; and the ready market which Marius found for the prisoners taken in the town Capua, although Sallust acknowledges that the sale was contrary to the laws of war, show that slavery was then no strange thing to the Numidians. It seems indeed to have prevailed through all Africa from the very first peopling of that unexplored country; and we doubt if in any age of the world the unhappy negro was absolutely secure of his personal freedom, or even of not being sold to a foreign trader.

It is the common opinion that the practice of commerce in negroes has been carried on with the greatest profusion by the Portuguese and other nations since the discovery of Guinea begun by the Spaniards. But the trade was carried on by the Arabs some hundreds of years before the Portuguese embarked in that traffic, or history, had even seen a woolly-headed negro. Even the wandering Arabs of the desert, who never had any friendly correspondence with the Christians of Europe, had from time immemorial been served by negro slaves. The Arab must be poor indeed (says M. Sauvignier) not to have at least one negro slave. His and his countrymen's occupation is the care of the herd. They are never employed in war, but they have it in their power to carry their women and children, who are trained to do all the domestic work, and are roughly treated by the Arabian women, and by the Arabs themselves. Their children are slaves like them, and put to all kinds of drudgery. Surely no man whose judgment is not completely warped by prejudice will pretend that those roving tribes of savages, so remarkable for their independent spirit and attachment to ancient customs, learned to enslave the negroes from the Europeans. In all probability they have, without interruption, continued the practice of slavery from the days of their great ancestor Ishmael; and it seems evident, that none of the European nations had ever seen a woolly-headed negro till the year 1500, when the crusaders fell in with a small party of them near the town of Hebron in Judea, and were so struck with the novelty of their appearance, that the army burst into a general fit of laughter. Long before the crusades, however, we know with certainty that the natives of Guinea had been exposed to sale in foreign countries. In 611 the Mahometans of Egypt so harassed the king of Nubia or Ethiopia, who was a Christian, that he agreed to send them annually, by way of tribute, a vast number of Nubian or Ethiopian
Slavery. — Slave traders in Egypt. Such a tribute as this at that time, we are told, was more agreeable to the khalif than any other, as the Arabs then made no small account of those slaves. * Modern Universal History, vol. i. pp. 352.

The levy proposal of such a tribute, and the estimation in which black slaves were held in Egypt, shows that a commerce in bond-servants could not then be a new branch of trade either to the Arabs or the Ethiopians; but the vast number which the Ethiopian monarch was once compelled to furnish every year, induced him to feed this great drain upon his subjects from the natives of the neighboring countries. He ranged accordingly into all that vast blank of geography upon the map of the world, the spreading bosom of the African continent; and even pushed through it to its farthest extremities in the west. He thus brought the blacks of Guinea, for the first time, into the service and families of the east; and the slaves which he paid in tribute to the Arabs, whether derived from the nearer neighborhood of Ethiopia, fetched from the Mediterranean regions of Africa, or brought from the distant shores of the Atlantic, were all denominated Ethiopians, from the country by which they were conveyed into Egypt.*

* Whitaker's Revised.

At this time, therefore, according to Mr. Whitaker, began that kind of traffic in human flesh

"Which spoils unhappy Guinea of its sons."

There are not many authors from whom, in questions of antiquity, we differ with greater hesitation; but, as we meet with a female Ethiopian slave in the Eunuch of Terence, we cannot help suspecting that Guinea was occasionally "spoiled of its sons" at a much earlier period. At any rate, from the observations made by the European travellers who first penetrated into that continent, it appears undeniable that slavery must have prevailed from time immemorial among such of the tribes as had never carried on any commerce with foreign nations. When Battel first visited the Giaagas, those people had never before seen a white man; yet they welcomed him and the English, with whom he had come, to their country, invited them to bring their goods on shore, and without hesitation loaded the ships with slaves. The Giaagas were indeed waging war with the kingdom of Benguela; and being cannibals, who prefer human flesh to all others, the slaves whom they had sold to the English were probably prisoners whom they would have killed and eaten if they had not found an opportunity of otherwise disposing of them to greater advantage. But as they had not been incited by the Europeans to eat their prisoners, there can be no reason to suppose that by the Europeans they had been first induced to sell them; for we have seen that this kind of commerce prevailed in Africa among people much more polished than the Giaagas so early as in the reign of Jogurtha.

That it was not introduced among the negroes either by the Arabs or by the Portuguese, appears still more evident from the behavior of the Dahomans at the conquest of Whidah, and from the manner in which the people of Angola at the earliest stage of their foreign trade procured a supply of slaves for the Portuguese market. The greater part of the slaves whom the Angolans exported from St. Paulo de Loanda were brought from interior countries, by a thread of leagues distant, where they could not have been regularly purchased, or had commerce been till then unknown in those countries. The Dahomans, in the beginning of the year 1727, had never seen a white man; and when their victorious prince and his army, in their route through Whidah, first met with some Europeans in the town of Sabi, they were so shocked at their complexion and their dress, that they were afraid to approach them, and could not be persuaded that they were men till they heard them speak, and were assured by the Whidanese that these were the merchants who purchased all the slaves that were sold in Guinea. * Modern Universal History, vol. viii.

Therefore, it prevailed among the Dahomans before that period, could not have been introduced among them by European or Arabian intriguers: but we are assured by Snelgrave, who was then in the army, that those people treated their captives with such horrid cruelty as was shocking to the natives of the sea-coast, and leaves no room for doubt but that slavery had been practised among them from the earliest ages. A great part of their prisoners were sacrificed to their gods or eaten by the soldiers; and when our author expressed to a colonel of the guard some surprise that a prince so enlightened as the sovereign of Dahomy should sacrifice so many men whom he might have sold to great advantage, he was gravely told, that it had been the custom of their nation, from time immemorial, to offer, after victory, a certain number of prisoners to the gods; and that they selected the old men for victims, because they were of less value at market, and more dangerous from their experience and cunning, than the young men. To those persons who fancy that the wars between the African princes are carried on for the sole purpose of supplying the European ships with slaves, it may be proper to remark, that one of the kings of Dahomy slaughtered at once not only all the captives taken in war, but also 127 prisoners of different kinds, that he might have a sufficiency of skulls to adorn the walls of his palace; though at the very time of that massacre he knew that there were six slave-ships in the road of Whidah, from which he could have got for every prime slave a price little short of thirty pounds sterling.

These facts, and numberless others which the reader will find detailed in the 13th volume of the Modern Universal History, by writers who were at the greatest pains to procure authentic information; who were neither biased by interest nor blinded by enthusiasm; and who appear to have held the infamous traffic in utter abhorrence — prove beyond the possibility of doubt, that slavery of the worst kind must have prevailed among all the negro nations before they were visited either by the Portuguese or by the Arabs (1). These two nations may

(1) The same thing appears from the voyages of M. Saugnier, who had an opportunity of conversing with many tribes of negroes, and who always speaks of slavery as an established practice among them; adding, that such as are sold for crimes are put to death by their own countrymen if they fly from their master. It appears likewise in a still more striking light from Daizel's History of Dahomy, where we are told that all the Dahomans,
may indeed have been the first who dragged the unhappy negro from his native continent, and made his slavery harsher, by compelling him to labour, without his own consent, for masters whom he hardly considered as human beings.

On the beginning of this commerce, or the dreadful cruelty with which it has been carried on to the present day, it is impossible to reflect without horror; but there is some consolation, however small, in knowing that its original authors were not Europeans. The purchase of Guinea blacks for slaves by foreign nations commenced ages before the Portuguese had laid that country open to the intercourse of Europe. Even after they had made many incursions into it, the inhabitants were as regularly purchased for slaves by some of the adjoining states as they are now by the maritime Europeans.

"The Arabs of Egypt having reduced all the north of Africa, and carrying with them their love of black servants, would be sure to open a ready communication for themselves to their country. They certainly had one as early as 1512, and before the Europeans had any for that purpose (k). They went from Barbary by a route that was so much practised, as to be denounced expressly 'the way of the camels.' Meeting together at the town of Cape Caun, or that of Valadie near it, the commercial caravan traversed the vast deserts, those of Sarras, which run like the tropic of Cancer over them in a long line across the country; to a place of great population called Hoden, the Waden or Haden of our maps, and a little to the south-west of Cape Blanc. From Hoden they turned to the left, and pushed directly into the interior of the continent, to reach Tegazza, the Taguesso or Tegossa of our maps, and lying nearly east of Hoden. Here assuredly did, as the caravan does certainly at this day; and added to the other wares upon their camels a quantity of salt from those mines of rock-salt, which are extraordinary enough to be noticed as rocks in our maps. This they carried, as they still carry it, to Tanbut, the Tombut of the maps, and a town in the heart of the African continent. And from this town they turned on the right for the sea coast again, and reached it in the great kingdom of Mele, the Melli of our maps, to the south of the Gambia, and just at the springing as it were of that grand arch

of sea which curves so deeply into the body of the land, and constitutes the extensive gulf of Guinea.

At Melli and at Tombut they received a measure of gold for a measure of salt. The caravan collects gold at Tombut to the present time; but at Melli they purchased gold and also silver, in pieces as large as pebbles. And at Hoden they had a great mart for slaves; the blacks being brought thither from the countries adjoining, and bartered away to the traders. Such was the Slave Coast and the Gold Coast of former days. The staple commodity of Hoden is only transferred now to Whidah; and diverted from the Arabs of Barbary to the Christians of Europe," by whom the negroes are now carried to the continent of America or to the Sugar Islands in the West Indies. In these countries they the negroes are all sold like beasts in a market; but they experience pangs, very different degrees of servitude from the different masters who hold them as property. Such of them as are reconciled to the appearance of white men, or have been born in the European colonies, feel themselves as happy under a humane master as they could be in their native continent (l); and we believe that few of them in such circumstances have expressed a desire to return.

In the French West India islands, before the late revolution in the mother country, which has produced in all its dependencies anarchy and massacre, the condition of the negro slaves was better than that of the bondmen among the ancient Germans. "Those of them old governors who cultivated the plantations were attached to the soil, and could not be drawn off to pay debts, or be sold separately from the estate on which they lived. This gave them a lasting property in their huts and little spots of ground, which they might safely cultivate without dread of being turned out of possession, or transferred contrary to their interest and feelings from one proprietor to another. They were under the protection of law as soon as they arrived in the colony. Proper missionaries were appointed for the purpose of training them up to a certain degree of religious knowledge, and ample funds were allotted for the maintenance of those ecclesiastics. On ill treatment received from his master, or on being deprived of his allowance of food and raiment, the slave was directed to apply to the king's attorney,

(k) In the year 1442, Anthony Gonzalez, a Portuguese adventurer, restored to their native country some Moorish prisoners whom he had two years before forcibly carried off from the coast of Africa. He landed them at Río del Oro, and received from the Moors in exchange ten blacks and a quantity of gold dust. This transaction proves, that a commerce in black servants was then regularly carried on by the Moors and not by the Portuguese. So early as the year 1502, the Spaniards began to employ a few negroes in the mines of Hispaniola; but in the year following, Ovando, the governor of that island, forbade the further importation of them, alleging that they taught the Indians all manner of wickedness, and rendered them less tractable than formerly: and it was not till the year 1517 that the supply of negroes to the Spanish American plantations became an established and regular branch of commerce. Edward Jenner's History of the West Indies, Book IV. chap. ii.

(l) "I have observed many of my slaves go on board the vessel with joy, on my assurance that they would be well treated and happy in the plantation where I was going to send them. When the Barbarians find that they are trusted by the whites, they never think of making their escape, choosing to be the slaves of Europeans rather than of a black man, who would treat them with the greatest cruelty. Voyages to the Coast of Africa by Messrs. Sauvage and Brison, p. 332. 335. English Translation.
Slavery.

f We wish it were in our power to say, that in the British West India colonies slaves are equally protected by law as they were in the French islands under the old government, and that the same care is taken of their moral and religious improvement. This, however, we are afraid, cannot be said with truth. In the island of Jamiaca, before the passing of the consolidated slave act, not many years ago, a white man, whether proprietor or not, who had killed a negro, or by an act of severity been the cause of his death, was, for the first offence, intitule to benefit of clergy, and not liable to capital punishment till a repetition of the crime. By the present law, it is enacted, "That if any person, whether owner or superintendent of slaves, shall be convicted of having, by any act of passion or cruelty, occasioned the death of any negro, it shall be capital for the first offence: and for the greater security of the property, and as a check on those who may have the punishment of slaves in their power, it is particularly required, that every surgeon or doctor belonging to each estate shall swear to the cause of the death of each negro, to the best of his knowledge and belief; and if any negro dies, and is interred by the owner or overseer, without the doctor's having seen or been sent for to such negro, in this case the owner or overseer causing the negro to be so interred is liable to a prosecution for such conduct."

This law must doubtless be productive of good effects; but being a colonial act, it cannot have the vigour of the Code Noir; nor do we know of any attorney in the island who is obliged to defend the rights of the negroes, or prosecute the master whose cruelty has by any means come to his knowledge. The justices and vestry of each parish are indeed constituted a council of protection, for the express purpose of making full inquiry into the barbarities exercised on slaves, and bringing the authors to punishment at the public expense; and by a new slave act at Grenada, the justices are required annually to nominate three freeholders to be guardians of the slaves, who are to take an oath to see the law duly executed. These are benevolent regulations; but we doubt if protection can be so promptly afforded by a council of guardians as by an individual attorney who has no other employment. In some of the other British islands, we have been confidently told that the unfortunate sons of Africa have no protection whatever against the tyranny of a sordid owner, or the caprice of a boisterous overseer (M); though it is added, that the humanity of many masters more than supplies the want of laws in every respect but that of improvement, and that the attachment of others has in them a like effect. In some cases good sense, a regard for their reputation, and a well-informed conviction of their interest, induce men to treat their slaves with discretion and humanity. The slaves of many a planter possess advantages beyond what the labourer even of Britain enjoys; yet these advantages, if not in full, yet in a great part, depend upon the good will of his master; and in no part of the British colonies are the slaves attached to the soil. This single circumstance, together with the total neglect of their moral and religious culture, makes their situation much less eligible than was that of the French slaves under the old government; and affords a striking proof of what the humane author whom we have just quoted well observes, that "those men and nations whom liberty hath exalted, and who therefore ought to regard it tenderly in others, are constantly for restraining its blessings within their own little circle, and delight more in augmenting the train of their dependents than in adding to the rank of fellow-citizens, or in diffusing the benefits of freedom among their neighbours."

Having given this ample detail of the rise and progress of slavery in the world, and shown that it has prevailed in every age, and under all religions, we shall now proceed to inquire whether a practice so general be in any instance lawful; and if it be, how it must be modified, in order to be rendered consistent with the rights of man and the immutable laws of nature.

That in a state of nature one man has a right to seize upon another, and to compel him by force to labour for his subsistence, is a position which we believe has never been seriously maintained. But independent communities stand to each other in the very same relation that individuals do in a state of nature: and therefore in such a state the man of greater bodily strength or mental sagacity would have no right to convert his weaker neighbour into personal property, neither can the more powerful and enlightened nation have a right to carry off by force, or cut the subjects of a weaker and more barbarous community for the purpose of reducing them to a state of servitude. This is a truth so obvious as to admit neither of proof nor of denial.

In thus stating the case between two independent nations, we have in our eye that traffic in slaves which is carried on between the civilized Europeans and the barbarous Africans: and the utmost length which we think an apologist for that trade can go is to contend, that we may lawfully purchase slaves in those countries where from time immemorial they have been a common branch of commerce. But the European right to purchase cannot be better than the African right to sell; and we have never yet been informed what gives one African a right to sell another. Such a right cannot be natural, for the reason which we have elsewhere assigned (see Right): neither can it be adventitious; for adventitious rights are immediately derived from the municipal law, which is the public will of the state. But the state has no authority to deprive an innocent man of his personal freedom, or of the produce of his own labour; for it is only to secure these, by protecting the weak

(M) In Barbadoes there is said to be a law for the protection of slaves, which is the most insolent trifling with justice and humanity that the writer of this article has ever seen. It is enacted, forsooth, "That if any man shall, of wantonness or only of bloody-mindedness, or cruel intention, wilfully kill a negro or other slave, if his own, he shall pay into the public treasury fifteen pounds sterling!" See Dickson's Letters on Slavery, p. 4.
It may perhaps be said, that by patiently submitting to governments which authorize the traffic in human flesh, men virtually give up their personal liberty, and vest their governors with a right to sell them as slaves: but no man can vest another with a right which he possesses not himself; and we shall not hesitate to affirm, that in a state of nature where all have equal rights, no individual can submit himself to the absolute disposal of another without being guilty of the greatest crime. The reason is obvious. From the relation in which men stand to one another as fellow-creatures, and to God as their common Creator, there are duties incumbent upon each peculiar to himself; in the performance of which he can be guided only by his own reason, which was given him for that very purpose. But he who renounces his personal freedom, and submits unconditionally to the caprice of a master, impiously attempts to set himself free from the obligation of that law which is interwoven with his very being, and chooses a director of his conduct different from that which God has assigned him. A man therefore cannot put himself in a state of unconditional servitude; and what he cannot do for himself, he surely cannot authorize others to do for him either by a tacit or by an open consent.

These considerations have often made us regret that writers, for whose talents and integrity we have the highest respect, should, without accurately defining what they mean by slavery, have peremptorily affirmed, that, consistently with the law of nature men may be reduced to that state as a punishment for crimes, or to discharge debts which they cannot otherwise pay. That a criminal, who has forfeited his life to the laws of his country, may have his punishment commuted for hard labour, till death in the course of nature shall put a period to his terrestrial existence, is a truth which we apprehend cannot be controverted; but to make such a commutation of punishments consistent with the laws of nature and of nature’s God, it appears to us that the kind and degree of labour must be precisely ascertained, and the conduct of the criminal not left to the capricious direction of any individual.

Punishments can be justly inflicted only for one or other of two ends, or for both. They may be calculated either to reform the criminal or to be a warning to the innocent; and those which most effectually answer both these purposes are surely to be preferred to such as answer but one of them. For this reason we consider hard labour as a much fitter punishment for most crimes than death: but to entitle it to preference, the kind and degree of the labour must be ascertained by the law; for if these circumstances be omitted, and the offender delivered over as a slave to the absolute disposal and caprice of a private master, the labour to which he is condemned, instead of operating to his reformation, may be converted into the means of tempting him to the commission of new crimes. A young woman, in the state of servitude, would hardly be able to maintain her virtue against the solicitations of a master who should promise her liberty or a remission of toll upon her yielding to his desires; and the felon, who had long been accustomed to a life of vagrancy and idleness, would not strenuously object to the perpetration of any wickedness to obtain his freedom, or even a diminution of his daily task. Indeed such temptations might be thrown in his way, as human nature could not resist but by means of much better principles than felonous can be supposed to possess. He might be scourged into compliance; or his labour might be so increased as to make him for a little respite eagerly embrace the most nefarious proposal which his master could make: for being absolute property, there is no earthly tribunal to which he could appeal for justice; and felons do not commonly support themselves under trials by pious meditations on a future state.

By reasoning in this way, we are far from meaning to insinuate that slave-holders in general torture their slaves into the commission of crimes. God forbid! Many of them we know to be religious, humane, and beneficent: but they are not infallible; and some of them may be instigated, some of them undoubtedly have been instigated, by avarice and other worse principles, to compel creatures, who are so absolutely their dependents, to execute deeds of darkness too hazardous for themselves. But the morality or immorality of any action, and the moral fitness of any state, are to be judged of by their natural tendency, if the one were universally practised and the other universally prevalent (see Moral Philosophy, No. 156): and as the natural tendency of absolute domestic slavery among such creatures as men is to throw the most powerful temptations to vice in the way both of master and of slave, it must be in every instance, even when employed as a punishment, inconsistent with the fundamental principles of moral virtue.

Some writers indeed have maintained, and the civil children of a law seems to suppose, that children are the property of not the their parents, and may be sold as slaves in cases of urgent necessity: but if we duly consider how property is acquired (see Property), and attend to the natural consequences of slavery, we shall soon be convinced that this opinion is very ill founded. The rights of parents result from their duties; and it is certainly the duty of that man who has been the instrument of bringing into the world an intellectual and moral being, to do every thing in his power to render the existence of that being happy both in the present life and in that which is to come. If this duty be conscientiously discharged, the parent has a manifest right to the gratitude, love, and reasonable obedience, of his child: but he cannot, in consequence of any duty performed, claim a right to transfer that child as property to the uncontrolled disposal of any private master; for this plain reason, that the man who is considered as the private property of another, cannot reasonably be supposed to enjoy happiness in this world, and is under many temptations to do what must necessarily render him miserable in the next. See Moral Philosophy, No. 158.

If criminals cannot be lawfully reduced to a state of absolute private slavery, much less surely can it be lawful to reduce insolvent debtors and prisoners of war to that state. Many a virtuous man, who has contracted debts with the fairest prospect of paying them, has been suddenly rendered insolvent by fire, by shipwreck, or by the bankruptcy of others with whom he was necessarily engaged in the course of his trade. Such a man can be considered in no respect as criminal. He has been indeed unfortunate; but it would be greatly unjust, as
well as shockingly cruel, to add to his misfortune by reducing him to a state to which we have just seen that the vilest felon cannot be reduced without a violation of the laws of morality. Fraudulent bankrupts, indeed, of whom we daily see many, might with great propriety and the strictest justice be compelled to exterminate their debts by labouring for the benefit of those whom they have injured; and criminals of other descriptions might be made to work for the benefit of the public: but in both cases the task to be performed should be ascetria by the law, and the persons of the labourers be protected by the state. If such can be called slaves, their slavery is undoubtedly consistent with every principle of virtue and religion; for they suffer nothing but the due reward of their deeds. Prisoners of war, however, can upon no honest principle be reduced even to this state of mitigated bondage; for they are so far from incurring guilt by fighting for their country, that even to their enemies their courage and conduct in such a cause must appear worthy of reward. A victorious general has certainly a right to prevent the prisoners taken in battle from again drawing their swords against him during the continuance of the war; but there are many ways by which this may be done effectually without chaining the unfortunate captives to the oar, or selling them like cattle to private purchasers, by whom they may be treated with capricious cruelty, and driven to the perpetration of the greatest crimes.

To these conclusions, and the reasoning on which they are built, we are aware it may be objected, that if private slavery were in every instance unlawful and inconsistent with the fundamental principles of morality, it would not have prevailed among the ancient patriarchs, and far less have been authorised by the Jewish law.

In reply to this objection, it may be observed, that Abraham, Isaac, and Jacob, though excellent men, were not characters absolutely perfect; that as their practice does not authorise polygamy or incest among us, it will not authorise the reducing of our fellow-creatures to a state of hopeless servitude; and that from the circumstances of the age in which they lived, many things were permitted to them, and were indeed harmless, which are forbidden to us, and would now be pernicious. The character of Abraham appears to have been much more perfect than that of his son or grandson; and was certainly equal, if not superior, to that of any other mere man of whom we read either in profane or even in sacred history. We are to remember, however, that he was born amidst idolaters, and was probably an idoler himself till enlightened by the inspiration of Jehovah, and called from his kindred and from his father's house. Before his conversion, he must have had much cattle and many slaves, which constituted the riches of that early period; and his case would indeed have been peculiarly hard, had he been commanded to divest himself of his servants, and to depart into a strange country very thinly inhabited, without people to protect his flocks and flocks from beasts of prey. Nor would his loss have contributed in any degree to the benefit of his slaves, who, as the ranks of men were then adjusted, could not long have preserved their liberty. Had they not been forcibly reduced to their former state by their idolatrous countrymen, which in all probability they would have been, they must have soon submitted to it, or perished by hunger. Let it be remembered, too, that the bond-servants of Abraham, though constituting the most valuable part of his property, were not considered as a species of inferior beings, but were treated rather as children than as slaves. This is evident from his speaking of the steward of his house as his heir, when complaining to God of the want of seed. Indeed the manner in which this circumstance is mentioned shows that it was then the general practice to consider domestic slaves as members of the family; for the patriarch does not say, "I will leave my substance to this Eliezer of Damascus;" but his words are, "Behold to me thou hast given no seed; and lo, one born in my house is my heir." From this mode of expression we are strongly inclined to think that captives taken in war were in that age of simplicity incorporated into the family or tribe of the conquerors, as they are said to be at present among the North American Indians, to supply the place of those who had fallen in battle. If so, slavery was then a very mild thing, unattended with the evils which are now in its train, and must often have been highly beneficial to the captive.

The other part of the objection appears at first sight more formidable; but perhaps a little attention to the design of the Mosaic economy may enable us to remove it even more completely than this. We need not inform our theological readers, that one great purpose for which the posterity of Abraham were separated from the heathen nations around them, was to preserve the knowledge of the true God in a world running headlong into idolatry. As idolatry appears to have had something in its forms of worship extremely captivating to rude minds, and as the minds of the Israelites at the era of their departure from Egypt were exceedingly rude, every method was taken to keep their separation from their idolatrous neighbours as complete as possible. With this view they were commanded to sacrifice the animals which their Egyptian masters had worshipped as gods, and were taught to consider hogs and such other creatures as the heathen offered in sacrifice, when celebrating their mystical and magic rites, as too unclean to be eaten or even to be touched. Of this distinction between clean and unclean beasts, God himself assigns the reason: "I am the Lord your God (says he), who have separated you from other people; ye shall therefore put difference between clean and unclean beasts, and between unclean fowls and clean." For the same reason they were prohibited from intermarrying with the heathen, or having any transaction whatever with them as neighbours; and the seven idolatrous nations of Canaan they were strictly commanded to exterminate. "When the Lord thy God (says Moses) shall deliver them before thee, thou shalt smite them, and utterly destroy them: thou shalt make no covenant with them, nor show mercy unto them: neither shalt thou make marriages with them; thy daughter thou shalt not give unto his son, nor his daughter shalt thou take to thy son; for they will turn away thy son from following me, that they may serve other gods." But under these laws, it is plain that no intercourse whatever could have place between an Israelite and a man of any other nation, unless the latter was reduced to such a state as that he could neither tempt the former, nor practise himself the rites of his idolatrous worship.
But the Israelites were not separated from the rest of the world for their own sake only: They were intended to be the repositories of the lively oracles of God, and gradually spread the light of divine truth through other nations, till the fulness of time should come, when in Christ all things were to be gathered together in one. To answer this end, it was necessary that there should be some intercourse between them and their Gentile neighbours; but we have seen that such an intercourse could only be that which subsists between masters and their slaves.

Should this apology for the slavery which was authorized by the Jewish law be deemed fanciful, we beg leave to submit to the consideration of our readers the following account of that matter, to which the same objection will hardly be made. It was morally impossible that between nations differing so widely in religion, customs, and manners, as the Jews and Gentiles, peace should for ever reign without interruption; but when wars broke out, battles would be fought, and prisoners would be taken. How were these prisoners to be disposed of? Cartels for exchange were not then known: it was the duty of the Israelites to prevent their captives from taking up arms a second time against them; they could not establish them among themselves either as artificers or as husbandmen; for their law enjoined them to have no communication with the heathen. There was therefore no other alternative but either to massacre them in cold blood, or to reduce them to the condition of slaves. It would appear, however, that those slaves were raised to the rank of citizens, or at least that their burdens were much lightened, as soon as they were convinced of the truth of the Mosaic revelation, and received into covenant with God by the rite of circumcision. They were then admitted to the celebration of the passover; concerning which one law was decreed to the stranger, and to him that was home-born. Indeed, when we consider who was the legislator of the Jews; when we reflect upon the number of laws enacted to mitigate slavery among them, and call to mind the means by which the due execution of all their laws was enforced, (see Theology,) we cannot help being of opinion that the heathen, who was reduced to slavery in Judea, might be happier, if he pleased, than when living as a freeman in his own country. But whether this be so or not, is a matter with which we have no concern. On account of the hardness of their hearts, and the peculiarity of their circumstances, many things, of which slavery may have been one, were permitted to the Jews, which, if practised by Christians, would render them highly guilty.

After treating thus largely of slavery in general, we need not occupy much of the reader’s time with the

SLAVE-TRADE carried on by the merchants of Europe with the natives of Africa. It is well known that the Portuguese were the first Europeans who embarked in this trade, and that their example was soon followed by the Dutch and the English. Of the rise and progress of the English commerce in slaves, the reader will find a sufficient account in other articles of this work. That commerce, though long cherished by the government as a source of national and colonial wealth, was from its commencement considered by the thinking part of the nation as a traffic inconsistent with the rights of men, and suspected to be carried on by acts of violence. These suspicions were gradually spread through the people at large, and confirmed, in many instances, by evidence incontrovertible. Laws were in consequence enacted to make the negroes more comfortable on what is called the middle passage, and to protect them against the wanton cruelty of their masters in the West Indies: but the humanity of the nation was roused; and not many years ago a number of gentlemen of the most respectable characters, finding that no adequate protection could be afforded to persons in a state of hopeless servitude, formed themselves into a society at London, for the purpose of procuring a total abolition of the slave-trade. That the motives which influenced the leading men of this society were of the purest kind, cannot, we think, be questioned; for their object was to deliver those who had none to help them, and from whom they could expect no other reward for their labours of love than the blessing of them who were ready to perish. To a cause truly Christian, who did not pray for success? or who but must have felt the most pungent regret, if that success had been rendered doubtful, or even delayed, by the imprudence of some of the agents employed by the society? This we apprehend was really the case. Language calculated only to exasperate the planters could not serve the negroes; and the legislature of Great Britain would never suffer itself to be forced into any measure by the menaces of individuals.

In the year 1793, petitions were presented to parliament for the abolition of this inhuman traffic, which gave a pleasing picture of the philanthropy of the nation; but, unfortunately for the cause of freedom, it was discovered that many of the names subjoined to those petitions had been collected by means not the most honourable. The discovery, perhaps, would never have been made, had not the insulting epithets indifferently heaped upon the slave-holders provoked those men to watch with circumspection over the conduct of their opponents. The consequence was, that suspicions of unfair dealing on the part of the petitioners were excited in the breasts of many who, though they ardently wished well to the cause, chose not to add their names to those of school-boys under age, and of peasants who knew not what they were subscribing. Let the rights of the Africans be maintained with ardour and firmness; but never let their advocates suppose that the cause of humanity requires the support of artificers. Absolute slavery, in which the actions of one man are regulated by the caprice of another, is a state demonstrably inconsistent with the obvious plan of the moral government of the world. It degrades the mental faculties of the slave, and throws, both in his way and in his master’s, temptations to vice almost insurmountable. Let these truths be set in a proper light by those who have doubtless seen them exemplified; and they will surely have their full effect on the minds of a generous, and, we trust, not an impious people (N). The trade will be generally abolished; pains will be taken

(N) We have not insisted upon the impolicy of the slave trade, or endeavoured to prove that its abolition would be
Slave-trade.

36 Objection to the abolition

ken to cultivate the minds of the West Indian negroes; and the era may be at no great distance when slavery shall cease through all the British dominions.

But what benefit, it will be asked, will the negroes of Africa reap from an abolition of the slave-trade? Should anything so wildly incredible happen, as that all the nations of Christendom, in one common paroxysm of philanthropy, should abandon this commerce in servants, which has been prosecuted in all ages, and under all religions; they would only abandon it to those who were originally possessed of it, who still penetrate into the country, and who even push up to Cairo at the very head of the Slave coast, and leave the wool-headed natives of it to Mahometan masters, in preference to Christian. Under such masters they were in Judea at the time of the crusades. Under such, as we learn from Messrs Saugnier, Brissin, and others, they still are in the deserts of Africa, as well as in the islands of Johanna and Madagascar; and it is universally known that they enslave one another as a punishment for the most whimsical crimes. Among them, indeed, slavery seems to be reduced to a system, and to descend, as it has done in more polished nations, from father to son; for both Saugnier and Wadstrom speak of particular families of negroes who are exempted from that degrading state by the laws of the country.

All this we admit to be true. Most certainly the negroes would not be exempted from the miseries of servitude, though Europe and the West Indies were swallowed up in the ocean. The customs of the country, as the king of Dahomy assured Mr Abson, will be made as long as black men shall continue to possess their own territories, in their present state of depravity and ignorance; and these customs appear to involve slavery of the cruelest kind. But if slavery be in itself unlawful, is it a sufficient excuse for our continuing the traffic that it is carried on by the rude negroes and the savage Arabs? Are people, whom we sometimes affect to consider as an inferior order of beings, to furnish examples of conduct to those who boast of their advancements in science, in literature, and in refinement? Or will the benevolent Lord of all things pardon us for oppressing our helpless brethren, merely because they are cruelly oppressed by others? It is indeed true that the natives of Guinea cannot be made really free, but by introducing among them the blessings of religion and the arts of civil life; but surely they would have fewer temptations than at present to kidnap one another, or to commence unprovoked wars for the purpose of making captives, were the nations of Europe to abandon the commerce in slaves. That commerce, we grant, would be continued by the Arabs, and perhaps by others of the eastern nations; but the same number of people could not be carried off by them alone that is now carried off both by them and by the Europeans.

Were it indeed possible to put the slave-trade under proper regulations, so as to prevent all kidnapping and unjust wars among the Africans, to supply the markets; and were it likewise possible to ensure to the negroes in the West Indies mild treatment and religious instruction, we are far from being sure that while the natives of Guinea continue so rude, and their neighbours the Arabs so selfishly savage, it would be proper to abandon at once to hordes of barbarians the whole of this commerce in bond servants. "The trade, which in its present form is a reproach to Britain, might be made to take a new shape, and become ultimately a blessing to thousands of wretches who, left in their native country, would have dragged out a life of miserable ignorance, unknowing the hand that framed them, unconscious of the reason of which they were made capable, and heedless of the happiness laid up for them in store." Slavery is, indeed, in every form an evil; but it seems to be one of those many evils which, having long prevailed in the world, can be advantageously removed only by degrees, and as the moral cultivation of the slaves may enable them to support the rank and discharge the duties of free men. This is doubtless the reason why it was not expressly prohibited by the divine Author of our religion, but suffered to vanish gradually before the mild influence of his Heavenly doctrines. It has vanished from before these doctrines in most countries of Europe, and it affords us no small gratification to have it in our trade in power to record, what indeed must be fresh in the memory of our readers, that the abolition of the slave-trade was accomplished by the steady perseverance and generous exertions of some of the most enlightened and respectable characters in the kingdom, who, after a long and arduous struggle, obtained a decree of the legislature, prohibiting, after a limited period, the trade in slaves to be continued by subjects of Britain. The bill originated in the house of lords, and having undergone considerable discussion in the house of commons, finally passed on the 16th of March, and received his majesty's assent.

would be advantageous to the sugar-planters; for the planters surely understand their own interest better than those can do, who, having never been in the West Indies, are obliged to content themselves with what information they can glean on the subject from a number of violent and contradictory publications. To countenance slavery under any form is undoubtedly immoral. This we know; and therefore upon this ground have we opposed the slave-trade, which cannot be continued without preferring interest to virtue.

(o) In a speech which Mr Dalzel says the king of Dahomy made to Mr Abson, when he was informed of what had passed in England on the subject of the slave-trade, are these remarkable words: "In the name of my ancestors and myself, I aver that no Dahoman ever embarked in war merely for the sake of procuring wherewithal to purchase your commodities." We must take the liberty to question the truth of this solemn averment. That the slave-trade is not the sole cause of the Dahoman wars every man will admit, who does not fancy that those people have neither passions nor appetites, but for the commodities of Europe: but the bare affirmation of this bloody despot, who boasted of having killed many thousands at the customs, will not convince those who have read either Wadstrom's Essay on Colonization, or the evidence respecting the slave-trade given at the bar of the house of commons, that no Dahoman ever embarked in war merely to procure slaves to barter for European commodities."
assent on the 23d March 1807. The time fixed by
the bill, for the total abolition of the trade, we believe,
was the beginning of the following year, viz. January
1808.

We cannot conclude without expressing a hope, that
the period is not very distant when the slaves in the
West Indies shall be so much improved in moral and
religious knowledge, as that they may be safely trusted
with their own freedom. To set them free in their pre-
sent state of ignorance and depravity, is one of the wild-
est proposals that the ardour of innovation has ever made.
Such freedom would be equally ruinous to themselves and
to their masters; and we may say of it what Cicero said of some unseasonable indulgences pro-
posed to be granted to the slaves in Sicily: Quae cum
accidunt, nemo est, quin intelligent urae ilum rempubli-
cam; hac ubi sumunt, nemo est, qui ullam saluti
retiquam esse arbitret.

Those of our readers who wish to enter into a detail
of this subject, may consult, with much advantage, The
History of the Rise, Progress, and Accomplishment of
the Abolition of the African Slave-Trade, by Mr Clark-
son, 2 vols 8vo.

SLAUGHTER. See MANSLAUGHTER, HOMICIDE,
MURDER, &c.

SLEDGE, a kind of carriage without wheels, for the
conveyance of very weighty things, as huge stones,
bells, &c. The sledge for carrying criminals, condem-
ned for high treason, to execution, is called HURDLE.
The Dutch have a kind of sledge on which they can
carry a vessel of any burden by land. It consists of a
plank of the length of the keel of a moderate ship,
raised a little behind, and hollow in the middle; so that
the sides go a little aslape, and are furnished with holes
to receive pins, &c. The rest is quite even.

SLEDGE is a large smith's hammer, to be used with
both hands: of this there are two sorts, the up-hand
sledge, which is used by workmen, when the work
is not of the largest sort; it is used with both the
hands before, and they seldom raise it higher than their
head. But the other, which is called the about-sledge,
and which is used for battering or drawing out the lar-
gest work, is held by the handle with both hands, and
swung round over their heads, at their arm's end, to
strike as hard a blow as they can.

SLEEP, that state of the body in which, though the
vital functions continue, the senses are not affected by
the ordinary impressions of external objects. See DREAMS
and PHYSIOLOGY.

SLEEP-WALKER, one who walks in his sleep. Many
instances might be related of persons who were addicted
to this practice; but it will be sufficient to select one
remarkable instance from a report made to the Physical
Society of Lausanne, by a committee of gentlemen ap-
pointed to examine a young man who was accustomed
to walk in his sleep.

"The disposition to sleep-walking seems, in the op-
inion of this committee, to depend on a particular afection
of the nerves, which both seizes and quits the pa-
ient during sleep. Under the influence of this afection,
the imagination represents to him the objects that
struck him while awake, with as much force as if they
really affected his senes; but does not make him percive
any of those that are actually presented to his
senses, except in so far as they are connected with the
dreams which engross him at the time. If, during this
state, the imagination has no determined purpose, he
receives the impression of objects as if he were awake;
only, however, when the imagination is excited to bend
its attention towards them. The perceptions obtained
in this state are very accurate, and, when once received,
the imagination renews them occasionally with as much
force as if they were again acquired by means of the
senses. Lastly, these academicians suppose, that the
impressions received during this state of the senses dis-
appear entirely when the person awakes, and do not re-
turn till the return of the same disposition in the nervous
system.

"Their remarks were made on the Sieur Devaud, a
lad thirteen years and a half old, who lives in the town
of Vevey, and who is subject to that singular afection or
disease called Somnambulism or sleep-walking. This lad
possesses a strong and robust constitution, but his nervous
system appears to be organised with peculiar delicacy,
and to discover marks of the greatest sensibility and ir-
ritability. His senses of smell, taste, and touch, are ex-
quise; he is subject to fits of immediate and involuntary
laughter, and he sometimes likewise weeps without any
apparent cause.

"This young man does not walk in his sleep every
night; several weeks sometimes pass without any ap-
ppearance of a fit. He is subject to the disease generally
two nights successively, one fit lasting for several hours.
The longest are from three to four hours, and they com-
monly begin about three or four o'clock in the morn-
ing.

"The fit may be prolonged, by gently passing the
finger or a feather over his upper lip, and this slight irri-
tation likewise accelerates it. Having once fallen asleep
upon a staircase, his upper lip was thus irritated with a
feather, when he immediately ran down the steps with
great precipitation, and resumed all his accustomed ac-
tivity. This experiment was repeated several times.

"The young Devaud thinks he has observed, that,
on the evenings previous to a fit, he is sensible of a cer-
taxed heaviness in his head, but especially of a great
weight in his eyelids.

"His sleep is at all times unquiet, but particularly
when the fits are about to seize him. During his sleep,
motions are observable in every part of his body, with-
starting and palpitations; he utters broken words, some-
times sits up in his bed, and afterwards lies down again.
He then begins to pronounce words more distinctly, be-
rises abruptly, and acts as he is instigated by the dream
that then possesses him. He is sometimes in sleep sub-
ject to continued and involuntary motions.

"The departure of the fit is always preceded by two
or three minutes of calm sleep, during which he snores.
He then awakes rubbing his eyes like a person who has
slept quietly.

"It is dangerous to awaken him during the fit, espe-
cially if it is done suddenly; for then he sometimes falls
into convulsions. Having risen one night with the in-
tention of going to eat grapes, he left the house, passed
through the town, and went to a vineyard where he ex-
pected good cheer. He was followed by several persons,
who kept at some distance from him, one of whom fired
a pistol, the noise of which instantly awakened him,
and he fell down without sense. He was carried home and
brought to himself, when he recollected very well the

having been awakened in the vineyard; but nothing more, except the fright at being found there alone, which had made him swoon.

"After the fit he generally feels a degree of lassitude: sometimes, though rarely, of indisposition. At the end of one of these fits, of which the gentlemen of the committee were witnesses, he was affected with vomitings; but he is always soon restored.

"When he is awakened, he never for the most part recollects any of the actions he has been doing during the fit.

"The subject of his dreams is circumscribed in a small circle of objects, that relate to the few ideas with which at his age his mind is furnished; such as his lessons, the church, the bells, and especially tales of ghosts. It is sufficient to strike his imagination the evening before a fit with some tale, to direct his somnambulism towards the object of it. There was read to him while in this situation the story of a robber; he imagined the very next moment that he saw robbers in the room. However, as he is much disposed to dream that he is surrounded with them, it cannot be affirmed that this was an effect of the reading. It is observed, that when his supper has been more plentiful than usual, his dreams are more dismal.

"In their report, the gentlemen of the committee dwell much on the state of this young man's senses, on the impression made upon them by strange objects, and on the use they are of to him.

"A bit of strong smelling wood produced in him a degree of restlessness; the fingers had the same effect, whether from their smell or their transpiration. He knew wine in which there was wormwood by the smell, and said that it was not wine for his table. Metals make no impression on him.

"Having been presented with a little common wine while he was in a state of apathy, and all his motions were performed with languor, he drank of it willingly; but the irritation which it occasioned produced a deal of vivacity in all his words, motions, and actions, and caused him to make involuntary grimaces.

"Once he was observed dressing himself in perfect darkness. His clothes were on a large table, mixed with those of some other persons; he immediately perceived this, and complained of it much; at last a small light was brought, and then he dressed himself with sufficient precision. If he is teased or gently pinched, he is always sensible of it, except he is at the time strongly engrossed with some other thing, and wishes to strike the offender; however, he never attacks the person who has done the ill, but an ideal being whom his imagination presents to him, and whom he pursues through the chamber without running against the furniture, nor can the persons whom he meets in his way divert him from his pursuit.

"While his imagination was employed on various subjects, he heard a clock strike, which repeated at every stroke the note of the cuckoo. There are cuckoos here, said he; and upon being desired, he imitated the song of that bird immediately.

"When he wishes to see an object, he makes an effort to lift his eyelids; but they are so little under his command, that he can hardly raise them a line or two, while he draws up his eyebrows; the iris at that time appears fixed, and his eye dim. When any thing is presented to him, and he is told of it, he always half opens his eyes with a degree of difficulty, and then shuts them after he has taken what was offered to him.

"The report infers from these facts, and from many others, relative to the different senses, that their functions are not suspended as to what the sleep-walker wishes to see, that is, as to all those perceptions which accord with the objects about which his imagination is occupied; that he may also be disposed to receive these impressions, when his imagination has no other object at the time; that in order to see, he is obliged to open his eyes as much as he can, but when the impression is once made, it remains; that objects may strike his sight without striking his imagination, if it is not interested in them; and that he is sometimes informed of the presence of objects without either seeing or touching them.

"Having engaged him to write a theme, say the committee, we saw him light a candle, take pen, ink, and paper, from the drawer of his table, and begin to write, while his master dictated. As he was writing, we put a thick paper before his eyes, notwithstanding which he continued to write and to form his letters very distinctly; showing signs, however, that something was incommoding him, which apparently proceeded from the obstruction which the paper, being held too near his nose, gave to his respiration.

"Upon another occasion, the young somnambulist arose at five o'clock in the morning, and took the necessary materials for writing, with his copy-book. He meant to have begun at the top of a page; but finding it already written on, he came to the blank part of the leaf, and wrote some lines from the following words, Fiant ignari vigilantes—Ils deviennent ignorans par la paresse; and, what is remarkable, after several lines he perceived he had forgotten the s in the word ignorans, and had put erroneously a double r in paresse; he then gave over writing, to add the s he had forgotten, and to erase the superfluous r.

"Another time he had finished, of his own accord, a piece of writing, in order, as he said, to please his master. It consisted of three kinds of writing, text, half text, and small hand; each of them performed with the proper pen. He drew, in the corner of the same paper, the figure of a bat; he then asked for a penknife to take out a blot of ink which he had made between two letters, and he erased it without injuring them. Lastly, he made some arithmetical calculations with great accuracy.

"In order to explain some of the facts observed by the academicians which we have here mentioned, they establish two general observations, which result from what they have said with respect to the senses and the dreams of this sleep-walker.

"1. That he is obliged to open his eyes, in order to recognise objects which he wishes to see; but the impression once made, although rapidly, is vivid enough to supersede the necessity of his opening them again, to view the same objects anew; that is, the same objects are afterwards presented to his imagination with as much force and precision as if he actually saw them.

"2. That his imagination, thus warmed, represents to him objects, and such as he figures to himself, with as much vivacity as if he really saw them; and, lastly, that all his senses, being subordinate to his imagination,
he had been perpetually turning over the almanac of Vevey. He calculated the days and the hours that were to elapse before the arrival of his wished-for holidays; he showed to his friends and acquaintance the dates of those days which he expected with so much impatience; every time he took up the almanac, it was only to consult the month of December. We now see why that date presented itself to his mind. He was performing a task, because he imagined the day to be the Monday which had so long engrossed him. It is not surprising, that it should have occurred to his imagination, and that on opening the almanac in the dark he might have thought he saw this date which he was seeking, and that his imagination might have represented it to him in as lively a manner as if he had actually seen it. Neither is it surprising that he should have opened the almanac at the month of December; the custom of perusing this month must have made him fond of it in the dark by a mere mechanical operation. Man never seems to be a machine so much as in the state of somnambulism; it is then that habit comes to supply those of the senses that cannot be serviceable, and that it makes the person act with such precision as if all its senses were in the utmost activity. These circumstances destroy the idea of there being anything miraculous in the behaviour of young Devaud with respect to the date and the month that he was in quest of; and the reader, who has entered into our explanations, will not be surprised at his knowing the German almanac; the touch alone was sufficient to point it out to him; and the proof of this is the shortness of the time that it remained in his hands.

An experiment was made by changing the place of the ink-standish during the time that Devaud was writing. He had a light beside him, and had certified himself of the place where his ink-holder was standing by means of sight. From that time he continued to take ink with precision, without being obliged to open his eyes again; but the ink-standish being removed, he returned as usual to the place where he thought it was: It must be observed, that the motion of his hand was rapid till it reached the height of the standish, and then he moved it slowly, till the pen gently touched the table as he was seeking for the ink: he then perceived that a trick had been put on him, and complained of it; he went in search of his ink-standish and put it in its place. This experiment was several times repeated, and always attended with the same circumstances. Does not what we have here stated prove, that the standish, the paper, the table, &c. are painted on his imagination in as lively a manner as if he really saw them, as he sought the real standish in the place where his imagination told him it ought to have been? Does it not prove that the same lively imagination is the cause of the most singular actions of this sleep-walker? And lastly, does it not prove, that a mere glance of his eye is sufficient to make his impressions as lively as durable?

The committee, upon the whole, recommend to such as wish to repeat the same experiments, 1. To make their observations on different sleep-walkers. 2. To examine often whether they can read books that are unknown to them in perfect darkness. 3. To observe whether they can tell the hours on a watch in the dark. 4. To remove when they write the ink-standish from its place, to see whether they will return to the same place.
in order to take ink. And, lastly, to take notice whether they walk with the same confidence in a dark and unknown place, as in one with which they are acquainted.

"They likewise recommend to such as would confirm or invalidate the above observations, to make all their experiments in the dark; because it has been hitherto supposed that the eyes of sleep-walkers are of no use to them."

SLEEPERS, in Natural History, a name given to those animals which sleep all winter; such as bears, marmots, dormice, bats, hedgehogs, swallows, &c. These do not feed in winter, have no sensible evacuations, breathe little or none at all, and most of the viscers cease from their functions. Some of these animals seem to be dead, and others return to a state like that of the fucus before birth: in this state they continue, till by an increase of heat the animal is restored to its former functions.

SLEEPERS, in a ship, timbers lying before and aft in the bottom of the ship, as the rungheads do: the lowest of them is bolted to the rungheads, and the uppermost to the futtocks and rungs.

SLEIDAN, John, an excellent German historian, born of obscure parents, in 1506, at Sleidan, a small town on the confines of the duchy of Juliers. After studying some time in his own country, together with his townman the learned John Sturmius, he went to France, and in 1525 entered into the service of the cardinal and archbishop John du Bellay. He retired to Strasburg in 1542, where he acquired the esteem and friendship of the most considerable persons, particularly of James Sturmius; by whose advice and assistance he was enabled to write the history of his own time. He was employed in some public negotiations; but the death of his wife, in 1555, plunged him into so deep a melancholy, that he lost his memory entirely, and died the year following. In 1555 came out, in folio, De statu Religionis et Republicae sub Carolo Quinto, &c. in 13 books; from the year 1517, when Luther began to preach, to the year of its publication; which history was presently translated into most of the languages of Europe. Besides this great work, he wrote, De quatuor summis Imperiis, libri tres; with some other historical and political pieces.

SLEIGHT OF HAND. See LEGERDEMAIN.

SLEBSWICK, an ancient and considerable town of Denmark, the metropolis of a duchy of the same name, in the province of Gottorp, the see of a bishop, which was secularized in the year 1586. The old palace of Gottorp is close to it, which was formerly the ducal residence, but afterwards inhabited by the governor. This town at one period was much more extensive than it is now, having suffered greatly by the German wars. It is seated on the gulf of Sley, where there is a commodious harbour, 65 miles north-west of Lubeck, and 125 south-west of Copenhagen. The people boast that the German language is here spoken with as much accuracy as at Vienna, of which, however, a good German scholar can alone be judge. Sleswick has but little trade, as nowhere at small boats can have access to it, the passage of the Sley having been long since choked up with sand and mud; before which period it was both flourishing and populous. It is now chiefly inhabited by the officers of the castle, and the poorer classes, or the attendants on the court and on them. The present population is said to be about 7,000. E. Long. 10. o. N. Lat. 54. 40.

SLEBSWICK, the duchy of, or South Jutland, is about 100 miles in length and 60 in breadth, and contains 3,600 square English miles, and in 1802 about 340,800 inhabitants. It is bounded on the north by North Jutland, on the east by the Baltic sea, on the south by Holstein, and on the west by the ocean. It contains 24 cities, 17 towns, 12 castles, 278 parishes, 218 villages, 162 farms, 116 water-mills, and 106 gentlemen’s seats. It is a pleasant, fertile, populous country, and a sovereign duchy. Formerly the king of Denmark had half of it, and the other belonged to the house of Holstein-Gottorp; but the former having conquered this duchy, had the possession of it confirmed to him by the treaty of the north in 1720.

SLEIJT-HOunde, the ancient Scots name of the blood-hound. The word is from the Saxon slot, "the impression that a deer leaves of its foot in the mire," and hound; "a dog" so they derive their name from following the track. See the article Blood-Hound.

SLICH, in Metallurgy, the ore of any metal, particularly of gold, when it has been pounded, and prepared for further working.

The manner of preparing the slich at Chemnitz in Hungary is this; they lay a foundation of wood three yards deep, upon this they place the ore, and over this there are 24 beams, armed at their bottoms with iron; these, by a continual motion, beat and grind the ore, till it is reduced to powder. During this operation, the ore is covered with water. There are four wheels used to move these beams, each wheel moving six; and the water, as it runs off, carrying some of the metallic particles with it, is received into several basons, one placed behind another; and finally, after having passed through them all, and deposited some sediment in each, it is let off into a very large pit, almost half an acre in extent; in which it is suffered to stand so long as to deposit all its sediment, of whatever kind, and after this it is let out. This work is carried on day and night, and the ore taken away and replaced by more as often as occasion requires. That ore which lies next the beams, by which it was pounded, is always the cleanest or richest.

When the slich is washed as much as they can, a hundred weight of it usually contains about an ounce, or perhaps but half an ounce of metal, which is not all gold; for there is always a mixture of gold and silver, but the gold is in the largest quantity, and usually is two-thirds of the mixture: they then put the slich into a furnace with some limestone, and slacken, or the scoria of former meltings, and run them together. The first melting produces a substance called leach; this leach they burn with charcoal, to make it lighter, to open its body, and render it porous, after which it is called rost; to this rost they add sand in such quantity as they find necessary, and then melt it over again.

At Chemnitz many other ways are practised of reducing gold out of its ore, but particularly one, in which they employ no lead to do, and which is the most curious and regular of all these processes. See ORES, Reduction of.

SLIDING RULE, a mathematical instrument, serving to work questions in gaging, measuring, &c. without...
out the use of compasses: merely by the sliding of the
parts of the instrument one by another, the lines and
divisions wherefore give the answer by inspection.

This instrument is variously contriv'd, and applied
by various authors, particularly Everard, Coggehall,
Gunter, Hunt, and Partridge; but the most common
and useful are those of Everard and Coggehall.

SLOGO, a county in the province of Connaught, Ire-
land, 31 miles in length, and 29 in breadth; bounded
on the east by that of Leitrim, on the west by the county
of Mayo, on the north and north-west by the western
ocean, and on the south and south-west by Roscommon
and Mayo. It contains 11,500 houses, 41 parishes,
62,000 inhabitants, and sends two members to parlia-
ment.

SLOGO, the only market town in the county, contains
8300 inhabitants, and enjoys a considerable trade, is
situated on a bay of the same name, 30 miles west of
Killala, and 110 north-east of Dublin. W. Long,

SLING, an instrument serving for casting stones with
great violence. The inhabitants of the Balkaric islands
were famous in antiquity for the dexterous manage-
ment of the sling; it is said they used three kinds of slings,
some longer, others shorter, which they used according
as their enemies were either nearer or more remote.
It is added, that the first served them for a head-band,
the second for a girdle, and that the third they constant-
ly carried in their hand.

SLINGING is used variously at sea; but chiefly for
hoisting up casks or other heavy things with slings, i.e.
contrivances of ropes spliced into themselves at either
end, with one eye big enough to receive the cask or
whatever is to be slung. There are other slings, which
are made longer, and with a small eye at each end;
one of which is put over the breech of a piece of ord-
nance, and the other eye comes over the end of an iron
crow, which is put into the mouth of the piece, to weigh
and hoist the gun as they please. There are also slings
by which the yards are bound fast to the cross-tree aloft,
and to the head of the mast, with a strong rope or chain,
that if the tie should happen to break, or to be shot to
pieces in fight, the yard, nevertheless, may not fall up-
on the hatches.

Slinging a Man overboard, in order to stop a leak
in a ship, is done thus: the man is truss'd up about the
middle in a piece of canvas, and a rope to keep him
from sinking, with his arms at liberty, a mallet in one
hand, and a plug, wrapped in oaken and well tarred in
a tarpowling cloath, in the other, which he is to beat
with all dispatch into the hole or leak.

SLOANE, Sir Hans, Baronet, eminently distin-
guished as a physician and a naturalist, was of Scotch
extraction, his father Alexander Sloane being at the
head of that colony of Scots which King James I. set-
tled in the north of Ireland, where our author was born,
at Killiecrankie, on the 19th of April 1665. At a very
early period, he displayed a strong inclination for natu-
ral history; and this propensity being encouraged by a
suitable education, he employed those hours which young
people generally lose by pursuing low and trifling amuse-
ments, in the study of nature, and contemplating her
works. When about sixteen, he was attacked by a spitt-
ing of blood, which threatened to be attended with
considerable danger, and which interrupted the regular
course of his application for three years; he had, how-
ever, already learned enough of physic to know that a
malady of this kind was not to be removed suddenly,
and he prudently abstained from wine and other liquors
that were likely to increase it.

By strictly observing this severe regimen, which in
some measure he continued ever after, he was enabled
to prolong his life beyond the ordinary bounds; being
an example of the truth of his own favourite maxim,
that sobriety, temperance, and moderation, are the best
and most powerful preservatives that nature has granted
to mankind.

As soon as he recovered from this infirmity, he re-
solved to perfect himself in the different branches of
physic, which was the profession he had made choice of;
and with this view he repaired to London, where he
hoped to receive that assistance which he could not find
in his own country.

On his arrival in the metropolis, he entered himself
as a pupil to the great Stafforth, an excellent chemist,
bred under the illustrious Stahl; and by his instructions
he gained a perfect knowledge of the composition and
preparation of the different kinds of medicines then in
use. At the same time, he studied botany at the cele-
brated garden at Chelsea, assiduously attended the pub-
lic lectures of anatomy and physic, and in short neglect-
ed nothing that he thought likely to prove serviceable
to him in his future practice. His principal merit,
however, was his knowledge of natural history; and it
was this part of his character which introduced him
early to the acquaintance of Mr Boyle and Mr Ray,
two of the most eminent naturalists of that age. His
intimacy with these distinguished characters continued
as long as they lived; and as he was careful to com-
municate to them every object of curiosity that at-
tracted his attention, the observations which he occasionally
made often excited their admiration and obtained their
applause.

After studying four years at London with unremit-
ting severity, Mr Sloane determined to visit foreign
countries for further improvement. In this view he
set out for France in the company of two other stu-
dents, and having crossed to Dieppe, proceeded to Paris.
In the way thither they were elegantly entertained by
the famous M. Lemery the elder; and in return Mr Sloane presented that eminent chemist with a specimen
of four different kinds of phosphorus, of which, upon the
credit of other writers, M. Lemery had treated in his
book of chemistry, though he had never seen any of
them.

At Paris Mr Sloane lived as he had done in London.
He attended the hospitals, heard the lectures of Tourn-
fort, De Verney, and other eminent masters; visited
all the literati, who received him with particular marks of
esteem, and employed himself wholly in study.

From Paris Mr Sloane went to Montpellier; and,
being furnished with letters of recommendation from
M. Tournfort to M. Chirac, then chancellor of that
university, he found easy access, through his means, to
all the learned men of the province, particularly to M.
Magnol, whom he always accompanied in his botanical
excursions in the environs of that city, where he beheld
with pleasure and admiration the spontaneous produc-
tions of nature, and learned under his instructions to
class them in a proper manner.

3 E 2

Having
Having here found an ample field for contemplation, which was entirely suited to his taste, he took leave of his two companions, whom a curiosity of a different kind led into Italy.

After spending a whole year in collecting plants, he travelled through Languedoc with the same design; and passing through Toulouse and Bordeaux, returned to Paris, where he made a short stay. About the end of the year 1684 he set out for England, with an intention of settling there as a physician. On his arrival in London, he made it his first business to visit his two illustrious friends Mr. Ray and Mr. Boyle, in order to communicate to them the discoveries he had made in his travels. The latter he found at home, but the former had retired to Essex; to which place Mr. Sloane transmitted a great variety of plants and seeds, which Mr. Ray has described in his History of Plants, and for which he makes a proper acknowledgement.

About the year 1706 our author became acquainted with the celebrated Sydneyham; who soon contracted so warm an affection for him that he took him into his house, and recommended him in the strongest manner to his patients. He had not been long in London before he was proposed by Dr. Martin Lister as a candidate to be admitted a member of the Royal Society, on the 26th of November 1684; and being approved, he was elected on the 21st of January following.

In 1687 he communicated some curiosities to the Society; and in July the same year he was a candidate for the office of their assistant secretary, but without success, as he was obliged to give way to the superior interest of his competitor Dr. Halley. On the 12th of April 1689, he was chosen a fellow of the college of physicians in London; and the same year his friend and fellow traveller Dr. Tancred Robinou, having mentioned to the Society the plant called the star of the earth, as a remedy newly discovered for the bite of a mad dog, Dr. Sloane acquainted them that this virtue of the plant was to be found in a book called Dr. Grey's Folly, and that he knew a man who had cured with twenty couple of doses. This observation he made on the 13th of July, and on the 12th of September following he embarked at Portsmouth for Jamaica with the duke of Albemarle, who had been appointed governor of that island. The doctor attended his grace in quality of physician, and arrived at Jamaica on the 19th of December following.

Here a new field was opened for fresh discoveries in natural productions; but the world would have been deprived of the fruits of them, had not our author, by incredible application, converted, as we may say, his minutes into hours. The duke of Albemarle died soon after he landed, and the duchess determined to return to England whenever an answer should be received to the letter she had sent to court on that melancholy occasion. As Dr. Sloane could not think of leaving her grace in her distress, whilst the rest of her retinue were preparing for their departure, he improved it in making collections of natural curiosities; so that, though his whole stay at Jamaica was not above fifteen months, he brought together such a prodigious number of plants, that on his return to England, Mr. Ray was astonished that one man could procure in one island, and in so short a space, so vast a variety.

On his arrival in London, he applied himself to the practice of his profession; and soon became so eminent, that he was chosen physician to Christ's hospital on the 17th October 1694; and this office he held till the year 1730, when, on account of his great age and infirmities, he found it necessary to resign. It is somewhat singular, and redounds much to the doctor's honour, that though he received the emoluments of his office punctually, because he would not lay down a precedent which might hurt his successors, yet he constantly applied the money to the relief of those who were the greatest objects of compassion in the hospital, that it might never be said he enriched himself by giving leath to the poor. He had been elected secretary to the Royal Society on the 30th of November 1693; and upon this occasion he re-ceived the publication of the Philosophical Transactions, which had been omitted for some time. He continued to be the editor of this work till the year 1712; and the volumes which appeared during that period are monuments of his industry and ingenuity, many of the pieces contained in them being written by himself.

In the mean time he published Catalogus Plantarum que in Insula Jamaica sponte procurrent, &c.; seu Prodromi Historiae Naturalis pars prima; which he dedicated to the Royal Society and College of Physicians. About the same time he formed the plan of a dispensary, where the poor might be furnished at prime cost with such medicines as their several maladies might require; which he afterwards carried into execution, with the assistance of the president and other members of the college of physicians.

Our author's thirst for natural knowledge seems to have been born with him, so that his cabinet of curiosities may be said to have commenced with his being. He was continually enriching and enlarging it; and the same which, in the course of a few years, it had acquired, brought every thing that was curious in art or nature to be first offered to him for purchase. These acquisitions, however, increased it but very slowly in comparison of the augmentation it received in 1701 by the death of Mr. Courten, Esq. a gentleman who had employed all his time in the greater part of his fortune, in collecting rarities, and who bequeathed the whole to Dr. Sloane, on condition of his paying certain debts and legacies with which he had charged it. These terms our author accepted, and he executed the will of the donor with the most scrupulous exactness, on which account some people have said, that he purchased Mr. Courten's curiosities at a dear rate.

In 1707 the first volume of Dr. Sloane's Natural History of Jamaica appeared in folio, though the publication of the second was delayed till 1725. By this very useful as well as magnificent work, the materia medica was enriched with a great number of excellent drugs not before known. In 1708 the Doctor was elected a foreign member of the Royal Academy of Sciences at Paris, in the room of Mr. Tschirnhaus; an honour so much the greater, as we were then at war with France, and the queen's express consent was necessary before he could accept it. In proportion as his credit rose among the learned, his practice increased among the people of rank: Queen Anne herself frequently consulted him, and in her last illness was blooded by him.

On the advancement of George I. to the throne, that prince, on the 3d of April 1716, created the Doctor a baronet, an hereditary title of honour to which...
Sloane [405]

The same time made him physician general to the army, in which station he continued till 1727, when he was appointed physician in ordinary to George II. He attended the royal family till his death; and was particularly favoured by Queen Caroline, who placed the greatest confidence in his prescriptions. In the mean time he had been unanimously chosen one of the electors of the college of physicians June 1, 1716, and he was elected president of the same body on September 30, 1719, an office which he held for sixteen years. During that period he not only gave the highest proofs of his zeal and assiduity in his discharge of his duty, but in 1721 made a present to that society of 1000; and so far remitted a very considerable debt, which the corporation owed him, as to accept it in such small sums as were least inconvenient to the state of their affairs. Sir Hans was no less liberal to other learned bodies. He had no sooner purchased the manor of Chelsea, than he gave the company of apothecaries the entire freedom of their botanical garden there, upon condition only that they should present yearly to the Royal Society fifty new plants, till the number should amount to 2000 (a). He gave besides several other considerable donations for the improvement of this garden; the situation of which, on the banks of the Thames, and in the neighbourhood of the capital, was such that to render it useful in two respects: First, by producing the most rare medicinal plants; and, secondly, by serving as an excellent school for young botanists; an advantage which he himself had derived from it in the early part of his life.

The death of Sir Isaac Newton, which happened in 1727, made way for the advancement of Sir Hans to the presidency of the Royal Society. He had been vice-president, and frequently sat in the chair for that great man; and by his long connection with this learned body he had contracted so strong an affection for it, that he made them a present of an hundred guineas, caused a curious bust of King Charles II. its founder, to be erected in the great hall where it met, and, as is said, was very instrumental in procuring Sir Godfrey Copley's benefaction of a medal of the value of five guineas, to be annually given as an honorary mark of distinction to the person who communicates the best experiments to the Society.

On his being raised to the chair, Sir Hans laid aside all thoughts of further promotion, and applied himself wholly to the faithful discharge of the duties of the offices which he enjoyed. In this laudable occupation he employed his time from 1727 to 1740, when, at the age of fourscore, he formed a resolution of quitting the service of the public, and of living for himself. With this view he resigned the presidency of the Royal Society much against the inclination of that respectable body, who chose Martin Folkes, Esq. to succeed him, and in a public assembly thanked him for the great and eminent services he had rendered them. In the month of January 1741, he began to remove his library, and his cabinet of rarities, from his house in Bloomsbury to that at Chelsea; and on the 12th of March following, having settled all his affairs, he retired thither himself, to enjoy in peaceful tranquillity the remains of a well spent life. He did not, however, bury himself in that solitude which excludes men from society. He received in Chelsea, as he had done in London, the visits of people of distinction, of all learned foreigners, and of the royal family, who sometimes did him the honour to wait on him; but what was still more to his praise, he never refused admission or advice to rich or poor who came to consult him concerning their health. Not contented with this contracted method of doing good, he now, during his retirement, presented to the public such useful remedies as success had warranted, during the course of a long continued practice. Among these is the efficacious receipt for distempers in the eyes, and his remedy for the bite of a mad dog.

During the whole course of his life, Sir Hans had lived with so much temperance, as had preserved him from feeling the infirmities of old age; but in his 90th year he began to complain of pains, and to be sensible of an universal decay. He was often heard to say, that the approach of death brought no terrors along with it; that he had long expected the stroke; and that he was prepared to receive it whenever the great Author of his being should think fit. After a short illness of three days, he died on the 11th of January 1752, and was interred on the 18th at Chelsea, in the same vault with his lady, the solemnity being attended with the greatest concourse of people, of all ranks and conditions, that had ever been seen before on the like occasion.

Sir Hans being extremely solicitous lest his cabinet of curiosities, which he had taken so much pains to collect, should be again dissipated at his death, and being at the same time unwilling that so large a portion of his fortune should be lost to his children, he bequeathed it to the public, on condition that 20,000l. should be made good by parliament to his family. This sum, though large in appearance, was scarcely more than the intrinsic value of the gold and silver medals, the ores and precious stones that were found in it; for in his last will he declares, that the first cost of the whole amounted at least to 50,000l. Besides his library, consist

Sloane

sitting of more than 30,000 volumes, 347 of which were illustrated with cuts finely engraved and coloured from nature, there were 3560 manuscripts, and an infinite number of rare and curious works of every kind. The parliament accepted the legacy, and fulfilled the conditions.

SLOANEA, a genus of plants belonging to the class of polyandria, and order of monogyria; and in the natural system ranging under the 50th order, Amaranthaceae. See Botany Index.

SLOOE. See Fraxinus, Botany Index.

SLOOP, a small vessel furnished with one mast, the mainmast of which is attached to a gaff above, or to the mast on its foremost edge, and to a long boom below, by which it is occasionally shifted to either quarter. See Ship.

Sloop of War, a name given to the smallest vessels of war except cutters. They are either rigged as ships or sloops.

SLOT, in the sportsman's language, a term used to express the mark of the foot of a stag or other animal proper for the chase in the clay or earth, by which they are able to guess when the animal passed, and which way he went. The slot, or treading of the stag, is very nicely studied on this occasion; if the slot be large, deep printed in the ground, and with an open cleft, and, added to these marks, there is a large space between mark and mark, it is certain that the stag is an old one. If there be observed the slots or treadings of two, the one long and the other short, and both of one size, the long slot is always that of the larger animal. There is also another way of knowing the old ones from the young ones by the treading; which is, that the hinder feet of the old ones never reach to their fore feet, whereas those of the young ones do.

SLOTH. See Bradypus, Mammalia Index.

SLOUGH, a deep muddy place. The cast skin of a snake, the damp of a coal-pit, and the scar of a wound, are also called by the same appellation. The slough of a wild boar is the bed, soil, or mire, wherein he wallows, or in which he lies in the day-time.

SLUCZK, a large and populous town in Russian Poland, in Lithuania, and formerly capital of a duchy of the same name; famous for three battles gained here by Constantine duke of Ostrog over the Tartars, in the reign of Sigismund I. It is seated on the river Slucz, 72 miles south-east of Minski, and 70 south of Novogrodek. E. Long. 27° 44', N. Lat. 53° 2'.

SLUG. See Limax, Helminthology Index.

SLUICE, a frame of timber, stone, or other matter, serving to retain and raise the water of a river, &c. and on occasion to let it pass.

Such is the sluice of a mill, which stops and collects the water of a rivulet, &c. to let it fall at length in the greater plenty upon the mill-wheel; such also are those used as vents or drains to discharge water off land. And such are the sluices of Flanders, &c. which serve to prevent the waters of the sea from overflowing the lower lands.

Sometimes there is a kind of canal included between two gates or sluices, in artificial navigations, to save the water, and render the passage of boats equally easy and safe, upwards and downwards; as in the sluices of Briere in France, which are a kind of massive walls built parallel to each other, at the distance of 20 or 24 feet, closed with strong gates at each end, between which is a kind of canal or chamber, considerably longer than broad; wherein a vessel being inclosed, the water is let out at the first gate, by which the vessel is raised 15 or 16 feet, and passed out of this canal into another much higher. By such means a boat is conveyed out of the Loire into the Seine, though the ground between them rise above 150 feet higher than either of those rivers. * See Can.

Sluices are made different ways, according to the use for which they are intended: when they serve for navigation, they are shut with two gates, presenting an angle towards the stream; when they are made near the sea, two pair of gates are made, the one to keep the water out and the other in, as occasion requires; in this case, the gates towards the sea present an angle that way, and the others the contrary way; and the space inclosed by those gates is called the chamber. When sluices are made in the ditches of a fortress, to keep up the water in some parts instead of gates, shutters are made so as to slide up and down in grooves; and when they are made to raise an inundation, they are then shut by means of square timbers let down in culsâs, so as to lie close and firm.

The word sluice is formed of the French exclauze, which Menage derives from the Latin exclauze, found in the Salic law in the same sense. But this is to be restrained to the sluices of mills, &c. for as to those serving to raise vessels, they were wholly unknown to the ancients.

SLUR, in Music, a mark like the arch of a circle, drawn from one note to another, comprehending two or more notes in the same or different degrees. If the notes are in different degrees, it signifies that they are all to be sung to one syllable; for wind instruments, that they are to be made in one continued breath; and for stringed instruments, that are struck with a bow, as a violin, &c. that they are made with one stroke. If the notes are in the same degree, it signifies that it is all one note, to be made as long as the whole notes are connected; and this happens most frequently between the last note of one line and the first of the next; which is particularly called syncope.

SLUYS, a town of Dutch Flanders, opposite the island of Cadzand, with a good harbour, 10 miles north of Bruges, containing 14,000 inhabitants. E. Long. 3° 25', N. Lat. 51° 19'.

SMACK, a small vessel, commonly rigged as a sloop or hoy, used in the coasting or fishing trade, or as a tender in the king's service.

SMALAND, or CALMAR, a province in the south of Sweden, which makes part of Gotland. It is about 112 miles in length, and 62 in breadth, and contains about 4200 square miles. In 1828 it contained 66,121 townships or about 83,000 acres of arable land, and 136,296 inhabitants. Calmar is the capital town.

SMALKALD, a town of Germany, in Franconia, and in the county of Henneberg; famous for the confederacy entered into by the German Protestants against the emperor, commonly called the league of Smalkald. The design of it was to defend their religion and liberties. It is seated on the river Werra, 25 miles southwest of Erford, and 50 north-west of Bamberg. E. Long. 10° 53', N. Lat. 50° 49'. It is subject to the prince of Hesse-Cassel.

SMALLAGE. See Aphyum, Botany Index.
SMALT, a kind of glass of a dark blue colour, which when levigated appears of a most beautiful colour; and if it could be made sufficiently fine, would be an excellent succedaneum for ultramarine, as not only resisting all kinds of weather, but even the most violent fire. It is prepared by melting one part of calcined cobalt with two of flint powder, and one of potash. At the bottoms of the crucibles in which the smalt is manufactured, we generally find a regulus of a whitish colour inclined to red, and extremely brittle. This is melted aresh, and when cold separates into two parts; that at the bottom is the cobaltic regulus, which is employed to make more of the smalt; the other is bismuth.

SMARAGDITE, a species of mineral belonging to the magnesian genus. See Mineralogy, p. 197.

SMARAGDUS, an old name for the emerald. See Emerald, Mineralogy, p. 159.

SMEATON, John, an eminent civil engineer, was born the 28th of May 1724, O. S. at Austhorpe, near Leeds, in a house built by his grandfather, and where his family have resided ever since.

The strength of his understanding and the originality of his genius appeared at an early age; his playthings were not the playthings of children, but the tools which men employ; and he appeared to have greater entertainment in seeing the men in the neighbourhood work, and asking them questions, than in any thing else. One day he was seen (to the distress of his family) on the top of his father's barn, fixing up something like a windmill; another time, he attended some men fixing a pump at a neighbouring village, and observing them cut off a piece of bored pipe, he was so lucky as to procure it, and he actually made with it a working pump that raised water. These anecdotes refer to circumstances that happened while he was in petiocts, and most likely before he attained his sixth year.

About his 14th and 15th year, he made for himself an engine for turning, and made several presents to his friends of boxes in ivory or wood very neatly turned. He forged his iron and steel, and melted his metal; he had tools of every sort for working in wood, ivory, and metals. He made a lathe, by which he cut a perpetual screw in brass, a thing little known at that day, which was the invention of Mr Henry Hindley of York; with whom Mr Smeaton soon became acquainted, and they spent many a night at Mr Hindley's house till day-light, conversing on those subjects.

Thus had Mr Smeaton, by the strength of his genius and indefatigable industry, acquired, at the age of 18, an extensive set of tools, and the art of working in most of the mechanical trades, without the assistance of any master. A part of every day was generally occupied in forming some ingenious piece of mechanism.

Mr Smeaton's father was an attorney, and desirous of bringing him up to the same profession; Mr Smeaton therefore came up to London in 1742, and attended the courts in Westminster hall; but finding (as his common expression was) that the law did not suit the bent of his genius, he wrote a strong memorial to his father on that subject; whose good sense from that moment left Mr Smeaton to pursue the bent of his genius in his own way.

In 1751, he began a course of experiments to try a machine of his invention to measure a ship's way at sea. Smeaton, and also made two voyages in company with Dr Knight to try it, and a compass of his own invention and making, which was made magnetical by Dr Knight's artificial magnets: the second voyage was made in the Fortune sloop of war, commanded at that time by Captain Alexander Campbell.

In 1753 he was elected member of the Royal Society; the number of papers published in their Transactions will show the universality of his genius and knowledge. In 1759 he was honoured by an unanimous vote with their gold medal for his paper intitled "An Experimental Inquiry concerning the Natural Powers of Water and Wind to turn Mills, and other Machines depending on a Circular Motion."

This paper, he says, was the result of experiments on working models in the years 1752 and 1753, but not communicated to the Society till 1759; before which time he had an opportunity of putting the effect of these experiments into real practice, in a variety of cases, and for various purposes, so as to assure the Society he had found them to answer.

In December 1755, the Eddystone lighthouse was burnt down: Mr Weston, the chief proprietor, and the others, being desirous of rebuilding it in the most substantial manner, inquired of the earl of Macclesfield (then president of the Royal Society) whom he thought the most proper to rebuild it; his lordship recommended Mr Smeaton.

Mr Smeaton undertook the work, and completed it in the summer of 1759. Of the preparation for this extraordinary work, of its commencement and progress, Mr Smeaton has given an ample and interesting description in a splendid folio volume which was first published in 1791. The same volume contains the history of the different buildings which have been erected on the Eddystone rock. See EDDYSTONE.

Though Mr Smeaton completed the building of the Eddystone lighthouse in 1759 (a work that does him much credit) yet it appears he did not soon get into full business as a civil engineer, but in 1764, while in Yorkshire, he offered himself a candidate for one of the receivers of the Derwentwater estate, and on the 31st of December in that year, he was appointed at a full board of Greenwich hospital, in a manner highly flattering to himself, when two other persons strongly recommended and powerfully supported were candidates for the employment. In this appointment he was very happy, by the assistance and abilities of his partner Mr Walton one of the receivers, who taking upon himself the management and accounts, left Mr Smeaton leisure and opportunity to exert his abilities on public works, as well as to make many improvements in the mills and in the estates of Greenwich hospital. By the year 1775 he had so much business as a civil engineer, that he wished to resign this appointment; and would have done it then, had not his friend the late Mr Stuart the hospital surveyor, and Mr Ibbetson their secretary, prevailed upon him to continue in the office about two years longer.

Mr Smeaton having now got into full business as a civil engineer, performed many works of general utility. He made the river Calder navigable; a work that required great skill and judgment, owing to the very impetuous floods in that river: He planned and attended
tended the execution of the great canal in Scotland for conveying the trade of the country either to the Atlantic or German ocean; and having brought it to the place originally intended, he declined a handsome yearly salary, in order that he might attend to the multiplicity of his other business.

On the opening of the great arch at London bridge, the excavation around and under the stonings was so considerable, that the bridge was thought to be in great danger of falling. He was then in Yorkshire, and was sent for by express, and arrived with the utmost dispatch: "I think (says Mr. Holmes, the author of his life) it was on a Saturday morning, when the apprehension of the bridge falling was so general that few would pass over or under it. He applied himself immediately to examine it, and to sound about the stonings as minutely as he could; and the committee being called together, adopted his advice, which was to repair the stones that had been taken from the middle pier, then lying in Moorfields, and to throw them into the river to guard the stonings." Nothing shows the apprehensions concerning the falling of the bridge more than the alacrity with which this advice was pursued; the stonings were repurchased that day, horses, carts, and barges were got ready, and they began the work on Sunday morning. Thus Mr. Smeaton, in all human probability, saved London bridge from falling, and secured it till more effectual methods could be taken.

The vast variety of mills which Mr. Smeaton constructed, so greatly to the satisfaction and advantage of the owners, will show the great use which he made of his experiments in 1752 and 1753; for he never trusted to theory in any case where he could have an opportunity to investigate it by experiment. He built a steam engine at Austhorpe, and made experiments thereon, purposely to ascertain the power of Newcomen's steam-engine, which he improved and brought to a greater degree of perfection, both in its construction and powers, than it was before.

Mr. Smeaton during many years of his life was a frequent attendant on parliament, his opinion being continually called for; and here his strength of judgment and perspicacity of expression had its full display: it was his constant custom, when applied to, to plan or support any measure, to make himself fully acquainted with it, to see its merits before he would engage in it: by this caution, added to the clearness of his expression and the integrity of his heart, he seldom failed to obtain for the bill which he supported an act of parliament. No one was heard with more attention, nor had any one ever more confidence placed in his testimony. In the courts of law he had several compliments paid him from the bench by Lord Mansfield and others, for the new light which he threw on difficult subjects.

About the year 1785 Mr. Smeaton's health began to decline; and he then took the resolution to endeavour to avoid all the business he could, so that he might have leisure to publish an account of his inventions and works, which was certainly the first wish of his heart; for he has often been heard to say, that he thought he could work harder and longer, for the benefit of his country, in his present state. He got only his account of the Edystone lighthouse completed, and some preparations to his intended Treatise on Mills; for he could not resist the solicitations of his friends in various works: and Mr. Aubert, whom he greatly loved and respected, being chosen chairman of Hammersmith harbour, prevailed upon him to accept the place of engineer to that harbour; and to their joint efforts the public is chiefly indebted for the improvements that have been made there within these few years, which fully appears in a report that Mr. Smeaton gave in to the board of trustees in 1791, which they immediately published.

Mr. Smeaton being at Austhorpe, walking in his garden on the 16th of September 1792, was struck with the palsy, and died the 28th of October. "In his illness (says Mr. Holmes) I had several letters from him, signed with his name, but written and signed by another's pen; the diction of them showed that the strength of his mind had not left him. In one written the 26th of September, after minutely describing his health and feelings, he says, "in consequence of the foregoing, I conclude myself nine-tenths dead; and the greatest favour the Almighty can do me (as I think), will be to complete the other part; but as it is likely to be a lingering illness, it is only in His power to say when that is likely to happen."

Mr. Smeaton had a warmth of expression that might appear to those who did not know him well to border on harshness; but those more intimately acquainted with him, knew it arose from the intense application of his mind, which was always in the pursuit of truth, or engaged in investigating difficult subjects. He would sometimes break out hastily, when any thing was said that did not tally with his ideas; and he would not give up any thing he argued for, till his mind was convinced by sound reasoning.

In all the social duties of life he was exemplary: he was a most affectionate husband, a good father, a warm, zealous, and sincere friend, always ready to assist those whom he respected, and often before it was pointed out to him in what way he could serve them. He was a lover and encourager of merit wherever he found it; and many men are in a great measure indebted to his assistance and advice for their present situation. As a companion, he was always entertaining and instructive; and none could spend any time in his company without improvement.

SMELL; this word has in most languages two meanings, signifying either that sensation of mind of which we are conscious, in consequence of certain impressions made on the nostrils, and conveyed to the brain by the olfactory nerves; or that unknown virtue, or quality in bodies, which is the cause of our sensations of smell.

SMELLING is the act by which we perceive smells, or become sensible of the presence of odorous bodies. The sensations of smell are excited by certain effluvia, which, in the open air, are always issuing from the surfaces of most bodies, and striking on the extremities of the olfactory nerves, give them a peculiar sort of impression, which is communicated to the brain. The particles which issue thus from bodies are extremely volatile, and produce sensation by a degree of contact, which, though insensible, is still more efficacious than if it were more gross and palpable. It is by a similar species of insensible contact that the eye and ears are affected by external objects; whilst, in the excitation of the sensations of touch and of taste, an actual and sensible contact of the object with the organ is neces-
The organs of smelling are the nostrils and olfactory nerves; the minute ramifications of the latter being distributed throughout the whole concavity of the former. For a description of these, see Anatomy.

The effluvia from odorous bodies are constantly floating about in the atmosphere, and must of course be drawn into the nostrils along with the air in inspiration; "so that there is," as Dr. Reid observes, "a manifest appearance of design in placing the organ of smell in the inside of that canal, through which the air is continually passing in inspiration and expiration." It has been affirmed by Boerhaave, that the matter in animals, vegetables, fossils, &c. which chiefly affects the sense of smelling, is that attenuated substance, inherent in their oily parts, called spirits; because, when this is taken away from the most fragrant bodies, what remains has scarcely any smell at all; but this, he says, if poured on the most inodorous bodies, gives them a fragrance*. We cannot, however, enter at present upon this inquiry. The sense of smell has a close alliance with that of taste; and it seems probable from the proximity in the situation of their organs in all animals, that both are principally intended to guide them in the choice of their food; so that from this close connection, they are better enabled to choose what is good for them, and to reject what would be injurious. This is the opinion of Dr. Reid, as it was, in a very early period of the history of philosophy, that of Socrates and of Cicero (a). Dr. Reid also remarks, that the sense of smell probably serves the same purpose in the natural state of man; but it is not always a sure guide for this purpose. The organs of smell differ, like those of the other senses, according to the destination of the animals to which they belong; and we know, that this sense is in man much less acute, than it is in many other animals. We see, that in the choice of their food, they are guided by the senses of smell and of taste, except when man has brought them into a sort of unnatural state by domestication. And this circumstance renders it probable, that both these senses were intended to serve the same purpose in the natural state of our species, although less calculated for this end than they were in the brutes, on account of the great superiority of their smelling organs. Besides, since it is probable that man, in the natural state, acts more by instinct than when civilized in society, so also it is reasonable to think, that he may possess some of the senses, (this of smell for instance), in greater acuteness than we do. This indeed we are assured to be a fact; for we are told in the Histoire des Antilles, that there are negroes who, by the smell alone, can distinguish the footsteps of a Frenchman from those of a negro.

The sense of smell is much more obtuse in man than in some of the lower animals. Dogs we know possess a power of smelling, of which we can scarcely form a conception, and which, it is happy for us we do not possess (b); and birds of prey are said to possess this sense in still greater acuteness. But although this be more perfect, still the sense of smelling in man, who has other means of judging of his food, &c. is such as to fit him for deriving enjoyment from a diversity of scents, particularly those of flowers and perfumes, to which dogs and other animals seem perfectly insensible. It has been said, we are aware, that some animals, the elephant for instance, are capable of this enjoyment (c); but of this fact we cannot help being very doubtful.

There is a very great sympathy between the organs of smell and of taste; for any defect or disease of one is generally attended with some corresponding defect or disease of the other. There is also a greater similarity between the sensations of both these, than between those of any other two senses: and hence it is, that we can sometime tell the taste of an object from its smell, and vice versa. Hence also the reason why we apply the same epithets to the names of both these classes of sensations; as a sweet smell or taste, &c.

It deserves also to be remarked, that both these senses seem subservient to the preservation of the animal existence, rather than to any other purpose. They accordingly constitute an object of the natural history of man, rather than of intellectual or of moral philosophy. The other three senses, on the contrary, seem rather intended for (as they certainly are essential to) our intellectual improvement, and become, of course, a proper object of investigation in the sciences of moral philosophy, or metaphysics.

The advantages derived by man and the other animals from the sense of smelling are not confined to the assistance which it affords them in the choice of their food. Most bodies in nature, when exposed to the open air, are constantly sending forth emanations or effluvia of such extreme minuteness as to be perfectly invisible. These diffuse themselves through the air, and however noxious or salutary, would not be perceived without the sense of smelling, which if not vitiated by unnatural habits, is not only a faithful monitor when danger is at hand, but conveys to us likewise the most exquisite pleasures.

---

(a) "Ut gustus (says a learned physiologist) cibi itineri, sic olfactus ostio viarum, quas aër subire debet, custos praedonitum, monitorus ne quid noccti, viaque semper patet, in corpus admitatur. Porro, ut gustus, sic quoque olfactus ad salutarem eibum invitat, a noxio aut corrupto, putrido imprimit vel rancido, deterret."

("When thou seest the mouth, through which animals take in whatever they desire, always placed near the nose and eyes, thinkst thou not, says Socrates to Aristodemus, that this is the work of a providence." Xenophon's Memorabilia, book i. chap. 4.

(b) "The excessive eagerness which dogs express on smelling their game, seems to be but little connected with the appetite for food, and wholly independent of any preconceived ideas of the objects of their pursuit being fit for it. Hence several kinds of them will not eat the game which they pursue with such wild impetuousity, and of which the scent seems to animate them to a degree of ecstasy far beyond what the desire of food can produce." Knight on Taste.

(c) There is an animal to which, naturalists say, perfume is so agreeable and so necessary, that nature has provided it with a little bag stored with an exquisite odour. "On pretend, (says Buffon), que la mangouste ouvre cette poche, pour se refaichir lorrq' elle a trop chaud."
pleasures. The fragrance of a rose, and of many other flowers, is not only pleasant, but gives a refreshing and delightful stimulus to the whole system, whilst the odours proceeding from hemlock, or any noxious vegetable, or other substance, are highly offensive to our nostrils. Hence we are naturally led to seek the one class of sensations, and to avoid the other.

In some species of animals the sense of smell seems to be connected with certain mental sympathies, as those of hearing and sight are in all that possess them in any high degree: for not only their sexual desires appear to be excited by means of it, but other instinctive passions, which, according to the usual system of nature, should be still more remote from its influence. Dogs, although wholly unacquainted with lions, will shudder at their roar; and an elephant that has never seen a tiger, will in the same manner show the strongest symptoms of horror and affright at the smell of it. "The late Lord Clive (says an ingenious writer), exhibited a combat between two of these animals at Calcutta; but the scent of the tiger had such an effect upon the elephant, that nothing could either force or allure him to go along the road, where the cage in which the tiger was inclosed, had passed, until a gallon of arrack was given him. Upon this, his horror suddenly turning into fury, he broke down the paling to get at his enemy, and killed him without difficulty."

If riding along a road, near which a dead horse, or part of its carcass, happens to be lying, we know, that our horse, although he sees it not, cannot be made to pass the place but with difficulty. Where blood has been shed, particularly that of their own species, oxen will assemble, and upon smelling it, roar and bellow, and show the most manifest signs of horror and distress. And yet these symptoms could not arise from any associated notions of danger or death, since they appear in such as never had any opportunities of acquiring them. They must therefore be instinctive, like other instinctive antipathies and propensities. But although in their mutual intercourse, animals make much use of the sense of smell, still it does not seem to be further concerned in exciting their sexual desires, than in indicating their object.

Some of those splenetic philosophers, who are ready upon all occasions to quarrel with the constitution of nature, have taken the liberty of condemning their Maker, because it has pleased his unfathomable wisdom to bestow in some instances upon the brutes senses and instincts more perfect than he has given to man, without reflecting that he has given to man an ample equivalent; for it may be asked with the poet,

"Is not his reason all these powers in one?"
"Is Heaven unkind to man and man alone?"
"Shall be alone, whom rational we call,"
"Be pleased with nothing if not blessed with all."

With respect to that unknown peculiarity of bodies, which is the cause of our sensations of smell, the opinions of philosophers have been very various. Until of late, the doctrine of Descartes and Locke on this subject was pretty generally received; but, since the publication of Doctor Reid’s works, his opinion, which we deem the most correct and satisfactory, has become very popular. We will endeavour to abridge his account of this matter. For this purpose, let us suppose a person, who has grown up without the sense of smell, to be immediately endowed with the use of this organ, and placed near some flowers of an exquisite savour. When he examines what he feels in such a situation, he can find no resemblance between this new sensation, and any thing with which he is already acquainted. He finds himself unable to explain its nature, and cannot ascribe to it figure, extension, or any known property of matter. It is a simple affection, or feeling of mind, and, considered abstractedly, can have no necessary connection with the nerves, the nostrils, or effluvia, or with any thing material whatever. By the nature of his constitution he is, however, led to refer this peculiar sensation to the nostrils, as its organ; and when, from experience, and by means of touch, he learns that external objects have the power of exciting this sensation, he concludes, that there must exist in bodies some unknown cause by which it is excited. In the first part of this process he considers the feeling, or sensation, abstractedly. As such it exists in the mind only; and cannot exist there but when the mind is conscious of it. His consciousness soon enables him to distinguish different sorts of smells, all of them very distinct from one another, but, conformably to the nature of all sensation, extremely simple. He concludes, that each of these must have a distinct cause; and finding, by experience, that this cause is an unknown something in bodies, he concludes, that it must be a property of matter, and, for want of another, gives it the name of smell. When he removes an odorous body from the organ, the sensation vanishes: when the body is again applied, the sensation is excited: and hence it is, that he is led naturally to connect the sensation with this unknown peculiarity of bodies by which it is produced. But since we see, that the sensation is, in a great degree, related to other objects besides its unknown cause, to the mind in which it exists, for instance, and to the organ which is its instrument, it may be asked why it becomes associated in the mind with its cause only? The reason seems pretty obvious. No single sensation or class of sensations, is more connected with the mind, than any others of which it is susceptible. Nor is the connection subsisting between the organ and any of the sensations peculiar to it greater than that which subsists between it and every other sensation of which it is the inlet. Hence the connection between the smell of an orange and the mind, or between it and the nostrils, is very general, and cannot, in the former instance, distinguish it from any other sensation of whatever kind, nor, in the latter from any other particular smell. But the connexion between this sensation and the orange is peculiar and permanent; and we accordingly find them always associated in the mind, just as we associate the notion of fire with the sensation of burning. The relation which a sensation of smell, or any sensation, bears to the mind, to an organ, or to the memory and conception of itself, is common to all sensations. The relation which any sensation bears to its own cause, suppose of the sensation of smell to a particular virtue or quality of bodies, is common to it with every other sensation, when considered with respect to its peculiar cause. And finally, a sensation of any kind bears the same sort of relation to the memory and conception of itself, that any other feeling or operation of mind bears to the conception and memory of that particular feeling or operation.

Whatever then be the nature of the minute particles of
Smelling of bodies by which our sensations of smell are excited, we cannot help considering their unknown cause as a virtue or quality of matter. Like all other modifications of material substance, it must be confessed, that this can have no resemblance to the sensations of mind. But we are not therefore, to conclude with the followers of Des Cartes and Locke, that this secondary quality is a mere sensation; especially as we can readily conceive it existing where it is not smelled, or even after supposing the annihilation of every sentient being throughout the universe. The existence of the sensation we know to be momentary and fugitive; but in the existence of its cause we can, without difficulty, or inconsistency, conceive a permanency independent of mind and of its sensations.

The doctrine we have been illustrating has of late been called in question by a sceptical writer, who, it appears to us, has upon this occasion been entirely deficient in his accustomed acuteness. Dr Reid's account of this affair seems so full, so clear and convincing, that we are at a loss to conceive how his meaning can be misunderstood; and yet the arguments and objections of the writer to whom we allude, derive all their plausibility from a misinterpretation of Dr Reid's meaning, and from a deviation from the established use of language. "An eminent metaphysician* (says this author) has declared that he has not the least difficulty in conceiving the air perfumed with aromatic odours in the deserts of Arabia; and he has decided, that the man who maintains smells to exist only in the mind, must be mad, or must abuse language and disgrace philosophy. There are some authors, nevertheless, who differ widely on this subject from the learned metaphysician. Is it possible for a sensation to exist where there is no sentient? The authors to whom I allude think it impossible." And so, we may tell this learned author, does Dr Reid, if he will take his word for it. Of the sensation of smell he remarks: "It is indeed impossible, that it can be in any body: it is a sensation; and a sensation can be in a sentient thing only." Again: "I can think of the smell of a rose when I do not smell it; and it is possible that when I think of it there is no rose anywhere existing; but, when I smell it, I am necessarily determined to believe that the sensation really exists. This is common to all sensations, that, as they cannot exist but in being perceived, so they cannot be perceived but they must exist." But continues this acute metaphysician, "a smell is nothing else than a sensation. It is a feeling, which may be agreeable or disagreeable; which may, as some think, be excited by various combinations of elements; but which, since it is a feeling, cannot be those elements which are said to cause it, and cannot exist where there is no creature to perceive it. What is to be understood, in philosophical strictness, by the perfumes of the desert? We can excuse the poet when he makes the ocean smile, the winds dance, and the flowers expire; or even were he to perfume the desert. But the philosopher is no such magician, and had better not wander through the regions of fancy in search of sensations where there is no sentient. And is it then true that the word smell means only a sensation? A sensation is no more than an effect; it is a transient modification of the mind, which the mind itself can never produce. It must then have some cause which is external to the mind. Now, it is to this cause, and not to the sensation, that the name smell is most frequently applied in all languages; and it is this cause which Dr Reid supposes capable of existing in the deserts of Arabia, where there is no sentient being to perceive it. But let us hear himself: "We have considered smell as signifying a sensation, feeling, or impression upon the mind; and in this sense it can only be in a mind or sentient being; but it is evident that mankind give the name of smell much more frequently to something which they conceive to be external, and to a quality of body; they understand by it something which does not at all infer a mind, and have not the least difficulty in conceiving the air perfumed with aromatic odours in the deserts of Arabia, or some uninhabited island where the human foot never trod." The faculty of smelling is something very different from the actual sensation of smelling; for the faculty may remain when we have no sensation. And the mind is no less different from the faculty, for it continues the same individual being when the faculty is lost. What is smell in the rose? It is a quality or virtue of the rose, or of something proceeding from it, which we perceive by the sense of smelling; and this is all we know of the matter. But what is smelling? It is an act of the mind, but is never imagined to be a quality of the mind. Again, the sensation of smelling is conceived to infer necessarily a mind or sentient being; but smell in the rose infers no such thing. We say, this body smells sweet and that stinks; but we do not say, this mind smells sweet and that stinks; therefore, smell in the rose, and the sensation which it causes, are not conceived, even by the vulgar, to be things of the same kind, although they have the same name." There are some other remarks on Dr Reid's opinion in the work upon which we have been commenting, which we shall pass by; we may, however, notice the author's concluding argument: after mentioning some examples, he observes, "Now in these instances we see men and animals that must have perception of smell, if I may be permitted to say so, altogether different from each other. Is not smell sensation when the spaniel finds sport in the field for his master; when the shark pursues through the ocean its expected victim; and when the camel conducts the thirsty wanderer to a fountain of fresh water across the burning sands of the Arabian desert? If no animal had the sensation of smell, there would be no odour; for aroma and oils may be thought to be material compositions, but are neither agreeable nor disagreeable feelings." If men and animals differ in their perceptions of smell, (and no doubt, difference of organization will cause them to do so) the conclusion should not be, we think, that smell is merely sensation, but that there is actually something external which is the cause of their sensations, and about which they differ.

A rose put to the nostrils of a man and then to those of a dog, may excite very different sensations; but we cannot think that the peculiarity of the rose, which excites those different sensations, varies by thus changing the position of the rose. If at table one person mistakes mutton for beef, and another thinks that it is venison, the conclusion may be, that it is neither venison nor beef; but no man in his senses can conclude that there is no meat at the table. But, "is not smell sensation when the spaniel finds sport for his master in the field?" There is sensation with no doubt; but we may be permitted to ask, what would become of the spaniel's sensation of smell and of his master's sport, were there no game in the

the field? What of the shark's sensation of smell and pursuit, were there no victim in the ocean? and what of the camel and the thirsty wanderer, were there no fountain of fresh water in the Arabian deserts? "The smell of a rose signifies two things, says Dr. Reid; First, a sensation which can have no existence but when it is perceived, and can only be in a sentient being or mind. Secondly, it signifies some power, quality, or virtue, in the rose, or in effluvia proceeding from it, which hath a permanent existence independent of the mind; and which, by the constitution of nature, produces the sensation in us. By the original constitution of our nature we are both led to believe that there is a permanent cause of the sensation, and prompted to seek after it; and experience determines us to place it in the rose. The names of all smells, tastes, sounds, as well as heat and cold, have a like ambiguity in all languages; but it deserves our attention, that these names are but rarely, in common language, used to signify the sensations; for the most part, they signify the external qualities which are indicated by the sensations*. We have been induced thus to discuss this topic at some length, because we regretted to see Dr. Reid's opinion and reasoning misrepresented; and we shall now conclude, as this modern Berkleian does, "that, if no animal had the sensation of smell, there would be no odour;" but, if that there were no odour or external cause of smell, no animal would have this sensation.

The sense of smell becomes sometimes too acute, either in consequence of some defect or disease of the organ, or from too great a sensibility of the whole nervous system, such as we sometimes observe in fevers, in phrenitis, and in hysterical diseases. It is however more frequently blunted in consequence of affections of the brain and nerves, arising from blows on the head, or from internal causes; or this may happen on account of too great a dryness of the organ, owing to a suppression of the accustomed humours, or to their being conveyed off by some other channel; or it may arise from too great a quantity of tears and of mucus choking up the nostrils. We have instances of both in cases of common cold, in which, at the beginning of the disease, the nostrils are dry, but as it advances, begin to discharge a great deal of humour, or become obstructed by a thick mucus. Whatever hinders the free entrance of the air into the nostrils or its passage through them, must also injure the sense of smell. It is also sometimes so depraved as to perceive smells when there is no odorous body present, or to perceive smells different from those that are really present. Some of the particles of the odorous effluvia, after having remained for some time in the caverns of the nostrils, issuing forth again and affecting the organ, will sometimes cause this species of false perception, even in the most healthy persons.

The sense of smelling may be diminished or destroyed by diseases; as by the moisture, dryness, inflammation, or suppuration of the olfactory membrane, the compression of the nerves which supply it, or some fault in the brain itself at their origin. A defect, or too great a degree of solidity of the small spongy bones of the upper jaw, the caverns of the forehead, &c. may likewise impair this sense; and it may be also injured by a collection of blood matter in these caverns, which is continually exuding from them, and also by immediate use of snuff. When the nose aboundeth with moisture, after gentle evacuations, such things as tend to take off irritation and conglute the thin sharp serum may be applied; as the oil of anise mixed with fine flour, camphor dissolved in oil of almonds, &c. the vapours of amber, frankincense, gum-mastic, and benjamin, may likewise be received into the nose and mouth. For moistening the mucus when it is too dry, some recommend snuff made of the leaves of marjoram, mixed with oil of amber, marjoram, and aniseed; or a sterntutory of calcined white vitriol, twelve grains of which may be mixed with two ounces of marjoram water and filtrated. The steam of vinegar upon hot iron, and received up the nostrils, is also of use for softening the mucus, removing obstructions, &c. If there be an ulcer in the nose, it ought to be dressed with some emollient ointment, to which, if the pain be very great, a little laudanum may be added. If it be a venereal ulcer, 12 grains of corrosive sublimate may be dissolved in a pint and a half of brandy, a table spoonful of which may be taken twice a-day. The ulcer ought likewise to be washed with it, and the fumes of cinnabar may be received up the nostrils.

If there be reason to suspect that the nerves which supply the organs of smelling are inert, or want stimulating, volatile salts, or strong snuffs, and other things which occasion sneezing, may be applied to the nose; the forehead may likewise be anointed with balsam of Peru, to which may be added a little oil of amber.

SMELT. See Salmo, Ichthyology Index.

SMELTING, in Metallurgy, the fusion or melting of the ores of metals, in order to separate the metallic part from the earthy, stony, and other parts. See Ores, Reduction of.

SMEW. See Mergus, Ornithology Index.

SMILAX, Rough Bindweed, a genus of plants belonging to the class of Dicera and order of Hexandra; and in the natural system ranging under the 11th order, Sarmentaceae. See Botany and Materia Medica Index.

SMITH, Sir Thomas, was born at Walden in Essex in 1512. At 14 he was sent to Queen's college Cambridge, where he distinguished himself so much, that he was made Henry VIII's scholar, together with John Cheke. He was chosen a fellow of his college in 1537, and appointed two years after to read the public Greek lecture. The common mode of reading Greek at that time was very faulty; the same sound being given to the letters and diphthongs, u, o, u, et, ete. Mr Smith and Mr Cheke had been for some time sensible that this pronunciation was wrong; and after a good deal of consultation and research, they agreed to introduce that mode of reading which prevails at present. Mr Smith was lecturing on Aristotel de Republica in Greek. At first he dropped a word or two at intervals in the new pronunciation, and sometimes he would stop as if he had committed a mistake, and correct himself. No notice was taken of this for two or three days; but as he repeated more frequently, his audience began to wonder at the unusual sounds, and at last some of his friends mentioned to him what they had remarked. He owned that something was in agitation, but that it was not yet sufficiently digested to be made public. They entreated him earnestly to discover his project: he did so; and in a short time great numbers resorted to him for information. The new pronunciation was
was adopted with enthusiasm, and soon became universal at Cambridge. It was afterwards opposed by Bishop Gardiner the chancellor; but its superiority to the old mode was so visible, that in a few years it spread over all England.

In 1538 he travelled into foreign countries and studied for some time in the universities of France and Italy. On his return he was made regius professor of civil law at Cambridge. About this time he published a treatise on the mode of pronouncing English. He was useful likewise in promoting the reformation. Having gone into the family of the duke of Somerset, the protector during the minority of Edward VI, he was employed by that nobleman in public affairs; and in 1548 was made secretary of state, and received the honour of knighthood. While that nobleman continued in office, he was sent ambassador, first to Brussels and afterwards to France.

Upon Mary's accession he lost all his places, but was fortunate enough to preserve the friendship of Gardiner and Bonner. He was exempted from persecution, and was allowed, probably by their influence, a pension of 100l. During Elizabeth's reign he was employed in public affairs, and was sent three times by that princess as her ambassador to France. He died in 1577. His abilities were excellent, and his attainments uncommonly great: He was a philosopher, a physician, a chemist, mathematician, linguist, historian, and architect. He wrote, 1. A treatise called the English Commonwealth. 2. A letter De Recta et Emendata Linguæ Graecæ Pronuntiatione. 3. De Moribus Turcicorum. 4. Dr. Dwividum Moribus.

Smith, Edmund, an English poet, the only son of Mr Neale an eminent merchant, by a daughter of Baron Lechmere, was born in 1668. By his father's death he was left young to the care of Mr Smith, who had married his father's sister, and who treated him with so much tenderness, that at the death of his generous guardian he assumed his name. His writings are not many, and those are scattered about in miscellanies and collections: his celebrated tragedy of Phaedra and Hippolitus was acted in 1707; and being introduced at a time when the Italian opera so much engaged the polite world, gave Mr Addison, who wrote the prologue, an opportunity to rally the vitiated taste of the public. However, notwithstanding the esteem it has always been held in, it is perhaps rather to be considered as a fine poem than as a good play. This tragedy, with a Poem to the memory of Mr John Philips, three or four Odes, with a Latin oration spoken at Oxford in laudem Thomas Bodleii, were published as his works by his friend Mr Oldisworth. Mr Smith died in 1713, sunk into indolence and intemperance by poverty and disappointments: the hard fate of many a man of genius.

Smith, John, an excellent mezzotint, flourished about 1700; but neither the time of his birth nor death is accurately known. He united softness with strength, and finished with freedom. He served his time with one Tillet a painter in Moorfields; and as soon as he became his own master, learned from Beckett the secret of mezzotinto, and being farther instructed by Van der Vaart, was taken to work in Sir Godfrey Kneller's house; and as he was to be the publisher of that master's works, doubtless received considerable hints from him, which he amply repaid. "To posterity perhaps his prints (says Mr Walpole) will carry an idea of something burlesque; perukes of an enormous length flowing over suits of armour, compose wonderful habits. It is equally strange that fashion could introduce the one, and establish the practice of representing the other when it was out of fashion. Smith excelled in exhibiting both, as he found them in the portraits of Kneller, who was less happy in what he substituted to armour. In the Kit-cat club he has pour'd full bottoms chiefly over night-gowns. If those streams of hair were uncommon in a battle, I know nothing (he adds) they were adapted to that can be done in a night-gown. Smith composed two large volumes, with proofs of his own plates, for which he asked 50l. His finest works are Duke Schomberg on horseback; that duke's son and successor Maynhard: the earls of Pembroke, Dorset, and Albemarle; three plates with two figures in each, of young persons or children, in which he shone: William Cowper; Gibbons and his wife; Queen Anne; the duke of Gloucester, a whole length, with a flowerpot; a very curious one of Queen Mary, in a high head, fan, and gloves; the earl of Godolphin; the duchess of Ormond, a whole length, with a black; Sir George Rooke, &c. There is a print by him of James II. with an anchor, but no inscription; which not being finished when the king went away, is so scarce that it is sometimes sold for above a guinea. Smith also performed many historic pieces: as the loves of the gods, from Titus, at Blenheim, in ten plates; Venus standing in a shell, from a picture by Correggio, and many more, of which perhaps the most delicate is the holy family with angels, after Carlo Maratti."

Smith, Dr Adam, the celebrated author of the Philosophical Inquiries into the Nature and Causes of the Wealth of Nations, was the only son of Adam Smith comptroller of the customs at Kirkaldy, and of Margaret Douglas. He was born in Edinburgh, at Kirkaldy on the 5th June 1723, a few months after vol. iii. the death of his father. His constitution during his infancy was infirm and sickly, and required all the care of his surviving parent. When only three years old he was carried by his mother to Strathenburg on a visit to his uncle Mr Douglas; and having one day to be amusing himself alone at the door of the house, he was stolen by a party of those vagrants who in Scotland are called tinkers. Luckily he was missed immediately, and the vagrants pursued and overtaken in Leslie wood; and thus Dr Smith was preserved to extend the bounds of science, and reform the commercial policy of Europe.

He received the rudiments of his education in the school of Kirkaldy under David Miller, a teacher of considerable eminence, and whose name deserves to be recorded in account of the great number of eminent men which that seminary produced while under his direction. Dr Smith, even while at school, attracted notice by his passionate attachment to books, and by the extraordinary powers of his memory; while his friendly and generous disposition gained and secured the affection of his schoolfellows. Even then he was remarkable for those habits which remained with him through life, of speaking to himself when alone and of absence in company. He was sent in 1737 to the university of Glasgow, where he remained till 1740, when he went to
measure escaped their notice. It abounds everywhere with the purest and most elevated maxims concerning the moral conduct of life; and when the subject of his work leads him to address the imagination and the heart, the variety and felicity of his illustrations, the richness and fluency of his eloquence, and the skill with which he wins the attention and commands the passions of his readers, leave him among our British moralists without a rival.

Towards the end of 1763 Dr Smith received an invitation from Mr Charles Townend to accompany the duke of Buccleugh on his travels; and the liberal terms in which this proposal was made induced him to resign his office at Glasgow. He joined the duke of Buccleugh at London early in the year 1764, and set out with him for the continent in the month of March following. After a stay of about ten days at Paris, they proceeded to Toulouse, where they fixed their residence for about 18 months; thence they went by a pretty extensive route through the south of France to Geneva, where they passed two months. About Christmas 1765 they returned to Paris, and remained there till October following. The society in which Dr Smith passed these ten months may be conceived in consequence of the recommendation of Mr Hume. Turcot, Quessai, Neckler, d'Alembert, Holteiut, Marmandel, Madame Riccoboni, were among the number of his acquaintances; and some of them he continued ever after to reckon among the number of his friends. In October 1766 the duke of Buccleugh returned to England.

Dr Smith spent the next ten years of his life with his mother at Kirkaldy, occupied habitually in intense study, but unbending his mind at times in the company of some of his old schoolfellows, who still continued to reside near the place of their birth. In 1776 he published his Inquiry into the Nature and Causes of the Wealth of Nations; a book so universally known, that any panegyric on it would be useless. The variety, importance, and (may we not add,) novelty, of the information which it contains; the skill and comprehensiveness of mind displayed in the arrangement; the admirable illustrations with which it abounds; together with a plainness and perspicuity which make it intelligible to all—render it unquestionably the most perfect work which has yet appeared on the general principles of any branch of legislation.

He spent the next two years of his life in London, where he enjoyed the society of some of the most eminent men of the age: but he removed to Edinburgh in 1778, in consequence of having been appointed, at the request of the Duke of Buccleugh, one of the commissioners of the customs in Scotland. Here he spent the last twelve years of his life in an affluence which was more than equal to all his wants. But his studies seemed entirely suspended till the infirmities of old age reminded him, when it was too late, of what he yet owed to the public and to his own fame. The principal materials of the works which he had announced had long ago been collected, and little probably was wanting but a few years of health and retirement to complete them. The death of his mother, who had accompanied him to Edinburgh in 1784, together with that of his cousin Miss Douglas in 1788, contributed to frustrate these projects. They had been the objects of his affection for
Smith

for more than 60 years, and in their society he had enjoyed from his infancy all that he ever knew of the endearments of a family. He was now alone and help-less; and though he bore his loss with equanimity, and regained apparently his former cheerfulness, yet his health and strength gradually declined till the period of his death, which happened in July 1790. Some days before his death he ordered all his papers to be burnt except a few essays, which have since been published.

Of the originality and comprehensiveness of his views; the extent, the variety, and the correctness of his information; the inexhaustible fertility of his invention—he has left behind him lasting monuments. To his private worth, the most certain of all testimonies may be found in that confidence, respect, and attachment, which followed him through all the various relations of life. He was habitually absent in conversation, and was apt when he spoke to deliver his ideas in the form of a lecture. He was rarely known to start a new topic himself, or to appear unprepared upon those topics that were introduced by others. In his external form and appearance there was nothing uncommon. When perfectly at ease, and when warmed with conversation, his gestures were animated and not ungraceful; and in the society of those he loved, his features were often brightened by a smile of inexpressible benignity. In the company of strangers, his tendency to absence, and perhaps more his consciousness of that tendency, rendered his manners somewhat embarrassed; an effect which was probably not a little heightened by those speculative ideas of propriety which his recluse habits tended at once to perfect in his conception, and to diminish his power of realizing.

SMITHIA, a genus of plants belonging to the diadelphia class; and in the natural method ranking under the 32d order, Popilionaceae. See Botany Index.

SMITHERY, a smith's shop; also the art of a smith, by which iron is wrought into any shape by means of fire, hammering, filing, &c.

SMITING-LINE, in a ship, is a small rope fastened to the mizen-yard-arm, below at the deck, and is always furled up with the mizen-sail, even to the upper end of the yard, and thence it comes down to the poops. Its use is to loose the mizen-sail without striking down the yard, which is easily done, because the mizen-sail is furled up only with rope-yarns; and therefore when this rope is pulled hard, it breaks all the rope-yarns, and so the sail falls down itself. The sailor's phrase is, smile the mizen (whence this rope takes its name), that is, bale by this rope that the sail may fall down.

SMOKE, a dense elastic vapour, arising from burning bodies. As this vapour is extremely disagreeable to the senses, and often prejudicial to the health, mankind have fallen upon several contrivances to enjoy the benefit of fire, without being annoyed by smoke. The most universal of these contrivances is a tube leading from the chamber in which the fire is kindled to the top of the building, through which the smoke ascends, and is dispersed into the atmosphere. These tubes are called chimneys; which, when constructed in a proper manner, carry off the smoke entirely; but, when improperly constructed, they carry off the smoke imperfectly, to the great annoyance of the inhabitants. As our mansions at present seem to have a very imperfect knowledge of the manner in which chimneys ought to be built, we can hardly perform a more acceptable service to the public than to point out the manner in which they ought to be constructed, so as to carry off the smoke entirely; as well as to explain the causes from which the defects so often complained of generally proceed, and the method of removing them.

Those who would be acquainted with this subject, should begin by considering on what principle smoke ascends in any chimney. At first many are apt to think that smoke is in its nature, and of itself, specifically lighter than air, and rises in it for the same reason that cork rises in water. These see no cause why smoke should not rise in the chimney though the room be ever so close. Others think there is a power in chimneys to draw up the smoke, and that there are different forms of chimneys which afford more or less of this power. These amuse themselves with searching for the best form. The equal dimensions of a funnel in its whole length is not thought artificial enough, and it is made, for fancied reasons, sometimes tapering and narrowing from below upwards, and sometimes the contrary, &c. &c. A simple experiment or two may serve to give more correct ideas. Having lighted a pipe of tobacco, plunge the stem to the bottom of a decanter half filled with cold water; then putting a rag over the bowl, blow through it, and make the smoke descend in the stem of the pipe, from the end of which it will rise in bubbles through the water; and being thus cooled, will not afterwards rise to go out through the neck of the decanter, but remain spreading itself and resting on the surface of the water. This shows that smoke is really heavier than air, and that it is carried upwards only when attached to or acted upon by air that is heated, and thereby rarefied and rendered specifically lighter than the air in its neighbourhood.

Smoke being rarely seen but in company with heated air, and its upward motion being visible, though that of the rarefied air that drives it is not so, has naturally given rise to the error. It is now well known that air is a fluid which has weight as well as others, though about 800 times lighter than water; that heat makes the particles of air recede from each other, and take up more space, so that the same weight of air heated will have more bulk than equal weights of cold air which may surround it, and in that case must rise, being forced upwards by such colder and heavier air, which presses to get under it and take its place. That air is so rarefied or expanded by heat, may be proved to their comprehension by a lank blown bladder, which laid before a fire, will soon swell, grow tight, and burst.

Another experiment may be to take a glass tube about an inch in diameter, and 12 inches long, open at both ends, and fixed upright on legs so that it need not be handled, for the hands might warm it. At the end of a quill fasten five or six inches of the finest light filament of silk, so that it may be held either above the upper end of the tube or under the lower end, your warm hand being at a distance by the length of the quill. If there were any motion of air through the tube, it would manifest itself by its effect on the silk; but if the tube and the air in it are of the same temperature with the surrounding air, there will be no such motion, whatever may be the form of the tube, whether crooked or straight, narrow below and widening upwards.

Plate
Smoke. Warm the tube, and you will find as long as it continues warm, a constant current of air entering below and passing up through it till discharged at the top; because the warm air within, being communicated to the air outside, makes it rise and thus makes the air without lighter than the air within; which therefore presses in below, forces it upwards, follows and takes its place, and is rarified in its turn. And, without warming the tube, if you hold under it a knob of hot iron, the air thereby heated will rise and fill the tube, going out at its top; and this motion in the tube will continue as long as the knob remains hot, because the air entering the tube below, is heated and rarified by passing near and over that knob.

That this motion is produced merely by the difference of specific gravity between the fluid within and that without the tube, and not by any fancied form of the tube itself, may appear by plunging it into water contained in a glass jar a foot deep, through which such motion might be seen. The water within and without the tube being of the same specific gravity, balance each other, and both remain at rest. But take out the tube, stop its bottom with a finger, and fill it with olive oil, which is lighter than water; then stopping the top, place it as before, its lower end under water, its top a very little above. As long as you keep the bottom stopped the fluids remain at rest; but the moment it is unstoped, the heavier enters below, forces up the lighter, and takes its place; and the motion then ceases, merely because the new fluid cannot be successively made lighter, as air may be by a warm tube.

In fact, no form of the funnel of a chimney has any share in its operation or effect respecting smoke except its height. The longer the funnel, the greater its force when filled with heated and rarified air to draw in below and drive up the smoke, if one may, in compliance with custom, use the expression draw, when in fact it is the superior weight of the surrounding atmosphere that pressed to enter the funnel below, and so drives up before it the smoke and warm air it meets with in its passage.

What is it then which makes a smoky chimney, that is, a chimney which, instead of conveying up all the smoke, discharges a part of it into the room, offending the eyes and damaging the furniture?

The causes of this effect may be reduced to mine, differing from each other, and therefore requiring different remedies.

1. Smoky chimneys in new houses are frequently from want of air. The workmanship of the rooms being all good, and just out of the workman’s hands, the joints of the boards of the flooring, and of the panells of wainscoting, are all true and tight; the more so as the walls, perhaps not yet thoroughly dry, preserve a dampness in the air of the room which keeps the woodwork swelled and close. The doors and the mashes too, being worked with trust, shut with exactness, so that the chimney is as tight as a snuff-box, no passage being left open for air to enter except the key-hole, and even that is sometimes covered by a little dropping shutter. Now if smoke cannot rise but as connected with rarified air, and a column of such air, suppose it filling the funnel, cannot rise unless other air be admitted to supply its place; and if therefore no current of air enter the opening of the chimney—there is nothing to prevent the smoke from coming out into the room. If the motion upwards of the air in a chimney that is freely supplied be observed by the rising of the smoke or a feather in it, and be considered that in the time such feather or smoke is rising from the fire to the top of the chimney, a column of air equal to the content of the funnel must be discharged, and an equal quantity supplied from the room below, it will appear absolutely impossible that this operation should go on if the tight room is kept shut; for were there any force capable of drawing constantly so much air out of it, it must soon be exhausted like the receiver of an air-pump, and no animal could live in it. Those therefore who stop every crevice in a room to prevent the admission of fresh air, and yet have their chimney carry up the smoke, require inconsistencies, and expect impossibilities. Yet under this situation it is not uncommon to see the owner of a new house in despair, and ready to sell it for much less than its cost; conceiving it uninhabitable because not a chimney in any one of its rooms will carry off the smoke unless a door or window be left open. Much expense has also been made to alter and amend new chimneys which had really no fault: in one house particularly which Dr Franklin knew that belonged to a nobleman in Westminster, that expense amounted to no less than 300£ after his house had been, as he thought, finished and all charges paid. And after all, several of the alterations were ineffectual, for want of understanding the true principles.

Remedies. When you find on trial that opening the door or a window enables the chimney to carry up all the smoke, you may be sure that want of air from without is the cause of its smoking. “I say from without, (adds Dr Franklin), to guard you against a common mistake of those who may tell you the room is large, contains abundance of air sufficient to supply any chimney, and therefore it cannot be that the chimney wants air. These reasons are ignorant that the largeness of a room, if tight, is in this case of small importance, since it cannot part with a chimney full of its air without occasioning so much vacuum; which it requires a great force to effect, and could not be borne if effected.”

It appearing plainly then, that some of the outward air must be admitted, the question will be, how much is absolutely necessary? for you would avoid admitting more, as being contrary to one of your intentions in having a fire, viz. that of warming your room. To discover this quantity, shut the door gradually while a middling fire is burning, till you find that before it is quite shut the smoke begins to come out into the room; then open it a little till you perceive the smoke comes out no longer. There hold the door, and observe the width of the open crevice between the edge of the door and the rabbet it should shut into. Suppose the distance to be half an inch, and the door eight feet high; you find thence that your room requires an entrance for air equal in area to 96 half inches, or 48 square inches, or a passage of 6 inches by 8. This, however, is a large supposition; there being few chimneys that, having a moderate opening and a tolerable height of funnel, will not be satisfied with such a crevice of a quarter of an inch: Dr Franklin found a square of 6 by 6, or 36 square inches, to be pretty good medium that
that will serve for most chimneys. High funnels with small and low openings may indeed be supplied through a less space; because, for reasons that will appear hereafter, the force of levity, if one may so speak, being greater in such funnels, the cool air enters the room with greater velocity, and consequently more enters in the same time. This, however, has its limits; for experience shows, that no increased velocity so occasioned has made the admission of air through the key hole equal in quantity to that through an open door, through the door the current moves slowly, and through the key-hole with great rapidity.

It remains then to be considered, how and where this necessary quantity of air from without is to be admitted so as to be least inconvenient: for if at the door, left so much open, the air thence proceeds directly to the chimney, and in its way comes cold to your back and breezes as you sit before your fire. If you keep the door shut, and wave before so the sash of your window, you feel the same inconvenience. Various have been the contrivances to avoid this; such as bringing in fresh air through pipes in the jams of the chimney, which pointing upwards should blow the smoke up the funnel; opening passages into the funnel above, to let in air for the same purpose. But these produce an effect contrary to that intended: for as it is the constant current of air passing from the room through the opening of the chimney into the funnel which prevents the smoke from coming out into the room, if you supply the funnel by other means or in other ways with the air which it wants, and especially if that air be cold, you diminish the force of that current, and the smoke in its efforts to enter the room finds less resistance.

The wanted air must then indispensably be admitted into the room, to supply what goes off through the opening of the chimney. M. Guagey, a very ingenious and intelligent French writer on the subject, proposes with judgment to admit it above the opening of the chimney; and to prevent inconvenience from its coldness, he directs that it may be so made, that it shall pass in its entrance through winding cavities made behind the iron back and sides of the fire-place, and under the iron hearth-plate; in which cavities it will be warmed, and even heated as far as to acquire much, instead of cooling, to the warming of the room. This invention is excellent in itself, and may be used with advantage in building new houses; because the chimneys may then be so disposed as to admit conveniently the cold air to enter such passages: but in houses built without such views, the chimneys are often so situated as not to afford that convenience without great and expensive alterations. Easy and cheap methods, though not quite so perfect in themselves, are of more general utility; and such are the following.

In all rooms where there is a fire, the body of air warmed and rarified before the chimney is continually changing place, and making room for other air that is to be warmed in its turn. Part of it enters and goes up the chimney, and the rest rises and takes place near the ceiling. If the room be lofty, that warm air remains above our heads as long as it continues warm, and we are little benefited by it, because it does not descend till it is cooler. Few can imagine the difference of climate between the upper and lower parts of such a room, who have not tried it by the thermometer, or by going up a ladder till their heads are near the ceiling.

It is then among this warm air that the wanted quantity of outward air is best admitted, with which being mixed, its coldness is abated, and its inconvenience diminished so as to become scarce observable. This may be easily done by drawing down about an inch the upper sash of a window; or, if not moveable, by cutting such a crevice through its frame; in both which cases it will be well to place a thin shelf of the length to conceal the opening, and sloping upwards, to direct the entering air horizontally along and under the ceiling. In some houses the air may be admitted by such a crevice made in the wainscot, cornice, or plastering, near the ceiling and over the opening of the chimney. This, if practicable, is to be chosen, because the entering cold air will there meet with the warmest rising air from before the fire, and be soonest tempered by the mixture. The same kind of shelf should also be placed here. Another way, and not a very difficult one, is to take out an upper pane of glass in one of your sashes, set it in a tin frame, giving it two springing angular sides, and then replacing it, with hinges below on which it may be turned to open more or less above. It will then have the appearance of an internal skylight. By drawing this pane in, more or less, you may admit what air you find necessary. Its position will naturally throw that air up and along the ceiling. This is what is called in France a Wos ist das? As this is a German question, the invention is probably of that nation, and takes its name from the frequent asking of that question when it first appeared. In England some have of late years cut a round hole about five inches diameter in a pane of the sash, and placed against it a circular plate of tin hung on an axis, and cut into vanes; which, being separately beat a little obliquely, are acted upon by the entering air, so as to force the plate continually round like the vanes of a windmill. This admits the outward air, and by the continual whirling of the vanes, does in some degree disperse it. The noise only is a little inconvenient.

2. A second cause of the smoking of chimneys is, their openings in the room being too large; that is, too wide, too high, or both. Architects in general have no other ideas of proportion in the opening of a chimney than what relate to symmetry and beauty respecting the dimensions of the room; while its true proportion respecting its function and utility depends on quite other principles; and they might as properly proportion the step in a staircase to the height of the story, instead of the natural elevation of men’s legs in mounting. The proportion then to be regarded, is what relates to the height of the funnel. For as the funnels in the different stories of a house are necessarily of different heights or lengths, that from the lowest floor being the highest or longest, and those of the other floors shorter and shorter, till we come to those in the garrets, which are of course the shortest; and the force of draft being, as already said, in proportion to the height of funnel filled with rarified air, and a current of air from the room into the chimney, sufficient to fill the opening, being necessary to oppose and prevent the smoke from coming out into the room; it follows, that the openings of the longest funnels may be larger, and that those of the shorter funnels should be smaller. For if there be a large opening to a chimney that does not draw strongly, the funnel may
Smoke may happen to be furnished with the air which it demands by a partial current entering on one side of the opening, and leaving the other side free of any opposing current, may permit the smoke to issue there into the room. Much too of the force of draft in a funnel depends on the degree of rarefaction in the air it contains, and that depends on the nearness to the fire of its passage in entering the funnel. If it can enter far from the fire on each side, or far above the fire, in a wide or high opening, it receives little heat in passing by the fire, and the contents of the funnel are by those means less different in lewity from the surrounding atmosphere; and its force in drawing consequently weaker. Hence if too large an opening be given to chimneys in upper rooms, those rooms will be smoky: On the other hand, if too small openings be given to chimneys in the lower rooms, the entering air operating too directly and violently on the fire, and afterwards strengthening the draft as it ascends the funnel, will consume the fuel too rapidly.

Remedy. As different circumstances frequently mix themselves in these matters, it is difficult to give precise dimensions for the openings of all chimneys. Our fathers made them generally much too large: we have lessened them; but they are often still of greater dimensions than they should be, the human eye not being easily reconciled to sudden and great changes. If you suspect that your chimney smokes from the too great dimension of its opening, contract it by placing moveable boards so as to lower and narrow it gradually till you find the smoke no longer issues into the room. The proportion so found will be that which is proper for that chimney, and you may employ the bricklayer or mason to reduce it accordingly. However, as in building new houses something must be sometimes hazarded, Dr. Franklin proposes to make the openings in the lower rooms about 30 inches square and 18 deep, and those in the upper only 18 inches square and not quite so deep; the intermediate ones diminishing in proportion as the height of the funnel is diminished. In the larger openings, latches of two feet long, or half the common length of cordwood, may be burnt conveniently; and for the smaller, such wood may be sawed into thirds. Where coals are the fuel, the grate will be proportioned to the openings. The same depth is nearly necessary to all, the funnels being all made of a size proper to admit a chimney-sweeper. If in large and elegant rooms custom or fancy should require the appearance of a larger chimney, it may be formed of expensive marginal decorations, in marble, &c. But in time perhaps, that which is fittest in the nature of things may come to be thought handsomest.

3. Another cause of smoky chimneys is too short a funnel. This happens necessarily in some cases, as where a chimney is required in a low building; for, if the funnel be raised high above the roof, in order to strengthen its draft, it is then in danger of being blown down, and crushing the roof in its fall.

Remedies. Contract the opening of the chimney, so as to oblige all the entering air to pass through or very near the fire; whereby it will be more heated and rarefied, the funnel itself be more warmed, and its contents have more of what may be called the force of lewity, so as to rise strongly and maintain a good draft at the opening.

4. Another very common cause of the smoking of chimneys is, their overpowering one another. For instance, if there be two chimneys in one large room, and you make fires in both of them, the doors and windows close shut, you will find that the greater and stronger fire shall overpower the weaker, from the funnel of which it will draw air down to supply its own demand; which air descending in the weaker funnel, will drive down its smoke, and force it into the room. If, instead of being in one room, the two chimneys are in two different rooms, communicating by a door, the case is the same whenever that door is open. In a very tight house, a kitchen chimney on the lowest floor, when it had a great fire in it, has been known to overpower any other chimney in the house, and draw air and smoke into its room as often as the door communicating with the staircase was open.

Remedy. Take care that every room have the means of supplying itself from without with the air which its chimney may require, so that no one of them may be obliged to borrow from another, nor under the necessity of lending. A variety of these means have been already described.

5. Another cause of smoking is, when the tops of chimneys are commanded by higher buildings, or by a hill, so that the wind blowing over such eminences falls like water over a dam, sometimes almost perpendicularly on the
Remedy. There is but one remedy, which is to raise such a funnel higher than the roof, supporting it if necessary by iron bars. For a turncap in this case has no effect, the dammed-up air pressing down through it in whatever position the wind may have placed its opening.

Dr Franklin mentions a city in which many houses are rendered smoky by this operation. For their kitchens being built behind, and connected by a passage with the houses, and the tops of the kitchen chimneys lower than the tops of the houses, the whole side of a street when the wind blows against its back forms such a dam as above described; and the wind so obstructed forces down those kitchen-chimneys (especially when they have but weak fires in them) to pass through the passage and house into the street. Kitchen-chimneys so formed and situated have another inconvenience. In summer, if you open your upper room windows for air, a light breeze blowing over your kitchen chimney towards the house, though not strong enough to force down its smoke as aforesaid, is sufficient to waft it into your windows, and fill the rooms with it; which, besides the disagreeableness, damages your furniture.

7. Chimneys, otherwise drawing well, are sometimes made to smoke by the improper and inconvenient situation of a door. When the door and chimney are on the same side of the room, if the door being in the corner is made to open against the wall, which is common, as being there, when open, more out of the way, it follows, that when the door is only opened in part, a current of air rushing in passes along the wall into and across the opening of the chimney, and flits some of the smoke out into the room. This happens more certainly when the door is shutting, for then the force of the current is augmented, and becomes very inconvenient to those who, warming themselves by the fire, happen to sit in its way.

The remedies are obvious and easy. Either put an intervening screen from the wall round great part of the fireplace; or, which is perhaps preferable, shift the hinges of your door, so as it may open the other way, and then open throw the air along the other wall.

8. A room that has no fire, but its chimney is sometimes filled with smoke which is received at the top of its funnel, and descends into the room. Funnels without fires have an effect according to their degree of coldness or warmth on the air that happens to be contained in them. The surrounding atmosphere is frequently changing its temperature; but stacks of funnels covered from winds and sun by the house that contains them, retain a more equal temperature. If, after a warm season, the outward air suddenly grows cold, the empty warm funnels begin to draw strongly upward; that is, they rarefy the air contained in them, which of course rises, cooler air enters below to supply its place, is rarefied in its turn, and rises; and its operation continues until the funnel grows cooler, or the outward air warmer, or both, when the motion ceases. On the other hand, if after a cold season the outward air suddenly grows warm and of course lighter, the air contained in the cool funnels being heavier descends into the room; and the warmer air which enters their tops being cooled in its turn, and made heavier, continues to descend; and this operation goes on till the funnels are warmed by the passing of warm air through them, or the air itself grows cooler.

3 G 2
In Venice, the custom is to open or widen the top of the flue, rounding it in the true form of a funnel. In other places the contrary is practised; the tops of the flues being narrowed inwards, so as to form a slit for the issue of the smoke, long as the breadth of the funnels, and only four inches wide. This seems to have been contrived on a supposition that the entry of the wind would thereby be obstructed; and perhaps it might have been imagined that the whole force of the rising warm air being condensed, as it were, in the narrow opening, would thereby be strengthened, so as to overcome the resistance of the wind. This, however, did not always succeed; for when the wind was at north-east and blew fresh, the smoke was forced down by fits into the room where Dr. Franklin commonly sat, so as to oblige him to shift the fire into another. The position of the slit of this funnel was indeed north-east and south-west. Perhaps if it had lain across the wind, the effect might have been different. But on this we can give no certainty. It seems a matter proper to be referred to experiment. Possibly a turncap might have been serviceable, but it was not tried.

With all the science, however, that a man shall suppose himself possessed of in this article, he may sometimes meet with cases that shall puzzle him. "I once lodged (says Dr. Franklin) in a house at London, which in a little room had a single chimney and funnel. The opening was very small; yet it did not keep in the smoke, and all attempts to have a fire in this room were fruitless. I could not imagine the reason, till at length observing that the chamber over it, which had no fireplace in it, was always filled with smoke when a fire was kindled below, and that the smoke came through the cracks and crevices of the wainscots; I had the wainscot taken down, and discovered that the funnel which went up behind it had a crack many feet in length, and wide enough to admit my arm; a breach very dangerous with regard to fire, and occasioned probably by an apparent irregular settling of one side of the house." The air entering this breach freely, destroyed the drawing force of the funnel. The remedy would have been, filling up the breach, or rather rebuilding the funnel: but the landlord rather chose to stop up the chimney.

Another puzzling case I met with at a friend's country house near London. His best room had a chimney in which, he told me, he never could have a fire, for all the smoke came out into the room. I flattered myself I could easily find the cause and prescribe the cure. I opened the door, and perceived it was not want of air. I made a temporary contraction of the opening of the chimney, and found that it was not its being
being too large that caused the smoke to issue. I went out and looked up at the top of the chimney: Its funnel was joined in the same stalk with others; some of them shorter, that drew very well, and I saw nothing to prevent its doing the same. In fine, after every other examination I could think of, I was obliged to own the insufficiency of my skill. But my friend, who made no pretension to such kind of knowledge, afterwards discovered the cause himself. He got to the top of the funnel by a ladder, and looking down found it filled with twigs and straw cemented by earth and lined with feathers. It seems the house after being built, had stood empty some years before he occupied it; and he concluded that some large birds had taken the advantage of its retired situation to make their nest there. The rubbish, considerable in quantity, being removed, and the funnel cleared, the chimney drew well, and gave satisfaction."

Chimneys whose funnels go up in the north wall of a house, and are exposed to the north winds, are not so apt to draw well as those in a south wall; because when rendered cold by those winds, they draw downwards.

Chimneys inclosed in the body of a house are better than those whose funnels are exposed in cold walls.

Chimneys in stacks are not apt to draw better than separate funnels, because the funnels that have constant fires in them warm the others in some degree that have none.

_Smoke-Jack._ This injurious machine is of German origin, and Messenger, in his Collection of Mechanical Performances, says it is very ancient, being represented in a painting at Nuremberg, which is known to be older than the year 1350.

Its construction is abundantly simple. An upright iron spindle GA (fig. 5.), placed in the narrow part of the kitchen chimney, turns round on two points H and L. The upper point H passes through an iron bar, which is built in across the chimney; and the lower point I is of tempered steel, and is conical or pointed, resting in a conical metal socket fixed on another cross bar. On the upper end of the spindle is a circular fly G, consisting of 4, 6, 8, or more thin iron plates, set obliquely on the spindle like the sails of a windmill, as we shall describe more particularly by and by. Near the lower end of the spindle is a pinion A, which works in the teeth of a conic or cone wheel B, turning on a horizontal axis BC. One pivot of this axis turns in a cock fixed on the cross bar, which supports the lower end of the upright spindle HI, and the other pivot turns in a cock fixed on the side wall of the chimney; so that this axis is parallel to the front of the chimney. On the remote end of this horizontal axle there is a small pulley C, having a deep angular groove. Over this pulley there passes a chain CDE, in the lower bight of which hangs the large pulley E of the spit. This end of the spit turns loosely between the branches of the fork of the rack or raxe F, but without resting on it. This is on the top of a moveable stand, which can be shifted nearer to or farther from the fire. The other end turns in one of the notches of another rack. The number of teeth in the pinion A and wheel B, and the diameters of the pulleys C and E, are so proportioned that the fly G makes from 12 to 20 turns for one turn of the spit.

The manner of operation of this useful machine is easily understood. The air which contributes to the burning of the fuel, and passes through the midst of it, is greatly heated, and expanding prodigiously in bulk, becomes lighter than the neighboring air, and is therefore pushed by it up the chimney. In like manner, all the air which comes near the fire is heated, expanded, becomes lighter, and is driven up the chimney. This is called the draught or suction, but would with greater propriety be termed the drift of the chimney. As the chimney gradually contracts in its dimensions, and as the same quantity of heated air passes through every section of it, it is plain that the rapidity of its ascent must be greatest in the narrowest part. There the fly G should be placed, because it will then be exposed to the strongest current. The air, striking the fly vanes obliquely pushes them aside, and thus turns them round with a considerable force. If the joint of meat is exactly balanced on the spit, it is plain that the only resistance to the motion of the fly is what arises from the friction of the pivots of the upright spindle, the friction of the pinion and wheel, the friction of the pivots of the horizontal axis, the friction of the small end of the spit, and the friction of the chain in the top pulleys. The whole of this is but a mere trifle. But there is frequently a considerable inequality in the weight of the meat on different sides of the spit: there must therefore be a sufficient overplus of force in the impulse of the ascending air on the vanes of the fly, to overcome this want of equilibrium occasioned by the unskilfulness or negligence of the cook. There is, however, commonly enough of power when the machine is properly constructed. The utility of this machine will, we hope, procure us the indulgence of some of our readers, while we point out the circumstances on which its performance depends, and the maxims which should be followed in its construction.

The upward current of air is the moving power, and should be increased as much as possible, and applied in the most advantageous manner. Everything will increase the current which improves the draught of the chimney and secures it from smoking. A smoky chimney must always have a weak current. For this particular, therefore, we refer to what has been delivered in the article Pneumatics, No. 359; and the article Smoke.

With respect to the manner of applying this force, it is evident that the best construction of a windmill sails will be nearly the best construction for the fly. According to the usual theory of the impulse of fluids, the greatest effective impulse (that is, in the direction of the fly's motion) will be produced if the plane of the vane be inclined to the axis in an angle of 54 degrees 46 minutes. But, since we have pronounced this theory to be so very defective, we had better take a determination founded on the experiments on the impulse of fluids made by the academy of Paris. These authorize us to say, that 45° or 50 degrees will be the best angle to give the vane: but this must be understood only of that part of it which is close adjoining to the axis. The vane itself must be twisted, or weathered as the millwrights term it, and must be much more oblique at its outer extremity. The exact position cannot be determined with any precision; because this depends on the proportion...
proportion of the velocity of the vane to that of the current of heated air. This is subject to no rule, being changed according to the load of the jack. We imagine that an obliquity of 65 degrees for the outer ends of the vanes will be a good position for the generality of cases. Messinger describes an ingenious contrivance for changing this angle at pleasure, in order to vary the velocity of the motion. Each vane is made to turn round a midrib, which stands out like a radius from the spindle, and the vane is moved by a stiff wire attached to one of the corners, so that the vane has a small end to slide on a raddle like a spad of an umbrella; and it is stopped on any part of the spindle by a pin thrust through a hole in the spindle and ring. We mention this briefly, it being easily understood by any mechanic, and but of little consequence, because the machine is not susceptible of much precision.

It is easy to see that an increase of the surface of the vanes will increase the power: therefore they should occupy the whole space of the circle, and not consist of four narrow arms like the sails of a windmill. It is better to make many narrow vanes than a few broad ones; as will appear plain to one well acquainted with the mode of impulse of fluids acting obliquely. We recommend eight or twelve at least; and each vane should be so broad, that when the whole is held perpendicular between the eye and the light, no light shall come through the fly, the vanes overlapping each other a very small matter. We also recommend the making them of stiff plate. Their weight contributes to the steady motion, and enables the fly, which has acquired a considerable velocity during a favourable position of things, to retain a momentum sufficient to pull round the spit while the heavy side of the meat is rising from its lowest position. In such a situation a light fly soon loses its momentum, and the jack stagger under its load.

It is plain, from what has been said, that the fly should occupy the whole of that section of the vent where it is placed. The vent must therefore be brought to a round form in that place, that none of the current may pass uselessly by it.

It is an important question where the fly should be placed. If in a wide part of the vent, it will have a great surface, and act by a long lever; but the current in that place is slow, and its impulse weak. This is a fit subject of calculation. Suppose that we have it in our choice to place it either as it is drawn in the figure, or farther up at $g$, where its diameter must be one half of what it is at $G$. Since the same quantity of heated air passes through both sections, and the section $g$ has only one-fourth of the area of the section $G$, it is plain that the air must be moving four times faster, and that its impulse is 16 times greater. But the surface on which it is acting is the fourth part of that of the fly $G$; the actual impulse therefore is only four times greater, supposing both flies to be moving with the same relative velocity in respect of the current; that is, the rim of each moving with the same portion of the velocity of the current. This will be the case when the small fly turns eight times as often as the large fly; for then, the time of turning four times as quick at $g$, and the diameter of $g$ is one-half that of $G$. Therefore, when the small fly is turning eight times as quick as the great one, there is a quadruple impulse acting at half the distance from the axis. The momentum or energy therefore of the current is double. Therefore, supposing the pinion, wheel, and pulleys of both jacks to be the same, the jack with the small fly, placed in the narrow part of the vent, will be 16 times more powerful.

By this example, more easily understood than a general process, it appears that it is of particular importance to place the fly in an elevated part of the vent, where the area may be more contracted. In order still further to increase the power of the machine, it would be very proper to lengthen the spindle still more, and to put another fly on it at a considerable distance above the first, and a third above this, &c.

As the velocity of the current changes by every change of the fire, the motion of this jack must be very unsteady. To render it as adjustable as may be to the particular purpose of the cook, the pulley $E$ has several grooves of different diameters, and the spit turns more or less slowly, by the same motion of the fly, according as it hangs in the chair by a larger or smaller pulley or groove.

Such is the construction of the smoke-jack in its most simple form. Some are more artificial and complicated, having, in place of the pulleys and connecting chain, a spindle coming down from the horizontal axis BC. On the upper end of this spindle is a horizontal contra-wheel, driven by a pinion in place of the pulley $C$. On the lower end is a pinion, driving a contrate wheel in place of the pulley $E$. This construction is represented in fig. 6. Others are constructed more simply, in fig. 7. But our first construction has great advantage in point of simplicity, and allows a more easy adjustment of the spit, which may be brought nearer to the fire or removed farther from it without any trouble; whereas, in the others, with a train of wheels and pinions, this cannot be done without several changes of pins and screws. The only imperfection of the pulley is, that by long use the grooves become slippery, and an ill-balanced joint is apt to hold back the spit, while the chain slides in the grooves. This may be completely prevented by making the grooves flat instead of angular (which greatly diminishes the friction), and furnishing them with short studs or pins which take into every third or fourth link of the chain. If the chain be made of the simplest form, with flat links, and each link be made of an exact length (making them all on a mould), the motion will be as easy as with any wheelwork, and without the least chance of slipping.

It is always of importance to avoid this slipping of the chain by balancing the loaded spit. For this purpose it will be extremely convenient to have what is called a balance-skewer. Let a part of the spit, immediately adjoining to the pulley, be made round, and let an arm be made to turn on it stiffly, so that it may be made fast in any position by a screw. Let a leaden ball be made to slide along this arm, with a screw to fasten it at any distance from the spit. When the meat is spitted, lay it on the racks, and the heaviest side will immediately place itself undermost. Now turn round the balance-skewer, so that it may point straight upwards, and make it fast in that position by the screw. Put the leaden ball on it, and slide it inwards or outwards.
The greatest difficulty is to keep the machine in repair. The essential part of it, the first mover, the fly, and the pinion and wheel, by which its motion is transmitted to the rest of the machine, are situated in a place of difficult access, and where they are exposed to violent heat and to the smoke and soot. The whole weight of the fly, resting on the lower pivot, must exert a great pressure there, and occasion great friction, even when this pinion is reduced to the smallest size that is compatible with the necessary strength. The pivot must be of hardened steel, tapered like an obtuse cone, and must turn in a conical socket, also of hardened steel or of bell-metal; and this seat of pressure and friction must be continually supplied with oil, which it consumes very quickly. It is not sufficient that it be from time to time smeared with an oiled feather; there must be an iron cup formed round the socket, and kept filled with oil. It is surprising how quickly it disappears; it soon becomes clammy by evaporation, and by the soot which gathers about it. The continued rubbing of the pivot and socket wears them both very fast; and this is increased by hard powders, such as sandy dust, that are hurled up by the rapid current every time that the cook stirs the fire. These, getting between the rubbing parts, cause them to grind and wear each other prodigiously. It is a great improvement to invent these rubbing parts. Let the lower end of the spindle be of a considerable thickness, and have a conical hollow nicely drilled in its extremity. Let a blunt-pointed conical pin rise up in the middle of the oil cup, on which the conical hollow of the spindle may rest. Here will be the same steady support, and the same friction as in the other way; but no grinding dust can now lodge between the pivot and its socket: and if this upright pin be screwed up through the bottom of the cup, it may be screwed farther up in proportion as it wears; and thus the upper pivot will never desert its hole, a thing which soon happens in the common way. We can see from experience, that a jack constructed in this way will not require the fifth part of the repairs of one done in the other way.

It is of importance that the whole be so put together as to be easily taken down, in order to sweep the vent, or to be repaired, &c. For this purpose, let the cross bar which carries the lower end of the upright spindle be placed a little on one side of the perpendicular line from the upper pivot hole. Let the cock which carries the oil cup and the pivot of the horizontal axis BC be screwed to one side of this cross bar, so that the centre of the cup may be exactly under the upper pivot hole. By this construction we have only to unscrew this cock, and then both axles come out of their places at once, and may be replaced without any trouble. We have sketched in fig. 8, the manner in which this may be done, where M represents a section of the lower cross bar. BCDE is the cock, fixed to the bar by the pins which go through both, with finger nuts a and b on the opposite side. F is the hard steel pin with the conical top, on which the lower end I of the upright spindle AG rests, in the manner recommended as the best and most durable. The pivot of the horizontal axis turns in a hole at E the top of the cock.

After all, we must acknowledge that the smoke-jack is inferior to the common jack that is moved by a weight. It is more expensive at first, and requires more frequent repairs; its motion is not so much under command; it occasions soot to be thrown about the fire, to the great annoyance of the cook; and it is a great encumbrance when we would clean the vent.

Smoke Farthings. The pentecostals or customary oblations offered by the dispersed inhabitants within a diocese when they made their procession to the mother or cathedral church, came by degrees into a standing annual rent called smoke farthings.

Smoke Silver. Lands were held in some places by the payment of the sum of 6d. yearly to the sheriff, called smoke-silver (Par. 4. Edw. VI.). Smoke-silver and smoke-penny are to be paid to the ministers of divers parishes as a modus in lieu of tithe-wood: and in some manors formerly belonging to religious houses, there is still paid, as appertaining to the said manors, the ancient Peter-pence, by the name of Smoke-money (Tweed. Hist. Fyndcat. 77.).—The bishop of London anno 1444, issued out his commission, Ad levandum le smoke-farthings, &c.

SMOLENSKO, a large and strong city of Russia, and capital of a government of the same name, with a castle seated on a mountain, and a bishop's see. It is strong by its situation. It has been taken and retaken several times by the Poles and Russians; but these last have had possession of it ever since the year 1687. It was taken by the French in their irruption into Russia in 1812. It is seated on the river Nieper, near the frontiers of Lithuania, 188 miles south-west of Moscow. E. Long. 31. 22. N. Lat. 54. 50.

SMOLENSKO, a government of Russia, bounded on the north by Twer, on the east by Moscow, on the south by Kalouga, and on the west by Witepék. It is full of forests and mountains, but is fertile in grain. The population in 1815 was 965,500.

SMOLLET, Dr Tobias, an author whose writings will transmit his name with honour to posterity, was born in the year 1720 at a small village within two miles of Cameron, on the banks of the river Leven. He appears to have received his early education at school, but was bred to the practice of physic and surgery; and in the early part of his life served as a surgeon's mate in the navy.

The incidents that befell him during his continuance in this capacity served as a foundation for Roderick Random, one of the most entertaining novels in the English tongue. He was present at the siege of Carthagena; and in the before-mentioned novel he has given a faithful, though not very pleasing, account of the management of that ill-conducted expedition, which he censures in the warmest terms, and from circumstances which fell under his own particular observation.

His connection with the sea seems not to have been of long continuance; and it is probable that he wrote several pieces before he became known to the public by his capital productions. The first piece we know of with certainty is a Satire in two parts, printed first in the years 1746 and 1747, and reprinted in a Collection of his Plays and Poems in 1777. About this period, or some time before, he wrote for Mr Rich an opera intitled Alceste, which has never been performed nor printed.

At the age of 18 he wrote a tragedy intitled The Regicide,
Regicide, founded on the story of the assassination of James I. of Scotland. In the preface to this piece, published by subscription in the year 1749, he bitterly exclaimed against false patrons, and the duplicity of theatrical managers. The warmth and impetuosity of his temper hurried him, on this occasion, into unjust reflections against the late George Lord Lyttleton and Mr. Garrick: the character of the former he characterised in the novel of Peregrine Pickle, and he added a burlesque of the Monody written by that nobleman on the death of his lady. Against Mr. Garrick he made illiberal ill-founded criticisms; and in his novel of Roderick Random gave a very unfair representation of his treatment of him respecting this tragedy. Of this conduct he afterwards repented, and acknowledged his errors; though in the subsequent editions of the novel the passages which were the hasty effusions of disappointment were not omitted.

However, in giving a sketch of the liberal arts in his History of England, he afterwards remarked, "the exhibitions of the stage were improved to the most exquisite entertainment by the talents and management of Garrick, who greatly surpassed all his predecessors of this and perhaps every other nation, in his genius for acting, in the sweetness and variety of his tones, the irresistible magic of his eye, the fire and vivacity of his action, the eloquence of attitude, and the whole pathos of expression.

Not satisfied with this public declaration, he wrote an apology to Mr. Garrick in still stronger terms. With these ample concessions, Mr. Garrick was completely satisfied; so that in 1757, when Dr. Smollett’s comedy of the Reprisals, an afterpiece of two acts, was performed at Drury Lane theatre, the latter acknowledged himself highly obliged for the friendly care of Mr. Garrick exerted in preparing it for the stage; and still more for his acting the part of Lucignan in Zara for his benefit, on the sixth instead of the ninth night, to which he was only intitled by the custom of the theatre.

The Adventures of Roderick Random, published in 1748, 2 vols 12mo, a book which still continues to have a most extensive sale, first established the Doctor’s reputation. All the first volume and the beginning of the second appear to consist of real incident and character, though certainly a good deal heightened and disguised. The Judge his grandfather, Crab and Potion the apothecaries; and Squier Gawky, were characters well known in that part of the kingdom where the scene was laid. Captains Oakham and Whistle, Doctors Mackshane and Morgan, were also said to be real personages; but their names we have either never learned or have now forgotten. A bookbinder and barber long eagerly contended for being shadowed under the name of Strap. The Doctor seems to have enjoyed a peculiar felicity in describing sea characters, particularly the officers and sailors of the navy. His Trunnon, Hatchway, and Pipes, are highly finished originals; but what exceeds them all, and perhaps equals any character that has yet been painted by the happiest genius of ancient or modern times, is his Lieutenant Bowling. This is indeed nature itself; original, unique and sui generis.

By the publication of this work the Doctor had acquired so great a reputation, that henceforth a certain degree of success was insured to every thing known or suspected to proceed from his hand. In the course of a few years, the Adventures of Peregrine Pickle appeared; a work of great ingenuity and contrivance in the composition, and in which an uncommon degree of erudition is displayed, particularly in the description of the entertainment given by the Republican Doctor, after the manner of the ancients. Under this personage the late Dr. Akenside, author of The Pleasures of Imagination, is supposed to be typified; and it would be difficult to determine whether profound learning or genuine humour predominate most in this episode. Another episode of the Adventures of a Lady of Quality, likewise inserted in this work, contributed greatly to its success, and is indeed admirably executed; the materials, it is said, the lady herself (the celebrated Lady Jane) furnished.

These were not the only original compositions of this stamp with which the Doctor has favoured the public. Ferdinand Count Fathom, and Sir Launcelot Greaves, are still in the list of what may be called reading novels, and have gone through several editions; but there is no injustice in placing them in a rank far below the former. No doubt invention, character, composition, and contrivance, are to be found in both; but then situations are described which are hardly possible, and characters are painted which, if not altogether unexamined, are at least incompatible with modern manners; and which ought not to be, as the scenes are laid in modern times.

The last work which we believe the Doctor published was of much the same species, but cast into a different form—the Expedition of Humphrey Clinker. It consists of a series of letters, written by different persons to their respective correspondents. He has here carefully avoided the faults which may be justly charged to his two former productions. Here are no extravagant characters nor unnatural situations. On the contrary, an admirable knowledge of life and manners is displayed; and most useful lessons are given applicable to interesting but to very common situations.

We know not whether the remark has been made, but there is certainly a very obvious similitude between the characters of the three heroes of the Doctor’s chief productions. Roderick Random, Peregrine Pickle, and Matthew Bramble, are all brothers of the same family. The same satirical, cynical disposition, the same generosity and benevolence, are the distinguishing and characteristic features of all three: but they are far from being servile copies or imitations of each other. They differ as much as the Ajax, Diomed, and Achilles of Homer. This was undoubtedly a great effort of genius; and the Doctor seems to have described his own character at the different stages and situations of his life.

Before he took a house at Chelsea, he attempted to settle as practitioner of physic at Bath; and with that view wrote a treatise on the waters; but was unsuccessful, chiefly because he could not render himself agreeable to the women, whose favour is certainly of great consequence to all candidates for eminence, whether in medicine or divinity. This, however, was a little extraordinary; for those who remembered Dr. Smollet at that time, cannot but acknowledge that he was as graceful and hand-some a man as any of the age he lived in; besides,
The admiral immediately commenced a fresh action against the Doctor, who was found guilty, fined 100l. and condemned to three months imprisonment in the King's Bench. It is there he is said to have written the Adventures of Sir Launcelot Greaves, in which he has described some remarkable characters, then his fellow-prisoners.

When Lord Bute was called to the chief administration of affairs, he was prevailed upon to write in defence of that nobleman's measures; which he did in a weekly paper called the Briton. This gave rise to the famous North Briton; wherein, according to the opinion of the public, he was rather baffled. The truth is the Doctor did not seem to possess the talents necessary for political altercation. He wanted temper and coolness; and his friends accused his patron of having denied him the necessary information, and even neglected the fulfilling of some of his other engagements with him. Be that as it will, the Doctor is said not to have forgotten him in his subsequent performances.

Besides the Briton, Dr Smollet is supposed to have written other pieces in support of the cause he espoused. The Adventures of an Atom, in two volumes, are known to be his production.

His constitution being at last greatly impaired by a sedentary life and assiduous application to study, he went abroad for his health in June 1763, and continued in France and Italy two years. He wrote an account of his travels in a series of letters to some friends, which were afterwards published in two volumes octavo, 1766. During all that time he appears to have laboured under a constant fit of chagrín. A very slight perusal of these letters will sufficiently evince that this observation is founded in fact, and is indeed a melancholy instance of the influence of bodily distemper over the best disposition.

His relation of his travels is actually cynical; for which Sterne, in his Sentimental Journey, has animadverted upon him, under the character of Smelfungus. The Doctor lived to return to his native country: but his health continuing to decline, and meeting with fresh mortifications and disappointments, he went back to Italy, where he died October 21. 1771. He was employed, during the last years of his life, in abridging the Modern Universal History, great part of which he had originally written himself, particularly the histories of France, Italy, and Germany.

He certainly met with many mortifications and disappointments; which, in a letter to Mr Carrick, he thus feelingly expresses: "I am old enough to have seen and observed, that we are all playthings of Fortune; and that it depends more sometimes as insignificant and precarious as the tossing up of a halfpenny, whether a man rises to affluence and honours, or continues to his dying day struggling with the difficulties and disgraces of life."

It would be needless to expatiate on the character of a man so well known as Dr Smollet, who has, besides, given so many strictures of his own character and manner of living in his writings, particularly in Humphrey Clinker; where he appears under the appellation of Mr Serle, and has an interview with Mr Bramble; and his manner of living is described in another letter, where young Melford is supposed to dine with him at his house in Chelsea. No doubt he made money by his connec-

Smollett's Smugglers

tions with the booksellers; and had been a rigid economist, or endowed with the gift of retention (an expression of his own), he might have lived and died very independent. However, to do justice to his memory, his difficulties, whatever they were, proceeded not from extravagance or want of economy. He was hospitable, but not ostentatiously so; and his table was plentiful, but not extravagant. No doubt he had his failings; but still it would be difficult to name a man who was so respectable for the qualities of his head, or more amiable for the virtues of his heart.

Since his death a monument has been erected to his memory near Leghorn, on which is inscribed an epitaph written in Latin by his friend Dr Armstrong, author of The Art of Preserving Health, and many other excellent pieces. An inscription written in Latin was likewise inscribed on a pillar erected to his memory on the banks of the Leven by one of his relations.

To these memoirs we are extremely sorry to add, that so late as 1783 the widow of Dr Smollett was residing in indigent circumstances at Leghorn. On this account the tragedy of Venice Preserv'd was acted for her benefit at Edinburgh on the 5th of March, and an excellent prologue spoken on that occasion.

The pieces inserted in the posthumous collection of Dr Smollett's plays and poems are, The Regicide, a tragedy; The Reprisal, a comedy; Advice and Reproof, two satires; The Tears of Scotland; Verses on a Young Lady; a Love Elegy, in imitation of Tibullus; two Songs; a Burlesque Ode; Odes to Mithra, to Sleep, to Leven Water, to Blue-y'd Ann, and to Independence.

SMUGGLERS, persons who import or export prohibited goods without paying the duties appointed by the law.

The duties of customs, it is said, were originally instituted, in order to enable the king to afford protection to trade against pirates: they have since been continued as a branch of the public revenue. As duties imposed upon the importation of goods necessarily raise their price above what they might otherwise have been sold for, a temptation is presented to import the commodity clandestinely and to evade the duty. Many persons, prompted by the hopes of gain, and considering the violation of a positive law of this nature as in no respect criminal (an idea in which they have been encouraged by a great part of the community, who make no scruple to purchase smuggled goods), have engaged in this illicit trade. It was impossible that government could permit this practice, which is highly injurious to the fair trader, as the smuggler is enabled to undersell him, while at the same time he impairs the national revenue, and thus wholly destroys the end for which these duties were appointed. Such penalties are therefore inflicted as was thought would prevent smuggling.

Many laws have been made with this view. If any goods be shipped or landed without warrant and presence of an officer, the vessel shall be forfeited, and the wharfinger shall forfeit 100l. and the master or mariner of any ship inward bound shall forfeit the value of the goods: and any carman, porter, or other assisting, shall be committed to gaol, till he find surety of his good behaviour, or until he shall be discharged by the exchequer (13 and 14 C. II. c. 11.). If goods be relanded after drawback, the vessel and goods shall be forfeited; and every person concerned therein shall forfeit double the value of the drawback (8 An. c. 13.). Goods taken in at sea shall be forfeited, and also the vessel into which they are taken; and every person concerned therein shall forfeit treble value (9 G. II. c. 35.). A vessel hovering near the coast shall be forfeited, if under 50 tons burden; and the goods shall also be forfeited, or the value thereof (5 G. III. c. 43.). Persons receiving or buying run goods shall forfeit 2cl. (8 G. c. 18.). A concealed of run goods shall forfeit treble value (8 G. c. 18.). Offering run goods to sale, the same shall be forfeited, and the person to whom they are offered may seize them; and the person offering them to sale shall forfeit treble value (11 G. c. 30.). A porter or other person carrying run goods shall forfeit treble value (9 G. II. c. 35.). Persons armed or disguised carrying run goods shall be guilty of felony, and transported for seven years (8 G. c. 18. 9 G. II. c. 35.).

But the last statute, 19 G. II. c. 34, is for this purpose instar omnium; for it makes all forcible acts of smuggling, carried on in defiance of the laws, or even in disguise to evade them, felony without benefit of clergy; enacting, that if three or more persons shall assemble, with fire-arms or other offensive weapons, to assist in the illegal exportation or importation of goods, or in rescuing the same after seizure, or in rescuing offenders in custody for such offences; or shall pass with such goods in disguise; or shall wound, shoot at, or assault, any officers of the revenue when in the execution of their duty; such persons shall be felons, without the benefit of clergy.

When we consider the nature, and still more the history of mankind, we must allow that the enacting of severe penal laws is not the way to prevent crimes. It were indeed much to be wished that there were no such thing as a political crime; for the generality of men, but especially the lower orders, not discerning the propriety or utility of such laws, consider them as oppressive and tyrannical, and never hesitate to violate them when they can do it with impunity. Instead therefore of punishing smugglers, it would be much better to remove the temptation. But the high duties which have been imposed upon the importation of many different sorts of foreign goods, in order to discourage their consumption in Great Britain, have in many cases served only to encourage smuggling; and in all cases have reduced the revenue of the customs below what more moderate duties would have afforded. The saying of Dr Swift, that in the arithmetic of the customs two and two, instead of making four, make sometimes only one, holds perfectly true with regard to such heavy duties, which never could have been imposed, had not the mercantile system taught us, in many cases, to employ taxation as an instrument, not of revenue, but of monopoly.

The bounties which are sometimes given upon the exportation of home produce and manufactures, and the drawbacks which are paid upon the re-exportation of the greater part of foreign goods, have given occasion to many frauds, and to a species of smuggling more destructive of the public revenue than any other. In order to obtain the bounty or drawback, the goods, it is well known, are sometimes shipped and sent to sea, but
SMYRNA is the largest and richest city of Asia Minor, situated in north latitude 39° 28', and in E. Long. 27° 25' from Greenwich, and about 183 miles west by south of Constantinople. The town extends along the shore about half a mile on a gentle declivity. The houses of the English, French, and Dutch consuls, are handsome structures; these, with most of those occupied by the Christian merchants, are washed on one side by the sea, forming a street named Frank-street, from its being solely inhabited by European Christians. In the year 1763 the whole of this quarter was consumed by fire; the loss sustained by this calamity in merchandise was estimated at a million and a half of Turkish dollars, or near 200,000 sterling. The port is one of the finest of the Levant, it being able to contain the largest fleets; and indeed there are seldom in it fewer than 100 ships of different nations.

A castle stands at its entrance, and commands all the shipping which sails in or out. There is likewise an old ruinous castle, near a mile in circumference, which stands in the upper part of the city, and according to tradition, was built by the empress Helena: and near it is an ancient structure, said to be the remains of a palace where the Greek council was held when Smyrna was the metropolis of Asia Minor. They also show the ruins of an amphitheatre, where it is said St Polycarp, the first bishop, fought with lions.

This city is about four miles in circumference, and nearly of a triangular form; but the side next the mountain is much longer than the other sides. The houses are low, and mostly built with clay walls, on account of the earthquakes to which the country is subject; but the caravanseras and some of the public buildings have an air of magnificence. The streets are wide, and almost a continued bazaar, in which a great part of the merchandise of Europe and Asia is exposed to sale, with plenty of provisions; though these are not so cheap as in many other parts of Turkey, on account of the populousness of the place, and the great resort of foreigners. It is said to contain 15,000 Turks, 10,000 Greeks, 1800 Jews, 200 Armenians, and 200 Franks: but the whole population is computed at 120,000. The Turks have 10 mosques; two churches belong to the Greeks; one to the Armenians; and the Jews have eight synagogues. The Romanists have three convents. There is also one of the fathers Della Terra Santa. Here resides an archbishop of the Greek church; a Latin bishop who has a salary from Rome, with the title of bishop of Smyrna in partibus infidelium; and the English and Dutch factories have each their chaplain.

The walks about the town are extremely pleasant, particularly on the west side of Frank street, where there are several little groves of orange and lemon trees, which being always clothed with leaves, blossoms, and fruit, regale several of the senses at the same time. The vines which cover the little hills about Smyrna afford both a delightful prospect and plenty of grapes, of which good wine is made. These hills are agreeably interspersed with fertile plains, little forests of olives and other fruit-trees, and many pleasure-houses, to which the Franks usually retire during the summer. In the neighbourhood of Smyrna is great plenty of game and wild-fowl, and particularly deer and wild-hogs. The sea also abounds with a variety of good fish. The European Christians are here allowed all imaginable liberties, and usually clothe themselves after the European manner.

The chief commerce of this city consists in raw silk, silk-stuffs, programs, and cotton yarn.

However, the unhealthfulness of the situation, and more especially the frequent earthquakes, from which it is said, they are scarcely ever free for two years together, and which have been felt 40 days successively, are an abatement of the pleasure that might otherwise be enjoyed here. A very dreadful one happened in June 1668, which overthrew a great number of the houses; and the rock opening where the castle stood, swallowed it up, and no less than 5000 persons perished on this occasion.

In the year 1758, so desolating a plague raged here, that scarcely a sufficient number of the inhabitants survived to gather in the fruits of the earth. In the year 1772, three-fourth parts of the city were consumed by fire; and six years after it was visited by the most dreadful earthquakes, which continued from the 25th of June to the 5th of July; by which successive calamities the city has been so much reduced, that its former consequence is never likely to be restored.

The ladies here wear the oriental dress, consisting of large trousers or breeches, which reach to the ankle; long vests of rich silk or velvet, lined in winter with costly furs; and round their waist an embroidered zone with clasps of silver or gold. Their hair is plaited, and descends down the back often in great profusion. The girls have sometimes above twenty thick tresses, besides two or three encircling the head as a cornet, and set off with flowers and plumes of feathers, pearls, or other jewels. They commonly stain it of a chesnut colour, which is the most desired. Their apparel and carriage are alike antique. It is remarkable that the trousers are mentioned in a fragment of Sappho as part of the female dress.

SMYRIUM, ALEXANDER: a genus of plants belonging to the class of pentandria, and to the order of digynia; and in the natural system ranging under the 4th order, Umbellate. See Botany Index.

SNAFFLE, in the manege, is a very slender bitmouth without any branches, much used in England; the true bridles being reserved for war.

SNAIL, in Zoology. See Helix, Conchology Index, and Limax, Helminthology Index.
SNAKE, in Zoology. See Angus and Serpens, Ophiology Index.

Snake-Stones, Ammonites, in Natural History, the names of a large genus of fossil shells, very few if any of which are yet known in their recent state, or living either on our own or any other shores; so that it seems wonderful to us how so vast a number and variety of them should be brought into our subterranean regions. They seem indeed dispersed in great plenty throughout the world, but nowhere are found in greater numbers, beauty, and variety, than in our island.

Mr Harenberg found prodigious numbers of them on the banks of a river in Germany. He traced this river through its several windings for many miles; and among a great variety of helminites, cornea ammonis, and cochitite, of various kinds, he found also great quantities of wood of recent petrification, which still preserved plain marks of the axe by which it had been cut from the trees then growing on the shore. The water of this river he found in dry seasons, when its natural springs were not diluted with rains, to be considerably heavier than common water; and many experiments showed him that it contained ferruginous, as well as stony particles, in great quantity, whence the petrifications in it appeared the less wonderful, though many of them of recent date.

Of the cornua ammonis, or serpent-stones, he there observed more than 30 different species. They lie immersed in a bluish fossil stone, of a soft texture and fatty appearance, in prodigious numbers, and of a great variety of sizes, from the larger known sorts down to such as could not be seen without very accurate inspection or the assistance of a microscope. Such as lie in the softest of these stones are soft like their matrix, and easily crumble to pieces; others are harder. In a piece of this stone, of the bigness of a finger, it is common to find 30 or more of these fossils; and often they are seen only in form of white specks, so minute that their figure cannot be distinguished till examined by the microscope.

They all consist of several volutes, which are different in number in the different species, and their striae also are extremely various; some very deep with very high ridges between them, others very slight; some straight, others crooked; others undulated, and some terminating in dots, tubercles, or cavities, towards the back, and others having tubercles in two or three places. They are all composed of a great number of chambers or cells, in the manner of the nautilus Cereorurum, each having a communication with the others, by means of a pipe or sphincterus. There is a small white shell fish of Barbadoes, which seems truly a recent animal of this genus; and in the East Indies there is another also, small and grayish; but the large and beautifully marked ones are found only fossil.

They are composed of various fossil bodies, often of quarry stone, sometimes of the matter of the common pyrites, and of a great variety of other substances; and though they appear usually mere stones, yet in some the partly original shell is preserved in all its beauty. Sometimes also, while the outer substance is of the matter of the pyrites, or other coarse, stony, or mineral matter, the inner cavity is filled with a pure white spar of the common plated texture. This gives a great beauty to the specimen. The cornua ammonis, or snake-stones, are found in many parts of England, particularly in Yorkshire, where they are very plentiful in the alum rocks of several sizes.

Snake-Root. See Polygala, Botany Index.

Snake-Weed. See Polygonum, Botany Index.

SNAPEDRAGON. See Antirrhinum, Botany Index.

SNEEZING, a convulsive motion of the muscles of the breast, whereby the air is expelled from the nose with much vehemence and noise. It is caused by the irritation of the upper membrane of the nose, occasioned by acid substances floating in the air, or by medicines called sternutatories.

This irritation is performed either externally, by strong smells, as marjoram, roses, &c. or by dust floating in the air, and taken in by inspiration; or by sharp pungent medicines, as cresses and other sternutatories, which vellicate the membrane of the nose; or internally, by the acrimony of the lymph or mucus, which naturally moistens that membrane. The matters cast forth in sneezing come primarily from the nose and throat; the pituitary membrane continually exuding a mucus thinner; and, secondarily, from the breast, the trachea, and the bronchia of the lungs.

The practice of saluting the person who sneezed existed in Africa, among nations unknown to the Greeks and Romans. The accounts we have of Monomotapa inform us, that when the prince sneezes, all his subjects in the capital are advertised of it, that they may offer up prayers for his safety. The author of the Conquest of Peru assures us, that the cacique of Guachoa having sneezed in presence of the Spaniards, the Indians of his train fell prostrate before him, stretched forth their hands, and displayed to him the accustomed marks of respect, while they invoked the sun to enlighten him, to defend him, and to be his constant guard.

Every body knows that the Romans saluted each other on these occasions: and Pliny relates, that Titus allowed sacrifices to be offered to the gods in the chariot. Superstition, whose influence can debase every thing, had degraded this custom for several ages, by attaching favourable or unfavourable omens to sneezing according to the hour of the day or night, according to the signs of the zodiac, according as a work was more or less advanced, or according as one had sneezed to the right or to the left. If a man sneezed at rising from his table or from his bed, it was necessary for him to sit or lie down again. You are struck with astonishment, said Timotheus to the Athenians, who wished to return into the harbour with their fleet, because he had sneezed; you are struck with astonishment, because among 10,000 there is one man whose brain is moist.

Polydore Virgil pretends, that in the time of Gregory the Great, there reigned in Italy an epidemic distemper, which carried off by sneezing all those who were seized by it; and that this pontiff ordered prayers to be made against it, accompanied by certain signs of the cross. But besides that, there are very few cases in which sneezing can be considered as dangerous, and that it is frequently a favourable symptom; it is evident, that we ought not to date from the sixth century the origin of a custom which loses itself in the obscurity of antiquity. Avicenna and Cardan say, it is a sort of convulsion, which gives occasion to dread an epilepsy, and that
that this disease is endeavoured to be warded off by prayers. Clement of Alexandria considers it as a mark of intemperance and effeminacy, which ought to be proscribed. And he inveighs bitterly against those who endeavoured to procure sneezing by external aid. Montaigne, on the contrary, explains this fact in a tone rather cynical. It is singular enough, that so many ridiculous, contradictory, and superstitious opinions, have not abolished those customary civilities which are still preserved equally among high and low; and which annoy the Anabaptists and Quakers have rejected, because they have renounced salutations in every case.

Among the Greeks sneezing was almost always a good omen. It excited marks of tenderness, of respect, and attachment. The genius of Socrates informed him by sneezing, when it was necessary to perform any action. The young Parthenis, hurried on by her passion, resolved to write to Sarpedon an avowal of her love; she sneezes in the most tender and impassioned part of her letter: This is sufficient for her; this incident supplies the place of an answer, and persuades her that Sarpedon is her lover. Penelope, harassed by the vexatious courtship of her suitors, begins to curse them all, and to pour forth vows for the return of Ulysses. Her son Telemachus interrupts her with a loud sneeze. She instantly exults with joy, and regards this sign as an assurance of the approaching return of her husband. Xenophon was haranguing his troops; a soldier sneezed in the moment when he was exerting them to embrace a dangerous but necessary resolution. The whole army, moved by this presage, determined to pursue the project of their general; and Xenophon orders sacrifices to Jupiter the preserver.

This religious reverence for sneezing, so ancient and so universal in the times of Homer, always excited the curiosity of the Greek philosophers and of the rabbins. These last have spread a tradition, that, after the creation of the world, God made a general law to this purport, that every living man should sneeze but once in his life, and that at the same instant he should render up his soul into the hand of his Creator, without any preceding indisposition. Jacob obtained an exemption from the common law, and the favour of being informed of his last hour: He sneezed and did not die; and this sign of death was changed into a sign of life. Notice of this was sent to all the princes of the earth; and they ordained that in future sneezing should be accompanied with forms of blessing, and vows for the persons who sneezed.

Aristotle remonstrates likewise to the sources of natural religion. He observes, that the brain is the origin of the nerves, of our sentiments, our sensations, the seat of the soul, the image of the Divinity; that upon all these accounts, the substance of the brain has ever been held in honour; that the first men swore by their head; that they durst not touch nor eat the brains of any animal; that it was even a sacred word which they dared not to pronounce. Filled with these ideas, it is not wonderful that they extended their reverence even to sneezing. Such is the opinion of the most ancient and sagacious philosophers of Greece.

According to mythology, the first sign of life Prometheus's artificial man gave was by stertor. This supposed creator is said to have stolen a portion of the solar rays; and filling with them a phial, which he had made on purpose, sealed it up hermetically. He instantly flies back to his favourite automaton, and opening the phial holds it close to the statue; the rays still retaining all their activity, insinuate themselves through the pores, and set the fictitious man a sneezing. Prometheus, transported with the success of his machine, offers up a fervent prayer, with wishes for the preservation of so singular a being. His automaton observed him, remembering his ejaculations, was very careful, on the like occasions, to offer these wishes in behalf of his descendants, who perpetuated it from father to son in all their colonies.

SNIFFLING, a method of fishing for eels, chiefly used in the daytime, when they are found to hide themselves near wears, mills, or flood-gates. It is performed thus: Take a strong line and hook, baited with a garden worm, and observing the holes where the eels lie hid, thrust your bait into them by the help of a stick; and if there be any, you shall be sure to have a bite; and may, if your tackling hold, get the largest eels.

SNIPE, in Ornithology. See SCOLOPAX and SHOOTING.

SNORING, in Medicine, otherwise called stertor, is a sound like that of the cerchnos, but greater and more manifest.

Many confound those affections, and make them to differ only in place and magnitude, calling by the name of stertor that sound or noise which is heard or supposed to be made in the passage between the palate and the nostrils, as in those who sleep; that boiling or bubbling noise, which in respiration proceeds from the larynx or head, or orifice of the aspera arteria, they call cerchnos; but if the sound comes from the aspera arteria itself, it is called cerchnos, that is, as some understand it, a rattling, or as others a stridulous or wheezing roughness of the aspera arteria. In dying persons this affection is called by the Greeks rheno, rhenechos, which is a snoring or rattling kind of noise, proceeding as it were from a conflict between the breath and the humours in the aspera arteria.

This and such like affections are owing to a weakness of nature, as when the lungs are full of pus or humours: to which purpose we read in the Prognostics of Hippocrates, "it is a bad sign when there is no expectation, and no discharge from the lungs, but a noise as from an ebullition is heard in the aspera arteria from a plenitude of humour." Expectoration is suppressed either by the viscosity of the humour, which requires to be discharged, and which adhering to the aspera arteria, and being there agitated by the breath, excites that bubbling noise or stertor; or by an obstruction of the bronchiae; or, lastly, by a compression of the aspera arteria and throat, whence the passage is straitened, in which the humours being agitated, excite such a kind of noise as before described. Hence Galen calls those who are strait-breasted stertorous. That author assigns but two causes of this symptom, which are either the strength of the passage of respiration or redundancy of humours, or both together; but it is necessary to add a third, to wit, the weakness of the faculty, which is the cause of the rhenechos in dying persons, where nature is too weak to make discharges.

From what has been said we conclude, that this symptom or this sort of favour or ebullition in the throat,
Snow, a well-known meteor, formed by the freezing of the vapour of water in the atmosphere. It differs from hail and hoar-frost, in being as it were crystallized, which they are not. This appears in examining a flake of snow by a magnifying glass; when the whole of it will appear to be composed of fine shining spicula diverging like rays from a centre. As the flakes fall down through the atmosphere, they are continually joined by more of these radiated spicula, and thus increase in bulk like the drops of rain or hailstones. Dr. Grew, in a discourse of the nature of snow, observes, that many parts thereof are of a regular figure, for the most part stars of six points, and are as perfect and transparent ice as we see on a pond, &c. Upon each of these points are other collateral points, set at the same angles as the main points themselves; among which there are divers other irregular, which are chiefly broken points, and fragments of the regular ones. Others also, by various winds, seem to have been thinned and frozen again into irregular clusters; so that it seems as if the whole body of snow were an infinite mass of icicles irregularly figured. That is, a cloud of vapours being gathered into drops, the said drops forthwith descend; upon which descent, meeting with a freezing air as they pass through a colder region, each drop is immediately frozen into an icicle, shooting itself forth into several points; but these still continuing their descent, and meeting with some intermittating gales of warmer air, or in their continual waftage to and fro touching upon each other, some of them are a little thawed, blunted, and again frozen into clusters, or entagled so as to fall down in what we call flakes.

The lightness of snow, although it is firm ice, is owing to the excess of its surface, in comparison to the matter contained under it; as gold itself may be extended in surface till it ride upon the least breath of air. The whiteness of snow is owing to the small particles into which it is divided; for ice, when pounded, will become equally white. An artificial snow has been made by the following experiment. A tall phial of aquafortis being placed by the fire till it is warm, and blings of pure silver, a few at a time, being put into it; after a brisk ebullition, the silver will dissolve slowly. The phial being then placed in a cold window, as it cools the silver particles will shoot into crystals, several of which running together will form a flake of snow, which will descend to the bottom of the phial. While they are descending, they represent perfectly a shower of silver snow, and the flakes will lie upon one another at the bottom, like real snow upon the ground.

According to Signior Beccaria, clouds of snow differ in nothing from clouds of rain, but in the circumstance of cold that freezes them. Both the regular diffusion of the snow, and the regularity of the structure of its parts (particularly some figures of snow or hail which fall about Turin, and which he calls rosette) show that clouds of snow are acted upon by some uniform cause like electricity; and he endeavours to show how electricity is capable of forming these figures. He was confirmed in his conjectures by observing, that his apparatus for observing the electricity of the atmosphere never failed to be electrified by snow as well as by rain. Professor Winthrop sometimes found his apparatus electrified by snow when driven about by the wind, though it had not been affected by it when the snow itself was falling. A more intense electricity, according to Bec- caria, unites the particles of hail more closely than the more moderate electricity does those of snow, in the same manner as we see that the drops of rain which fall from thunder-clouds are larger than those which fall from others, though the former descend through a less space.

But we are not to consider snow merely as a curious and beautiful phenomenon. The Great Dispenser of universal bounty has so ordered it, that it is eminently subservient, as well as all the works of creation, to his benevolent designs. Were we to judge from appearances only, we might imagine, that so far from being useful to the earth, the cold humidity of snow would be detrimental to vegetation. But the experience of all ages asserts the contrary. Snow, particularly in those northern regions where the ground is covered with it for several months, fructifies the earth, by guarding the corn or other vegetables from the intenser cold of the air, and especially from the cold piercing winds. It has been a vulgar opinion, very generally received, that snow fertilizes the lands on which it falls more than rain, in consequence of the nitrous salts which it is supposed to acquire by freezing. But it appears from the experiments of M. Margraf, in the year 1751, that the chemical difference between rain and snow water is exceedingly small; that the latter contains a less proportion of earth than the former; but neither of them contain either earth or any kind of salt in any quantity which can be sensibly efficacious in promoting vegetation. Allowing, therefore, that nitre is a fertilizer of lands, which many are upon good grounds disposed utterly to deny, yet so very small is the quantity of it contained in snow, that it cannot be supposed to promote the vegetation of plants upon which the snow has fallen. The peculiar agency of snow, as a fertilizer in preference to rain, may admit of a very rational explanation, without recurring to nitrous salts supposed to be contained in it. It may be rationally ascribed to its furnishing a covering to the roots of vegetables, by which they are guarded from the influence of the atmospheric cold, and the internal heat of the earth is prevented from escaping.

The internal part of the earth, by some principle which we do not understand, is heated uniformly to the 48th degree of Fahrenheit's thermometer. This degree of heat is greater than that in which the watery juices of vegetables freeze, and it is propagated from the inward parts of the earth to the surface, on which the vegetables grow. The atmosphere being variably heated by the action of the sun in different climates, and in the same climate at different seasons, communicates to the surface of the earth and to some distance below it the degree of heat or cold which prevails in itself. Different vegetables are able to preserve life under different degrees of cold, but all of them perish when the cold which reaches their roots is extreme. Providence has therefore, in the coldest climates, provided a covering
Snow. of snow for the roots of vegetables, by which they are protected from the influence of the atmospheric cold. The snow keeps in the internal heat of the earth, which surrounds the roots of vegetables, and defends them from the cold of the atmosphere.

Snow or ice water is always deprived of its fixed air, which escapes during the process of congelation. Accordingly, as some of the inhabitants of the Alps who use it for their constant drink have enormous wenions upon their throats, it has been ascribed to this circumstance. If this were the cause of these wens, it would be easy to remove it by exposing the snow-water to the air for some time. But several eminent physicians have rejected the notion that snow-water is the cause of these wens; for in Greenland, where snow-water is commonly used, the inhabitants are not affected with such swellings: on the other hand, they are common in Sumatra where snow is never seen.

Snow, in sea-affairs, is generally the largest of all two-masted vessels employed by Europeans, and the most convenient for navigation.

The sails and rigging on the mainmast and foremost of a snow are exactly similar to those on the same masts in a ship; only that there is a small mast behind the mainmast of the former, which carries a sail nearly resembling the mizen of a ship. The root of the mast is fixed on a block of wood on the quarter-deck abait the mainmast; and the head of it is attached to the after-top of the maintop. The sail, which is called the try-sail, is extended from its mast towards the stern of the vessel.

When the slopes of war are rigged as snows, they are furnished with a horse, which answers the purpose of the try-sail-mast, the fore-part of the sail being attached by rings to the said horse, in different parts of its height.

Snow-grotto, an excavation made by the waters on the side of Mount Etna, by making their way under the layers of lava, and by carrying away the bed of pozzolana below them. It occurred to the proprietor, that this place was very suitable for a magazine of snow: for in Sicily, at Naples, and particularly at Malta, they are obliged for want of ice to make use of snow for cooling their wine, sherbert, and other liquors, and for making sweetmeats.

This grotto was hired or bought by the knights of Malta, who having neither ice nor snow on the burning rock which they inhabit, have hired several caverns on Etna, into which people whom they employ collect and preserve quantities of snow to be sent to Malta when needed. The grotto has therefore been repaired within at the expense of that order; flights of steps are cut into it, as well as two openings from above, by which they throw in the snow, and through which the grotto is enlightened. Above the grotto they have also levelled a piece of ground of considerable extent: this they have inclosed with thick and lofty walls, so that when the winds, which at this elevation blow with great violence, carry the snow from the higher parts of the mountains, and deposit it in the inclosure, it is retained and amassed by the walls. The people then remove it into the grotto through the two openings; and it is there laid up, and preserved in such a manner as to resist the force of the summer heats; as the layers of lava with which the grotto is arched above prevent them from making any impression.

When the season for exporting the snow comes on, it is put into large bags, into which it is pressed as closely as possible; it is then carried from the grotto, and laid upon mules, which convey it to the shore, where small vessels are waiting to carry it away.

But before those lumps of snow are put into bags, they are wrapped in fresh leaves; so that while they are conveyed from the grotto to the shore, the leaves may prevent the rays of the sun from making any impression upon them.

The Sicilians carry on a considerable trade in snow, which affords employment to some thousands of nules, horses and men. They have magazines of it on the summits of their loftiest mountains, from which they distribute it through all their cities, towns, and houses; for every person in the island makes use of snow. They consider the practice of cooling their liquors as absolutely necessary for the preservation of health; and in a climate the heat of which is constantly relaxing the fibres, cooling liquors, by communicating a proper tone to the fibres of the stomach, must greatly strengthen them for the performance of their functions.

In this climate a scarcity of snow is no less dreaded than a scarcity of corn, wine, or oil. We are informed by a gentleman who was at Syracuse in the year 1777, when there was a scarcity of snow, the people of the town learned that a small vessel loaded with that article was passing the coast without a moment's deliberation they ran in a body to the shore, and demanded her cargo; which, when the crew refused to deliver up, the Syracusans attacked and took, though with the loss of several men.

Snow-drop. See Chionanthus, Botany Index.

Snowdon Hill, the name of a mountain in Caernarvon-shire in Wales, generally thought to be the highest in Britain; though some have been of opinion that its height is equalled, or even exceeded, by mountains in the Highlands of Scotland. The mountain is surrounded by many others, called in the Welsh language Crib Coch, Crib y DISTILL, Lliwedd yr Arran, &c.

According to Mr Pennant*, this mountainous tract* yields scarcely any corn. Its produce is cattle and sheep; and during the summer, keep very high in the mountains, which, followed by their owners with their families, who reside during that season in hovodits, or "summer dairy-houses," as the farmers in the Swiss Alps do in their senner. These houses consist of a long low room, with a hole at one end to let out the smoke from the fire which is made beneath. Their furniture is very simple; stones are substituted for stools and their beds are of hay ranged along the sides. They manufacture their own clothes, and dye them with the lichen omphaloides and lichen poracitus, mosses collected from the rocks. During summer the men pass their time in tending their herds or in making hay, &c. and the women in milking or in making butter and cheese. For their own use they milk both ewes and goats, and make cheese of the milk. Their diet consists of milk, cheese, and butter; and their ordinary drink is whey; though they have, by way of reserve, a few bottles of very strong beer, which they use as a cordial when sick. They are people of good understanding, wary, and circumspect; tall, this,
SNOWDEN, hill, and of strong constitutions. In the winter-time they descend into the hen-dref, or, "old-dwelling," where they pass their time in inactivity.

The view from the highest peak of Snowden is very extensive. From it Mr. Pennant saw the country of Chester, the high hills of Yorkshire, part of the north of England, Scotland, and Ireland; a plain view of the isle of Man; and that of Anglesea appeared like a map extended under his feet, with every rivulet visible. Our author took much pains to have this view to advantage; sat up at a farm on the west, till about 12, and walked up the whole way. The night was remarkably fine and starry; towards morning the stars faded away, leaving an interval of darkness, which, however, was soon dispelled by the dawn of day. The body of the sun appeared most distinct, with the roundness of the moon, before it appeared too brilliant to be looked at. The sea, which bounded the western part of the prospect, appeared girt with the sun-beams, first in slender streaks, and at length glowed with redness. The prospect was disclosed like the gradual drawing up of a curtain in a theatre; till at last the heat became sufficiently strong to raise mists from the various lakes, which in a slight degree obscured the prospect. The shadow of the mountains extended many miles, and showed its bicipitated form; the Wyndfa making one head, and Crib y Distill the other. At this time be counted between 20 and 30 lakes either in Caernarvon or in Merionethshire. In making another visit, the sky was obscured very soon after he get up. A vast mist involved the whole circuit of the mountain, and the prospect done was horrible. It gave an idea of numbers of abysses, concealed by a thick smoke furiously circulating around them. Very often a gust of wind made an opening in the clouds, which gave a fine and distinct vista of lake and valley. Sometimes they opened in one place, at others in many at once; exhibiting a most strange and perplexing sight of water, fields, rocks, and chasms. They then closed again, and everything was involved in darkness; in a few minutes they would separate again, and repeat the above-mentioned scene with infinite variety. From this prospect our traveller descended with great reluctance; but before he had reached the place where his horses were left, he was overtaken by a thunder storm. The rolling of the thunder-claps, being reiterated by the mountains, was inexpressibly awful; and after he had mounted, he was in great danger of being swept away by the torrents which poured down in consequence of a very heavy rain.

It is very rare (Mr. Pennant observes) that the traveller gets a proper day to ascend this hill; it indeed often appears clear; but by the evident attraction of the clouds by this lofty mountain, it becomes suddenly and unexpectedly enveloped in mist, when the clouds have just before appeared very high and very remote. At times he observed them lower to half their height; and notwithstanding they have been dispersed to the right and left, yet they have met from both sides, and united to involve the summit in one great obscurity.

The height of Snowden was measured, in 1682, by Mr. Caswell, with instruments made by Flamstead: according to his measurement, the height is 3720 feet; but more moderate computations make it only 3568, reckoning from the quay at Caernarvon to the highest peak. The stone that composes this mountain is excessively hard. Large coarse crystals, and frequently cubic pyrites, are found in the fissures. An immense quantity of water rushes down the sides of Snowden and the neighbouring mountains, insomuch that Mr. Pennant supposes, if collected into one stream, they would exceed the waters of the Thames.

SNUFF, a powder chiefly made of tobacco, the use of which is too well known to need any description here.

Tobacco is usually the basis of snuff; other matters being only added to give it a more agreeable scent, &c. The kinds of snuff, and their several names, are infinite, and new ones are daily invented; so that it would be difficult, not to say impossible, to give a detail of them. We shall only say, that there are three principal sorts: the first granulated; the second an impalpable powder; and the third the bran, or coarse part remaining after sifting the second sort.

"Every professed, inveterate, and incurable snuff-taker (says Lord Stanhope) at a moderate computation, takes one pinch in ten minutes. Every pinch with the agreeable ceremony of blowing and wiping the nose and other incidental circumstances, consumes a minute and a half. One minute and a half out of every ten, allowing 16 hours to a snuff-taking day, amounts to two hours and 24 minutes out of every natural day, or one day out of every ten. One day out of every 10 amounts to 36 days and a half in a year. Hence if we suppose the practice to be persisted in 40 years, two entire years of the snuff-taker's life will be dedicated to tickling his nose, and two more to blowing it. The expence of snuff, snuff-boxes, and handkerchiefs, will be the subject of a second essay; in which it will appear, that this luxury encroaches as much on the income of the snuff-taker as it does on his time; and that by a proper application of the time and money thus lost to the public, a fund might be constituted for the discharge of the national debt." See NICOTIANA.

SNYDERS, FRANCIS, a Flemish painter, born at Antwerp in 1579, and bred under his countryman Henry Van Balen. His genius first displayed itself in painting fruit: he afterwards attempted animals, hunting, &c. in which he excelled all his predecessors. He also painted kitchins, &c. and gave dignity to subjects that seemed incapable of it. He was made painter to Ferdinand and Isabella, archduke and duchess, and became attached to the house of the cardinal infant of Spain. The king of Spain and the elector Palatine adorned their palaces with hunting by this artist. Rubens, Jordaeus, and Synders, used to co-operate in the engraving of each other's pictures according to their several talents; and thus they became more valuable than if finished by either of them singly. Synders died in 1657.

SOAL-FISH. See Pleuronectes, Ichthyology Index.

SOAP, a composition of caustic, fixed alkaline salt, and oil, sometimes hard and dry, sometimes soft and liquid; much used in washing, whitening linens, and by dyers and fullers.—Soap may be made by several methods, which, however, all depend upon the same principle. The soap which is used in medicine is made without heat.

In manufactures where large quantities of it are prepared, soap is made with heat. A Lixivium of quicklime and
and soda is made, but is less concentrated than that above referred to, and only so much that it can sustain a fresh egg. A part of this lixivium is to be even diluted and mixed with an equal weight of oil of olives. The mixture is to be put on a gentle fire, and agitated, that the union may be accelerated. When the mixture begins to unite well, the rest of the lixivium is to be added to it; and the whole is to be digested with a very gentle heat, till the soap be completely made. A trial is to be made of it, to examine whether the just proportion of oil and alkali has been observed. Good soap of this kind ought to be firm, and very white when cold; not subject to become moist by exposure to air, and entirely miscible with pure water, to which it communicates a milky appearance, but without any drops of oil floating on the surface. When the soap has not these qualities, the combination has not been well made, or the quantity of salt or oil is too great, which faults must be corrected.

In soft or liquid soaps, green or black soaps, cheaper oils are employed, as oil of nuts, of hemp, of fish, &c. These soaps, excepting in consistence, are not essentially different from white soap.

Fixed alkalies are much disposed to unite with oils that are not volatile, both vegetable and animal, since this union can be made even without heat. The compound resulting from this union partakes at the same time of the properties of oil and of alkali; but these properties are modified and tempered by each other, according to the general rule of combinations. Alkali formed into soap has not nearly the same acrimony as when it is pure; it is even deprived of all its causticity, and its other saline alkaline properties are almost entirely abridged. The same oil contained in soap is less combustible, than when pure, from its union with the alkali, which is an inflammable body. It is miscible, or even soluble, in water, to a certain degree, by means of the alkali. Soap is entirely soluble in spirit of wine; and still better in aquavitae sharpened by a little alkaline salt, according to an observation of Mr. Geoffroy.

The manufacture of soap in London first began in the year 1524; before which time this city was served with white soap from foreign countries, and with grey soap speckled with white from Bristol, which was sold for a penny a pound; and also with black soap, which sold for a halfpenny the pound.

The principal soaps of our own manufacture are the soft, the hard, and the ball soap. The soft soap is either white or green. The process of making each of these shall now be described.

Green soft soap. The chief ingredients used in making this are lees drawn from potash and lime, boiled up with tallow and oil. First, the ley of a proper degree of strength (which must be estimated by the weight of the liquor), and tallow, are put into the copper together, and as soon as they boil up the oil is added; the fire is then damped or stopped up, while the ingredients remain in the copper to unite; when they are united, the copper is again made to boil, being fed or filled with lees as it boils, till there be a sufficient quantity put into it; then it is boiled off and put into casks. When this soap is made it appears uniform; but in about a week’s time the tallow separates from the oil into those white grains which we see in common

Vol. XIX. Part II.

Soap thus made would appear yellow, but by a mixture of indigo added at the end of the boiling, it is rendered green, that being the colour which results from the mixture of yellow and blue.

White soap. Of this one sort is made after the same manner as green soft soap, oil alone excepted, which is not used in white. The other sort of white soft soap is made from the lees of ashes of lime boiled up two different times with tallow. First, a quantity of lees and tallow are put into the copper together, and kept boiling, being fed with lees as they boil, until the whole is boiled sufficiently; then the ley is discharged or discharged from the tallowish part, which part is removed into a tub, and the lees are thrown away; this is called the first half-boil: then the copper is filled again with fresh tallow and lees, and the first half-boil is put out of the tub into the copper a second time, where it is kept boiling with fresh lees and tallow till the soap is produced. It is then put out of the copper into the same sort of casks as are used for green soft soap. The common soft soap used about London, generally of a greenish hue, with some white lumps, is prepared chiefly with tallow: a blackish sort, more common in some other places, is said to be made with whale oil.

Hard soap is made with lees from ashes and tallow, and is most commonly boiled twice: the first, called the half-boil, hath the same operation as the first half-boil of soft white soap. Then the copper is charged with fresh lees again, and the first half-boil put into it, where it is kept boiling, and fed with lees as it boils, till it grains or is boiled enough: then the ley is discharged from it, and the soap put into a frame to cool and harden. Common salt is made use of for the purpose of softening the soap; for when the oil or tallow has been united with the ley, after a little boiling, a quantity of salt is thrown into the mass, which dissolving readily in water, but not in the oil or tallow, draw out the water in a considerable degree, so that the oil or tallow united with the salt of the ley swims on the top. When the ley is of a proper strength, less salt is necessary to raise the curd than when it is too weak. It must be observed, that there is no certain time for bringing off a boiling of any of these sorts of soap: it frequently takes up part of two days.

Ball soap, commonly used in the north, is made with lees from ashes and tallow. The lees are put into the copper, and boiled till the watery part is quite gone, and there remains nothing in the copper but a sort of saline matter (the very strength or essence of the ley): to this the tallow is put, and the copper is kept boiling and stirring for above half an hour, in which time the soap is made; and then it is put out of the copper into tubs or baskets with sheets in them, and immediately (whilst soft) made into balls. It requires near 24 hours in this process to boil away the watery part of the ley.

When oil unites with alkali in the formation of soap, it is little altered in the connection of its principles; for it may be separated from the alkali by decomposing soap with any acid, and may be obtained nearly in its original state. Concerning the decomposition of soap by means of acids, we must observe, first, that all acids, even the weakest vegetable acids, may occasion this decomposition, because every one of them has a greater affinity than
Soap. 

Sop. than oil with fixed alkali. Secondly, these acids, even when united with any bases, excepting fixed alkali, are capable of occasioning the same decomposition; whence all ammoniacal salts, all salts with bases of earth, and all those with metallic bases, are capable of decomposing soap, in the same manner as disengaged acids are; with this difference, that the oil separated from the fixed alkali, by the acid of these salts, may unite more or less intimately with the substance which was the basis of the neutral salt employed for the decomposition.

Soap may also be decomposed by distillation, as Lemery has done. When first exposed to fire, it yields a phlegm called by him a spirit; which nevertheless is neither acid nor alkaline, but some water which enters into the composition of soap. It becomes more and more coloured and empyreumatic as the fire is increased, which shows that it contains the most subtle part of the oil. It seems even to raise along with it, by help of the oil and action of the fire, a small part of the alkali of the soap: for as the same chemist observes, it occasions a precipitate in a solution of corrosive sublimate. After this phlegm the oil rises altered, precisely as if it had been distilled from quicklime, that is, empyreumatic, soluble in spirit of wine, at first sufficiently subtle and afterwards thicker. An alkaline residue of coal remains in the retort, consisting chiefly of the mineral alkali contained in the soap, and which may be disengaged from the coal by calcination in an open fire, and obtained in its pure state.

Alkaline soaps are very useful in many arts and trades, and also in chemistry and medicine. Their principal utility consists in a degressive quality that they receive from their alkali, which, although it is in some measure saturated with oil, is yet capable of acting upon oily matters, and of rendering them saposonaceous and miscible with water. Hence soap is very useful to cleanse any substances from all fat matters with which they happen to be soiled. Soap is therefore daily used for the washing and whitening of linen, for the cleansing of woollen cloths from oil, and for whitening silk and freeing it from the resinous varnish with which it is naturally covered. Pure alkaline lixiviums being capable of dissolving oils more effectually than soap, might be employed for the same purposes; but when this activity is not mitigated by oil, as it is in soap, they are capable of altering, and even of destroying entirely by their causticity, most substances, especially animal matters, as silk, wool, and others: whereas soap cleanses from oil almost as effectually as pure alkali, without danger of altering or destroying; which renders it very useful.

Soap was imperfectly known to the ancients. It is mentioned by Pliny as made of fat and ashes, and as an invention of the Gauls. Aristotle and others inform us, that the Greeks obtained their knowledge of its medical use from the Romans. Its virtues, according to Bergius, are detergent, resolvent, and aperient, and its use recommended in jaundice, gout, calculous complaints, and in obstructions of the viscera. The efficacy of soap in the first of these diseases was experienced by Sylvius, and since recommended very generally by various authors who have written on this complaint; and it has also been thought of use in supplying the place of bile in the prime valve. The utility of this medicine in ictual cases was inferred chiefly from its supposed power of dissolving biliary concretions; but this medicine has lost much of its reputation in jaundice, since it is now known that gall-stones have been found in many after death who had been daily taking soap for several months and even years. Of its good effects in urinary calculous affections, we have the testimony of several, especially when dissolved in lime-water, by which its efficacy is considerably increased; for it thus becomes a powerful solvent of mucus, which an ingenious modern author supposes to be the chief agent in the formation of calculi; it is, however, only in the incipient state of the disease that these remedies promise effectual benefit; though they generally abate the more violent symptoms where they cannot remove the cause. With Boerhaave soap was a general medicine: for as he attributed most complaints to viscosity of the fluids, he, and most of the Boerhaavian school, prescribed it in conjunction with different resinos and other substances, in gout, rheumatism, and various visceral complaints. Soap is also externally employed as a resolvent, and gives name to several officinal preparations.

From the properties of soap we may know that it must be a very effectual and convenient anti-acid. It absorbs acids as powerfully as pure alkalis and absorbent earths, without having the causticity of the former, and without oppressing the stomach by its weight like the latter.

Lastly, we may perceive that soap must be one of the best of all antidotes to stop quickly, and with the least inconveniency, the bad effects of acid corrosive poisons, as aquafortis, corrosive sublimate, &c.

Soap imported is subject by 10 Ann. cap. 19. to a duty of 2d. a pound (over and above former duties); and by 12 Ann. stat. 2. cap. 9. to the further sum of 1d. a pound. And by the same acts, the duty on soap made in the kingdom is 1d. a pound. By 19 G. III. cap. 52. no person within the limits of the head office of excise in London shall be permitted to make any soap unless he occupy a tenement of 10l. a-year, be assessed, and pay the parish rates; or elsewhere, unless he be assessed, and pay to church and poor. Places of making are to be entered on pain of 50l. and covers and locks to be provided under a forfeiture of 100l.; the furnace-door of every utensil used in the manufacture of soap shall be locked by the excise officer, as soon as the fire is damped or drawn out, and fastenings provided, under the penalty of 50l.; and opening or damaging such fastening incurs a penalty of 100l. Officers are required to enter and survey at all times, by day or night, and the penalty of obstructing is 20l.; and they may unlock and examine every copper, &c. between the hours of five in the morning and eleven in the evening, and the penalty of obstructing is 100l. Every maker of soap before he begins any making, if within the bills of mortality, shall give 12 hours, if elsewhere 24 hours, notice in writing to the officer, of the time when he intends to begin, on pain of 50l. No maker shall remove any soap unsurveyed on pain of 20l. without giving proper notice of his intention. And if any maker shall conceal any soap or materials, he shall forfeit the same, and also 500l. Every barrel of soap shall contain 236 lb. voided up, half barrel 128 lb. firkin 64 lb. half-firkin 32 lb. besides the weight or tare of each cask: and all soap, excepting hard cake soap and ball soap, shall be put into such casks and no other, on pain of forfeiture, and 5l. The maker shall weekly
weekly enter in writing at the next office the soap made
by him in each week, with the weight and quantity at
each boiling, on pain of 50l.; and within one week
after entry clear off the duties, on pain of double duty.
See, besides the statutes above cited, 5 Geo. III. cap. 43.
12 Geo. III. cap. 46. 11 Geo. cap. 30. 1 Geo. stat. 2.
cap. 36.
Acid Soap. This is formed by the addition of con-
centrated acids to the expressed oils. Thus the oil is
rendered partially soluble in water; but the union is not
sufficiently complete to answer any valuable purpose.
Soap-Berry Tree. See Sapindus, Botany Index.
Soap-Earth. See Steatites, Mineralogy Index.
SOAPWORT. See Saponaria, Botany Index.
SOC (Sax.). signifies power or liberty to minister
justice or execute laws; also the circuit or territory
wherein such power is exercised. Whence our law-
Latin word soccera is used for a seigniory or lordship en-
franchised by the king, with the liberty of holding or
keeping a court of his socken: And this kind of
liberty continues in divers parts of England to this day,
and is known by the names of soke and soken.
SOCAGE, in its most general and extensive signifi-
cation, seems to denote a tenure by any certain and
determinate service. And in this sense it is by our
ancient writers constantly put in opposition to chivalry
or knight-service, where the render was precarious and
uncertain. The service must therefore be certain, in or-
der to denominate it socage; as to hold by fealty and
20s. rent; or, by homage, fealty, and 20s. rent; or,
by homage and fealty without rent; or, by fealty and
certain corporal service, as ploughing the lord's land
for three days; or, by fealty only without any other ser-
vice: for all these are tenures in socage.
Socage is of two sorts: free-socage, where the ser-
vice are not only certain but honourable; and villein-
socage, where the services, though certain, are of a baser
nature (see Villenage). Such as held by the former
tenure are called, in Clavil and other subsequent au-
tors, by the name of liber sokenami, or tenants in
free-socage. The word is derived from the Saxon
appellation soc, which signifies liberty or privilege; and,
being joined to an usual termination, is called socage, in
Latin socagium; signifying thereby a free or privileged
tenure.
It seems probable that the socage-tenures were the
reliefs of Saxon liberty; retained by such persons as had
neither forfeited them to the king, nor been obliged
to exchange their tenure for the more honourable, as it
was called, but at the same time more burthensome, ten-
ure of knight-service. This is peculiarly remarkable
in the tenure which prevails in Kent, called gavelkind,
which is generally acknowledged to be a species of so-
cage-tenure; the preservation whereof inviolate from
the innovations of the Norman conqueror is a fact uni-
versally known. And those who thus preserved their
liberties were said to hold in free and common socage.
As therefore the grand criterion and distinguishing
mark of this species of tenure are the having its renders
or services ascertained, it will include under it all other
methods of holding free lands by certain and invariable
rents and duties; and in particular, Petit SERJEANTY,
Tenure in BURGAGE, and GAVELKIND. See these ar-
ticles.

I. Definitions. SOCIETY, a number of rational and moral be-
ings, united for their common preservation and happi-
ness.
There are shoals of fishes, herds of quadrupeds, and
flocks of birds. But till observation enable us to de-
termine with greater certainty, how far the inferior ani-
capable of moral distinctions—we cannot with
propriety apply to them the term Society. We call
men and women, and several other species of animals,
gregarious; but it is hardly good English to say that they
are social.

It is only human society, then, that can become the
subject of our present investigation. The phenomena
which it presents are highly worthy of our notice.
Such are the advantages which each individual evi-
ciently derives from living in a social state; and so help-
less does any human being appear in a solitary state,
that we are naturally led to conclude, that if there ever
was a period at which mankind were solitary beings, and a
that period could not be of long duration; for their aver-
ience to solitude and love of society would soon in-
duce them to enter into social union. Such is the
opinion which we are led to conceive, when we compare
our own condition as members of civilized and en-
litened society with that of the brutes around us, or
with that of savages in the earlier and ruder periods of
social life. When we hear of Indians wandering naked
through the woods, destitute of arts, unskilled in agri-
culture, scarce capable of moral distinctions, void of all
religious sentiments, or possessed with the most absurd
notions concerning superior powers, and procuring
means of subsistence in a manner equally precarious
with that of the beasts of prey—we look down with
pity on their condition, or turn from it with horror.
When we view the order of cultivated society, and
consider our institutions, arts, and manners—we rejoice
over our superior wisdom and happiness.
Man in a civilized state appears a being of a superior
order to man in a savage state; yet some philosophers
tell us, that it is only he who, having been educated in
society, has been taught to depend upon others, that
can be helpless or miserable when placed in a solitary
state. They view the savage who exerts himself with
intrepidity to supply his wants, or bears them with for-
titude, as the greatest hero, and possessing the greatest
happiness. And therefore if we agree with them, that
the propensities of nature may have prompted men to
enter into social union, though they may have hoped
to enjoy superior security and happiness by engaging
in prosecuting and supporting each other, we must con-
clude that the Author of the universe has destined man to
attain greater dignity and happiness in a savage and so-
licitarian than in a social state; and therefore that those
dispositions and views which lead us to society are fal-
lacious and inimical to our real interest.
Whatever be the supposed advantages of a solitary
state, certain it is that mankind, at the earliest periods,
were united in society. Various theories have been
formed concerning the circumstances and principles
which gave rise to this union: but we have elsewhere
shown, that the greater part of them are founded in er-
er; that they suppose the original state of man to have,

312
been that of savages; and that such a supposition is contradicted by the most authentic records of antiquity. For though the records of the earlier ages are generally obscure, fabulous, and imperfect; yet happily there is one free from the imperfections of the rest, and of undoubted authenticity, to which we may safely have recourse. This record is the Pentateuch of Moses, which presents us with a genuine account of the origin of man and of society, perfectly consonant to what we have laid down in the article referred to (see Savage).

According to Moses, the first society was that of a husband and wife united in the bonds of marriage: the first government that of a father and husband, the master of his family. Men lived together under the patriarchal form of government while they employed themselves chiefly in tending flocks and herds. Children in such circumstances cannot soon rise to an equality with their parents, where a man's importance depends on his property, not on his abilities. When flocks and herds are the chief articles of property, the son can only obtain these from his father; in general therefore, the son must be entirely dependent on the father for the means of subsistence. If the parent during his life bestowed on his children any part of his property, he may do it on such conditions as shall make their dependence upon him continue till the period of his death. When the community are by this event deprived of their head, instead of continuing in a state of union, and selecting some one from among themselves whom they may invest with the authority of a parent, they separate into so many distinct tribes, each subjected to the authority of a different lord, the master of the family, and the proprietor of all the flocks and herds belonging to it. Such was the state of the first societies which the narrative of Moses exhibits to our attention.

Those philosophers who have made society, in its various stages between rudeness and refinement, the subject of their speculations, have generally considered mankind, in whatever region of the globe, and under whatever climate, as proceeding uniformly through certain regular gradations from one extreme to the other. They regard them, first, as gaining a precarious subsistence by gathering the spontaneous fruits of the earth, preying on the inhabitants of the waters, if placed on the sea-shore, or along the banks of large rivers; or hunting wild beasts, if in a situation where these are to be found in abundance; without foresight or industry to provide for future wants when the present call of appetite is gratified. Next, they say, man rises to the shepherd state, and next to that of husbandmen, when they turn their attention from the management of flocks to the cultivation of the ground. Next, these husbandmen improve their powers, and better their condition, by becoming artisans and merchants; and the beginning of this period is the boundary between barbarity and civilization.

These are the stages through which they who have employed themselves on the natural history of society have generally conducted mankind in their progress from rudeness to refinement: but they seem to have overlooked the manner in which mankind were at first established on this earth; for the circumstances in which the parents of the human race were originally placed; for the degree of knowledge communicated to them; and for the instruction which they must have been capable of communicating to their posterity. They rather appear to consider the inhabitants of every different region of the globe as aborigines, springing at first from the ground, or dropped on the spot which they inhabit; no less ignorant than infants of the nature and relations of the objects around them, and of the purposes which they may accomplish by the sacrifice of their organs and faculties.

The absurdity of this theory has been fully demonstrated in another place: and if we agree to receive the Mosaic account of the original establishment of mankind, we shall be led to view the phenomena of social life in a light very different. We must first allow, that though many of the rudest tribes are found in the state of hunters or fishers; yet the hunting or fishing state cannot have been invariably the primary form of society. Notwithstanding the powers with which we are endowed, we are in a great measure the creatures of circumstances. Physical causes exert, though indirectly, a mighty influence in forming the character and directing the exertions of the human race. From the information of Moses we gather, that the first societies of men lived under the patriarchal form of government, and employed themselves in the cultivation of the ground and the management of flocks. And as we know that mankind, being subjected to the influence both of physical and moral causes, are no less liable to degeneracy than capable of improvement; we may easily conceive, that though descending all from the same original pair, and though enlightened with more traditional knowledge relative to the arts of life, the order of society, moral distinctions, and religious obligations; yet as they were gradually, and by various accidents, dispersed over the earth, being removed to situations in which the arts with which they were acquainted could but little avail them, where industry was overpowered, or indolence encouraged, by the severity or the profusion of nature, they might degenerate and fall into a condition almost as humble and precarious as that of the brutal tribes. Other moral causes might also concur to degrade or elevate the human character in that early period. The particular character of the original settlers in any region, the manner in which they were connected with one another, and the arts which they were best qualified to exercise, with various other causes of a similar nature, would have considerable influence in determining the character of the society.

When laying aside the spirit of theory and system, we set ourselves, with due humility, to trace facts, and to listen to evidence, though our discoveries may be fewer than we should otherwise fancy them; yet the knowledge which we thus acquire will be more useful and solid, and our speculations more consistent with the spirit of true philosophy. Here, though we learn from the information of the sacred writings, that the first family of mankind was not cruelly exposed in this world, as children whom the inhumanity of their parents induceth them to desert; yet we are not, in consequence of admitting this fact, laid under any necessity of denying or explaining away any of the other phenomena which occur to our observation when tracing the natural history of society. Tradition may be corrupted; arts and sciences may be lost; the sublimest religious doctrines may be debased into absurdity.

If then we are desirous of surveying society in its rudest
Society. In the earliest period of its existence, but to those districts of the globe where external circumstances concur to drive them into a state of stupendous and wretchedness. Thus in many places of the happy clime of Asia, which is a species of ancient records concurred with the sacred writings in representing as the first peopled quarter of the globe, we cannot trace the form of society backwards beyond the shepherd state. In that state indeed the bonds which connect society extend not to a wide range of individuals, and men remain for a long period in distinct families; but yet that state is highly favourable to knowledge, to happiness, and to virtue. Again, the torrid and the frozen regions of the earth, though probably peopled at a later period, and by tribes sprung from the same stock with the shepherds of Asia, have yet exhibited mankind in a much lower state. It is in the parched deserts of Africa and the wilds of America that human beings have been found in a condition approaching the nearest to that of the brutes.

We may therefore with some propriety desert the order of time, and take a view of the different stages through which philosophers have considered mankind as advancing, beginning with that of rudeness, though we have shown that it cannot have been the first in the progress. Where the human species are found in the lowest and rudest state, their rational and moral powers are very faintly displayed; but their external senses are acute and their bodily organs active and vigorous. Hunting and fishing are then their chief employments on which they depend for support. During that period of their time which is not spent in these pursuits, they are sunk in listless indolence. Destitute of foresight, they are reased to active exertion only by the pressure of immediate necessity or the urgent calls of appetite. Accustomed to endure the severity of the elements, and but scantily provided with the means of subsistence, they acquire habits of resignation and fortitude, which are beheld with astonishment by those who enjoy the plenty and indulgence of cultivated life. But in this state of want and depression, when the powers and possessions of every individual are scarcely sufficient for his own support, when even the calls of appetite are repressed because they cannot always be gratified, and the more refined passions, which either originate from such as are merely animal, or are intimately connected with them, have not yet been felt— in this state all the milder affections are unknown; or if the beast is at all sensible to their impulse, it is extremely feeble. Husband and wife, parent and child, brother and brother, are united by the weakest ties. Want and misfortune are not pitied. Why indeed should they, where they cannot be relieved? It is impossible to determine how far beings in this condition can be capable of moral distinctions. One thing certain is, that in no state are the human race entirely incapable of these. If we listen, however, to the relations of respectable travellers, we must admit that human beings have sometimes been found in that abject state where no proper ideas of subordination, government, or distinction of ranks, could be formed. No distinct notions of Deity can be here entertained. Beings in so humble a condition cannot look through the order of the universe and the harmony of nature to that Eternal Wisdom and Goodness which contrived, and that Almighty Power which brought into existence, the system of things. Of arts they must be almost totally destitute. They may use some instruments for fishing or the chase; but these must be extremely rude and simple. If they be acquainted with any means to shelter them from the inclemency of the elements, both their houses and clothing will be awkward and inconvenient.

But human beings have not been often found in so rude a state as this. Even those tribes which we denominate savage, are for the most part farther removed from mere animal life. They generally appear united under some species of government, exercising the powers of reason, capable of morality, though that morality be not always very refined; displaying some degree of social virtues, and acting under the influence of religious sentiments. Those who may be considered as but one degree higher in the scale than the stupid and wretched beings whose condition we have surveyed, are to be found still in the hunting and fishing state; but they are farther advanced towards social life, and are become more sensible to the impulse of social affection. By unavoidable intercourse in their employments, a few individual hunters or fishers contract a certain degree of fondness for each other’s company, and are led to take some part in each other’s joys and sorrows; and when the social affections thus generated (see PASSION) begin to exert themselves, all the other powers of the mind are at the same time called forth, and the circumstances of the little society are immediately improved. We behold its members in a more comfortable condition, and find reason to view the human character with more complacency and respect. Huts are now built, more commodious clothes are fashioned, instruments for the annoyance of wild beasts and even of enemies are contrived; in short, arts, and science, and social order, and religious sentiment, and ceremonies, now make their appearance in the rising society, and serve to characterize it by the particular form which distinguishes each of them. But though social order is no longer unknown nor unobserved, yet the form of government is still extremely simple, and its ties are but loose and feeble. It will perhaps bear some resemblance to the patriarchal; only all its members are on a more equal footing, and as the same time less closely connected than in the shepherd state, to which that form of government seems almost peculiar. The old men are treated with veneration; but the young are not entirely subject to them. They may listen respectfully to their advice; but they do not submit to their arbitrary commands. Where mankind are in the state of hunters and fishers, where the means of subsistence are precarious acquired, and prudent foresight does not prompt to accumulate much provision for the future, no individual can acquire comparative wealth. As soon as the son is grown up, he ceases to be dependent on his father, as well as on the society in general. Difference of experience therefore constitutes the only distinction between the young and the old; and if the old have experience, the young have strength and activity. Here, then, neither age nor property can give rise to any striking distinction of ranks. All who have attained to manhood, and are not disabled by unusual deficiency of strength or agility, or by the infirmities of old age, are on an equal footing; or if any one possess a pre-eminence over the rest, he owes it to superior
superior address or fortune. The whole tribe deliberate; the old give their advice; each individual of the assembly receives or rejects it at his pleasure (for the whole body think not of exercising any compulsory power over the will of individuals); and the warrior who is most distinguished for strength, address, and valour, leads out the youth of the tribe to the chase or against the enemy. War, which in the former stage did not prevail, as they were strangers to social sentiments were, at the same time, scarce capable of being enemies, now begins to depopulate the thinly inhabited regions where those hunters and fishers pursue their prey. They are scattered, possibly in scantly and separate tribes, over an immense tract of country; but they know no medium between the affection which brethren of the same tribe bear to each other and the hatred of enemies. Though thinly scattered over the earth, yet the hunting parties of different tribes will sometimes meet as they range the forests; and when they meet, they will naturally view each other with a jealously eye; for the success of the one party in the chase may cause the other to be unsuccessful; and while the one snatches the prey, the other must return home to all the pangs of famine. Inventive hostility will therefore long prevail among neighbouring tribes in the hunting state.

If we find them not incapable of social order, we may naturally expect that their conduct will be influenced by some sentiments of religion. They have at this period ideas of superior beings. They also practise certain ceremonies to recommend them to those beings; but both their sentiments and ceremonies are superstitious and absurd.

We have elsewhere shown (see POLYTHEISM) how savage tribes have probably degenerated from the pure worship of the one true God to the adoration of a multitude of imaginary divinities in heaven, earth, and hell. We have traced this idolatrous worship from that of the heavenly bodies, through all the gradations of demon-worship, hero-worship, and statue-worship, to that wonderful instance of absurd superstition which induced the inhabitants of some countries to fall prostrate in adoration before the vilest reptiles. But though we are convinced that the heavenly bodies have by all idolaters been considered as their first and greatest gods, we pretend not that the progress through the other stages of polytheism has been everywhere in the very same order. It is indeed impossible to exhibit under one general view an account of arts, manners, and religious sentiments, which may apply to some certain period in the history of every nation. The characters and circumstances of nations are scarce less various and anomalous than those of individuals. Among many of the American tribes, among the ancient inhabitants of the forests of Germany, whose manners have been so accurately delineated by the masterly pen of Tacitus, and in some of the islands scattered over the southern ocean, religion, arts, and government, have been found in that state which we have described as characterising the second stage of social life. But neither can we pretend that all those simple and rude societies have been described by historians and travellers as agreeing precisely in their arts, manners, and religious sentiments; or that the difference of circumstances always enables us to account in a satisfactory manner for the distinction of their characters. There is a variety of facts in the history of the early periods of society, which no ingenuity, no industry, however painful, can reduce under general heads.

Here, as well as when we attempt to philosophize on the phenomena of the material world, we find reason to confess that our powers are weak, and our observation confined within a narrow sphere.

But we may now carry our views a little forward, Third stage and survey human life as approaching somewhat nearer in the progress of society, to a civilized and enlightened state. As property is acquired, inequality and subordination of ranks necessarily follow: and when men are no longer equal, the many of property are soon subjected to the will of the few. But what and inequality gives rise to these new phenomena is, that after having often suffered from the precariousness of the hunting and fishing state, men begin to extend their cares beyond the present moment, and to think of providing some supply for future wants. When they are enabled to provide such a supply, either by pursuing the chase with new eagerness and perseverance, by gathering the spontaneous fruits of the earth, or by breeding tame animals—these acquisitiveness are at first the property of the whole society, and distributed from a common store to each individual according to his wants: But as various reasons will soon concur to convince the community, that by this mode of distribution, industry and activity are treated with injustice, while negligence and indolence receive more than their due, each individual will in a short time become his own steward, and a community of goods will be abolished. As soon as distinct ideas of property are formed, it must be unequally distributed; and as soon as property is unequally distributed, there arises an inequality of ranks. Here we have the origin of the depression of the female sex in rude ages, of the tyrannical authority exercised by parents over their children, and perhaps of slavery. The women cannot display the same perseverance, or activity, or address, as the men, in pursuing the chase. They are therefore left at home; and from that moment are no longer equals, but slaves and dependants, who must subsist by the bounty of the males, and must therefore submit with implicit obedience to all their capricious commands. Even before the era of property, the female sex were viewed as inferiors; but till that period they were not reduced to a state of absolute slavery.

In this period of society new notions are formed of the relative duties. Men now become citizens, masters, and servants, husbands, parents, &c. It is impossible to enumerate all the various modes of government which take place among the tribes who have advanced to this stage; but one thing certain is, that the authority of the few over the many is now first established, and that the rise of property first introduces inequality of ranks. In one place, we shall perhaps find the community subjected during this period to the will of a single person; in another, power may be lodged in the hands of a number of chiefs; and in a third, every individual may have a voice in creating public officers, and in enforcing laws for the support of public order. But as no code of laws is formed during this period, justice is not very impartially administered, nor are the rights of individuals very faithfully guarded. Many actions, which will afterwards be considered as heinously immoral, are now considered as praiseworthy or indifferent. This is the age of hero-worship, and of household and tutelary gods;
Society.

for it is in this stage of society that the invention of arts, which gave rise to that worship, contributes most conspicuously to the public good. War, too, which we considered as beginning first to ravage the earth during the former period, and which is another cause of the deification of dead men, will still prevail in this age, and be carried on with no less ferocity than before, though in a more systematic form.

The prevalence of war, and the means by which subsistence is procured, cannot but have considerable influence on the character and sentiments of societies and individuals. The hunter and the warrior are characters in many respects different from the shepherd and the husbandman. Such, in point of government, arts, and manners, religious and moral sentiments, were several of the German tribes described by Tacitus; and the Britons whose character has been sketched by the pen of Caesar: such, too, were the Romans in the early period of their history; such too the inhabitants of Asia Minor about the time of the siege of Troy, as well as the Greeks whom Homer celebrates as the destroyers of the Trojan state: the northern tribes also, who poured through Asia, Africa, and Europe, and overthrew the Roman empire, appear to have been of a nearly similar character. It seems to be a general opinion among those who have directed their attention to the history of society, that, in the scale ascending from the lowest condition of human beings to the most civilized and enlightened state of society, the shepherd state is the next in order above the hunting; and that as mankind improve in knowledge and in moral sentiments, and as the forests are gradually depopulated of their inhabitants, instead of destroying the inferior animals, men become their guardians and protectors. But we cannot unreservedly subscribe to this opinion: we believe, that in the shepherd state societies have been sometimes found superior to the most polished tribes of hunters; but upon viewing the annals of mankind in early ages, we observe that there is often no considerable resemblance even between hunters and shepherds in point of the improvement of the rational faculties and the moral sense; and we are therefore led to think, that these two states are sometimes parallel: for instance, several of the American tribes, who still procure their subsistence by hunting, appear to be nearly in the state which we have described as the third stage in the progress of society; and the ancient shepherds of Asia do not appear to have been much more cultivated and refined. We even believe that men have sometimes turned their attention from hunting to agriculture, without passing through any intermediate state.

Let us remember, that much depends upon local circumstances, and somewhat undoubtedly on original inspiration and traditionary instruction. In this period of society the state of the arts well deserves our attention. We shall find, that the shepherds and the hunters are in that respect on a pretty equal footing. Whether we examine the records of ancient history, or view the islands scattered through the South sea, or range the wilds of America, or survey the snowy wastes of Lapland and the frozen coast of Greenland—still we find the useful arts in this period, though known and cultivated, in a very rude state; and the fine arts, or such as are cultivated merely to please the fancy or to gratify caprice, displaying an odd and fantastic, not a true or natural, taste; yet this is the period in which eloquence shines with the truest lustre: all is metaphor or glowing sentiment. Languages are not yet copious; and therefore speech is figurative, expressive, and forcible. The tones and gestures of nature, not being yet laid aside, as they generally are, from regard to decorum, in more polished ages, give a degree of force and expression to the harangues of the rustic or savage orator, which the most laborious study of the rules of rhetoric and eloquence could not enable even a more polished orator to display.

But let us advance a little farther, and contemplate Fourth Fourth our species in a new light, where they will appear with stage; in greater dignity and amiability of character. Let us, which agriculture view them as husbandmen, artisans, and legislators. Whatever circumstances might turn the attention of the arts are any people from hunting to agriculture, or cause the subdivided, herdsmen to yoke his oxen for the cultivation of the commerce, ground, certain it is that this change in the occupation and regular government would produce a happy change on the character and circumstances of men; it would oblige them to exert the introduced a more regular and persevering industry. The hunter is like one of those birds that are described as passing the winter in a torpid state. The shepherd's life is extremely indolent. Neither of these is very favourable to refinement. But different is the condition of the husbandman. His labours succeed each other in regular rotation through the year. Each season with him has its proper employments: he therefore must exert active persevering industry; and in this state we often find the virtues of rude and polished ages united. This is the period where barbarism ends and civilization begins. Nations have existed for ages in the hunting or the shepherd state, fixed as by a kind of stagnation, without advancing farther. But scarcely any instances occur in the history of mankind of those who once reached the state of husbandmen, remaining long in that condition without rising to a more civilized and polished state. Where a people turn their attention in any considerable degree to the objects of agriculture, a distinction of occupations naturally arises among them.

The husbandman is so closely employed through the several seasons of the year in the labours of the field, that he has no longer leisure to exercise all the rude arts known among his countrymen. He has not time to fashion the instruments of husbandry, to prepare his clothes, to build his house, to manufacture household utensils, or to tend those tame animals which he continues to rear. Those different departments therefore now begin to employ different persons; each of whom dedicates his whole time and attention to his own occupation. The manufacture of cloth is for a considerable time managed exclusively by the women; but smiths and joiners arise from among the men. Metals begin now to be considered as valuable materials. The intercourse of mankind is now placed on a new footing. Before, every individual practised all the arts that were known, as far as was necessary for supplying himself with the conveniences of life. Now he confines himself to one or to a few of them; and, in order to obtain a necessary supply of the productions of those arts which he does not cultivate himself, he gives in exchange part of the productions of his own labours. Here we have the origin of commerce.

After continuing perhaps for some time in this state, as arts and distinctions multiply in society, the ex...

Society.

change of one commodity for another is found troublesome and inconvenient. It is ingeniously contrived to adopt a medium of commerce, which being estimated not by its intrinsic value, but by a certain nominal value which it receives from the agreement of the society among whom it is used, serves to render the exchange of property, which is so necessary for the purposes of social life, easy and expeditious. Wherever metals have been known, they appear to have been adopted as the medium of commerce almost as soon as such a medium began to be used: and this is one important purpose for which they serve; but they have still more important uses. Almost all the necessary arts depend on them. Where the metals are known, agriculture practised, and the necessary arts distributed among different orders of artisans—civilization and refinement, if not obstructed by some accidental circumstances, advance with a rapid progress. With regard to the first applying of the precious metals as the medium of commerce, we may observe, that this was probably not accomplished by means of a formal contract. They might be first used as ornaments; and the love of ornament, which prevails among rude as much as among civilized nations, would render every one willing to receive them in exchange for such articles as he could spare. Such might be the change produced on society with regard to the necessary arts by the origin of agriculture. As soon as ornament and amusement are thought of, the fine arts begin to be cultivated. In their origin therefore they are not long posterior to the necessary and useful arts. They appear long before men reach the comfortable and respectable condition of husbandmen; but so rude is their character at their first origin, that our Dicta be would probably view the productions of that period with unspeakable contempt and disgust. But in the period of society which we now consider, they have aspired to a higher character; yet poetry is now perhaps less generally cultivated than during the shepherd state. Agriculture, considered by itself, is not directly favourable either to refinement of manners or to the fine arts. The conversation of shepherds is generally supposed to be far more elegant than that of husbandmen; but though the direct and immediate effects of this condition of life be not favourable to the fine arts, yet indirectly it has a strong tendency to promote their improvement. Its immediate influence is extremely favourable to the necessary and useful arts; and these are no less favourable to the fine arts.

One of the noblest changes which the introduction of the arts by agriculture produces on the form and circumstances of society, is the introduction of regular government and laws. In tracing the history of ancient nations, we scarcely ever find laws introduced at an earlier period. Minos, Solon, and Lycurgus, do not appear to have formed codes of wisdom and justice for regulating the manners of their countrymen, till after the Cretans, the Athenians, and even the Lacedaemonians, had made some progress in agriculture and the useful arts.

Religion, under all its various forms, has in every stage of society a mighty influence on the sentiments and conduct of men (see Religion); and the arts cultivated in society have on the other hand some influence on the system of religious belief. One happy effect which will result from the invention of arts, though perhaps not immediately, will be, to render the character of the deities more benevolent and amiable, and the rites of their worship more mild and humane.

The female sex in this period generally find the yoke of their slavery somewhat lightened. Men now become easier in their circumstances; the social affections assume stronger influence over the mind; plenty, and security, and ease, at once communicate both delicacy and kennis to the sensual desires. All these circumstances concur to make men relax in some degree that tyrannical sway by which they before depressed the softer sex. The foundation of that empire, where beauty triumphs over both wisdom and strength, now begins to be laid. Such are the effects which history warrants as to attribute to agriculture and the arts; and such the outlines of the character of that which we reckon the fourth stage in the progress of society from rudeness to refinement.

Let us advance one step farther. We have not yet arrived at the stage of society. Society is rude at the period when the arts first begin to show themselves, in comparison of that state to which it is raised by the industrious cultivation of nature. The neighbouring commonwealths of Athens, and Lacedaemon afford us a happy opportunity of comparing this with the former stage in the progress of society. The chief effect produced by the institutions of Lycurgus seems to have been, to fix the manners of his countrymen for a considerable period in that state to which they had attained in his days. Spartan virtue sagging aspect has been admired and extolled in the language of enthusiasm; but in the same manner has the character and the condition of the savage inhabitants of the wilds of America, been preferred by some philosophers, to the virtues and the enjoyments of social life in the most polished and enlightened state. The Spartans in the days of Lycurgus had begun to cultivate the ground, and were not unacquainted with the useful arts. They must soon have advanced farther had not Lycurgus arisen, and by effecting the establishment of a code of laws, the tendency of which appears to have been in many particulars directly opposite to the designs of nature, retarded their progress towards complete civilization and refinement. The history of the Lacedaemonians, therefore, while the laws of Lycurgus continued in force, exhibits the manners and character of a people in that which we have denominated the fourth stage in the progress of society. But if we turn our eyes to their neighbours the Athenians, we behold in their history the natural progress of opinions, arts, and manners. The useful arts are first cultivated with such steady industry, as to raise the community to opulence, and to furnish them with articles for commerce with foreign nations. The useful arts cannot be raised to this height of improvement without leading men to the pursuit of science. Commerce with foreign nations, skill in the useful arts, and a taste for science, mutually aid each other, and conspire to promote the improvement of the fine arts. Hence magnificent buildings, noble statues, paintings expressive of life, action, and passion; and poems in which imagination adds new grace and sublimity to nature, and gives the appearances of social life more irresistible power over the affections of the heart. Hence are moral distinctions more carefully studied, and the
nation against another)—war, however, no longer retains its former ferocity; nations no longer strive to exterminate one another: to procure redress for real or imaginary injuries; to humble, not to destroy, is now its object. Prisoners are no longer murdered in cold blood, subjected to horrid and excruciating tortures, or condemned to hopeless slavery. They are ransomed of exchanged; they return to their country, and again fight under its banners. In this period the arts of government are likewise better understood, and practised so as to contribute most to the interests of society. Whether monarchy, or democracy, or aristocracy, be the established form, the rights of individuals and of society are in general respected. The interests of society are so well understood, that the few, in order to preserve their influence over the many, find it necessary to act rather as the faithful servants than the imperious lords of the public. Though the liberties of a nation in this state be not accurately defined by law, nor the property guaranteed to them by any legal institutions, yet their governors dare not violate their liberties, nor deprive them wantonly of their properties. This is truly the golden age of society: every trace of barbarism is entirely effaced; and vicious luxury has not yet begun to sap the virtue and the happiness of the community. Men live not in listless indolence; but the industry in which they are engaged is not of such a nature as to overpower their strength or exhaust their spirits. The social affections have now the strongest influence on men’s sentiments and conduct.

But human affairs are scarcely ever stationary. The degenerating circumstances of mankind are almost always changing, every degree growing better or worse. Their manners are ever in the same fluctuating state. They either advance towards perfection or degenerate. Scarcely have they attained that happy period in which we have just contemplated them, when they begin to decline till they perhaps fall back into a state nearly as low as that from which we suppose them to have emerged. Instances of this unhappy degeneracy occur more often than once in the history of mankind; and we may finish this short sketch of the history of society by mentioning in what manner the degeneracy takes the appearance, but as yet she is the friend and benefactress of society. Commerce has stimulated and rewarded industry, but has not yet contracted the heart and debased the character. Wealth is not yet become the sole object of pursuit. The charms of social intercourse are known and relished; but domestic duties are not yet deserted for public amusements. The female sex acquire new influence, and contribute much to refine and polish the manners of their lords. Religion now assumes a milder and more pleasing form; splendid rites, magnificent temples, pompous sacrifices, and gay festivals, give even superstition an influence favourable to the happiness of mankind. The gloomy notions and barbarous rites of former periods fall into disuse. The system of theology produced in former ages still remains: but only the mild and amiable qualities of the deities are celebrated; and none but the gay, humane, and laughing divinities, are worshipped. Philosophy also teaches men to discard such parts of their religion as are unfriendly to good morals, and have any tendency to call forth or cherish unsocial sentiments in the heart. War (for in this period of society enough of causes will arise to arm one
unbridled passions, contributes so much to the corruption of virtuous manners. Selfishness, caprice, indolence, effeminacy, all join to loosen the bonds of society, to bring on the degeneracy both of the useful and the fine arts, to banish at once the mild and the austere virtues, to destroy civil order and subordination, and to introduce in their room anarchy or despotism.

Scarcely could we have found an example of the beautiful form of society which we last attempted to describe. Never, at least, has any nation continued long to enjoy such happy circumstances, or to display so amiable and respectable a character. But when we speak of the declining state of society, we have no difficulty in finding instances to which we may refer. History tells of the Assyrians, the Egyptians, and the Persians, all of them once flourishing nations, but brought low by luxury and an unhappy corruption of manners. The Greeks, the Romans, and the Assyrians, owed their fall to the same causes; and we know not if a similar fate does not now threaten many of those nations who have long made a distinguished figure in the system of Europe. The Portuguese, the Venetians, and the Spaniards, have already fallen; and what is the present state of our neighbours the French? They have long been a people destitute of religion, corrupted in morals, unsteady in conduct, and slaves to pleasure and public amusements. Among them luxury had arrived at its highest pitch; and the consequence has been, that after capriciously shaking off the yoke of despotism, they have established, or rather set up (if established it cannot be), a motley kind of government, which, in the course of a few years, has exhibited scenes of tyranny and oppression, to which we doubt if the annals of the world can furnish any parallel. Yet this is the people whose manners the other nations of Europe were ambitious to imitate. May those nations take warning in time, and avoid the rocks upon which they have split.

Thus have we viewed the several steps in which society appears in its progress from rudeness to refinement and decay. The intelligent reader will perceive, that the various and anomalous phenomena which occur in the natural history of society, cannot easily be solved; because the necessary information cannot be obtained. Others have been well accounted for by the researches of curious philosophical inquirers. Local circumstances, the influence of climate, the intercourse of nations in different states of civilization, have been taken notice of, as causes serving to accelerate or retard the progress of arts and manners. But our proper business here was merely to mark the gradations between barbarism and refinement: and as the painter who is to exhibit a series of portraits representing the human form in infancy, puacity, youth, and manhood, will not think of delineating all that variety of figures and faces which each of those periods of life affords, and will find himself unable to represent in any single figure all diversities of form and features; so we have not once thought of describing particularly under this article, all the various national characters reducible to any one of those divisions under which we have viewed the progress of society, nor have found it possible to comprehend under one consistent view, all the particulars which may be gathered from the remains of antiquity, from the relations of later travellers, and the general records of history concerning the progressive character of mankind in various regions, and under the influence of various accidents and circumstances. This indeed would even have been improper, as all that information appears under other articles in this Work.

SOCITIES, associations voluntarily formed by a number of individuals for promoting knowledge, industry, or virtue. They may therefore be divided into three classes; societies for promoting science and literature, societies for encouraging and promoting arts and manufactures, and societies for diffusing religion and morality and relieving distress. Societies belonging to the first class extend their attention to all the sciences and literature in general, or devote it to one particular science. The same observation may be applied to those which are instituted for improving arts and manufactures. Those of the third class are established, either with a view to prevent crimes, as the Philanthropic Society; for the diffusion of the Christian religion among unenlightened nations, as the Society for the Propagation of the Gospel in Foreign Parts; or for introducing arts and civilization, along with a knowledge of the Christian religion, as the Sierra Leona Company.

The honour of planning and instituting societies for those valuable purposes is due to modern times. A literary association is said to have been formed in the reign of Charlemagne (see Academy); but the plan seems to have been rude and defective. Several others were instituted in Italy in the 16th century; but from the accounts which we have seen of them, they seem to have been far inferior to those which are most flourishing at present. The most enlarged idea of literary societies seems to have originated with the great Lord Bacon, the father of modern philosophy, who recommended to the reigning prince to institute societies of learned men, who should give to the world from time to time a regular account of their researches and discoveries. It was the idea of this great philosopher, that the learned world should be united, as it were, into one immense republic; which, though consisting of many detached states, should hold a strict union and preserve a mutual intelligence with each other, in every thing that regards the common interest. The want of this union and intelligence becomes one of the chief obstacles to the advancement of science; and, justly considering the institution of public societies, in the different countries of Europe, under the auspices of the sovereign, to be the best remedy for that defect, he has given, in his fanciful work, the New Atlantis, the delineation of a philosophical society on the most extended plan, for the improvement of all arts and sciences; a work which, though written in the language, and tinted with the colouring of romance, is full of the noblest philosophical views. The plan of Lord Bacon, which met with little attention from the age in which he lived, was destined to produce its effect in a period not very distant. The scheme of a philosophical college by Cowley is acknowledged to have had a powerful influence in procuring the establishment of the Royal Society of London by charter from Charles II. ; and Cowley's plan is manifestly copied in almost all its parts from that in the New Atlantis. History of the Royal Society of London was soon followed by the establishment of the Royal Academy.
deny of Sciences at Paris: and these two have served as models to the philosophical academies of highest reputation in the other kingdoms of Europe.

The experience of ages has shown, that improvements of a public nature are best carried on by societies of liberal and ingenious men, uniting their labours without regard to nation, sect, or party, in one grand pursuit alike interesting to all, whereby mutual prejudices are worn off, and a humane philosophical spirit is cherished. Men united together, and frequently meeting for the purposes of advancing science; the arts, agriculture, manufactures, and commerce, may oftentimes suggest such hints to one another as may be improved to important ends; and such societies, by being the repositories of the observations and discoveries of the learned and ingenious, may from time to time furnish the world with useful publications which might otherwise be lost; for men of ingenuity and modesty may not choose to risk their reputation, by sending abroad unpatronized what a learned society might judge worth the public eye; or perhaps their circumstances being straitened, they may not be able to defray the expense of publication. Societies instituted for promoting knowledge may also be of eminent service, by exciting a spirit of emulation, and by enkindling those sparks of genius which otherwise might for ever have been concealed; and if, when possessed of funds sufficient for the purpose, they reward the exertions of the industrious and enterprising with pecuniary premiums or honorary medals, many important experiments and useful discoveries will be made, from which the public may reap the highest advantages.

Eminent instances of the beneficial effects of such institutions we have in the Royal Academy of Sciences at Paris, the Royal Society, and the Society instituted for the Encouragement of Arts, Manufactures, and Commerce, in London, and many others of a similar kind. Hereby a spirit of discovery and improvement has been excited among the ingenious in almost every nation; knowledge of various kinds, and greatly useful to mankind, has taken place of the dry and uninteresting speculations of schoolmen; and bold and erroneous hypothesis has been obliged to give way to demonstrative experiment. In short, since the establishment of these societies, solid learning and philosophy have more increased than they had done for many centuries before.

As to those societies established for promoting industry, religion and morality, and relieving distress, the design is laudable and excellent, and presents a beautiful picture of the philanthropy of modern times. We are happy to find, from the minutes of some of these societies, that their beneficial effects are already conspicuous.

We will now give some account of the most eminent societies, arranging them under the three classes into which we have divided them: 1. Religious and Humane Societies. II. Societies for Promoting Science and Literature. III. Societies for Encouraging Arts, Manufactures, &c.

I. Religious and Humane Societies.

1. Society for the Propagation of the Gospel in Foreign Parts, was instituted by King William III. in 1701, in order to secure a maintenance for an orthodox clergy, and to make other provisions for propagating the gospel in the plantations, colonies, and factories beyond the seas. To that end be incorporated the archbishops, several of the bishops, and others of the nobility, gentry, and clergy, to the number of 90, into one body, which, by the name of The Society for the Propagation of the Gospel in Foreign Parts, was to plead and be implored; to have perpetual succession, with privilege to purchase 2000l. a-year inheritance, and estates for lives or years, with other goods and chattels to any value. By its charter the society is authorised to use a common seal; and to meet annually on the third Friday in February for the purpose of choosing a president, vice president, and officers for the year ensuing; and on the third Friday in every month, or oftener if there should be occasion, to transact business, and to depute persons to take subscriptions, and collect money contributed for the purposes aforesaid; and of all moneys received and laid out, it is obliged to give account yearly to the lord-chancellor or keeper, the lord-chief-justice of the King's bench, the lord-chief-justice of the Common-pleas, or to any two of these magistrates. Of this society there is a standing committee at St Paul's chapter-house, to prepare matters for the monthly meeting, which is held at St Martin's library.

Before the incorporation of the society for the propagation of the gospel in foreign parts, there had been formed, for the promoting of Christian knowledge both at home and in the colonies, a voluntary association of persons of rank and respectability, who in March 1699 began to hold stated meetings in London for that purpose, regulating themselves by the laws of the land and the canons of the church: and when the new society was formed, they had already transmitted to America and the West Indies 800l. worth of Bibles, Books of Common Prayer, and treatises of practical religion, besides securing a tolerable maintenance to several clergymen on that continent. This association still subsists under the denomination of The Society for Promoting Christian Knowledge, and has been productive of much good in the cities of London and Westminster; but upon the formation of the new society, into which all its original members were incorporated by name, the care which the voluntary association had taken of the colonies devolved of course upon the incorporated society; of which incorporation we believe the object has been sometimes mistaken, and the labours of its missionaries grossly misrepresented. It has by many been supposed that the society was incorporated for the sole purpose of converting the savage Americans; and it has been much blamed for sending missionaries into provinces where, in the common language of the complainers, a gospel ministry was already established. But an impartial view of the rise and progress of the American provinces, now become independent states, will show the folly and injustice of those complaints.

The English colonies in North America were in the last century formed and first peopled by religious men; who, made uneasy at home by their intolerant brethren, left the old world to enjoy in peace that first and chief prerogative of man, the free worship of God according to his own conscience. At one time Puritans were driven across the Atlantic by the episcopal church; at another, Churchmen were forced away by the presbyterians, just as the revolutions of state threw the civil power into the hands of the one or the other party; and not a few
members of the CHURCH OF ROME were chased to the wilds of America by the united exertions of both. It has been often observed, that people persecuted for their religion become for the most part enthusiastically attached to it; and the conduct of those colonists was in perfect harmony with this observation. Their zeal, inflamed by their violent removal to the other hemisphere, kept religion alive and active among themselves; but their poverty disabled them from supplying fuel to the flame, by making provision for a ministry to instruct their offspring. The consequence was, that the new Christian commonwealth, without the kindly assistance of its mother country, would have been, in the words of the Roman historian, Res unius aetas. Against this danger a timely aid was to be provided by the society; which, as it consisted not of fanatical members, would not intrust the important business of the mission to fanatical preachers, who, though always ready for such spiritual enterprises, are never qualified to carry them on with success.

It was therefore thought fit to assign a decent maintenance for clergy members of the church of England, who might preach the gospel to their brethren in America: and though those missionaries in general carefully avoided the conduct of those of Rome, whose principal aim is to reduce all churches under submission to the papal tyranny; yet so lately as 1765, did one of the colonies, in which the puritanic spirit of the last century characterised the church established by law, raise a histrionic outcry against the society for sending a mission into their quarters, though only for the service of the dispersed members of the Episcopal church residing among them, and for the conversion of those men whom their rigid fanaticism had prejudiced against Christianity itself.

Indeed the commodity called freethinking, as Bishop Warburton expresses it, was at an early period imported by the opulent and fashionable colonists. The celebrated Berkeley, who had resided some years in Rhode Island, and at his return was called upon to preach the anniversary sermon before the society, informs us, that the island where he lived was inhabited by an English colony, consisting chiefly of sectaries of many different denominations; that several of the better sort of the inhabitants of towns were accustomed to assemble themselves regularly on the Lord's day for the performance of divine worship; but that most of those who were dispersed through the colony rivaled some well-bred people of other countries, in a thorough indifference for all that is sacred, being equally careless of outward worship and of inward principles. He adds, that the missionaries had done, and were continuing to do, good service in bringing those planters to a serious sense of religion. "I speak it knowingly (says he), that the ministers of the gospel, in those provinces which go by the name of New England, sent and supported at the expense of the society, have, by their sobriety of manners, discreet behaviour, and a competent degree of useful knowledge, shown themselves worthy of the choice of those who sent them." We have the honour to be acquainted with some of the missionaries sent at a later period, and we have reason to believe that, down to the era of the American revolution, they had the same virtues, and were doing the same good services, which procured to their predecessors this honourable testimony from one of the greatest and the best of men. Surely such a mission deserved not to be evil spoken of by sectaries of any denomination who believe in Christ; especially as the very charter of incorporation assigns as a reason for missionaries being sent to the colonies, "that by reason of their poverty those colonies were destitute and unprovided of a maintenance for ministers and the public worship of God."

The society, however, was incorporated for other purposes than this. It was obliged by its charter to attempt the conversion of the native Americans and the negro slaves; and we have reason to believe, that, as soon as the spiritual wants of the colonists were decently supplied, it was not inattentive to these glorious objects. Its success indeed in either pursuit has not been so great as could be wished; but it would be rash and unfair to attribute this failure to the president, vice-president, or other officers of the corporation at home.

An erroneous notion, that the being baptized is inconsistent with a state of slavery, rendered the selfish colonists for a long time averse from the conversion of their negroes, and made them throw every obstacle in the way of all who made the attempt; while the difficulties of the Indian mission are such as hardly any clergyman educated in a Protestant country can be supposed able to surmount.

He who hopes successfully to preach the gospel among a tribe of savage wanderers, must have an ardent zeal and unvaried diligence; appetites subdued to all the distresses of want; and a mind superior to all the terrors of mortality. These qualities and habits may be acquired in the church of Rome by him who from infancy has been trained up in the severities of some of the monastic orders, and afterwards sent to the college of propaganda fide to be instructed in the languages, and inured to the manners and customs of the barbarous nations whose conversion he is destined to attempt. But in the reformed churches of Britain there are no monastic orders, nor any college of propaganda fide; and yet without the regular preparation, which is to be looked for in such institutions alone, it is not in nature, whatever grace may effect, for any man cheerfully, and at the same time soberly, to undergo all the accumulated distresses ever ready to overtake a faithful missionary among savage idolators. A fanatic zealot will indeed undertake it, though he is totally unqualified for every sober and important work; and a man of ruined fortunes may be pressed into the service, though the impotency of his mind has shown him unable to bear either poverty or riches. The failure of the society therefore in its attempts to convert the American Indians may be attributed, we think, in the first instance, to the want of a college of propaganda fide for training up young men for the American mission.

Perhaps another cause of this failure may be found in the conduct of the missionaries, who, it is to be presumed, have not always employed in a proper manner even the scanty qualifications which they actually possessed. The gospel, plain and simple as it is, and fitted in its nature for what it was ordained to effect, cannot be apprehended but by an intellect somewhat raised above that of a savage. Such of the missionaries therefore as began their work with preaching to savage and brutal men, certainly set out at the wrong end; for to make the gospel understood, and much more to propagate it,
Society and establish it, those savages should have been first taught the necessary arts of civil life, which, while they improve every bodily accommodation, tend at the same time to enlarge and enlighten the understanding.

For want of this previous culture, we doubt not, it hath happened that such of the savages as have been baptized into the faith have so seldom persevered themselves, or been able in any degree to propagate among their tribe the Christianity which they had been taught, and that successive missions have always found it necessary to begin anew the work of conversion.

To one or other of these causes, or to both, may justly be attributed the little progress which reformed Christianity has made among the Indians of North America; and not to any want of zeal, attention, or liberality, in the directors of the society at home. During the dependence of the United States on the mother-country, great part of the society's funds was properly expended in keeping alive a just sense of religion among the Christian colonists from Europe, who had surely the first claims upon this best of charities; but now that America has separated herself from Great Britain, and shown that she is able to maintain her independence, and to make ample provision for a regular clergy of her own, the members of the corporation must feel themselves at liberty to bestow greater attention, and to expend more money than they could formerly do, on the conversion of such Indians as have any intercourse with the settlements which we still possess. To a body so respectable, we presume not to offer advice; but we cannot help thinking, with Bishop Berkeley, that the most successful missionaries would be children of Indians, educated in a considerable number together from the age of ten or twelve in a college de propaganda fide, where they should be in no danger of losing their mother-tongue while they were acquiring a competent knowledge of religion, morality, history, practical mathematics, and agriculture. "If there were a yearly supply (says he) of a dozen such missionaries sent abroad into their respective countries, after they had received the degree of master of arts, and been admitted into holy orders, it is hardly to be doubted but that in a little time the world would see good and great effects of their mission."

2. Society in Scotland for Propagating Christian Knowledge, was instituted in the beginning of the 18th century. At that period the condition of the Scotch Highlanders was truly deplorable. Shut up in desolate islands by tempestuous seas, or dispersed over a wide extent of country, intersected by high mountains, rapid rivers, and arms of the sea, without bridges or highways, by which any communication could be kept open either with remote or neighbouring districts, they lived in small detached companies in hamlets or solitary huts. Being thus secluded from intercourse with the more civilized part of the island, they could not enjoy the advantages of trade and manufactures. As their soil was barren and their climate severe, in agriculture no progress was to be expected; and as they were acquainted with no language but Gaelic, in which no books were then written, to possess knowledge was impossible. Their parishes being of great extent, often 30 or 40 miles long and of a proportionable breadth, and sometimes consisting of several islands separated by seas, which are often impassable, a considerable number of the inhabitants was entirely deprived of religious instruction or fell a prey to Popish emissaries. A single school in such extensive parishes could be of little benefit; yet many parishes were entirely destitute even of this resource; and where schools were established, the want of books prevented them from producing the useful effects otherwise to have been expected from them. To all this we must add, that they lived in a state of the greatest oppression: For though the Highlands formed a part of the British empire, the blessings of the British constitution had not reached them. The feudal system reigned in its utmost rigour; the chieftails exercising the most despotic sway over the inferior Highlanders, whom at their pleasure they deprived of their lives or property.

Thus the Highlanders were ignorant, oppressed, and civilized; slaves rather than subjects; and either entirely destitute of the advantages of the Christian religion, or unqualified to improve them. Hitherto they had been unhappy and useless to themselves and dangerous to the state; for they were ready at the call of their chieftails to issue from their mountains, and to turn their arms against their lawful king and his loyal subjects. This character, however, arose from their situation. It was therefore impossible for benevolent minds to contemplate this unhappy situation of their countrymen without feeling a desire to raise them to the dignity of rational beings, and to render them useful as citizens.

Accordingly, in the year 1701, some private gentlemen of the city of Edinburgh, who had formed themselves into a society for the reformation of manners, directed their attention to the Highlands of Scotland, and endeavoured to devise some plan for alleviating the distresses of the inhabitants. The remedy which promised to be most efficacious was, to establish charity schools in different places. But as the exigency was great, it was no easy matter to raise a sufficient fund for this purpose. They began therefore with what voluntary subscriptions they could procure, hoping afterwards to increase their capital by vacant stipends and public contributions. A memorial with this view was presented to the General Assembly in 1704, which received their approbation; and they accordingly passed an act, recommending a general contribution. In 1706 the General Assembly appointed some of their number to inquire more carefully into the state of the Highlands, and the year following appointed a select committee to confer with the gentlemen who had suggested the plan. The result of these conferences was the publication of proposals "for propagating Christian knowledge..."

(a) Even so late as the year 1758, not fewer than 175 parishes, within the bounds of 39 presbyteries, had no parochial school. We are sorry to add, that even in the present enlightened and benevolent age the complaint is not entirely removed.

(b) The feudal system was at length abolished in the year 1748 by the jurisdiction act.

Humane
Societies.

ledge in the Highlands and Islands of Scotland, and in foreign parts of the world." Copies of these proposals, with subscription papers, were distributed through the kingdom; and the contribution—having soon amounted to 1000£—her majesty Queen Anne encouraged this infant society by her royal proclamation, and at the same time issued letters patent under the great seal of Scotland for erecting certain of the subscribers into a corporation; the first nomination of whom was lodged with the lords of council and session.

This corporation held its first meeting on Thursday 30 November 1709. It was attended by several of the nobility, fourteen of the lords of session, many gentlemen of rank, together with most of the ministers of the city of Edinburgh and neighbourhood. A president, secretary, and treasurer, with a committee of fifteen directors were appointed for the dispatch of business. At their second meeting in January 1710, a scheme of management was formed and approved; in which it was proposed, 1. To erect and maintain schools in such places of Scotland, particularly in the Highlands and Islands, as should be found to need them most; in which schools all persons whatsoever should be taught by fit and well qualified schoolmasters, appointed by the society, to read the Holy Scriptures and other pious books; as also to write, and to understand the common rules of arithmetic, with such other things as should be thought suitable to their circumstances. 2. That the schoolmasters should be particularly careful to instruct their scholars in the principles of the Christian reformed religion; and for that end should be obliged to catechise them at least twice a week, and to pray publicly with them twice a-day. 3. That not only such as were unable to pay should be taught gratis, but that those whose circumstances required it, should have such further encouragement as the society should think fit in a consistency with their patent. 4. To name some prudent persons, ministers and others, to be overseers of those schools, who should take care that the schoolmasters do their duty, and that the instructions to be given from time to time by the society or their committee be punctually observed; which overseers should make their report to the society quarterly or half-yearly at farthest. 5. To give suitable encouragement to such ministers or catechists as should be willing to contribute their assistance towards the farther instruction of the scholars remote from church, by not only catechising, but preaching to them; which ministers or catechists should take the same care of the other inhabitants as of the scholars. 6. To extend their endeavours for the advancement of the Christian religion to heathen nations; and for that end to give encouragement to ministers to preach the gospel among them.

Having thus formed a plan, they immediately proceeded to establish schools in the most useful and economical manner; and as the capital continued to accumulate, the interest was faithfully applied, and the utility of the institution was more extensively diffused.

Until the year 1738 the attention of the society had been wholly directed to the establishment of schools; but their capital being then considerably augmented, they began to extend their views of utility much farther. The grand object of all public associations ought cer-

5

tainly to be the promoting of religion and morality. It must, however, be evident to every man of reflection, that these can neither be propagated nor preserved among a people without agriculture, unaccustomed to commerce and manufactures, and consequently without labour or exertion. Language and dexterity of mind must always be the companions of idleness. While the Highlanders roved about with arms in their hands, the latent vigour of their minds must often have been called forth into action; but when their arms were taken away, and themselves confined to a domestic life, where there was nothing to rouse their minds, they must have sunk into idleness and inactivity. All attempts therefore to instruct them in religion and morality, without introducing among them some of the necessary arts of life, would probably have been unavailing. The society accordingly resolved to adopt what appeared to them the most effectual methods of introducing industry among the Highlanders. But as their patent did not extend far enough, they applied to his majesty George II. for an enlargement of their powers; and accordingly obtained a second patent, by which they are empowered, "besides fulfilling the purposes of their original patent, to cause such of the children as they shall think fit to be bred to husbandry and housewifery, to trades and manufactures, or in such manual occupations as the society shall think proper."

The objects of this second patent the society have not failed to pursue; and though many obstacles and discouragements to their efforts occurred among a rude and barbarous people, yet their perseverance, and the obvious utility of their plans, at length so far overcame the reluctance of the inhabitants, that not fewer than 94 schools of industry in various parts of the Highlands and Islands are now upon their establishment, at which are educated 2350 scholars.

The society, while anxiously endeavouring to diffuse a spirit of industry through the Highlands, were still equally solicitous to promote the knowledge of the Christian religion. As the English language had been the only channel by which knowledge was conveyed to them (a language which, being not used in conversation, was in all respects foreign to them), it was judged requisite that they should have the Scriptures in their vernacular tongue. The society therefore first appointed a translation of the New Testament to be made into Gaelic: A translation was accordingly undertaken by the Rev. Mr Stewart, minister of Kilfin in Perthshire, and printed in 1767, which is said to be executed with much fidelity. Of this work many thousand copies have been distributed in the Highlands. The greater part of the Old Testament has also been translated by the Rev. Dr Smith of Campbellton and others, but chiefly by the Rev. Dr Stewart of Loss, by the appointment and at the expense of the society: and as soon as the remaining part can be got ready, the whole will be sold at so low a price as the poor may without difficulty afford. This plan the society have judiciously chosen, in order to prevent discontent and murmuring; effects which the diffusion of the Scriptures ought never to produce; but which could not possibly have been prevented, had the distribution been gratuitous, and of course partial.

For some years past the funds of the society have ra-

pidly
pidly accumulated, from the very liberal donations of several individuals.

Lady Glenorchy, - L. 5,000

Miss Grey of Teasses, - 3,500

In consequence of these great additions to their stock, institutions have been thrown out that the society have become so wealthy as to be at a loss for proper objects on which to bestow their increased revenue. If such an opinion be seriously entertained by any one, we must beg him to remember, that the society have erected and endowed not fewer than 323 schools for religion, the first principles of literature and industry, at the annual expense of 3214l. 10s. sterling; and that at these seminaries are educated from 14,000 to 15,000 children who, but for the means of instruction thus obtained, would in all probability be bred up in ignorance and idleness: That they employ 12 missionary ministers and catechists in remote parts of the Highlands and islands, or among the ignorant Highlanders settled in the great towns of Scotland, at the annual expense of 296l.: That they bestow a bursary or pension of 15l. per annum on each of six students of divinity having the Gaelic language: That they employ two missionary ministers and one schoolmaster among the Onida and Stockbridge Indians of North America (being the destination of certain legacies bequeathed to them for that purpose), at the annual expense of 140l. Such is their fixed scheme of annual expenditure, amounting in all to 3740l. 10s. sterling—a sum it will be acknowledged of very considerable magnitude. The whole of their incidental expenses arising from the Gaelic translation of the Scriptures of the Old Testament; from annuities which they have to pay, in consequence of sums left them as residuary legateses; from land and house taxes; from enabling candidates for the office of schoolmaster to come to Edinburgh for examination; from furnishing books to poor scholars in their various schools; and from removing schoolmasters from one station to another, is generally about 875l. which added to the former sum makes the whole annual expense amount to 461l. 10s.

If it be inquired at what expense, in the management of it, this extensive and complicated charity is annually conducted, we are authorised to say, that the treasurer, bookholder, and clerk, are allowed each 25l. per annum, the same salaries which were annexed to these offices from the commencement of the society. The bursar or officer is allowed 12l. per annum. No salary whatever is enjoyed by any of the other officers of the society. The secretary, comptroller, accountant, and librarian, although subjected, some of them especially, to no small expense of time and labour, have no pecuniary recompense or emolument. Theirs are labours of love, for which they seek and expect no other reward than the consciousness of endeavouring to promote the best interests of mankind. The whole amount of the expense of managing the business of the society, including the above salaries, and costs, candle, stationary ware, postages, and other incidental expenses, exceeds not at an average 115l. per annum. From this statement it appears, that hitherto at least the directors have been at no loss for important objects within the proper sphere of their institution on which to bestow their increased funds. They have, it is true, the disposal of very considerable sums for promoting the objects of the institution; but they are so far from accumulating wealth, that every year their expenditure, notwithstanding the late increase of their capital, exceeds rather than falls short of their income. They have depended upon a kind providence and a generous public to refund these anticipations of their revenue, and hitherto they have never been disappointed.

Thus has the Society for Propagating Christian Knowledge proceeded for almost a century. It was founded by the pious exertions of a few private individuals, whose names are unknown to the world; and its funds, by faithful and judicious management, as well as by generous contributions, have now become of such magnitude, as to excite the hope that they will be productive of the most valuable effects. The benefits arising from public societies, it is well known, depend entirely upon the management of their directors. If so, the advantages which have accrued from this society intitle it to the praise and gratitude of the nation. While eager to increase the number of schools, the society have not been inattentive to their prosperity. In the year 1771 Mr Lewis Drummond, a gentleman in whom they placed great confidence, was commissioned by them to visit their schools, and to make an exact report of their state and circumstances. Again, in the year 1790, a commission was granted to the Rev. Dr Kemp, one of the ministers of Edinburgh and secretary to the society, to visit all the schools on their establishment. This laborious and gratuitous task he accomplished in the course of four summers with much ability and care, and highly to the satisfaction of the society. At his return he communicated a variety of important information respecting the state of the Highlands and Islands, and the means necessary for their improvement in religion, literature, and industry; an abstract of which was published by the society in appendices to the anniversary sermons preached before them in the years 1789, 91, and 92 (c).

The following table will exhibit at a glance the funds, establishment, and expenditure, of the society, from a few years after its commencement to the present time.

Where

(c) It is well known, that the number of Roman Catholics in the Highlands is considerable; but it must give much pleasure to the Protestant reader to be informed, that the ancient malignant spirit of Popery has in that district given place to mildness and liberality. This is chiefly owing to the gentleman who superintends the priests in that quarter, whose mind is enlightened by science and learning. So far from being hostile to the views of the society, he recommended to his clergy to promote them. They accordingly received the secretary with much politeness; exhorted the people to send their children to the Protestant schools to be instructed in literature, to be taught to read the Scriptures in their own language, and to be made acquainted with those great principles of religion in which all Christians are agreed. What a blessed reformation!

Religious and Human Societies.

Where the number of scholars is not mentioned, the defect may be supplied by taking an average from those years where a computation has been made. Where the capital is not mentioned, it may easily be made out by considering the salaries as the interest.

Hitherto we have taken no notice of the corresponding board which was established at London so early as the year 1729, to receive subscriptions and lay out sums. That board indeed remained long inactive; but in 1773 its members began to co-operate more cordially with their brethren in Scotland. Since that period an annual sermon has been preached in recommendation of the charity; and the preacher is now selected without any regard to the religious denomination to which he belongs; sometimes from the church of England, sometimes from the church of Scotland, and sometimes from sectaries of different persuasions. The meetings of the correspondent board have been attended by many of the nobility and gentry, who have made great exertions to promote the views of the society. From its present flourishing state, therefore, from the indefatigable exertion and laudable zeal of the managers, and from the countenance and support which they have received from persons of the first rank and respectability in the nation, the benevolent mind may look forward with much confidence and satisfaction to a period not very distant, when its beneficial effects shall be felt not only in the Highlands, but shall be communicated to the rest of the nation.

We have been thus particular in our account of the Society for Propagating Christian Knowledge, because we have had access to the most authentic sources of information, and because we know it to be an institution calculated to enlighten and improve a considerable part of the British nation.

3. Society of the Sons of the Clergy, was incorporated by King Charles II. in 1675, by the name of The Governors of the Charity for Relief of the Poor Widows and Children of Clergymen. This society is under the direction and management of a president and vice-president, three treasurers, and a court of assistants composed of forty members. Several hundreds of widows and children of the clergy have annually received considerable relief from this useful charity.

4. Society for the Sons of the Clergy of the Established Church of Scotland, was instituted at Edinburgh in February 1793, and was constituted a body corporate by his majesty’s royal charter in 1792. The society, after several meetings, are of opinion, that the period in which the families of clergymen feel most urgently the need both of friends and of pecuniary aid, is that which commences with the introduction of the sons either to an university or to business, and terminates with their establishment in their respective professions; that many of the ministers of this church, living at great distances from the seats either of universities or of business, possess incomes which, in the present state of the country, are inadequate to the purposes of procuring for their sons either the literary or professional education which might enable them to come forward with credit and success in the world; that the sons of clergymen, from domestic tuition and example, have in general very advantageous means of receiving in their early years the impressions of virtue and honour, together with the rudiments of liberal knowledge; and that of course the public interest may be promoted, by enabling this class of young men to obtain their share in the respectable situations of life. The views of the society have been limited to the sons only of clergymen; as they are of opinion, that within the limits which they have fixed, the field of beneficence will be still very extensive, and the claims for aid as many and as great as their funds can be supposed able to answer, at least for many years to come. If the society shall ever be in a situation to undertake more than the aids which will be necessary in bringing forward the sons of the clergy, it may then be considered in what manner the daughters also may become sharers in its bounty.

A society of the same nature, and having the same objects in view, was instituted at Glasgow we think the year before; and both societies, we know, have in many cases proved highly beneficial in promoting the views for which they were instituted.

5. Royal Humane Society, was instituted in London in 1774, for the recovery of persons drowned or otherwise suffocated. We have already given some account of societies instituted in other countries with the same views, and have also copied the directions of this society for the recovery of life, for which see the article DROWNING. We have therefore only to state, that the plan of this society is so averse to any private interested views, that it acquires its founders of all sordid motives. For the medical practitioners accept no pecuniary recompense for the time which they devote to a difficult and tedious process; for the anxiety which they feel while the event is doubtful: for the mortification which they too often undergo, when death, in spite of all their efforts, at last carries off his prey; nor for the insults to which they willingly expose themselves from vulgar incredulity. Their sole reward is in the holy joy of doing good. Of an institution thus free in its origin from the suspicion of ambitious views, and in its plan renouncing self-interest in every shape, philanthropy must be the only basis. The good intention therefore of the society is proved by its constitution; the wisdom and utility of the undertaking are proved by its success: not fewer than 3500 fellow-creatures having since its commencement been (1794) restored to the community by its timely and indefatigable exertions. For it is to be observed, that the benefit of this society is by no means confined to the two cases of drowning and suspension. Its timely succours have roused the lethargy of opium taken in moderate or repeated doses; they have rescued the wretched victims of intoxication; rekindled the life extinguished by the sudden stroke of lightning; recovered the apoplectic; restored life to the infant that had lost it in the birth; they have proved efficacious
welfare, it is calculated to increase industry; and it directs that industry into the most useful and necessary channels. If we regard self-interest, its immediate object is to protect our persons from assault and murder, our property from depredation, and our peaceful habitations from the desperate fury of midnight incendiaries.

One guinea per annum constitutes a member of the society; and 10L at one payment a member for life. A life-subscription, or an annual payment of at least two guineas, is a necessary qualification for being elected into the committee.

II. SOCIETIES FOR PROMOTING SCIENCE AND LITERATURE.

1. The Royal Society of London is an academy or body of persons of eminent learning, instituted by Charles II. for the promoting of natural knowledge. The origin of this society is traced by Dr Sprat, its earliest historian, no farther back than to "some space after the end of the civil wars" in the 17th century. The scene of the first meetings of the learned men who laid the foundation of it, is by him fixed in the university of Oxford, at the lodgings of Dr Wilkens warden of Wadham college. But Dr Birch, on the authority of Dr Wallis, one of its earliest and most considerable members, assigns it an earlier origin. According to him, certain worthy persons, residing in London about the year 1645, being "inquisitive into natural and the new and experimental philosophy, agreed to meet weekly on a certain day, to discourse upon such subjects, and were known by the title of The Invisible or Philosophical College." In the years 1648 and 1649, the company who formed these meetings was divided, part retiring to Oxford and part remaining in London; but they continued the same pursuits as when united, corresponding with each other, and giving a mutual account of their respective discoveries. About the year 1659 the greater part of the Oxford society returned to London, and again uniting with their fellow-labourers, met once, if not twice, a-week at Gresham college, during term time, till they were scattered by the public disturbances of that year, and the place of their meeting made a quarter for soldiers. On the restoration 1660 their meetings were revived, and attended by a greater concourse of men eminent for their rank and learning. They were at last taken notice of by the king, who having himself a considerable taste for physical science, was pleased to grant them an ample charter, dated the 15th of July 1662, and afterwards a second dated 15th April 1763, by which they were erected into a corporation, consisting of a president, council, and fellows, for promoting natural knowledge; and to give their investigations, against which strange prejudices were entertained, every possible support, he sometimes honoured their meetings with his presence.

Their manner of electing fellows is by balloting. Their council are in number 21, including the president, vice-president, treasurer, and two secretaries; 11 of which are continued for the next year, and 10 more added to them; all chosen on St Andrew's day. Each member at his admission subscribes an engagement that he will endeavour to promote the good of the society; from which he may be freed at any time, by signifying to the president that he desires to withdraw. The charges have been different at different times, and were 3L at
at first irregularly paid: but they are now five guineas paid to the treasurer at admission, and 15s. per quarter unless the person continues a member; or, in lieu of the annual subscription, a composition of 25 guineas in one payment.

Their design is, to "make faithful records of all the works of nature or art which come within their reach; so that the present as well as future ages may be enabled to put a mark on errors which have been strengthened by long prescription; to restore truths that have been neglected; to push those already known to more various uses; to make the way more passable to what remains unrevealed," &c. To this purpose they have made a great number of experiments and observations on most of the works of nature; and also numbers of short histories of nature, arts, manufactures, useful engines, contrivances, &c. The services which they have rendered to the public are very great. They have improved naval, civil, and military architecture; advanced the security and perfection of navigation; improved agriculture; and put not only this kingdom, but also Ireland, the plantations, &c. upon planting. They have registered experiments, histories, relations, observations, &c. and reduced them into one common stock; and have, from time to time, published those which they reckoned most useful, under the title of Philosophical Transactions, &c. and laid the rest up in public registers, to be nakedly transmitted to posterity, as a solid groundwork for future systems.

They have a library adapted to their institution; towards which Mr Henry Howard, afterwards duke of Norfolk, contributed the Norfolcian library, and which is, at this time, greatly increased by a continual series of benefactions. The museum or repository of natural and artificial rarities, given them by Daniel Colwall, Esq. and since enriched by many others, is now removed to the British museum, and makes a part of that great repository. Their motto is Nullius in verba; and their place of assembling is Somerset house in the Strand. Sir Godfrey Copley, baronet, left five guineas to be given annually to the person who should write the best paper in the year, under the head of experimental philosophy. This reward, which is now changed to a gold medal, is the highest honour the society can bestow. It is conferred on St Andrew's day.

2. The Royal Society of Edinburgh, was incorporated by royal charter on the 29th of March 1783, and has for its object the cultivation of every branch of science, erudition, and taste. Its rise and progress towards its present state was as follows: In the year 1718 a literary society was established in Edinburgh by the learned Ruddiman and others, which in 1731 was succeeded by a society instituted for the improvement of medical knowledge. In the year 1739 the celebrated MacLaurin conceived the idea of enlarging the plan of this society, by extending it to subjects of philosophy and literature. The institution was accordingly new-modelled by a printed set of rules and regulations, the number of members was increased, and they were distinguished from that time by the title of The Society for Improving Arts and Sciences, or more generally by the title of The Philosophical Society of Edinburgh. Its meetings, however, were soon interrupted by the disorders of the country during the rebellion in 1745; and they were not renewed till the year 1752. Soon after
S O C [ 451 ]

Societies of the physical class are held on the first Mondays of
January, February, March, April, July, August, No-
ember, and December; and the meetings of the Lite-
rary class are held on the third Mondays of January,
February, March, April, June, July, November, and
December, at 7 o'clock afternoon.

At these meetings the written essays and observations of
the members of the society, or their correspondents,
are read publicly, and become the subjects of con-
aversation. The subjects of these essays and observations are
announced at a previous meeting, in order to engage the
time of those members who may be particularly interested in them. The author of each dissertation is
likewise desired to furnish the society with an abstract of
it, to be read at the next ensuing meeting, when the
conversation is renewed with increased advantage, from
the knowledge previously acquired of the subject.
At the same meetings are exhibited such specimens of
natural or artificial curiosities, such remains of antiquity,
and such experiments, as are thought worthy of the at-
tention of the society. All objects of natural history
presented to the society, are ordered by the charter of
the institution, to be deposited, on receipt, in the museum
of the university of Edinburgh; and all remains of an-
tiquity, public records, or ancient manuscripts, in the
library belonging to the faculty of advocates at Edin-
burgh.

The ordinary members, whose usual residence is in
the city of Edinburgh or its immediate neighbourhood,
are expected to attend regularly the monthly meetings;
and are required to defray, by an annual contribution,
the current expenses of the institution. The members
who reside at such a distance from Edinburgh, that they
cannot enjoy the advantages arising from a regular
attendance on the meetings of the society, are not sub-
jected to any contribution for defraying its expenses,
but have a right to attend those meetings when occa-
sionally in Edinburgh, and to take part in all their pro-
ceedings.

Five volumes of the Transactions of the society have
been published, which bear ample testimony to the learn-
ing and acuteness of their various authors.

3. Medical Society of London, instituted in the year
1755; on the plan recommended by Lord Bacon (De
Augm. Scient. lib. iv. cap. 2.), to revive the Hippocra-
tic method of composing narratives of particular cases,
in which the nature of the disease, the manner of treat-
ing it, and the consequences, are to be specified; to
attempt the cure of those diseases which, in his opinion,
have been too boldly pronounced incurable; and, last-
ly, to extend their inquiries after the powers of par-
ticular medicines in the cure of particular cases; the
collections of this society have been already published,
under the title of Medical Observations and Inquiries,
in several volumes.

4. The Medical Society of Edinburgh was incorporated
by royal charter in 1758; but there appears to have
been in that city a voluntary association of the same
name from the first establishment of a regular school of
physic in the university. To the voluntary society the
public is indebted for six volumes of curious and use-
ful essays, collected principally by the late Dr Monro
from June 1731 to June 1736; but in the year 1739
that society was united to another, as we have already
observed in a former article. The ordinary members
of the present medical society are elected by ballot, and
three dissentients exclude a candidate; an ordinary mem-
ber may also be elected an honorary member, who en-
joys the privileges of the others, and receives a diploma,
but is freed from the obligation of attendance, delivering
papers in rotation, &c. to which the ordinary mem-
bers are subject; but in this case the votes must be uni-
form. The meetings of this society are held every
Friday evening (formerly Saturday) in their own hall,
during the winter season, when papers on medical sub-
jects are delivered by the several members in rotation;
and four of these are annually elected to fill the chair in
rotation, with the title of annual presidents. This soci-
ety possesses an excellent library of books on sub-
jects connected with its pursuits.

5. The Royal Medical Society of Paris was instituted
in 1776. The members are divided into associates ordi-
ary, limited to 20, honorary to 12, extraordinary to 60,
and foreign to 60, and correspondents. This society has
published several volumes of Memoirs in 4to.

6. Asiatic Society, an institution planned by the late
illustrious Sir William Jones, and actually formed at
Calcutta on the 15th of January 1784, for the purpose
of tracing the history, antiquities, arts, sciences, and li-
terature, of the immense continent of Asia. As it was
resolved to follow as nearly as possible the plan of the
Royal Society of London, of which the king is pa-
tron, the patronage of the Asiatic Society was offered
to the governor-general and council, as the executive
power in the territories of the company. By their ac-
ceptance of this offer, Mr Hastings, as governor-gene-
al, appeared among the patrons of the new society;
but he seemed in his private station, as the first liberal
promoter of useful knowledge in Bengal, and especially
as the great encourager of Persian and Sanscrit li-
terature, to deserve a particular mark of distinction: he
was requested, therefore, to accept the honorary title of
president. This was handsomely declined in a letter
from Mr Hastings, in which he requested "to yield his
pretensions to the gentleman whose genius planned the
institution, and was most capable of conducting it to the
attainment of the great and splendid purposes of its for-

tation." On the receipt of this letter, Sir William
Jones was nominated president of the society; and we
cannot give the reader a view of the object of the insti-
tution in clearer language than that which he employed
in his first discourse from the chair.

"It is your design, I conceive (said the president),
to take an ample space for your learned investigations,
bounding them only by the geographical limits of Asia;
so that, considering Hindostan as a centre, and turning
your eyes in idea to the north, you have on your right
many important kingdoms in the eastern peninsula, the
ancient and wonderful empire of China with all her Tar-
tarian dependencies, and that of Japan, with the cluster
of precious islands, in which many singular curiosities
have too long been concealed; before you lies that pro-
digious chain of mountains, which formerly perhaps
were a barrier against the violence of the sea, and be-
beyond them the very interesting country of Tibet, and
the vast regions of Tartary, from which, as from the
Trojan horse of the poets, have issued so many consum-
ate warriors, whose domain has extended at least from
the banks of the Ilyssus to the mouths of the Ganges;
on your left are the beautiful and celebrated provinces

3 L 2 of
Societies of Iran or Persia, the unmeasured and perhaps unmea-
surably deserts of Arabia, and the once flourishing king-
dom of Yemen, with the pleasant isles that the Arabs
have subdued or colonized; and farther westward, the
Asianic dominions of the Turkish sultans, whose moon
seems approaching rapidly to its eclipse. By the great
circumference the field of your useful researches will be
inclosed; but since Egypt had unquestionably an old
connection with this country, if not with China, since
the language and literature of the Abyssinians bear a
manifest affinity to those of Asia, since the Arabian
arms prevailed along the African coast of the Medi-
erranean, and even erected a powerful dynasty on the
continent of Europe, you may not be displeased occa-
sionally to follow the streams of Asiatic learning a little
beyond its natural boundary; and, if it be necessary or
convenient that a short name or epithet be given to our
society, in order to distinguish it in the world, that of
Asiatic appears both classical and proper, whether we
consider the place or the object of the institution, and
preferable to Oriental, which is in truth a word merely
relative, and though commonly used in Europe, con-
veys no very distinct idea.

If now it be asked, What are the intended objects
of our inquiries within these spacious limits? we answer,
MAN and NATURE; whatever is performed by the one
or produced by the other. Human knowledge has been
elegantly analysed according to the three great faculties
of the mind, memory, reason, and imagination, which
we constantly find employed in arranging and retaining,
comparing and distinguishing, combining and diversify-
ing, the ideas, which we receive through our senses, or
acquire by reflection; hence the three main branches
of learning are, history, science, and art; the first com-
prehends either an account of natural productions, or
the genuine records of empires and states; the second
embraces the whole circle of pure and mixed mathematics,
together with ethics and law, as far as they de-
pend on the reasoning faculty; and the third includes
all the beauties of imagery and the charms of invention,
displayed in modulated language, or represented by co-
lor, figure, or sound.

Agreeable to this analysis, you will investigate
whatever is rare in the stupendous fabric of nature, will
correct the geography of Asia by new observations and
discoveries; will trace the annals and even traditions of
those nations who from time to time have peopled or
desolated it; and will bring to light their various forms
of government, with their institutions civil and religious;
you will examine their improvements and methods in
arithmetic and geometry; in trigonometry, mensuration,
mechanics, optics, astronomy, and geology; their
systems of morality, grammar, rhetoric, and dialect;
their skill in chirurgery and medicine; and their ad-
vancement, whatever it may be, in anatomy and che-
metry. To this you will add researches into their agri-
culture, manufactures, trade; and whilst you inquire
with pleasure into their music, architecture, painting,
and poetry, will not neglect those inferior arts by which
the comforts and even elegancies of social life are sup-
plied or improved. You may observe, that I have
omitted their languages, the diversity and difficulty of
which is a sad obstacle to the progress of useful know-
ledge; but I have ever considered languages as the mere
instruments of real learning, and think them in-
properly confounded with learning itself: the attain-
ment of them is, however, indispensably necessary; and
for Promot-
if to the Persian, Armenian, Turkish, and Arabic, could
be added not only the Shumacrit, the treasures of which
we may now hope to see unlocked, but even the Chi-
inese, Tartarian, Japanese, and the various insular dia-
lects, an immense mine would then be open, in which
we might labour with equal delight and advantage.

Of this society three volumes of the Transactions
have been published, which are replete with informa-
tion in a high degree curious and important; and we
hope that the European world shall soon be favoured
with another. The much-to-be-lamented death of the
accomplished president may indeed damp the spirit of
investigation among the members; for to conquer diffi-
culties so great as they must meet with, a portion seems
to be necessary of that enthusiasm which accompanied
all the pursuits of Sir William Jones; but his successor
is a man of great worth and learning, and we trust will
use his utmost endeavours to have the plan completed
of which Sir William gave the outlines.

5. The American Philosophical Society, held at Phi-
adelphia, was formed in January 1769 by the union of
two societies which had formerly subsisted in that city.
This society extends its attention to geography, math-
ematics, natural philosophy, and astronomy; medicine
and anatomy; natural history and chemistry; trade
and commerce; mechanics and architecture; husbandry
and American improvements. Its officers are a patron,
president, three vice-presidents, one treasurer, four
secretaries, and three curators, who are annually chosen
by ballot. The duty of the president, vice-presidents,
treasurer, and secretaries, is the same as in other soci-
ties. The business of the curators is to take the charge
of all specimens of natural productions, whether of the
animal, vegetable, or fossil kingdom; all models of
machines and instruments; and all other matters be-
longing to the society which shall be intrusted to them.
The ordinary meetings are held on the first and third
Fridays of every month from October to May inclusive.
This society was incorporated by charter 15th March
1780; and has published three volumes of its Transac-
tions, containing many ingenious papers on general li-
terature and the sciences, as well as respecting those
subjects peculiar to America. It is a delightful pro-
spect to the philosopher to consider, that Asia, Europe,
and America, though far separated and divided into a
variety of political states, are all three combined to pro-
move the cause of knowledge and truth.

6. A Literary and Philosophical Society of consider-
able reputation has been lately established at Man-
chester, under the direction of two presidents, four vice-
presidents, and two secretaries. The number of mem-
bers is limited to 50; besides whom there are several
honorary members, all of whom are elected by ballot;
and the officers are chosen annually in April. Five vol-
umes of valuable essays have been already published by
this society.

A society on a similar plan has been established at
Newcastle. It is composed of a number of most re-
spectable members, and possesses a very valuable library
and philosophical apparatus. Lectures on the different
branches of natural philosophy have been delivered for
several years at this institution.

7. Society for Promoting the Discovery of the Interior
Parts

Societies for Promoting Science and Literature.

Parts of Africa. This society or association for exploring the internal districts of Africa, of which so little is at present known, was formed in London by some opulent individuals in 1788; who, strongly impressed with a conviction of the practical utility and utility of thus enlarging the fund of human knowledge, determined if possible to rescue the age from that stagna which attaches to its ignorance of so large and so near a portion of the globe. The founders of this society resolved to admit no man a member for a shorter period than three years, during which he must pay annually into the public fund five guineas. After three years, any member, upon giving a year's notice, may withdraw himself from the association. During the first 12 months each of the members was allowed to recommend for the approval of the society such of his friends as he might think proper to be admitted into it; but since that period we believe all additional members have been elected by a ballot of the association at large. A committee was chosen by ballot to manage the funds of the society, to choose proper persons to be sent on the discovery of the interior parts of Africa, and to carry on the society's correspondence, with express injunctions to disclose no intelligence received from their agents but to the society at large. But a fuller account of the nature of this establishment, and the very happy efforts they have made, may be seen in the superb edition of their proceedings printed in 1790, for their own use; or in the 8vo edition since made public. They soon found two gentlemen, Mr Lucas and Mr Ledyard, who were singularly well qualified for the important mission. The information they have acquired will be found in the above work; with a new map by Mr Renne, exhibiting the geographical knowledge collected by the African association. Mr Ledyard very unfortunately died during his researches at Cairo.

Few of our readers are unacquainted with the travels of Mr Park under the patronage of the society. For an account of which see Africa. A second journey was undertaken by the same gentleman within these three years; but as he has not been heard of for a long time, the most serious apprehensions are entertained that he and his companions have fallen victims either to the inhospitable climate, or to the watchful jealousy of the Moors. Another enterprising traveller, Mr Horner, was sent out by the society about 1800. He departed from Cairo with a caravan, and reached Mourzook, a place situated south from Tripoli; and from thence sent a communication to his constituents which has since been published by the society. This is the last account that was received of this traveller, from which it is feared that he has also perished.

8. The Society of Antiquaries of London, was founded about the year 1752 by Archbishop Parker, a munificent patron of learned men. For the space of 20 years it assembled in the house of Sir Robert Cotton; in 1789 they resolved to apply to Queen Elizabeth for a charter, and a public building where they might hold their meetings; but it is uncertain whether any such application was ever made. In the mean time, the reputation of the society gradually increased, and at length it excited the jealousy of James I. who was afraid lest it should presume to canvas the secret transactions of his government. He accordingly dissolved it. But in the beginning of the last century, the Antiquarian society began to revive; and a number of gentlemen, eminent for their affection to this science, had weekly meetings, in which for Promoting the antiquities and history of Great Britain, they examined the antiquities and history of Great Britain and Literature. The chief object of the inquiries and researches of the society are British antiquities and history; not, however, wholly excluding those of other countries. It must be acknowledged, that the study of antiquity offers to the curious and inquisitive a large field for research and amusement. The inquirer in this branch furnishes the historian with his best materials, while he distinguishes from truth the fictions of a bold invention, and ascertains the credibility of facts; and to the philosopher he presents a fruitful source of ingenious speculation, while he points out to him the way of thinking, and the manners of men, under all the varieties of aspect in which they have appeared.

An antiquarian ought to be a man of solid judgment, possessed of learning and science, that he may not be an enthusiastic admirer of everything that is ancient merely because it is ancient; but be qualified to distinguish between those researches which are valuable and important, and those which are trifling and useless. It is from the want of these qualifications that some men have contracted such a blind passion for everything that is ancient, that they have exposed themselves to ridicule, and their study to contempt. But if a regard to utility were always to regulate the pursuits of the antiquarian, the shafts of satire would no longer be levelled at him; but he would be respected as the man who labours to restore or to preserve such ancient productions as are suited to illuminate religion, philosophy, and history, or to improve the arts of life.

We by no means intend to apply these observations to any particular society of antiquarians; but we throw them out, because we know that an assiduous study of antiquity is apt, like the ardent pursuit of money, to lose sight of its original object, and to degenerate into a passion which mistakes the mean for the end, and considers possession without a regard to utility as enjoyment.

An association similar to that of the Antiquarian Society of London was founded in Edinburgh in 1783, and received the royal charter in 1789. A volume of the Transactions of this society has been published; but with the exception of two or three memoirs, it contains little worthy of notice; and accordingly, it has never attracted the attention of the public.

Besides these literary societies here mentioned, there are a great number more in different parts of Europe, some of which are noticed under the article Academy. Those which are omitted are not omitted on account of any idea of their inferior importance; but either be-
cause we have had no access to authentic information, or because they resemble the societies already described so closely, that we could have given nothing but their names.

III. Societies for Encouraging and Promoting Arts, Manufactures, &c.

1. London Society for the Encouragement of Arts, Manufactures, and Commerce, was instituted in the year 1754 by Lord Folkestone, Lord Romney, Dr Stephen Hales, and a few private gentlemen; but the merit of this institution chiefly belonged to Mr William Shipley, an ingenious mechanic; who, though deriving no advantages from learning, by unwearied personal attendance found means to engage a few persons of rank and fortune to meet at Peele’s coffeehouse in Fleet-street, and to adopt a plan for promoting arts and manufactures.

The office-bearers of this society are a president, 12 vice-presidents, a secretary, and register. Their proceedings are regulated by a body of rules and orders established by the whole society, and printed for the use of the members. All questions and debates are determined by the holding up of hands, or by ballot if required; and no matter can be confirmed without the assent of a majority at two meetings. They invite all the world to propose subjects for encouragement; and whatever is deemed deserving of attention is referred to the consideration of a committee, which, after due inquiry and deliberation, make their report to the whole society, where it is approved, rejected, or altered. A list is printed and published every year of the matters for which they propose to give premiums; which premiums are either sums of money, and those sometimes very considerable ones; or the society’s medal in gold or silver, which they consider as the greatest honour they can bestow. All possible care is taken to prevent partiality in the distribution of their premiums, by desiring the claimant’s names to be concealed, and by appointing committees (who when they find occasion call to their assistance the most skilful artists) for the strict examination of the real merit of all matters and things brought before them, in consequence of their premiums.

The chief object of the attention of the Society for the Encouragement of Arts, Manufactures, and Commerce, in the application of their revenues, are ingenuity in the several branches of the polite and liberal arts, useful discoveries and improvements in agriculture, manufactures, mechanics, and chemistry, or the laying open of any such to the public; and, in general, all such useful inventions, discoveries, or improvements (though not mentioned in the book of premiums) as may appear to have a tendency to the advantage of trade and commerce.

The following are some of the most important regulations of this society. It is required that the matters for which premiums are offered be delivered in without names, or any Intimation to whom they belong; that each particular thing be marked in what manner each claimant thinks fit, such claimant sending with it a paper sealed up, having on the outside a corresponding mark, and on the inside the claimant’s name and address; and all candidates are to take notice, that no claim for a premium will be attended to, unless the conditions of the advertisement are fully complied with. No papers shall be opened but such as shall gain premiums, unless where it appears to the society absolutely necessary for the determination of the claim: all the rest shall be returned unopened, with the matters to which they belong, if inquired after by the marks within two years; after which time, if not demanded, they shall be publicly burnt unopened at some meeting of the society. All the premiums of this society are designed for that part of Great Britain called England, the dominion of Wales, and the town of Berwick upon Tweed, unless expressly mentioned to the contrary. No person shall receive any premium, bounty, or encouragement, from the society for any matter for which he has obtained or proposes to obtain a patent. No member of this society shall be a candidate for or intitled to receive any premium, bounty, or reward whatever, except the honorary medal of the society.

The respectability of the members who compose it may be seen by perusing the list which generally accompanies their Transactions. In the last volume (vol. xii.) it occupies no less than 43 pages. Some idea may be formed of the wealth of this society, by observing that the list of their premiums fills 96 pages, and amounts to 250 in number. These consist of gold medals, worth from 30 to 50, and in a few instances to 100 guineas; and silver medals valued at 10 guineas.

This society is one of the most important in Great Britain. Much money has been expended by it, and many are the valuable effects of which it has been productive. Among these we reckon not only the discoveries which it has excited, but the institution of other societies on the same principles to which it has given birth; and we do not hesitate to conclude, that future ages will consider the founding of this society as one of the most remarkable epochs in the history of the arts. We contemplate with pleasure the beneficial effects which must result to this nation and to mankind by the diffusion of such institutions; and rejoice in the hope that the active minds of the people of Great Britain, instead of being employed as formerly in controversies about religion, which engender strife, or in discussions concerning the theory of politics, which lead to the adoption of schemes inconsistent with the nature and condition of man, will soon be more generally united into associations for promoting useful knowledge and solid improvement, and for alleviating the distresses of their fellow creatures.

1. Society instituted at Bath for the Encouragement of Agriculture, Arts, Manufactures, and Commerce. It was founded in the year 1777 by several gentlemen who met at the city of Bath. This scheme met with a very favourable reception both from the wealthy and learned. The wealthy subscribed very liberally, and the learned communicated many important papers: On application to the London and provincial societies instituted for like purposes, they very politely offered their assistance. Several volumes of their Transactions have already been published, containing very valuable experiments and observations, particularly respecting agriculture, which well deserve the attention of all farmers in the kingdom. We have consulted them with much satisfaction on several occasions, and have frequently referred to them in the course of this work; and therefore, with pleasure,
S O C [ 455 ]

Societies for Encouraging and Promoting Arts, Manufactures, &c.

3. Society for working Mines, an association lately formed on the continent of Europe. This institution arose from the accidental meeting of several mineralogists at Skiena near Schemaitz in Hungary, who were collected in order to examine a new method of amalgamation. Struck with the shackles imposed on mineralogy by monopolizers of new and useful processes, they thought no method so effectual to break them, as forming a society, whose common labours should be directed to fix mining on its surest principles; and whose memoirs, spread all over Europe, might offer to every adventurer the result of the researches, of which they are the object. By these means they supposed, that there would be a mass of information collected; the interests of individuals would be lost in the general interest; and the one would materially assist the other. Imposture and quackery would, by the same means, be banished from a science, which must be improved by philosophy and experience; and the society, they supposed, would find, in the confidence which they inspired, the reward and the encouragement of their labours. They design, that the memoirs which they publish shall be short and clear; truth must be their basis, and every idle discussion, every foreign digression, must be banished; politics and finance must be avoided, though the dissertations may seem to lead towards them; and they oblige themselves to oppose the allusion of brilliancies, and the ostentation of empty speculation, when compared with plain, simple, and useful facts.

The object of the society is physical geography; mineralogy founded on chemistry; the management of ore in the different operations which it undergoes; subterraneous geometry; the history of mining; founders, and the processes for the extraction of metals from the ores, either by fusion or amalgamation, in every instance applied to practice. The end of this institution is to collect, in the most extensive sense, everything that can assist the operations of the miner, and to communicate it to the different members, that they may employ it for the public good, in their respective countries. Each member must consider himself as bound to send to the society everything which will contribute to the end of its institution; to point out, with precision, the several facts and observations; to communicate every experiment which occurs, even the unsuccessful ones, if the relation may seem to be advantageous to the public; to communicate to the society their examination of schemes, and their opinions on questions proposed by it; and to pay annually two ducats (about 18s. 6d.) to the direction every Easter. The society on the other hand, is bound to publish every novelty that shall be communicated to it; to communicate to each member, at the member's expense, the memoirs, designs, models, productions, and every thing connected with the institution; to answer all the necessary demands made, relating in any respect to mining; and to give its opinion on every plan or project communicated through the medium of an honorary member.

The great centre of all intelligence is to be at Zellernfeld in Hartz, Brunswick; but the society is not fixed to any one spot; for every particular state some practical mineralogist is nominated as director. Among these are the names of Baron Born, M. Pallas, M. Charpentier, M. Prebrun, and M. Henkel. Their office is to propose the members; to take care that the views of the society are pursued in the different countries where they reside; to answer the requests of the members of their country who are qualified to make them; in case of the death of a director, to choose another; and the majority is to determine where the archives and the strong box is to be placed.

All the eminent mineralogists in Europe are members of this society. It is erected on so liberal and so extensive a plan, that we entertain the highest hopes of its success; and have only to add, that we wish much to see the study of several other sciences pursued in the same manner.

4. The Society for the Improvement of Naval Architecture, was founded in 1791. The object of it is to encourage every useful invention and discovery relating to naval architecture as far as shall be in their power, both by honorary and pecuniary rewards. They have in view particularly to improve the theories of floating bodies and of the resistance of fluids; to procure draughts and models of different vessels, together with calculations of their capacity, centre of gravity, tonnage, &c.; to make observations and experiments themselves, and to point out such observations and experiments as appear best calculated to further their designs, and most deserving those premiums which the society can bestow. But though the improvement of naval architecture in all its branches be certainly the principal object of this institution, yet the society do not by any means intend to confine themselves merely to the form and structure of vessels. Every subordinate and collateral pursuit will claim a share of the attention of the society in proportion to its merits; and whatever may have any tendency to render navigation more safe, salutary, and even pleasant, will not be neglected.

This institution owes its existence to the patriotic disposition and extraordinary attention of Mr Sewell, a private citizen of London, who (though engaged in a line of business totally opposite to all concerns of this kind) has been led, by mere accident, to take such ocular notice of, and make such observations on, the actual state of naval architecture in this country, as naturally occurred to a man of plain understanding, zealous for the honour and interest of his country, and willing to bestow a portion of that time for the public good, which men of a different description would rather have devoted to their own private advantage. His attention was the more seriously excited by finding that it was the opinion of some private ship-builders, who, in a debate on the failure of one of our naval engagements, pronounced, that such “would ever be the case while that business (the construction of our ships of war) was not studied as a science, but carried on merely by precedent; that there had not been one improvement in our navy that did not originate with the French, who had naval schools and seminaries for the study of it; and that our ships were not a match for those of that nation either singly or in a fleet,” &c. &c.

In a short time the society were enabled to offer very considerable premiums for particular improvements in the construction of our shipping, &c. &c. and also to encourage our philosophers, mathematicians, and mechanics, to make satisfactory experiments, tending to ascertain
certain the laws of resistance of water to solids of different forms, in all varieties of circumstance. On this head the reward is not less than one hundred pounds or a gold medal. Other premiums of 50, 30, and 20 guineas, according to the importance or difficulty of the particular subject or point of investigation, are likewise offered, for different discoveries, inventions, or improvements. The terms of admission into the society are a subscription of two guineas annually, or twenty guineas for life.

5. Society of Artists of Great Britain, which consists of directors and fellows, was incorporated by charter in 1765, and empowered to purchase and hold lands, not exceeding 1000l. a-year. The directors of this society, annually elected, are to consist of 24 persons, including the president, vice-president, treasurer, and secretary; and it is required that they be either painters, sculptors, architects, or engravers by profession.

6. British Society for extending the Fisheries and Improving the Sea-Coasts of this Kingdom, was instituted in 1786. The end and design of this society will best appear from their charter, of which we present an abstract.

The preamble states, "the great want of improvement in fisheries, agriculture, and manufactures, in the Highlands and Islands of North Britain; the prevalence of emigration from the want of employment in those parts; the prospect of a new nursery of seamen, by the establishment of fishing towns and villages in that quarter. The act therefore declares, that the persons therein named, and every other person or persons who shall thereafter become proprietors of the joint stock mentioned therein, shall be a distinct and separate body politic and corporate, by the name of The British Society for Extending the Fisheries and Improving the Sea-Coasts of this Kingdom: That the said society may raise a capital joint stock not exceeding 150,000l. to be applied to purchasing otherwise acquiring lands and tenements in perpetuity, for the building thereon, and on no other land whatever, free towns, villages, and fishing stations: That the joint stock shall be divided into shares of 50l. each: That no person shall in his or her name possess more than ten shares, or 500l.: That the society shall not borrow any sum or sums of money whatsoever: That the sums to be advanced for this undertaking, and the profits arising therefrom, shall be divided proportionally to the sum subscribed; and that no person shall be liable for a larger sum than he or she shall have respectively subscribed; That one or two shares shall entitle to one vote, and no more, in person or by proxy, at all meetings of proprietors; three or four shares to two votes; five, six, or seven shares, to three votes; eight or nine shares to four votes; and ten shares to five votes and no more: That more persons than one inclining to hold in their joint names one or more shares shall be entitled to vote, by one of such persons, according to the priority of their names, or by proxy: That bodies corporate shall vote by proxy under their seal: That all persons holding proxies shall be proprietors, and that no one person shall hold more than five votes by proxy: That the affairs of the society shall be managed by a governor, deputy governor, and 13 other directors, to be elected annually on the 25th of March, from among the proprietors of the society, holding at least one full share, by signed lists of their names to be transmitted by the proprietors to the secretary of the society: That five Societies proprietors, not being governor, director, or other officer, shall be in like manner annually elected to audit the accounts of the society: That there shall be one general meeting of the proprietors annually on the 25th of October, and March: That occasional general meetings shall be called on the request of nine or more proprietors: That the general meetings of the proprietors shall make all by-laws and constitutions for the government of the society, and for the good and orderly carrying on of the business of the same: That no transfer shall be made of the stock of the society for three years from the 10th of August 1786: That the cash of the society shall be lodged in the bank of England, bank of Scotland, or the royal bank of Scotland: That no director, proprietor, agent, or officer of the society, shall retain any sum or sums of money in his hands beyond the space of 30 days on any account whatsoever: That all payments by the society shall be made by drafts on the said banks, under the hands of the governor or deputy-governor, countersigned by the secretary or his deputy, and two or more directors: And that the books in which the accounts of the society shall be kept shall be open to all the proprietors."

The institution of this public-spirited society was in a great measure owing to the exertions of the patriotic John Knox; who in the course of 23 years traversed and explored the Highlands of Scotland not fewer than 16 times, and expended several thousand pounds of his own fortune in pursuing his patriotic designs.

Society Isles, a cluster of isles, so named by Captain Cook in 1769. They are situated between the latitudes of 16. 10. and 16. 55. south, and between the longitudes of 150. 57. and 152. west. They are eight in number; namely, Otaheite, Huahine, Ulietea, Otaha, Bolabola, Maurua, Toobouai, and Tabouya-mano or Saunders's island. The soil, productions, people, their language, religion, customs, and manners, are so nearly the same as at Otaheite, that little need be added here on that subject. Nature has been equally bountiful in uncultivated plenty, and the inhabitants are as luxurious and as indolent. A plaintain branch is the emblem of peace, and exchanging names the greatest token of friendship. Their dances are more elegant, their dramatic entertainments have something of plot and consistency, and they exhibit temporary occurrences as the objects of praise or satire; so that the origin of ancient comedy may be already discerned among them. The people of Huahine are in general stouter and fairer than those of Otaheite, and this island is remarkable for its populousness and fertility. Those of Ulietea, on the contrary, are smaller and blacker, and much less orderly. Captain Cook put on shore a Cape swan at Bolabola, where a ram had been left by the Spaniards; and also an English boar and sow, with two goats, at Ulietea. If the valuable animals which have been transported thither from Europe should be suffered to multiply, no part of the world will equal these islands in variety and abundance of refreshments for future navigators.

SOCINAINS, in church history, a sect of Christian heretics, so called from their founder Faustus Socinus (see Socinus). They maintain, "That Jesus Christ was a mere man, who had no existence before he was conceived by the Virgin Mary; that the Holy Ghost is
Socinus, the first author of the sect of the Socinians, was born at Sienna in 1525. Being designed by his father for the law, he began very early to study for the foundation of that science in the Word of God; and by that study discovered that the Roman religion taught many things contrary to revelation; when, being desirous of penetrating farther into the true sense of the scriptures, he studied Greek, Hebrew, and even Arabic. In 1547 he left Italy, to go and converse with the Protestants; and spent four years in travelling through France, England, the Netherlands, Germany, and Poland, and at length settled at Zurich. He by this means became acquainted with the most learned men of his time, who testified by their letters the esteem they had for him: but as he discovered to them his doubts, he was greatly suspected of heresy. He, however, conducted himself with such address, that he lived among the capital enemies of his opinions, without receiving the least injury. He met with some disciples, who heard his instructions with respect; these were Italians who left their native country on account of religion, and wandered about in Germany and Poland. He communicated likewise his sentiments to his relations by his writings, which he caused to be conveyed to them at Sienna. He died at Zurich in 1562. Those who were of sentiments opposite to his, and were personally acquainted with him, confess that his outward behaviour was blameless. He wrote a paraphrase on the first chapter of St John; and other works are ascribed to him.

Socinus, Faustus, nephew of the preceding, and principal founder of the Socian sect, was born at Sienna in 1539. The letters which his uncle Lelius wrote to his relations, and which infused into them many seeds of heresy, made an impression upon him; so that, knowing himself not innocent, he fled as well as he could when the inquisition began to persecute that family. He was at Lyons when he heard of his uncle's death, and departed immediately to take possession of his writings. He returned to Tuscany; and made himself so agreeable to the grand duke, that the charms which he found in that court, and the honourable posts he filled there, hindered him for twelve years from remembering that he had been considered as the person who was to put the last hand to the system of samostetian divinity, of which his uncle Lelius had made a rough draught. At last he went into Germany in 1574, and paid no regard to the grand duke's advice to return. He lived three years at Breslau, and studied divinity there, and having adopted a set of principles very different from the system of Protestants, he resolved to maintain and propagate them; for which purpose he wrote a treatise De Jesu Christo Servatore. In 1579 Socinus retired into Poland, and desired to be admitted into the communion of the Unitarians; but as he differed from them in some points, on which he refused to be silent, he met with a repulse. However, he did not cease to write in defence of his churches against those who attacked them. At length his book against James Paleologus furnished his enemies with a pretext to exasperate the king of Poland against him; but though the mere reading of it was sufficient to refute his accused, Socinus thought proper to leave Cracow, after having resided there four years. He then lived under the protection of several Polish lords, and married a lady of a good family; but her death, which happened in 1587, so deeply afflicted him as to injure his health; and to complete his sorrow, he was deprived of his patrimony by the death of Francis de Medicis, great duke of Florence. The consolation he found in seeing his sentiments at last approved by several ministers, was greatly interrupted in 1598; for he met with a thousand insults at Cracow, and was with great difficulty saved from the hands of the rabble. His house was plundered, and he lost his goods; but this loss was not so uneasy to him as that of some manuscripts, which he extremely regretted. To deliver himself from such dangers, he retired to a village about nine miles distant from Cracow, where he spent the remainder of his days at the house of Abraham Blonski, a Polish gentleman, and died there in 1604. All Faustus Socinus's works are contained in the two first volumes of the Bibliotheca Fratrum Polonorum.

Socimans, Sokemens, or Socmen (Socmeni), are such tenants as hold their lands and tenements by socage tenure. See Socage.

Socotora, an island lying between Asia and Arabia Felix; about 50 miles in length, and 23 in breadth. It is particularly noted for its fine aloes, known by the name of Socotrine Aloes. The religion of the natives
Socrates

Socrates was born at Alopece, a village near Athens, in the fourth year of the 77th olympiad. His parents were of low rank; his father Sophroniscus being a statuary, and his mother Phainimata a midwife. Sophroniscus brought up his son, contrary to his inclination, in his own manual employment; in which Socrates, though his mind was continually aspiring after higher objects, was not unsuccessful, for whilst he was a young man, he is said to have formed statues of the habited Graces, which were allowed a place in the citadel of Athens. Upon the death of his father he was left in such straitened circumstances as laid him under the necessity of excising that art to procure the means of subsistence, though he devoted, at the same time, all the leisure which he could command to the study of philosophy. His distress, however, was soon relieved by Crito, a wealthy Athenian who, remarking his strong propensity to study, and admiring his ingenuous disposition and distinguished abilities, generously took him under his patronage, and intrusted him with the instruction of his children. The opportunities which Socrates by this means enjoyed of attending the public lectures of the most eminent philosophers, so far increased his thirst after wisdom, that he determined to relinquish his occupation, and every prospect of emolument which that might afford, in order to devote himself entirely to his favourite pursuits. Under Xenagoras and Archelaus he prosecuted the study of nature in the usual manner of the philosophers of the age, and became well acquainted with their doctrines. Proclus the sophist was his preceptor in eloquence, Euphues in poetry, Theodorus in geometry, and Damo in music. Aspasia, a woman no less celebrated for her intellectual than her personal accomplishments, whose house was frequented by the most celebrated characters, had also some share in the education of Socrates. Under such preceptors it cannot reasonably be doubted but that he became master of every kind of learning which the age in which he lived could afford; and being blessed with very uncommon talents by nature, he appeared in Athens, under the respectable characters of a good citizen and a true philosopher. Being called upon by his country to take arms in the long and severe struggle between Athens and Sparta, he signalized himself at the siege of Potidaea, both by his valour and by the hardness with which he endured fatigue. During the severity of a Thracian winter, whilst others were clad in furs, he wore only his usual clothing, and walked barefoot upon the ice. In an engagement in which he saw Alcibiades falling down wounded, he advanced to defend him, and saved both him and his arms; and though the prize of valour was on this occasion unquestionably due to Socrates, he generously gave his vote that it might be bestowed upon Alcibiades, to encourage his rising merit. He served in other campaigns with distinguished bravery, and had the happiness on one occasion to save the life of Xenophon, by hearing him, when covered with wounds, out of the reach of the enemy.

It was not till Socrates was upwards of 60 years of age that he undertook to serve his country in any civil office, when he was chosen to represent his own district, in the senate of five hundred. In this office, though he at first exposed himself to some degree of ridicule from the want of experience in the forms of business, he soon convinced his colleagues that he was superior to them all in wisdom and integrity. Whilst they, intimidated by the clamours of the populace, passed an unjust sentence of condemnation upon the commanders, who, after the engagement at the Argentinian islands, had been prevented by a storm from paying funeral honours to the dead, Socrates stood forth singly in their defence, and to the last refused to give his suffrage against them, declaring that no force should compel him to act contrary to justice and the laws. Under the subsequent tyranny he never ceased to condemn the oppressive and cruel proceedings of the thirty tyrants; and when his boldness provoked their resentment, so that his life was in hazard, fearing neither treachery nor violence, he still continued to support with undaunted firmness the rights of his fellow citizens.

Having given these proofs of public virtue both in a military and civil capacity, he wished to do still more for his country. Observing with regret how much the opinions of the Athenian youth were misled, and their principles and taste corrupted by philosophers who spent all their time in refined speculations upon nature and the origin of things, and by sophists who taught in their schools the arts of false eloquence and deceitful reasoning; Socrates formed the wise and generous design of instituting a new and more useful method of instruction. He justly conceived the true end of philosophy to be, not to make an ostentatious display of superior learning and ability in subtle disquisitions or ingenious conjectures, but to free mankind from the dominion of prenicious prejudices; to correct their vices; to inspire them with the love of virtue; and thus conduct them in the path of wisdom to true felicity. He therefore assumed the character of a moral philosopher; and, looking upon the whole city of Athens as his school, and all who were disposed to lend him their attention as his pupils, he seized every occasion of communicating moral wisdom to his fellow citizens. He passed the greater part of his time in public; and the method of instruction of which he chiefly made use was, to propose a series of questions to the person with whom he conversed, in order to lead him to some unforeseen conclusion. He first gained the consent of his respondent to some obvious truths, and then obliged him to admit others from their relation or resemblance to those to which he had already assented. Without making use of any direct argument or persuasion, he chose to lead the person he meant to instruct, to deduce the truths of which he wished to convince him, as a necessary consequence from his own concessions. He commonly conducted these conferences with such address as to conceal his design till the respondent had advanced too far to recede. On some occasions he made use of ironical language, that vain men might be caught in their own replies, and be obliged to confess their ignorance. He never assumed the air of a morose and rigid preceptor, but communicated useful instruction with all the ease and pleasantry of polite conversation. Though eminently furnished with every kind of learning, he preferred moral to speculative wisdom. Convinced that philosophy.
philosophy is valuable, not as it furnishes questions for the schools, but as it provides men with a law of life, he censured his predecessors for spending all their time in abstruse researches into nature, and taking no pains to render themselves useful to mankind. His favourite maxim was, Whatever is above us doth not concern us. He estimated the value of knowledge by its utility, and recommended the study of geometry, astronomy, and other sciences, only so far as they admit of a practical application to the purposes of human life. His great object in all his conferences and discourses was, to lead men into an acquaintance with themselves; to convince them of their follies and vices; to inspire them with the love of virtue; and to furnish them with useful moral instructions. Cicero might therefore very justly say of Socrates, that he was the first who called down philosophy from heaven to earth, and introduced her into the public walks and domestic retirements of men, that she might instruct them concerning life and manners.

Through his whole life this good man discovered a mind superior to the attractions of wealth and power. Contrary to the general practice of the preceptors of his time, he instructed his pupils without receiving from them any gratuity. He frequently refused rich presents, which were offered him by Alcibiades and others, though importunately urged to accept them by his wife. The chief men of Athens were his stews ters: they sent him in provisions, as they apprehended he wanted them; he took what he present wanted required, and returned the rest. Observing the numerous articles of luxury which were exposed to sale in Athens, he exclaimed, "How many things are there which I do not want!" With Socrates, moderation supplied the place of wealth. In his clothing and food, he consulted only the demands of nature. He commonly appeared in a neat but plain cloak, with his feet uncovered. Though his table was only supplied with simple fare, he did not scruple to invite men of superior rank to partake of his meals; and when his wife, upon some such occasion, expressed her dissatisfaction on being no better provided, he desired her to give herself no concern; for if his guests were wise men, they would be contented with whatever they found at his table; if otherwise, they were unworthy of notice. Whilst others, says he, live to eat, wise men eat to live.

Though Socrates was exceedingly unfortunate in his domestic connection, he converted this infelicity into an occasion of exercising his virtues. Xanthippe, concerning whose ill humour ancient writers relate many amusing tales, was certainly a woman of a high and unmanageable spirit. But Socrates, while he endeavoured to curb the violence of her temper, improved his own. When Alcibiades expressed his surprise that his friend could bear to live in the same house with so perverse and quarrelsome a companion, Socrates replied, that being daily inured to ill humour at home, he was the better prepared to encounter perverseness and injury abroad.

In the midst of domestic vexations and public disorders, Socrates retained such an unruffled serenity, that he was never seen either to leave his own house or to return home with a disturbed countenance. In acquiring this entire dominion over his passions and appetites, he had the greater merit, as it was not effected without a violent struggle against his natural propensities. Zu-
SOCRATES

who had insulted religion, by defacing the public statues of Mercury, and performing a mock representation of the Eleusinian mysteries, had in their youth been disciples of Socrates; and the minds of the populace, being thus prepared, a direct accusation was preferred against him before the supreme court of judicature. His accusers were Anytus, a leather-dresser, who had long entertained a personal enmity against Socrates, for reprehending his avarice, in depriving his sons of the benefits of learning, that they might pursue the gains of trade; Melitus, a young rhetorician, who was capable of undertaking anything for the sake of gain; and Lycon, who was glad of any opportunity of displaying his talents. The accusation, which was delivered to the senate under the name of Melitus, was this: “Melitus, son of Melitus, of the tribe of Pythos, accuses Socrates, son of Sophronicus, of the tribe of Alceo. Socrates violates the laws, in not acknowledging the gods which the state acknowledges, and by introducing new divinities. He also violates the laws by corrupting the youth. Be his punishment death.”

This charge was delivered upon oath to the senate; and Crito, a friend of Socrates, became surety for his appearance on the day of trial. Anytus soon afterwards sent a private message to Socrates, assuring him that if he would desist from censuring his conduct, he would withdraw his accusation. But Socrates refused to comply with so degrading a condition; and with his usual spirit replied, “Whilst I live I will never disguise the truth, nor speak otherwise than my duty requires.”

The interval between the accusation and the trial he spent in philosophical conversations with his friends, choosing to discourse upon any other subject rather than his own situation.

When the day of trial arrived, his accusers appeared in the senate, and attempted to support their charge in three distinct speeches, which strongly marked their respective characters. Plato, who was a young man, and a zealous follower of Socrates, then rose up to address the judges in defence of his master; but whilst he was attempting to apologise for his youth, he was abruptly commanded by the court to sit down. Socrates, however, needed no advocate. Ascending the chair with all the serenity of conscious innocence, and with all the dignity of superior merit, he delivered, in a firm and manly tone, an unpresaged meditation of himself, which silenced his opponents, and ought to have convinced his judges. After tracing the progress of the conspiracy which had been raised against him to its true source, the jealousy and resentment of men whose ignorance he had exposed, and whose vices he had ridiculed and reproved, he distinctly replied to the several charges brought against him by Melitus. To prove that he had not been guilty of impiety towards the gods of his country, he appealed to his frequent practice of attending the public religious festivals. The crime of introducing new divinities, with which he was charged, chiefly as it seems on the ground of the admonitions which he professed to have received from an invisible power, he disclaimed, by pleading that it was no new thing for men to consult the gods and receive instructions from them. To refute the charge of his having been a corrup-ter of youth, he urged the example which he had uniformly exhibited of justice, moderation, and temperance; the moral spirit and tendency of his discourses; and the effect which had actually been produced by his doctrine upon the manners of the young. Then, disdain-ning to solicit the mercy of his judges, he called upon them for that justice which their office and their oath obliged them to administer; and professing his faith and confidence in God, resigned himself to their pleasure.

The judges, whose prejudices would not suffer them to pay due attention to this apology, or to examine with impartiality the merits of the cause, immediately declared him guilty of the crimes of which he stood accused. Socrates, in this stage of the trial, had a right to enter his plea against the punishment which the accusers demanded, and instead of the sentence of death, to propose some pecuniary amercement. But he at first peremptorily refused to make any proposal of this kind, imagining that it might be construed into an acknowledge-ment of guilt; and asserted, that his conduct merited from the state reward rather than punishment. At length, however, he was prevailed upon by his friends to offer upon their credit a fine of thirty minae. The judges, notwithstanding, still remained inexorable: they proceeded, without farther delay, to pronounce sentence upon him: and he was condemned to be put to death by the poison of hemlock.

The sentence being passed, he was sent to prison: which, says Seneca, he entered with the same resolu-tion and firmness with which he had opposed the thirty tyrants; and took away all ignominy from the place, which could not be a prison while he was there. He lay in fetters 30 days; and was constantly visited by Crito, Plato, and other friends, with whom he passed the time in dispute after his usual manner. Anxious to save so valuable a life, they urged him to attempt his escape, or at least to permit them to convey him away: and Crito went so far, as to assure him that, by his in-tester with the jailor, it might be easily accomplished, and to offer him a retreat in Thessaly; but Socrates rejected the proposal, as a criminal violation of the laws, and asked them, whether there was any place out of Attica which death could not reach.

At length the day arrived when the officers to whose care he was committed delivered to Socrates early in the morning the final order for his execution, and im-mEDIATELY, according to the law, set him at liberty from his bonds. His friends, who came thus early to the prison that they might have an opportunity of conversing with their master through the day, found his wife sitting by him with a child in her arms. Socrates, that the tranquillity of his last moments might not be disturbed by her unavailing lamentations, requested that she might be conducted home. With the most frantic expressions of grief she left the prison. An interesting conversation then passed between Socrates and his friends, which chiefly turned upon the immor-tality of the soul. In the course of this conversation, he expressed his disapprobation of the practice of suicide, and as-sured his friends that his chief support in his present sit-uation was an expectation, though not unmixed with doubts, of a happy existence after death. “It would be inex-usable in me (said he) to desire death, if I were not persuaded that it will conduct me into the presence of the gods, who are the most righteous governors, and into the society of just and good men: but I derive confidence from the hope that something of man remains after death,
Socrates, as Crito afterwards said, wished to be buried in the same manner as he wished to die. Socrates replied with a smile, “As you please, provided I do not escape out of your hands.” Then, turning to the rest of his friends, he said, “It is not strange, after all that I have said to convince you that I am going to the society of the happy; that Crito still thinks that this body, which will soon be a lifeless corpse, is Socrates? Let him dispose of my body as he pleases, but let him not at its interment mourn over it as if it were Socrates.”

Towards the close of the day he retired into an adjoining apartment to bathe; his friends, in the mean time, expressing to one another their grief at the prospect of losing so excellent a father, and being left to pass the rest of their days in the solitary state of orphans. After a short interval, during which he gave some necessary instructions to his domestics, and took his last leave of his children, the attendant of the prison informed him that the time for drinking the poison was come. The executioner, though accustomed to such scenes, shed tears as he presented the fatal cup. Socrates received it without change of countenance or the least appearance of perturbation: then offering up a prayer to the gods that they would grant him a prosperous passage into the invisible world, with perfect composure he swallowed the poisonous draught. His friends around him burst into tears. Socrates alone remained unmoved. He upbraided their pusillanimity, and entreated them to exercise a manly constancy worthy of the friends of virtue. He continued walking till the chilling operation of the hemlock obliged him to lie down upon his bed. After remaining for a short time silent, he requested Crito (probably in order to refute a calumny which might prove injurious to his friends after his decease) not to neglect the offering of a cock, which he had vowed to Esculapius. Then, covering himself with his cloak, he expired. Such was the fate of the virtuous Socrates! A story, says Cicero, which I never read without tears.

The friends and disciples of this illustrious teacher of wisdom were deeply afflicted by his death, and attended his funeral with every expression of grief. Apprehensive, however, for their own safety, they soon afterwards privately withdrew from the city, and took up their residence in distant places. Several of them visited the philosopher Euclid of Megara, by whom they were kindly received. No sooner was the unjust condemnation of Socrates known through Greece, than a general indignation was kindled in the minds of good men, who universally regretted that so distinguished an advocate for virtue should have fallen a sacrifice to jealousy and envy. The Athenians themselves, so remarkable for their caprice, who never knew the value of their great men till after their death, soon became sensible of the folly as well as criminality of putting to death the man who had been the chief ornament of their city and of the age, and turned their indignation against his accusers. Melitus was condemned to death; and Anytus, to escape a similar fate, went into voluntary exile. To give a farther proof of the sincerity of their regret, the Athenians for a while interrupted public business; decreed a general mourning; recalled the exiled friends of Socrates; and erected a statue to his memory in one of the most frequented parts of the city. His death happened in the first year of the 96th Olympiad, and in the 70th year of his age.

Socrates left behind him nothing in writing; but his illustrous pupils Xenophon and Plato have in some measure supplied this defect. The Memoirs of Socrates, written by Xenophon, afford, however, a much more accurate idea of the opinions of Socrates, and of his manner of teaching, than the Dialogues of Plato, who everywhere mixes his own conceptions and dictation with the ideas and language of his master. It is related, that when Socrates heard Plato recite his Lysis, he said, “How much does this young man make me say which I never conceived!”

His distinguishing character was that of a moral philosopher; and his doctrine concerning God and religion was rather practical than speculative. But he did not neglect to build the structure of religious faith upon the firm foundation of an appeal to natural appearances: He taught that the Supreme Being, though invisible, is clearly seen in his works, which at once demonstrate his existence and his wise and benevolent providence. He admitted, besides the one Supreme Deity, the existence of beings who possess a middle station between God and man, to whose immediate agency he ascribed the ordinary phenomena of nature, and whom he supposed to be particularly concerned in the management of human affairs. Hence he declared it to be the duty of every one, in the performance of religious rites, to follow the customs of his country. At the same time, he taught, that the merit of all religious offerings depends upon the character of the worshipper, and that the gods take pleasure in the sacrifices of none but the truly pious.

Concerning the human soul, the opinion of Socrates, according to Xenophon, was, that it is allied to the Divine Being, not by a participation of essence, but by a similarity of nature; that man excels all other animals in the faculty of reason; and that the existence of good men will be continued after death in a state in which they will receive the reward of their virtue. Although it appears that on this latter topic he was not wholly free from uncertainty, the consolation which he professed to derive from this source in the immediate prospect of death, leaves little room to doubt that he entertained a real expectation of immortality: and there is reason to believe that he was the only philosopher of ancient Greece whose principles admitted of such an expectation (see Metaphysics, Part III. Chap. iv.). Of his moral system, which was in a high degree pure, and founded on the surest basis, the reader will find a short view in our article Moral Philosophy, No. 4.

Socrates was also the name of an ecclesiastical historian of the 5th century, born at Constantinople in the beginning of the reign of Theodosius: he professed the law and pleaded at the bar, whence he obtained the name of Scholasticus. He wrote an ecclesiastical history from the year 329, where Eusebius ended, down to 449; and wrote with great exactness and judgment. An edition of Eusebius and Socrates, in Greek and Latin, with notes by Reading, was published at London in 1722.

SODA, the name given by the French chemists to the mineral alkali, which is found native in many parts of the world: it is obtained also from common salt, and from,
The island of Iona was the place where the bishop of the Isles resided, the cathedral church of which, it is said, was dedicated to our Saviour in Greek, hence Sotorenese, which might be corrupted into sodorenese, a name frequently given by Danish writers to the western isles of Scotland. That we may be the more disposed to accede to this Grecian etymology, the advocates for this opinion tell us, that the name Sclamat-kil, which is often applied to this island, is also of Greek extraction, being derived from Columba, “a pigeon;” a meaning that exactly corresponds to the Celtic word Colum and the Hebrew word Iona. We must confess, however, that we have very little faith in the conjectures of etymologists, and think that upon no occasion they alone can establish any fact, though when concurring with facts they certainly tend to confirm and explain them. It is only from historical facts that we can know to what Sodor was applied.

It appears from the history of the Orkneys, compiled by an old Icelandic writer, translated and enlarged by Torfius, that the Æbode or Western Isles of Scotland were divided into two clusters, Nordureys and Sudeeys. The Nordureys, which were separated from the Sudeeys by the point of Ardmurcheon, a promontory in Argylshire, consisted of Muck, Egg, Rom, Canna, Skye, Raasay, Barra, South Uist, North Uist, Benbecula, and Lewis, including Harris, with a great number of small isles. The Sudeeys were, Man, Arran, Bute, Cumbra, Avon, Ida, Colonsay, Jura, Scarba, Mull, Iona, Tiree, Coll, Ulva, and other small islands. All these, when joined together, and subject to the same prince, made up the kingdom of Man and the Isles. In the Norwegian language, Sudder and Norder signify southern and northern, and by or ay an island. When the Æbode were under one monarch, the seat of empire was fixed in the Sudeeys, and the Nordureys were governed by deputies; hence the former are much oftener mentioned in history than the latter; hence, too, the Sudeeys often comprehended the Nordureys, as in our days Scotland is sometimes comprehended under England. Sudeeys, or Soder, when anglicised, became Sodor; and all the Western Isles of Scotland being included in one diocese under the Norwegian princes, the bishop appointed to superintend them was called the bishop of Man and the Isles, or the bishop of Soder and Man. Since Man was conquered by Edward III. it has been separated from the other isles, and its bishops have exercised no jurisdiction over them. Should it now be asked, why then is the bishop of Man still called the bishop of Soder and Man? we reply, that we have been able to discover no reason; but suppose the appellation to be continued in the same way, as the title king of France has been kept up by the kings of Great Britain, for several centuries after the English were entirely expelled from France.

SOFA, in the east, a kind of sloeve raised half a foot above the floor of a chamber or other apartment; and used as the place of state, where visitors of distinction are received. Among the Turks the whole floor of their state-rooms is covered with a kind of tapestry, and on the window-side is raised a sofa or sopha, laid with a kind of mattress, covered with a carpet much richer than the other. On this carpet the Turks are seated, both men and women, like the tailors in England, cross-legged, leaning against the wall, which is bolstered.
bolstered with velvet, satin, or other stuff suitable to the season. Here they eat their meals; only laying a skin over the carpet to serve as a tablecloth, and a round wooden board over all, covered with plates, &c.

SOFALA, or CEFALA, a kingdom of Africa, lying on the coast of Mozambique, near Zanguebar. It is bounded on the north by Monomotapa; on the east by the Mosambique sea; on the south by the kingdom of Sabia; and on the west by that of Manica. It contains mines of gold and iron, and a great number of elephants. It is governed by a king, tributary to the Portuguese, who built a fort at the principal town, which is of the same name, and of great importance for their trade to the East Indies. It is seated in a small island, near the mouth of a river. E. Long. 35° 40'. S. Lat. 20° 20.

SOFFIT, or SOFIT, in Architecture, any timber ceiling formed of cross beams of flying corniches, the square compartments or panels of which are enriched with sculpture, painting, or gilding; such are those in the palaces of Italy, and in the apartments of Luxembourg at Paris.

SOFFIT, or SOFIT, is also used for the underside or face of an architrave; and more particularly for that of the corona or larinier, the ancients called lacunar, the French plaquain, and we usually the drip. It is enriched with compartments of rosettes; and in the Doric order has 18 drops, disposed in three ranks, six in each, placed to the right of the muton, at the bottom of the triglyphs.

SOFT, or SOFTH. See SOFIH.

SOFTENING, in Painting, the mixing and diluting of colours with the brush or pencil.

SOHO, the name of a set of works, or manufactory of a variety of hardwares, belonging to the late Mr Boulton, situated on the borders of Staffordshire, within two miles of Birmingham; now so justly celebrated as to deserve a short historical detail.

About 30 years ago the premises consisted of a small mill and a few obscure dwellings. Mr Boulton, in conjunction with Mr Fothergill, then his partner, at an expense of £200l., erected a handsome and extensive edifice, with a view of manufacturing metallic toys. The first productions consisted of buttons, buckles, watch-chains, trinkets, and other such articles as were peculiar to Birmingham. Novelty, taste, and variety, were however always conspicuous; and plated wares, known by the name of Sheffield plate, comprising a great variety of useful and ornamental articles, became another permanent subject of manufacture.

To open channels for the consumption of these commodities, all the northern part of Europe was explored by the mercantile partner Mr Fothergill. A wide and extensive correspondence was thus established, the undertaking became well known, and the manufacturer, by becoming his own merchant, eventually enjoyed a double profit.

Impelled by an ardent attachment to the arts, and by the patriotic ambition of forming his favourite Soho into a fruitful seminary of artists, the proprietor extended his views; and men of taste and talents were now sought for, and liberally patronised. A successful imitation of the French or marble ornaments, consisting of vases, tripod, candelabra, &c. extended the celebrity of the works. Services of plate and other works in silver, both massive and airy, were added, and an assay office was established in Birmingham.

Mr Watt, the ingenious improver of the steam-engine, was afterwards taken into partnership with Mr Boulton; and they carried on at Soho a manufactory of steam-engines, not less beneficial to the public than lucrative to themselves. This valuable machine, the nature and excellencies of which are described in another place (see Steam-Engine), Mr Boulton proposed to apply to the operation of coining, and suitable apparatus was erected at a great expense, for the purpose of being employed by government to make a new copper-coingage for the kingdom. Artists of merit were engaged, and specimens of exquisite delicacy were exhibited; the works were also employed upon highly finished medals and private coins. To enumerate all the productions of this manufactory would be tedious (A).

In a national view, Mr Boulton's undertakings are highly valuable and important. By collecting around him artists of various descriptions, rival talents have been called forth, and by successive competition have been multiplied to an extent highly beneficial to the public. The manual arts partook of the benefit, and became proportionately improved.

A barren heath has been covered with plenty and population; and Mr Boulton's works, which in their infancy were little known and attended to, now cover several acres, give employment to more than 600 persons, and are said to be the first of their kind in Europe.

SOIL, the mould covering the surface of the earth, in which vegetables grow. It serves as a support for vegetables, and as a reservoir for receiving and communicating nourishment.

Soils are commonly double or triple compounds of the several reputed primitive earths, except the barytic. The magnesian likewise sparingly occurs. The more fertile soils afford also a small proportion of coaly substance arising from putrefaction, and some traces of marine acid and gypsum. The vulgar division into clay, chalk, sand, and gravel, is well understood. Loam denotes any soil moderately adhesive; and, according to the ingredient that predominates, it receives the epithets of clayey, chalky, sandy, or gravelly. The intimate mixture of clay with the oxides of iron is called till, and is of a hard consistence and a dark reddish colour. Soils are found by analysis to contain their earthly ingredients in very different proportions. According to M. Giobert, fertile soil mould in the vicinity of Turin, where the fall of rain amounts yearly to 40 inches, affords for each 100 parts, from 77 to 79 of silex, from 8 to 14 of argill, and from 5 to 12 of lime; besides about one-half of carbonic matter, and nearly an equal weight of gas, partly carbonic and partly hydrocarboxonic. The same experimenter represents the composition of barren soils in similar situations to be from 42 to 88 per cent. of silex,

(A) It was at this place, in the year 1772, that Mr Eginton invented an expeditious method of copying pictures in oil; but we do not know how far this method has succeeded.
SOLANDRA, a genus of plants belonging to the Solanaceae, the class of monogynia, and to the order of polyandria; and in the natural system arranged under the 28th order, Tricocca. See Botany Index.

SOLANUM, a genus of the monogynia order, belonging to the pentandria class of plants; and in the natural method ranked under the 28th order, Luridae. See Botany Index.

SOLAR, something belonging to the Sun. See Solar Index.

SOLAR SPOTS. See Astronomy Index.

SOLDAN. See Sultan.

SOLDANELLA, a genus of plants belonging to the class of pentandria, and order of monogynia; and in the natural system arranged under the 24th order, Precis. See Botany Index.

SOLDER, SODDER, or Soder, a metallic or mineral composition used in soldering or joining together other metals.

Solders are made of gold, silver, copper, tin, bismuth, and lead; usually observing, in the composition, there be some of the metal that is to be soldered mixed with some higher and finer metals. Goldsmiths usually make four kinds of solder, viz., solder of eight, where to seven parts of silver there is one of brass or copper; solder of six, where only a sixth part is copper; solder of four, and solder of three. It is the mixture of copper in the solder that makes raised plate come always cheaper than flat.

As mixtures of gold with a little copper are found to melt with less heat than pure gold itself, these mixtures serve as solders for gold: two pieces of fine gold are soldered by gold that has a small admixture of copper; and gold alloyed with copper is soldered by such as is alloyed with more copper: the workmen add a little silver as well as copper, and vary the proportions of the two to one another, so as to make the colour of the solder correspond as nearly as may be to that of the piece. A mixture of gold and copper is also a solder for fine copper as well as for fine gold. Gold being particularly disposed to unite with iron, proves an excellent solder for the finer kinds of iron and steel instruments.

The solder used by plumbers is made of two pounds of lead to one of block-tin. Its goodness is tried by melting it, and pouring the bigness of a crown-piece on a table; for, if good, there will arise little bright shining stars therein. The solder for copper is made like that of the plumbers; only with copper and tin; and for very nice works, instead of tin, they sometimes use a quantity of silver. Solder for tin is made of two-thirds of tin and one of lead, or of equal parts of each; but where the work is any thing delicate, as in organ-pipes, where the juncture is scarce discernible, it is made of one part of bismuth and three parts of pewter. The pewterers use a kind of solder made with two parts of tin and one of bismuth; this composition melts with the least heat of any of the solders.

Silver solder is that which is made of two parts of silver and one of brass, and used in soldering those metals. Spelter solder is made of one part of brass and two of spelter or zinc, and is used by the Braziers and COPPERSMITHS for soldering brass, copper, and iron. This solder is improved by adding to each ounce of it one pennyweight of silver; but as it does not melt without a considerable degree of heat, it cannot be used when it
it is inconvenient to beat the work red hot; in which case copper and brass are soldered with silver.

Though spelter solder be much cheaper than silver solder, yet workmen in many cases prefer the latter. And Mr Boyle informs us, that he has found it to run with so moderate a heat, as not much to endanger the melting of the delicate parts of the work to be soldered; and if well made, this spelter solder will lie even upon the ordinary kind itself; and so fill up those little cavities that may chance to be left in the first operation, which is not easily done without a solder more easily fusible than the first made use of. As to iron, it is sufficient that it be heated to a white heat, and the two extremities, in this state, be hammered together; by which means they become incorporated with one another.

SOLDERING, the joining and fastening together of two pieces of the same metal, or of two different metals, by the fusion and application of some metallic composition on the extremities of the metals to be joined.

To solder upon silver, brass, or iron: Take silver, five pennyweights; brass, four pennyweights; melt them together for soft solder, which runs soonest. Take silver, five pennyweights; copper, three pennyweights; melt them together for hard solder. Beat the solder thin, and lay it on the place to be soldered, which must be first fitted and bound together with wire as occasion requires; then take borax in powder, and temper it like pap, and lay it upon the solder, letting it dry; then cover it with live coals, and blow, and it will run immediately; take it presently out of the fire, and it is done. It is to be observed, that if any thing is to be soldered in two places, which cannot well be done at one time, you must first solder with the harder solder, and then with the soft; for if it be first done with the soft, it will unsolder again before the other is fastened. Let it be observed, that if you would not have your solder run about the piece that is to be soldered, you must rub such places over with chalk. In the soldering either of gold, silver, copper, or either of the metals above mentioned, there is generally used borax in powder, and sometimes resin. As to iron, it is sufficient that it be heated red hot, and the two extremities thus hammered together, by which means they will become incorporated with each other. For the finer kinds of iron and steel instruments, however, gold proves an excellent solder. This metal will dissolve twice or thrice its weight of iron in a degree of heat very far less than that in which iron itself melts; hence if a small plate of gold is warped round the parts to be joined, and afterwards melted by a blow-pipe, it strongly unites the pieces together without any injury to the instrument, however delicate.

SOLDIER, a military man listed to serve a prince or state in consideration of a certain daily pay. See CANCER, ENTOMOLOGY Index. Fresh-Water SOLDIER. See STRATIOTES, BOTANY Index.

SOLE, in the mange, a sort of horn under a horse's foot, which is much more tender than the other horn that encompasses the foot, and by reason of its hardness is properly called the horn or hoof.

SOLE. See PLEURONECTES, Ichthyology Index.

SOLEA. See SANDAL and SHOE.

SOLECISM, in Grammar, a false manner of speaking, contrary to the rules of grammar, either in respect of declension, conjugation, or syntax. — The word is Vol. XIX. Part II.

Greek, υλοκερασία, derived from the Soli, a people of Soli, and Attica, who being transplanted to Cilicia, lost the purity of their ancient tongue, and became ridiculous to the Athenians for the impurities into which they fell.

SOLEMN, something performed with much pomp, ceremony, and expence. Thus we say, solemn feasts, solemn funerals, solemn games, &c. — In law, solemn signifies something authentic, or what is clothed in all its formalities.

SOLEN, RAZOR-SHEATH, or Knife-handled Shell; a genus belonging to the class of Vermes, and order of testacea. See CONCHOLOGY Index.

SOLEURRE, a canton of Switzerland, the 11th in rank in the Helvetic confederacy, into which it was admitted in the year 1481. It stretches partly through the plain, and partly along the chains of the Jura. It contained in 1815 about 48,600 inhabitants, upon 385 square miles. The soil for the most part is exceedingly fertile in corn; and the districts within the Jura abound in excellent pastures. The trade of the town and canton is of little value, although they are commodiously situated for commerce. It is divided into 11 bailiwicks, the inhabitants of which are all Roman Catholics, except those of the bailiwick of Bueckeburg, who profess the reformed religion. The sovereign power resides in the great council, which, comprising the senate or little council of 36, consists of 102 members, chosen by the senate in equal proportions from the 11 tribes or companies into which the ancientburghers are distributed. A melancholy catastrophe took place in this canton on the 13th July 1813. The river Birs, swelled by the rains, overflowed its banks at Dornach, and undermined a house, which was thrown down and buried a number of persons in its ruins. An ancient tower, which was occupied as the prison, experienced a similar fate, fell on the bridge, broke it in the centre, and precipitated a great crowd of persons collected upon it into the torrent. By this accident 150 of the inhabitants lost their lives.

SOLEURE, an ancient and extremely neat town of Switzerland, capital of the canton of the same name. It contains about 4000 inhabitants, and is pleasantly seated on the Aar, which here expands into a noble river. Among the most remarkable objects of curiosity in this town is the new church of St Urs, which was begun in 1762 and finished in 1772; a noble edifice of a whitish grey stone or coarse marble, which admits a polish. This building cost at least 80,000. a considerable sum for such a small republic, whose revenue scarcely exceeds 12,000. a-year. Soleure is surrounded by regular stone fortifications, and is 20 miles north-north-east of Bern, 27 south-south-west of Basle, and 45 west of Zurich. E. Long. 7. 10. N. Lat. 47. 15.

SOLFAINING, in Music, the naming or pronouncing the several notes of a song by the syllables ut, re, mi, fa, sol, &c. in learning to sing it.

Of the seven notes in the French scale ut, re, mi, fa, sol, la, si, only four are used among us in singing, as mi, fa, sol, la: their office is principally, in singing, that by applying them to every note of the scale, it may not only be pronounced with more ease, but chiefly that by them the tones and semitones of the natural scale may be better marked out and distinguished. This design is obtained by the four syllables fa, sol, la, mi.

Thus
Thus from fa to sol is a tone, also from sol to la, and from la to mi, without distinguishing the greater or less tone; but from la to fa, also from mi to fa, is only a semitone. If then these be applied in this order, fa, sol, la, fa, sol, la, mi, fa, &c. they express the natural series from C; and if that be repeated to a second or third octave, we see by them how to express all the different orders of tones and semitones in the diatonic scale; and still above mi will stand fa, sol, la, and below it the same inverted la, sol, fa, and one mi is always distant from another an octave; which cannot be said of any of the rest, because after mi ascending come always fa, sol, la, which are repeated invertedly descending.

To conceive the use of this, it is to be remembered, that the first thing in learning to sing, is to make one raise a scale of notes by tones and semitones to an octave, and descend again by the same; and then to rise and fall by greater intervals at a leap, as thirds and fourths, &c. and to do all this by beginning at notes of different pitch. Then those notes are represented by lines and spaces, to which these syllables are applied, and the learners taught to name each line and space thereby, which makes what we call softening; the use whereof is, that while they are learning to tune the degrees and intervals of sound expressed by notes on a line or space, or learning a song to which no words are applied, they may not only do it the better by means of articulate sounds, but chiefly that by knowing the degrees and intervals expressed by those syllables, they may more readily know the places of the semitones, and the true distance of the notes. See the article Singing.

Solfaterra, a mountain of Italy in the kingdom of Naples, and Terra di Lavoro. This mountain appears evidently to have been a volcano in ancient times; and the soil is yet so hot, that the workmen employed there in making alum need nothing else besides the heat of the ground for evaporating their liquids. Of this mountain we have the following account by Sir William Hamilton. "Near Astroni (another mountain, formerly a volcano likewise) rises the Solfaterra, which not only retains its cone and crater, but much of its former heat. In the plain within the crater, smoke issues from many parts, as also from its sides; here, by means of stones and tiles heaped over the crevices, through which the smoke passes, they collect in an awkward manner what they call sale armoniant; and from the sand of the plain they extract sulphur and alum. This spot, well attended to, might certainly produce a good revenue, whereas I doubt if they have hitherto ever cleared 200l. a-year by it. The hollow sound produced by throwing a heavy stone on the plain of the crater of the Solfaterra, seems to indicate that it is supported by a sort of arched natura vault; and one is induced to think that there is a pool of water beneath this vault (which boils by the heat of a subterraneous fire still deeper), by the very moist steam that issues from the cracks in the plain of the Solfaterra, which, like that of boiling water, runs off a sword or knife, presented to it, in great drops. On the outside and at the foot of the cone of the Solfaterra, towards the lake of Agnano, water rushes out of the rocks so hot as to raise the quicksilver in Fahrenheit's thermometer to the degree of boiling water (A); a fact of which I was myself an eye-witness. This place, well worthy the observation of the curious, has been taken little notice of; it is called the Pisciarelli. The common people of Naples have great faith in the efficacy of this water; and make much use of it in all cutaneous disorders, as well as for another disorder that prevails here. It seems to be impregnated chiefly with sulphur and alum. When you approach your car to the rocks of the Pisciarelli, from whence this water oozes, you hear a horrid boiling noise, which seems to proceed from the huge cauldron that may be supposed to be under the plain of the Solfaterra. On the other side of the Solfaterra, next the sea, there is a rock which has communicated with the sea, till part of it was cut away to make the road to Pozzole; this is undoubtedly a considerable lava, that ran from the Solfaterra when it was an active volcano. Under this rock of lava, which is more than 75 feet high, there is a stratum of pumice and ashes. This ancient lava is about a quarter of a mile broad; you meet with it abruptly before you come in sight of Pozzole, and it finishes as abruptly within about 100 paces of the town. The ancient name of the Solfaterra was Eorum Volcanus; a strong proof of its origin from subterraneous fire. The degree of heat that the Solfaterra has preserved for so many ages, seems to have calcined the stones upon its cone and in its crater, as they are very white and crumble easily in the hottest parts.

Solicitor, a person employed to take care of and manage suits depending in the courts of law or equity. Solicitors are within the statute to be sworn, and admitted by the judges, before they are allowed to practise in our courts, in like manner as attorneys.

There is also a great officer of the law, next to the attorney-general, who is styled the king's solicitor-general; who holds his office by patent during the king's pleasure, has the care and concern of managing the king's affairs, and has fees for pleading, besides other fees arising by patents, &c. He attends on the privy council; and the attorney-general and he were anciently reckoned among the officers of the exchequer; they have their audience, and come within the bar in all other courts.

Solid, in Philosophy, a body whose parts are so firmly connected together, as not easily to give way or slip from each other; in which sense solid stands opposed to fluid.

Geometricians define a solid to be the third species of magnitude, or that which has three dimensions, viz. length, breadth, and thickness or depth.

Solids are commonly divided into regular and irregular. The regular solids are those terminated by regular and

(A) "I have remarked, that after a great fall of rain, the degree of heat in this water is much less; which will account for what Padre Torre says (in his book, intitled Histoire et Phenomenes du Vauve), that when he tried it in company with Monsieur de la Condamine, the degree of heat, upon Reaumur's thermometer, was 68°."
and equal planes, and are only five in number, viz. the tetrahedron, which consists of four equal triangles; the cube or hexahedron, of six equal squares; the octahedron, of eight equal triangles; the dodecahedron, of twelve; and the icosahedron, of twenty equal triangles.

The irregular solids are almost infinite, comprehending all such as do not come under the definition of regular solids; as the sphere, cylinder, cone, parallelogram, prism, parallelopiped, &c.

SOLIDS, in Anatomy, are the bones, ligaments, membranes, muscles, nerves and vessels, &c.

The solid parts of the body, though equally composed of vessels, are different with regard to their consistence; some being hard and others soft. The hard, as the bones and cartilages, give firmness and attitude to the body, and sustain the other parts: the soft parts, either alone or together with the hard, serve to execute the animal functions. See Anatomy.

SOLIDAGO, a genus of plants belonging to the class of angiospermia, and to the order of Polygonum superflua; in the natural system ranking under the 49th order, Composite. See Botany Index.

SOLIDITY, that property of matter, or body, by which it excludes all other bodies from the place which it possesses; and as it is absurd to suppose that two bodies could possess one and the same place at the same time, it follows, that the softest bodies are equally solid with the hardest. See Metaphysics, No. 44, 173, &c.

Among geometricians, the solidity of a body denotes the quantity or space contained in it, and is called also its solid content.

The solidity of a cube, prism, cylinder, or parallelopiped is had by multiplying its basis into its height. The solidity of a pyramid or cone is had by multiplying either the whole base into a third part of the height, or the whole height into a third part of the base.

SOLILOQUY, a reasoning or discourse which a man holds with himself; or, more properly, according to Papas, it is a discourse by way of answer to a question that a man proposes to himself.

Soliolques are become very common on the modern stage; yet nothing can be more inartificial, or more unnatural, than an actor’s making long speeches to himself, to convey his intentions to the audience. Where such discoveries are necessary to be made, the poet should rather take care to give the dramatic personages such confidences as may necessarily share their innermost thoughts; by which means they will be more naturally conveyed to the audience; yet even this is a shift which an accurate poet would not have occasion for. The following lines of the duke of Buckingham concerning the use and abuse of soliloquies deserve attention:

Soliloquies had need be very few,
Extremely short, and so brief in passion too.
Our lovers talking to themselves, for want
Of others, make the pit their confidant:
Nor is the matter mended yet, if thus
They trust a friend, only to tell it us.

SOLIMAN II. emperor of the Turks, surnamed the Magnificent, was the only son of Selim I. whom he succeeded in 1520. He was educated in a manner very different from the Ottoman princes in general; for he was instructed in the maxims of politics and the secrets of government. He began his reign by restoring those persons their possessions whom his father had unjustly plundered. He re-established the authority of the tribunals, which was almost annihilated, and bestowed the government of provinces upon none but persons of wealth and probity: “I would have my viceroy (as he used to say) resemble those rivers that fertilize the fields through which they pass, but not those torrents which sweep everything before them.”

After concluding a truce with Ismaili Sophy of Persia, and subduing Gozeli Bey, who had raised a rebellion in Syria, he turned his arms against Europe. Belgrade was taken in 1522, and Rhodes fell into his hands the year following, after an obstinate and enthusiastic defence. In 1526 he defeated and slew the king of Hungary in the famous battle of Mohatz. Three years after he conquered Buda, and immediately laid siege to Vienna itself. But after continuing 20 days before that city, and assaulting it 20 times, he was obliged to retreat with the loss of 80,000 men. Some time after he was defeated by the Persians, and disappointed in his hopes of taking Malta. He succeeded, however, in dispossessing the Genoese of Chio, an island which had belonged to that republic for more than 200 years.

He died at the age of 76, while he was besieging Sisgeth, a town in Hungary, on the 30th August 1566.

He was a prince of the strictest probity, a lover of justice, and vigorous in the execution of it; but he tarnished all his glory by the cruelty of his disposition. After the battle of Mohatz he ordered 1500 prisoners, most of them gentlemen, to be ranged in a circle, and beheaded in presence of his whole army.

Soliman thought nothing impossible which he commanded: A general having received orders to throw a bridge over the Drave, wrote him, that it was impossible. The sultan sent him a long band of linen with these words written on it: “The emperor Soliman, thy master, orders thee to build a bridge over the Drave in spite of the difficulties thou mayest meet with. He instructs thee at the same time, that if the bridge be not finished upon his arrival, he will hang thee with the very linen which informs thee of his will.”

SOLIPUGA, or SOLIFUGA, in Natural History, the name given by the Romans to a small venomous insect of the spider-kind, called by the Greeks heliocentros; both words signifying an animal which stings most in the country and seasons where the sun is most hot. Solinus makes this creature peculiar to Sardinia; but this is contrary to all the accounts given us by the ancients. It is common in Africa and some parts of Europe. Almost all the hot countries produce this venomous little creature. It lies under the sand to seize other insects as they go by; and if it meet with any uncovered part of a man, produces a wound which proves very painful; it is said that the bite is absolutely mortal, but probably this is not true. Solinus writes the word solifuga, and so do many others, erroneously deriving the name from the notion that this animal flies from the sun’s rays, and buries itself in the sand.

SOLIS, ANTONIO DE, an ingenious Spanish writer, of an ancient and illustrious family, born at Placentia in Old Castile, in 1610. He was intended for the law; but his inclination toward poetry prevailed, and he cultivated it with great success. Philip IV. of Spain made-
made him one of his secretaries; and after his death the
queen-appointed him historiographer of the
Indies, a place of great profit and honour: his History
of the Conquest of Mexico shows that she could not
have named a fitter person. He is better known by this
history at least abroad, than by his poetry and dramatic
writings, though in these he was also distinguished. He
turned priest at 57 years of age, and died in 1686.

SOLITARY, that which is remote from the com-
pany or commerce of others of the same species.

SOLITARIES, a denomination of nuns of St Peter
of Alcantara, instituted in 1676, the design of which
was to imitate the severe pious life of that saint.
Thus they are to keep a continual silence, never to
open their mouths to a stranger; to employ their time
wholly in spiritual exercises, and leave their temporal
concerns to a number of maids, who have a particular
superior in a separate part of the monastery: they al-
ways go bare-footed, without sandals; gird themselves
with a thick cord, and wear no linen.

SOLO, in the Italian music, is frequently used
in pieces consisting of several parts, to mark those that are
to perform alone; as "fisso solo," "clemente solo." It is also
used for sonatas composed for one violin, one German
flute, or other instrument, and a bass; thus we say,
"Cecile's solos," "Sembonia's solos," &c. When two or
three parts play or sing separately from the grand chorus,
they are called a "duo soli," a "tre soli," &c. Solo is some-
times denoted by S.

SOLOMON, the son of David king of Israel, re-
nowned in Scripture for his wisdom, riches, and magni-
ficent temple and other buildings. Towards the end
of his life he humbled all his former glory by his apostasy
from God; from which cause vengeance was denounced
against his house and nation. He died about 975
B. C.

SOLOMOn's Seal, a species of Convallaria, which
see, Botany Index.

SOLON, one of the seven wise men of Greece, was
born at Salamis, of Athenian parents, who were de-
scended from Codrus. His father leaving little patri-
mony, he had recourse to merchandizing for his subsis-
tence. He had, however, a greater thirst after knowl-
dge and fame than after riches, and made his mercan-
tile voyages subservient to the increase of his intellectu-
mal treasures. He very early cultivated the art of poe-
try, and applied himself to the study of moral and civil
wisdom. When the Athenians, tired out with a long
and troublesome war with the Megarians, for the re-
covery of the isle of Salamis, prohibited any one, under
pain of death, to propose the renewal of their claim to
that island, Solon thinking the prohibition dishonourable
to the state, and finding many of the younger citizens de-
sirous to revive the war, feigned himself mad, and took
care to have the report of his insanity spread through the
city. In the mean time he composed an elegy adapted
to the state of public affairs, which he committed to
memory. Every thing being thus prepared, he sailled
forth into the market place with the kind of cap on his
head which was commonly worn by sick persons, and,
ascending the herald's stand, he delivered, to a nume-
rous crowd, his lamentation for the desertion of Salamis.
The verses were heard with general applause; and Pi-
istratus seconded his advice, and urged the people to
renew the war. The decree was immediately repealed;
the claim to Salamis was resumed; and the conduct of
the war was committed to Solon and Pisistratus, who
by means of a stratagem, defeated the Megarians,
and recovered Salamis.

His popularity was extended through Greece, in con-
sequence of a successful alliance which he formed among
the states in defence of the temple at Delphi against the
Cyrreans. When dissensions had arisen at Athens be-
tween the rich creditors and their poor debtors, Solon
was created archon, with the united powers of supreme
legislator and magistrate. He was restored harmony
between the rich and poor: He cancelled the debts
which had proved the occasion of so much oppression;
and ordained that in future no creditor should be allow-
ed to seize the body of the debtor for his security: He
made a new distribution of the people, instituted new
courts of judicature, and framed a judicious code of
laws, which afterwards became the basis of the laws of
the twelve tables in Rome. Among his criminal laws
are many wise and excellent regulations; but the code
is necessarily defective with respect to those principles
which must be derived from the knowledge of the true
God, and of pure morality, as the certain foundations
of national happiness. Two of them in particular were
very exceptionable; the permission of a voluntary exile
to persons that had been guilty of premeditated mur-
der, and the appointment of a less severe punishment
for a rape than for seduction. Those who wish to see
accurately stated the comparative excellence of the laws
of Moses, of Lycurgus, and Solon, may consult Prize
Dissertations relative to Natural and Revealed Religion
by Teyler's Theological Society, vol. ix.

The interview which Solon is said to have had with
Crasus king of Lydia; the solid remarks of the sage
after surveying the monarch's wealth; the recollection
of those remarks by Crassus when doomed to die, and the
noble conduct of Cyrus on that occasion, are known to
every schoolboy. Solon died in the island of Cyprus
about the 8th year of his age. Statues were erected
to his memory both at Athens and Salamis. His thirst
after knowledge continued to the last: "I grow old
(said he) learning many things." Among the apoph-
thesms and precepts which have been ascribed to Solon,
are the following: Laws are like cobwebs, that en-
tangle the weak, but are broken through by the strong.
He who has learned to obey, will know how to com-
mand. In all things let reason be your guide. Dili-
gently contemplate excellent things. In every thing
that you do, consider the end.

SOLSTICE, in Astronomy, that time when the sun
is in one of the solstitial points; that is, when he is at
his greatest distance from the equator; thus called be-
cause he then appears to stand still, and not to change
his distance from the equator for some time; an appear-
ance owing to the obliquity of our sphere, and which
those living under the equator are strangers to.

The solstices are two in each year; the aestival or
summer solstice, and the byemal or winter solstice. The
summer solstice is when the sun seems to describe the
tropic of cancer, which is on June 22, when he makes
the longest day: the winter solstice is when the sun en-
ters the first degree, or seems to describe the tropic of
capricorn, which is on December 22, when he makes
the shortest day. This is to be understood as in our
northern hemisphere; for in the southern, the sun's en-
trance into capricorn makes the summer solstice, and that into cancer the winter solstice. The two points of the ecliptic, wherein the sun's greatest ascent above the equator, and his descent below it, are terminated, are called the solstitial points; and a circle, supposed to pass through the poles of the world and these points, is called the solstitial circle. The summer solstitial point is in the beginning of the first degree of cancer; and is called the axial or summer point; and the winter solstitial point is in the beginning of the first degree of capricorn, and is called the winter point. These two points are diametrically opposite to each other.

SOLUTION, in Chemistry, denotes an intimate union of solid with fluid bodies, so as to form a transparent liquor. See CHIMISTRY passim.

SOLVENT, that which dissolves a solid body into a transparent fluid.

SOLWAY MOSS. See MOVING MOSS.

SOMBRENO, the name of an uninhabited island in the West Indies in the form of a hat, whence the name is derived. It is also the name of one of the Nicobar islands in the East Indies.

Wonderful Plant of SOMBRENO, is a strange kind of sensitive plant growing in the East Indies, in sandy banks and in shallow water. It appears like a slender straight stick; but when you attempt to touch it, immediately withdraws itself into the sand. Mr Miller gives an account of it in his description of Sumatra.

He says, the Malays call it holon host, that is, sea grass. He never could observe any tentacles; but, after many unsuccessful attempts, drew out a broken piece about a foot long. It was perfectly straight and uniform, and resembled a worm drawn over a knitting needle. When dry it appears like a coral.

SOMERS, JOHN, lord high chancellor of England, was born at Worcester in 1632. He was educated at Oxford, and afterwards entered himself at the Middle Temple, where he studied the law with great vigour. In 1663 he was one of the counsel for the seven bishops at their trial, and argued with great learning and eloquence against the dispensing power. In the convention which met by the prince of Orange's summons, January 22, 1689, he represented Worcester; and was one of the managers for the House of Commons, at a conference with the House of Lords upon the word abdicated. Soon after the accession of King William and Queen Mary to the throne, he was appointed Solicitor-General, and received the honour of knighthood. In 1692 he was made Attorney-General, and in 1693 advanced to the post of Lord Keeper of the great seal of England. In 1695 he proposed an expedition to prevent the practice of clipping the coin. In 1697 he was created Lord Somers, baron of Evesham, and made lord high chancellor of England. In the beginning of 1700 he was removed from his post of lord chancellor, and the year after was impeached of high crimes and misdemeanors by the House of Commons, of which he was acquitted upon trial by the House of Lords. He then retired to a studious course of life, and was chosen president of the Royal Society. In 1706 he proposed a bill for the regulation of the law; and the same year was one of the principal managers for the union between England and Scotland. In 1708 he was made lord president of the council; from which post he was removed in 1710, upon the change of the ministry. In the latter end of

Queen Anne's reign his lordship grew very infirm in his health; which is supposed to be the reason that he held no other post than a seat at the council-table, after the accession of King George I. He died of an apoplectic fit in 1716. Mr Addison has drawn his character very beautifully in the Freeholder.

SOMERSETSHIRE, a county of England, taking its name from Somerton, once the capital, between 53° and 51° 27' north latitude, and between 1° 25' and 2° 59' west longitude. It is bounded on the west by Devonshire, on the south by Dorsetshire, on the north by Bristol Channel or the Severn sea, on the north-east by a small part of Gloucestershire, and on the east by Wiltshire. It is one of the largest counties in England, extending in length from east to west about 68 miles; in breadth, from south to north, about 47; and 240 in circumference. It is divided into 42 hundreds, in which are 3 cities, 32 market-towns, 1700 villages, 385 parishes, of which 132 are vicarages, containing more than 1,000,000 of acres, and in 1811 there were 303,880 souls. It sends 18 members to parliament, viz. two for the county, two for Bristol, two for Bath, two for Wells, two for Taunton, two for Bridgewater, two for Ilchester, two for Milborne-port, and two for Minehead.

The air of this county is very mild and wholesome, especially that of the hilly part. The soil in general is exceedingly rich, so that single acres very commonly produce forty or fifty bushels of wheat, and there have been instances of some producing sixty of barley. As there is very fine pasture both for sheep and black cattle, it abounds in both, which are as large as those of Lincolnshire, and their flesh of a finer grain. In consequence of this abundance of black cattle, great quantities of cheese are made in it, of which that of Cheddar is thought equal to Parmesan. In the hilly parts are found coal, lead, copper, and lapis calaminaris. Wood thrives in it as well as in any county of the kingdom. It abounds also in pease, beans, beer, cyder, fruit, wildfowl, and salmon; and its mineral waters are celebrated all over the world.

The riches of this county, both natural and acquired, exceed those of any other in the kingdom, Middlesex and Yorkshire excepted. The woollen manufacture in all its branches is carried on to a very great extent; and in some parts of the county great quantities of linen are made. If to these the produce of various other commodities in which it abounds is added, the amount of the whole must undoubtedly be very great. Its foreign trade must also be very extensive; it has a large trade for sea-coal, and possesses besides other ports, that of Bristol, a town of the greatest trade in England, next to London and Liverpool.

Besides small streams, it is well watered and supplied with fish by the rivers Severn, Avon, Parrel, Frome, Axe, Torre, and Tone. Its greatest hills are Mendip, Poulton, and Quantock, of which the first abounds in coal, lead, &c. The rivers Severn and Parrel breed very fine salmon. The chief town is Bristol. See SOMERSETSHIRE SUPPLEMENT.

SOMERTON, an ancient town in Somersetshire, from whence the county derives its name. It is 63 miles from London; it has five streets, containing 357 houses, which are mostly built of the blue stone from the quarries in the neighbourhood. It is governed by constables, and has a hall for petty sessions. The mar-
SON [ 470 ]

SON

Sentfor corn is considerable, and it has several fairs for cattle. The church has, what is not very frequent, an octagonal tower with six bells. It contained 1478 inhabitants in 1811. N. Lat. 51° 4'. W. Long. 1° 53'.

Somme, a department in the north-west of France, comprising the greater part of the ancient Picardy. The soil yields corn, flax, hemp, legumes, and excellent pasture, but no vines or vineyards. Sheep are pretty numerous. The manufactures are, especially those of woollens, among the most extensive in France. The territorial extent is 604,456 hectares, and the population in 1817 was 495,058. Amiens is the chief town.

Somnambuli, persons who walk in their sleep. See Sleepwalkers.

Somner, William, an eminent English antiquary, was born at Canterbury in 1606. His first treatise was The Antiquities of Canterbury, which he dedicated to Archbishop Laud. He then applied himself to the study of the Saxon language; and having made himself master of it, he perceived that the old glossary prefixed to Sir Roger Twisden's edition of the laws of King Henry I. printed in 1644, was faulty in many places; he therefore added to that edition notes and observations valuable for their learning, with a very useful glossary. His Treatise of Gavelkind was finished about 1648, though not published till 1660. Our author zealously attached to King Charles I.; and in 1648 he published a poem on his sufferings and death. His skill in the Saxon tongue led him to inquire into most of the European languages ancient and modern. He assisted Dugdale and Dodsworth in compiling the Monasticon Anglicanum. His Saxon Dictionary was printed at Oxford in 1659. He died in 1669.

Son, an appellation given to a male child considered in the relation he bears to his parents. See Parent and Filial Piety.

Sonata, in Music, a piece or composition, intended to be performed by instruments only; in which sense it stands opposed to cantata, or a piece designed for the voice. See Cantata.

The sonata then, is properly a grand, free, humorous composition, diversified with a great variety of motions and expressions, extraordinary and bold strokes, figures, &c. And all this purely according to the fancy of the composer; who, without confining himself to any general rules of counterpoint, or to any fixed number or measure, gives a loose to his genius, and runs from one mode, measure, &c. to another, as he thinks fit. This species of composition had its rise about the middle of the 17th century; those who have most excelled in it were Bassani and Corelli. We have sonatas of 1, 2, 3, 4, 5, 6, 7, and even 8 parts, but usually they are performed by a single violin, or with two violins, and a thorough bass for the harpsichord; and frequently a more figured bass for the bass viol, &c.

There are a thousand different species of sonatas; but the Italians usually reduce them to two kinds. Sonate de chiesa, that is, sonatas proper for church music, which usually begin with a grave solemn motion, suitable to the dignity and sanctity of the place and the service, after which they strike into a brisker, gayer, and richer manner. These are what they more peculiarly call sonatas. Sonate de camera, or sonatas for the chamber, are properly serious of several little pieces, for dancing, only composed to the same tune.

They usually begin with a prelude or little sonata, serving as an introduction to all the rest: afterwards come the allemand, pavane, courant, and other serious dances; then gyps, gavotes, minuets, chaconas, passacailles, and other gayer airs: the whole composed in the same tune or mode.

Sonchus, Sow-thistle, in Botany, a genus of plants belonging to the class of syngenesia, and to the order of Polygonum aquatilis. There are 13 species; four of these are natives of Britain.—1. Palustris, marsh sow-thistle. The stem is erect, from six to ten feet high, branched and hairy towards the top; the leaves are firm, broad, half pinnated, serrated, and sharp-pointed; the lower ones sagittate at the base: the flowers are of a deep yellow, large, and dispersed on the tops of the branches: the calyx is rough. It is frequent in marshes, and flowers in July or August.—2. Arvensis, corn sow-thistle. The leaves are alternate, runcinate, and heart-shaped at the base; the root creeps under ground; the stem is three or four feet high, and branched at the top. It grows in corn-fields, and flowers in August.—3. Oleraceus, common sow-thistle. The stalk is succulent, pustular, and a cubit high or more; the leaves are broad, embracing the stem, generally deeply sinuated, smooth, or prickly at the edges; the flowers are of a pale yellow, numerous, in a kind of umbel, and terminal; the calyx is smooth. It is frequent in waste places and cultivated grounds.—4. Pulcherrima, blue-flowered sow-thistle. The stem is erect, purplish, branched, or simple, from three to six feet high: the leaves are large, smooth, and sinuated; the extreme segment large and triangular: the flowers are blue, and grow on hairy viscid pedicles, in long spikes: the calyx is brown. This species is found in Northumberland.

Son, in Poetry, a little composition, consisting of easy and natural verses, set to a tune in order to be sung. See Poetry, No 120.

Song, in Music, is applied in general to a single piece of music, whether contrived for the voice or an instrument. See Air.

Song of Birds, is defined by the honourable Daines Barrington to be a succession of three or more different notes, which are continued without interruption, during the same interval, with a musical bar of four crotchets in an adagio movement, or whilst a pendulum swings four seconds.

It is affirmed, that the notes of birds are no more innate than language in man, and that they depend upon imitation, as far as their organs will enable them to imitate the sounds which they have frequent opportunities of hearing: and their adhering so stratified, even in a wild state, to the same song, is owing to the nestlings attending only to the instruction of the parent bird, whilst they disregard the notes of all others that may perhaps be singing round them.

Birds in a wild state do not commonly sing above 10 weeks in the year, whereas birds that have plenty of food in a cage sing the greatest part of the year; and we may add, that the female of no species of birds ever sings. This is a wise provision of nature, because her song would discover her nest. In the same manner, we may rationally account for her inferiority in plumage. The faculty of singing is confined to the cock birds; and accordingly Mr Hunter, in dissecting birds of several species, found the muscles of the larynx to be stronger.
SONN [ 471 ]

SONN, stronger in the nightingale than in any other bird of the same size; and in all those instances where he dissected both cock and hen, the same muscles were stronger in the cock. To the same purpose, it is an observation as ancient as the time of Pliny, that a capon does not crow.

Some have ascribed the singing of the cock-bird in the spring solely to the motive of pleasing his mate during incubation; others, who allow that it is partly for this end, believe it is partly owing also to another cause, viz. the great abundance of plants and insects in the spring, which as well as seeds, are the proper food of singing birds at that time of the year.

Mr Barrington remarks, that there is no instance of any singing bird which exceeds our blackbird in size; and this, he supposes, may arise from the difficulty of its concealing itself, if it called the attention of its enemies, not only by its bulk, but by the proportionable loudness of its notes. This writer farther observes, that some passages of the song in a few kinds of birds correspond with the intervals of our musical scale, of which the cuckoo is a striking and known instance; but the greater part of their song cannot be reduced to a musical scale; partly, because the rapidity is often so great, and it is also so uncertain when they may stop, that we cannot reduce the passages to form a musical bar in any time whatsoever; partly also, because the pitch of most birds is considerably higher than the most shrill notes of those instruments which have the greatest compass; and principally, because the intervals used by birds are commonly so minute, that we cannot judge of them from the more gross intervals into which we divide our musical octave. This writer apprehends, that all birds sing in the same key; and in order to discover this key, he informs us, that the following notes have been observed in different birds, A, B flat, C, D, F, and G; and therefore E only is wanting to complete the scale: now these intervals, he says, can only be found in the key of F with a sharp third, or that of G with a flat third; and he supposes it to be the latter, because admitting that the first musical notes were learned from birds, those of the cuckoo, which have been most attended to, form a flat third, and most of our compositions are in a flat third, where music is simple, and consists merely of melody. As a farther evidence that birds sing always in the same key, it has been found by attending to a nightingale, as well as a robin which was educated under him, that the notes reducible to our intervals of the octave were always precisely the same.

Most people, who have not attended to the notes of birds, suppose, that every species sing exactly the same notes and passages, but this is by no means true; though it is admitted that there is a general resemblance. Thus the London bird-catchers prefer the song of the Kentish goldfinches, and Essex chaffinches; and some of the nightingale fanciers prefer a Surrey bird to those of Middlesex.

Of all singing birds, the song of the nightingale has been most universally admired: and its superiority (deduced from a cage-bird) consists in the following particulars; its tone is much more mellow than that of any other bird, though at the same time, by a proper exertion of its musical powers, it can be very brilliant. Another point of superiority is its continuance of song without a pause, which is sometimes no less than 22 seconds; and when inspiration becomes necessary, it takes it with as much judgment as an opera singer. The sky-lark in this particular, as well as in compass and variety, is only second to the nightingale. The nightingale also sings (if the expression may be allowed) with superior judgment and taste. Mr Barrington has observed, that his nightingale, which was a very capital bird, began softly like the ancient authors, reserving its breath to swell certain notes, which by these means had a most astonishing effect. This writer adds, that the notes of birds, which are annually imported from Asia, Africa, and America, both singly and in concert, are not to be compared to those of European birds.

The following table, formed by Mr Barrington, agreeably to the idea of M. de Piles in estimating the merits of painters, is designed to exhibit the comparative merit of the British singing birds; in which 20 is supposed to be the point of absolute perfection.

SONNA, a book of Mahometan traditions, which the orthodox musulmans are required to believe.

SONNERATIA, a genus of plants belonging to the class of icosandraea, and to the order of monogynia. See BOTANIC INDEX.

SONNET, in Poetry, a composition contained in 14 verses, viz. two stanzas or measures of four verses each, and two of three, the first eight verses being all in three rhymes.

SONNITES, among the Mahometans, an appellation given to the orthodox musulmans or true believers; in opposition to the several heretical sects, particularly the Shiites, or followers of Ali.

SOOJU, or SOY. See DOLICHOS.

SOONTABURDAR, in the East Indies, an attendant, who carries a silver bludgeon in his hand about two or three feet long, and runs before the palanquin. He is inferior to the chubdar; the propriety of an Indian newary requiring two soontaburdares for every chubdar in the train. The chubdar proclaims the approach of visitors, &c. He generally carries a large silver
SOF, or SOFI, a title given to the emperor of Persia, importing as much as wise, sage, or philosopher.

The title is by some said to have taken its rise from a young shepherd named Sofi, who attained to the crown of Persia in 1370; others derive it from the sopko or sages, anciently called magi. Vossius gives a different account of the word: sophi in Arabic, he observes, signifies wool; and he adds, that it was applied by the Turks out of derision to the kings of Persia ever since Ishmael's time; because, according to their scheme of religion, he is to wear no other covering on his head but an ordinary red woollen stuff; whence the Persians are also called hekelbaschi, q. d. red-heads. But Bochart assures us, that sophi in the original Persian language, signifies one that is pure in his religion, and who prefers the service of God in all things: and derives it from an order of religious called by the same name. The sophi value themselves on their illustrous extraction. They are descended in a right line from Houssein, second son of Ali, Mahomet's cousin, and Faïra, Mahomet's daughter.

SOPHIS, or SOFEES, a kind of order of religious among the Mahometans in Persia, answering to what are otherwise called derivins, and among the Arabs and Indians faquire. Some will have them called sophis from a kind of coarse camelot which they wear, called sof, from the city Suf in Syria, where it is principally manufactured. The more eminent of these sophis are complimented with the title schiek, that is, reverend, much as in Roman countries the religious are called reverend fathers. Schiek Sophi, who laid the foundation of the grandeur of the royal house of Persia, was the founder, or rather the restorer of this order: Ishmael, who conquered Persia, was himself a sophi, and greatly valued himself on his being so. He chose all the guards of his person from among the religious of this order; and would have all the great lords of his court sophis. The king of Persia is still grandmaster of the order; and the lords continue to enter into it, though it be now fallen under some contempt.

SOPHISM, in Logic, a specious argument having the appearance of truth, but leading to falsehood. Sophisms are reduced by Aristotle into eight classes, an arrangement so just and comprehensive, that it is equally proper in present as in former times. 1. Ignoratio elenchii, in which the sophist seems to determine the question, while he does it only in appearance. Thus the question, "Whether the excess of wine be hurtful?" seems to be determined by proving, that wine revives the spirits and gives a man courage: but the principal point is here kept out of sight; for still it may be hurtful to health, to fortune, and reputation. 2. Petio principii, a begging of the question, or taking for granted that which remains to be proved, as if any one should undertake to prove that the soul is extended through all the parts of the body, because it resides in every member. This is affirmed, the same thing in different words. 3. Reasoning in a circle; as when the Roman Catholics prove the Scriptures to be the word of God by the authority of the church, and the authority of the church from the Scriptures. 4. Non causa pro causa, or the assigning of a false cause to any effect. Thus the supposed principle, that nature abhors a vacuum, was applied to explain the rising of water in a pump before Galileo discovered that it was owing to the pressure of the atmosphere. In this way the vulgar ascribe accidents to divine vengeance, and the heresies and infidelity of modern times are said to be owing to learning. 5. Fallacia accidentis, in which the sophist represents what is merely accidental as essential to the nature of the subject. This is nearly allied to the former, and is committed by the Mahometans and Roman Catholics. The Mahometans forbid wine, because it is sometimes the occasion of drunkenness and quarrels; and the Roman Catholics prohibit the reading of the Bible, because it has sometimes promoted heresies. 6. By deducing an universal assertion from what is true only in particular circumstances, and the reverse: thus some men argue, "transcribers have committed many errors in copying the Scriptures, therefore they are not to be depended on." 7. By asserting any thing in a compounded sense which is only true in a divided sense; so when the Scriptures assure us, that the worst of sinners may be saved, it does not mean that they shall be saved while they remain sinners, but that if they repent they may be saved. 8. By an abuse of the ambiguity of words. Thus Mr. Hume reasons in his Essay on Miracles: "Experience is our only guide in reasoning concerning matters of fact; now we know from experience, that the laws of nature are fixed and invariable. On the other hand, testimony is variable and often false; therefore since our evidence for the reality of miracles rests solely on testimony which is variable, and our evidence for the uniformity of the laws of nature is invariable, miracles are not to be believed." The sophistry of this reasoning depends on the ambiguity of the word experience, which in the first proposition signifies the maxims which we form from our own observation and reflection; in the second it is confounded with testimony; for it is by the testimony of others, as well as our own observation, that we learn whether the laws of nature are variable or invariable. The Essay on Miracles may be recommended to those who wish to see more examples of sophistry; as we believe most of the eight species of sophisms which we have mentioned are well illustrated by examples in that essay.

SOPHIST, an appellation assumed in the early periods of Grecian history by those who devoted their time to the study of science. This appellation appearing too arrogant to Pythagoras, he declined it, and wished to be called a philosophor; declaring that, though he could not consider himself as a wise man, he was indeed a lover of wisdom. True wisdom and modesty are generally
generally united. The example of Pythagoras was followed by every man of eminence; while the name sophist was retained only by those who with a pomp of words made a magnificent display of wisdom upon a very slight foundation of knowledge. Those men taught an artificial structure of language, and a false method of reasoning, by which, in argument, the worse might be made to appear the better reason (see SOPHISM). In Athens they were long held in high repute, and supported, not only by contributions from their pupils, but by a regular salary from the state. They were among the bitterest enemies of the illustrious Socrates, because he embraced every opportunity of exposing to contempt and ridicule their vain pretensions to superior knowledge, and the pernicious influence of their doctrines upon the taste and morals of the Athenian youth.

SOPHISTICATION, the mixing of any thing with what is not genuine; a practice too common in the making up of medicines for sale; as also among vintners, distillers, and others, who are accused of sophisticating their wines, spirits, oils, &c. by mixing them cheaper and coarser materials; and in many cases the cheat is carried on so artfully as to deceive the best judges.

SOPHOCLES, the celebrated Greek tragic poet, the son of Sophilus, an Athenian, was born at Colonus, and educated with great attention. Superior vigour and address in the exercises of the palestra, and skill in music, were the great accomplishments of young men in the states of Greece. In these, Sophocles excelled; nor was he less distinguished by the beauty of his person. He was also instructed in the noblest of all sciences, civil politly and religion: from the first of these he derived an unshaken love of his country, which he served in some embassies, and in high military command with Pericles; from the latter he was impressed with a pious reverence for the gods, manifested by the inviolable integrity of his life. But his studies were early devoted to the tragic muse; the spirit of Eschylus lent a fire to his genius, and excited that noble emulation which led him to contend with, and sometimes to bear away the prize from, his great master. He wrote 33 tragedies, of which 7 only have escaped the ravages of time; and having testified his love of his country by refusing to leave it, though invited by many kings; and having enjoyed the uninterrupted esteem and affection of his fellow citizens, which neither the gallant actions and sublime genius of Eschylus, nor the tender spirit and philosophic virtue of Euripides, could secure to them, he died in the 91st year of his age, about 426 years before Christ. The burial-place of his ancestors was at Decelia, which the Lacearidamenians had at that time seized and fortified: by Lysander, the Spartan chief, permitted the Athenians to inter their deceased poet; and they paid him all the honours due to his love of his country, integrity of life, and high poetic excellence. Eschylus had at once seized the highest poet of honour in the field of poetry, the true sublime; to that eminence his claim could not be disputed. Sophocles had a noble elevation of mind, but tempered with so fine a taste, and so chastened a judgment, that he never passed the bounds of propriety. Under his conduct the tragic muse appeared with the stately dignity of some noble matron at a religious solemnity; harmony is in her voice, and grace in all her motions. From him the theatre received some additional embellishments; and the drama the introduction of a third speaker, which made it more active and interesting; but his distinguished excellence is in the judicious disposition of the fable, and so nice a connection and dependence of the parts on each other, that they all agree to make the event not only probable, but even necessary. This is peculiarly admirable in his "Oedipus King of Thebes;" and in this important point he is far superior to every other dramatic writer.

The ingratification of the children of Sophocles is well known. They wished to become immediate masters of their father's possessions; and therefore tired of his long life, they accused him before the Areopagus of insanity. The only defence the poet made was to read his tragedy of Oedipus at Colonus, which he had lately finished; and then he asked his judges, whether the author of such a performance could be taxed with insanity! The father upon this was acquitted, and the children returned home covered with shame and confusion. The seven tragedies of Sophocles which still remain, together with the Greek Scholia which accompany them, have been translated into Latin by Johnson, and into English by Dr Franklin and Mr Potter.

SOPHORA, a genus of plants belonging to the class of decandria, and to the order of monogyinia; and in the natural system arranged under the 52d order, Papilionaceae. See Botany Index.

SOPORIFERIC, or Soporiferous, a medicine that produces sleep. Such are opium, laudanum, the seed of poppies, &c. The word is formed from the Latin sopor, "sleep." The Greeks in place of it use the word hypnotic.

SORBONNE, or Sorbon, the house or college of the faculty of theology established in the university of Paris. It was founded in 1253 by St Louis, or rather by Robert de Sorbon his confessor and abbot, in the church of Paris; who gave his own name to it, which he himself took from the village of Sorbon or Sorbon, near Sens, where he was born. The foundation was laid in 1253; Queen Blanche, in the absence of her husband, furnishing him with a house which had formerly been the palace of Julian the apostate, of which some remains are still seen. Afterwards the king gave him all the houses he had in the same place, in exchange for some others. The college has been since magnificently rebuilt by the cardinal de Richelieu. The design of its institution was for the use of poor students in divinity. There are lodgings in it for 36 doctors, who are said to be of the society of the Sorbonne; those admitted into it without being doctors, are said to be of the hospitality of the Sorbonne. Six regent doctors formerly held lectures every day for an hour and a half each, three in the morning, and three in the afternoon.

Sorbons, is also used in general for the whole faculty of theology at Paris; as the assemblies of the whole body are held in the house of the Sorbonne; and the bachelors of the other houses of the faculty, as the house of Navarre, &c. come hither to hold their sorbonning, or act for being admitted doctor in divinity.

SORBUS, Service-tree, a genus of plants belonging to the class of icossandria, and to the order of trigynia. See Botany Index.—The aucuparia, mountainash, quicken-tree, quick-beam, or roan tree, rise with
a straight upright stem and regular branching head, twenty or thirty feet high or more, covered with a smooth grayish brown bark; pinnate leaves of eight or ten pair of long, narrow, serrated foliules, and an odd one, smooth on both sides; and large umbellate clusters of white flowers at the sides and ends of the branches, succeeded by clusters of fine red berries, ripe in autumn and winter. There is a variety with yellow striped leaves. This species grows wild in many parts of this island, in mountainous places, woods, and hedge-rows, often growing to the size of timber; and is admitted into most ornamental plantations, for the beauty of its growth, foliage, flowers, and fruit; the latter, in particular, being produced in numerous red large bunches all over the tree, exhibit a fine appearance in autumn and winter, till devoured by the birds, especially the blackbird and thrush, which are so allured by this fruit as to flock from all parts and feed on it voraciously.—In the island of Jura the juice of the berries is employed as an acid for punch. It is probable that this tree was in high esteem with the Druids; for it is more abundant than any other tree in the neighbourhood of those Druidical circles of stones, so common in North Britain. It is still believed by some persons, that a branch of this tree can defend them from enchantment or witchcraft. Even the cattle are supposed to be preserved by it from danger. The dairy-maid drives them to the summer pastures with a rod of the rowan-tree, and drives them home again with the same. In Strathspey, we are told, a hoop is made of the wood of this tree on the 1st of May, and all the sheep and lambs are made to pass through it.

The domestica, or cultivated service-tree, with eatable fruit, grows with an upright stem, branching 30 or 40 feet high or more, having a brownish bark, and the young shoots in summer covered with a mealy down; pinnate leaves of eight or ten pair of broadish deeply serrated lobes and an odd one, downy underneath; and, large umbellate clusters of white flowers at the sides and ends of the branches, succeeded by bunches of large, fleshy, edible red fruit, of various shapes and sizes. This tree is a native of the southern warm parts of Europe, where its fruit is used at table as a dessert, and it is cultivated here in many of our gardens, both as a fruit-tree and as an ornament to diversify hardy plantations.

SORCERY, or MAGIC; the power which some persons were formerly supposed to possess of commanding the devil and the infernal spirits by skill in charms and invocations, and of soothing them by fumigations. Sorcery is therefore to be distinguished from witchcraft; an art which was supposed to be practised, not by commanding evil spirits, but by compact with the devil. As an instance of the power of bad smells over demons or evil spirits, we may mention the flight of the evil spirit mentioned in Tobit into the remote parts of Egypt, produced, it is said, by the smell of the burnt liver of a fish. Lilly informs us, that one Evans having raised a spirit at the request of Lord Bothwell and Sir Kenelm Digby, and forgetting a fumigation, the spirit, vexed at the disappointment, pulled him without the circle, and carried him from his house in the Minories into a field near Battersea Causeway.

King James, in his Daemonologia, has given a very full account of the art of sorcery. "Two principal things (says he) cannot well be in that errand be wanted: holy water (whereby the devill mockes the papists), and some present of a living thing unto him. There are likewise certaine daies and houres that they observe in this purpose. These things being all ready and prepared, circles are made, triangular, quadrangular, round, double, or single, according to the forme of the apparition they crave. When the conjured spirit appears, which will not be while after many circumstances, long prayers, and much muttering and murmurings of the conjurors, like a papist priest dispatching a hunting massae—how soon, I say, he appears, if they have missed one jote of all their rites; or if any of their feete once slyd over the circle, through terror of his fearfull apparition, he pases himself at that time, in his owne hand, of that due debt which they ought him, and otherwise would have dellaide longer to have paid him: I mean, he carries them with him, body and soule." How the conjurors made triangular or quadrangular circles, his majesty has not informed us, nor does he seem to imagine there was any difficulty in the matter. We are therefore led to suppose, that he learned his mathematics from the same system as Dr. Sacheverell, who, in one of his speeches or sermons, made use of the following simile: "They concurs like parallel lines, meeting in one common centre.

Another mode of consulting spirits was by the beryl, by means of a speculator or seer; who, to have a complete sight, ought to be a pure virgin, a youth who had not known woman, or at least a person of irregreable life and purity of manners. The method of such consultation is this: The conjuror having repeated the necessary charms and adjudgments, with the litany or invocation peculiar to the spirits or angels he wishes to call (for every one has his particular form), the seer looks into a crystal or beryl, wherein he will see the answer, represented either by types or figures; and sometimes, though very rarely, will hear the angels or spirits speak articulately. Their pronunciation is, as Lilly says, like the Irish, much in the throat. Lilly describes one of these beryls or crystals. It was, he says, as large as an orange, set in silver, with a cross at the top, and round about engraved the names of the angels Raphael, Gabriel, and Uriel. A delineation of another is engraved in the frontispiece to Aubery's Miscellanies.

These sorcerers or magicians do not always employ their art to do mischief; but, on the contrary, frequently exert it to cure diseases inflicted by witches; to discover thieves; recover stolen goods; to foretell future events, and the state of absent friends. On this account they are frequently called white witches. See MAGIC, WITCHCRAFT, &c.

Our forefathers were strong believers when they enacted, by statute 33 Hen. VIII. c. 8. all witchcraft and sorcery to be felony without benefit of clergy; and again, by statute 1 Jac. I. c. 12. that all persons invoking any evil spirit, or consulting, covenanting with, entertaining, employing, feeding, or rewarding any evil spirit; or taking up dead bodies from their graves to be used in any witchcraft, sorcery, charm, or enchantment; or killing or otherwise hurting any person by such infernal arts; should be guilty of felony without benefit of clergy, and suffer death. And if any person should attempt by sorcery to discover hidden treasure,
Sorrel, or to restore stolen goods, or to provoke unlawful love, or to hurt any man or beast, though the same were not effected, he or she should suffer imprisonment and pillory for the first offence, and death for the second. These acts continued in force till lately, to the terror of all ancient females in the kingdom; and many poor wretches were sacrificed thereby to the prejudice of their neighbours and their own illusions, not a few having by some means or other confessed the fact at the gallows. But all executions for this dubious crime are now at an end; our legislature having at length followed the wise example of Louis XIV. in France, who thought proper by an edict to restrain the tribunals of justice from receiving informations of witchcraft. And accordingly it is with us enacted, by statute 9 Geo. II. c. 5, that no prosecution shall for the future be carried on against any person for conjuration, witchcraft, sorcery, or enchantment: But the misdemeanour of persons pretending to use witchcraft, tell fortunes, or discover stolen goods, by skill in the occult sciences, is still deservedly punished with a year's imprisonment, and standing four times in the pillory.

Sorex, the Shrew, a genus of animals belonging to the class of mammalia, and order of carnifex. See Mammal Index.

Sorites, in Logic, a species of reasoning in which a great number of propositions are so linked together, that the predicate of the one becomes continually the subject of the next following, till at last a conclusion is formed by bringing together the subject of the first proposition and the predicate of the last. Such was the merry argument of Themistocles, to prove that his little son under ten years old governed the whole world. Thus: My son governs his mother; his mother me; I the Athenians; the Athenians the Greeks; Greece commands Europe; Europe the whole world: therefore my son commands the whole world. See Logic, No. 96, 97.

Sorning, in Scots Law. See Law, No. clxxvi.

Sorrel, in Botany, a species of the Rumex, which grows in pastures and meadows, and is well known. The natives of Lapland boil large quantities of the leaves in water, and mix the juice when cold with the milk of the rein-deer, which they esteem an agreeable and wholesome food. The Dutch are said to cultivate this plant for its usefulness in the dyeing of woollen cloths black; and we know that by means of the common broad-leaved sorrel an excellent black colour is, in many places of Scotland, given to woolen stuffs without the aid of copperas. As this mode of dyeing does not in the smallest degree injure the texture of the cloth, which continues to the last soft and silky, without that hardness to the touch which it acquires when dyed black by means of copperas, our readers will probably thank us for the following receipt, with which we have been favoured by a learned physician:

Let the stuff to be dyed be well washed with soap and water, and afterwards completely dried. Then of the broad-leaved sorrel boil as much as shall make an acid decoction of sufficient quantity to let the stuff to be dyed lie in it open and easy to be stirred. The greater quantity of sorrel that is used, the better will the colour be; and therefore if the pot or cauldron will not hold enough at once, when part has been sufficiently boiled, it must be taken out and wrung, and a fresh quantity be boiled in the same juice or decoction. When the liquor is made sufficiently acid, strain it from the sorrel through a sieve, put the cloth or yarn into it, and let it boil for two hours, stirring it frequently. If stockings be among the stuff to be dyed, it will be expedient, after they have been an hour in the boiling liquor, to turn them inside out, and at the end of the second hour let the whole be poured into a tub or any other vessel. The pot or cauldron must then be washed, and water put into it, with half a pound of logwood chips for every pound of dry yarn or cloth. The logwood and water should boil slowly for four hours; and then the cloth or yarn being wrung from the sour liquor, and put into the logwood decoction, the whole must be suffered to boil slowly for four hours, stockings, if there be any, being turned inside out at the end of two hours. Of this last decoction there must, as of the former, be enough to let the cloth lie open and easy to be stirred while boiling. At the end of the four hours the cloth must be taken out, and among the boiling liquor, first removed from the fire, must be poured a Scotch pint or half an English gallon of stale urine for every pound of dry cloth or other stuff to be dyed. When this compound liquor has been stirred and become cold, the cloth must be put into it and suffered to remain well covered for 12 hours, and then dried in the shade; it is then washed in cold water, and dried for use.

Wood-Sorrel. See Oxalis, Botany Index.

Sorrel-Colour, in the manege, is a reddish colour, generally thought to be a sign of a good horse.

Sorrento, sea-port town of Naples; seated in a peninsula, on the bay of Naples, at the foot of a mountain of the same name, and 15 miles south-east of Naples. Sorrentum was famous in ancient times for its beautiful earthen vessels, particularly goblets and drinking cups; and claims the honour of being the birth-place of Torquato Tasso. E. Long. 14, 24. N. Lat. 40, 40.

Sortilege, (Sortilegeum) a species of divination performed by means of sortes or lots.

The sortes Prvesentimae, famous in antiquity, consisted in putting a number of letters, or even whole words, into an urn; and then, after shaking them together, they were thrown on the ground; and whatever sentences could be made out of them, constituted the answer of the oracle. To this method of divination succeeded that which has been called the sortes Homericanae and sortes Virgiliana, a mode of inquiring into futurity, which undoubtedly took its rise from a general custom of the oracular priests of delivering their answers in verse; it subsisted a long time among the Greeks and Romans; and being from them adopted by the Christians, it was not till after a long succession of centuries that it became exploded. Among the Romans it consisted in opening some celebrated poet at random, and among the Christians the Scriptures, and drawing, from the first passage which presented itself to the eye, a prognostic of what would befall one's self or others, or direction for conduct when under any exigency. There is good evidence that this was none of the vulgar errors; the greatest persons, philosophers of the best repute, admitted this superstition. Socrates, when in prison, hearing this line of Homer,

Within three days I Phthia's shore shall see,
immediately said, within three days I shall be out of the
302 world;
Sor [476] Sou

Sorilege. world; gathering it from the double meaning of the word Pithia, which in Greek is both the name of a country and signifies corruption or death. This prediction, addressed to Æschines, was not easily forgotten, as it was verified.

When this superstition passed from Paganism into Christianity, the Christians had two methods of consulting the divine will from the Scriptures; the one, casually, to open the divine writings, and take their direction, as above mentioned; the other, to go to church with a purpose of receiving, as a declaration of the will of heaven, the words of the Scripture, which were singing at the instant of one's entrance.

This unwarrantable practice of inquiring into futurity prevailed very generally in England till the beginning of the 18th century; and sometimes the books of Scripture, and sometimes the poems of Virgil were consulted for oracular responses. One remarkable instance is that of King Charles I. who being at Oxford during the civil wars, went one day to see the public library, where he was shown, among other books, a Virgil nobly printed and exquisitely bound. The lord Falkland, to divert the king, would have his majesty make a trial of his fortune by the Sortes Virgilianae. Whereupon the king opening the book, the passage which happened to come up was this:

At, bella audacis populi vox at armis,
Fimbriae extorques, complexa avulsa Iuli,
Arcuil implorat ; sidetique indigna surorum
Funera: nec, cum se sub leges pacis iniquae
Tradiderat, regno aut optata luce frustra;
Sed cadat ante diem, mediique inhumatus arca.
Æn. iv. 197.

Yet let a race, untamed and haughty foes,
His peaceful entrance with dire arms oppose;
Oppressed with numbers in the unequal field,
His men discouraged, and himself expelled,
Let him for succour sue from place to place,
Torn from his subjects, and his son's embrace:
First let him see his friends in battle slain,
And their untimely fate lament in vain;
And when at length the cruel war shall cease,
On hard conditions may he buy his peace.
Nor let him then enjoy supreme command,
But fall untimely by some hostile hand,
And lie unburied on the barren sand.

Lord Falkland observing that the king was concerned at this accident, would likewise try his own fortune in the same manner, hoping he might fall upon some passage that would have no relation to his case, and thereby divert the king's thoughts from any impression which the other might have upon him; but the place he stumbled upon was as much suited to his destiny as the other had been to the king's; being the lamentation of Evander for the untimely death of his son Palma:* for this lord's eldest son, a young man of an amiable character, had been slain in the first battle of Newbury.

We have ourselves known several, whose devotion has not always been regulated by judgment, pursuing this method of divination; and have generally observed, that the consequence has been despair or presumption. To such we beg leave to recommence one passage in Scripture which will never disappoint them: Thou shalt not tempt the Lord thy God.

Soteria, in antiquity, sacrifices offered to the gods for delivering a person from danger; as also poetical pieces composed for the same purpose.

Soubise, a town of France, in the department of Lower Charente, and late territory of Saintonge. It is seated on the river Charente, 22 miles south of Rochelle, in W. Long. 1°. 2°. N. Lat. 45°. 37'.

Soudan, a kingdom of Africa, situated between 11° and 16° N. Lat. and 26° and 30° E. Long. See Dar Fur.

Sough, among miners, denotes a passage dug under ground, to convey off waters from mines. See Mine.

Sovereign, in matters of government, is applied to the supreme magistrate or magistrates of an independent government or state; because their authority is only bounded by the laws of God and the laws of the state: such are kings, princes, &c. See Prerogative, &c.

Sovereign Power, or Sovereignty, is the power of making laws; for wherever that power resides, all others must conform to it, and be directed by it, whatever appearance the outward form and administration of the government may put on. For it is at any time in the option of the legislature to alter that form and administration by a new edict or rule, and to put the execution of the laws into whatever hands it pleases: and all the other powers of the state must obey the legislative power in the execution of their several functions, or else the constitution is at an end. In our constitution the law ascribes to the king the attribute of sovereignty: but that is to be understood in a qualified sense, i.e., as supreme magistrate, not as sole legislator; as the legislative power is vested in the king, lords, and commons, not in any of the three estates alone.

Sow. See Sol.

Souffriere, a small town, situated at the bottom of a bay, near the leeward extremity of the island of St Lucia. Of itself it is not entitled to much notice, but the adjacent ground is very remarkable. The declivities of the surrounding hills are cultivated, and afford sugar-cane of a good quality.

The extremity of the south side of Souffriere bays runs into two steep hills of a conical shape, and nearly perpendicular, reckoned the highest on the island, and known by the appellation of the Sugar-Loaf Hills. It is impossible to ascend them; for although it was once attempted by two negroes, it is said that they never returned. Passing the hills to the windward of Souffriere, a fine level country presents itself, extending from 15 to 20 miles from the back of the Sugar-Loaf Hills along the sea coast, being wholly cultivated, and divided into rich estates. It is intersected by numerous rivers of very clear water, which, by art, are made subservient to the purpose of sugar-making. The rains here are less frequent than on any other part of the island, and the wind blows from the sea, or nearly so.

There is a volcano in the vicinity of this town. After passing one or two small hills, the smell of sulphur is sensibly felt before any vestige of the place is perceived. The first thing discerned is a rivulet of black running water, sending forth streams nearly in a state of ebullition, from which the volcano soon comes into view, situated.
SOUL, the principle of perception, memory, intelligence, and volition, in man; which, since the earliest era of philosophy, has furnished questions of difficult investigation, and materials of keen and important controversy (see Metaphysics, Part III, chap. ii. iii. iv. v.; and Resurrection, No. 42-48). In the 4th volume of the memoirs of the Literary and Philosophical Society of Manchester, the reader will find a very valuable paper by Dr Ferrier, proving by evidence apparently complete, that every part of the brain has been injured without affecting the act of thought. An abridgment of that memoir would weaken its reasoning; which, built on matters of fact and experience, appears to us to have shaken the modern theory of the Materialists from its very foundation.

SOUL of Brutes. See BRUTES.

SOUND, in Physics, a term which expresses a simple idea; it is that primary information which we obtain of external things by means of the sense of hearing. See ACOUSTICS.

SOUND, in Geography, denotes in general any strait or inlet of the sea between two headlands. It is given by way of eminence to the strait between Sweden and Denmark, joining the German ocean to the Baltic, being about three miles over. See DENMARK, No. 32, and ELBSNORE.

SOUND-BOARD, the principal part of an organ, and that which makes the whole machine play. It is a reservoir into which the wind, drawn in by the bellows, is conducted by a port-vent, and thence distributed into the pipes placed over the holes of its upper part. The wind enters them by valves, which open by pressing on the keys, after the registers are drawn, by which the air is prevented from going into any of the other pipes, besides those in which it is required.

SOUND-BOARD also denotes a thin broad board placed over the head of a public speaker, to enlarge or extend and strengthen his voice.

SOUNDBOARDS are found by experience to be of no use in theatres, as their distance from the speaker is too great to be impressed with sufficient force. But soundboards over a pulpit have frequently a good effect, when the case is constructed of a proper thickness, and according to particular principles.

SOUND-POST, is a post placed in the inside of a violin, &c., as a prop between the back and belly of the instrument, and nearly under the bridge.

SOUNDING, the operation of trying the depth of the sea, and the nature of the bottom, by means of a plummet sunk from a ship to the bottom.

There are two plummets used for this purpose in navigation; one of which is called the hand-lead, weighing about 8 or 9 pounds; and the other the deep-sea-lead, which weighs from 25 to 30 pounds; and both are shaped like the frustum of a cone or pyramid. The former is used in shallow waters, and the latter at a great distance from the shore; particularly on approaching the land after a sea voyage. Accordingly the lines employed for this purpose are called the deep-sea-lead-line and the hand-lead-line.

The hand-lead-line, which is usually 20 fathoms in length, is marked at every two or three fathoms; so that the depth of the water may be ascertained either in the day or night. As the depth of two or three fathoms there are marks of black leather; at 5 fathoms, there is a white rag; at 7, a red rag; at 10, black leather; at 13, black leather; at 15, a white rag; and at 17, a red ditto.

Sounding with the hand lead, which is called LEAVING the lead by seamen, is generally performed by a man who stands in the main-chains to windward. Having the line quite ready to run out without interruption, he holds it nearly at the distance of a fathom from the plummet, and having swung the latter backwards and forwards three or four times, in order to acquire the greater velocity, he swings it round his head, and thence as far forward as is necessary; so that by the lead's sinking whilst the ship advances, the line may be almost perpendicular when it reaches the bottom. The person sounding then proclaims the depth of the water in a kind of song resembling the cries of hawkers in a city. Thus if the mark of five fathoms is close to the surface of the water, he calls 'By the mark five!' and as there is no mark at four, six, eight, &c., he estimates those numbers, and calls, 'By the dip four,' &c. If he judges it to be a quarter or an half more than any particular number, he calls, 'And a quarter five! and a half four,' &c. If he conceives the depth to be three quarters more than a particular number, he calls it a quarter less than the next: thus, at four fathoms and three fourths he calls, 'A quarter less five! and so on.

The deep-sea-lead is marked with two knots at 20 fathoms, three at 30, and 4 at 40, and so on to the end. It is also marked with a single knot in the middle of each interval, as at 25, 35, 45 fathoms, &c. To use this lead more effectually at sea, or in deep water on the sea coast, it is usual previously to bring to the ship, in order to retard her course: the lead is then thrown as far as possible from the ship on the line of her drift, so that, as it sinks, the ship drives more perpendicularly over it. The pilot, feeling the lead strike the bottom, readily discovers the depth of the water by the mark on the line nearest its surface. The bottom of the lead being also well rubbed over with tallow, retains the distinguishing marks of the bottom, as shells, ooze, gravel, &c. which naturally adhere to it.

The depth of the water, and the nature of the ground, which is called the soundings, are carefully marked in the log-book, as well to determine the distance of the place from the shore, as to correct the observations of former pilots.

A machine for the same purpose has been invented by Mr. Mussey, of which the following description is given:

"The importance of obtaining true soundings at sea most.
Soundings. be admitted by every seaman; and it is rather singular, that no other method than the common lead has hitherto been brought into use; as its imperfections are very generally acknowledged.

Many vessels have been lost, by depending upon the soundings taken in the usual way. The difficulty of obtaining the true perpendicular, and the uncertainty as to the exact moment when the lead strikes the bottom, upon which the accuracy of the result depends, must always prevent the possibility of obtaining the true depth, while the ship has any considerable way upon her. Indeed, it has been acknowledged by experienced seamen, during some experiments, made at various times, in the river Mersey, that they could not depend upon the common lead, when going five or six knots in the hour, in ten or twelve fathoms of water. When the depth is considerable, the vessel must be hove to, which is an operation attended with great loss of time, and sometimes considerable injury to the sails; and during a chase, this inconvenience must be particularly felt.

True soundings may be taken with this machine in thirty fathoms water, without the trouble of heaving the vessel to, although she may be going at the rate of six miles in the hour. True soundings may also thus be obtained in very deep water, where it is not possible to take them by the common lead.

Plate fig. 1. represents the sounding machine. a is the sounding weight, containing a register, 1, 2, with two dials: the hand of the dial 1 makes one revolution when the weight has descended twenty fathoms, the other revolves once when the descent amounts to five hundred fathoms. A rotator, b, similar to that attached to the log, communicates with the wheel work of the dials 1, 2, by means of the rod c, on which there are three universal joints, 3, 4, and 5. This rod is supported during the descent of the weight, by the drop, d, at the end of which is a fork, e, and a friction wheel, f.

When the machine is to be used, a sounding line is fastened to the ring, e; and one of the vanes of the rotator is slipped into the spring 8: the rotator will then be in the position indicated by the dotted lines, x. The indices must be set at 0, and the cover or lid, f, be shut. The machine must then be projected perpendicularly into the sea. As soon as it reaches the surface, the resistance of the water forces the dotted rotator, x, out of the spring 8, and it assumes its perpendicular direction as represented by the rotator b. As the machine descends, it is evident the rotator will revolve, and its motion be communicated freely past the friction wheel, f, and the universal joint 5, to the wheel work of the dials 1, 2, and thus indicate the space passed through in fathoms. When the machine has arrived at the bottom, the rotator, as it is no longer buoyed up by the reaction of the water, will fall to the bottom, quitting the fork of the drop, d, which will also fall from its horizontal position, and in its descent, by means of the locking rod 5, prevent the rotator from revolving as the machine is drawn up. When at the bottom, the rotator will be in the position of the dotted lines, y.

This machine, simple in its construction, and scarcely more liable to accident than the common lead, affords with the utmost precision, the perpendicular depth, by the mere act of descent through the water. No mistake can arise from that common source of error, the drift or lee-way of the ship during the time of descent; nor does an operation of such importance depend upon soundings. The uncertain sensation caused by the lead striking the bottom, on which the accuracy of the common log altogether depends, and which, it is well known, frequently and materially misleads the best seaman; for though a thousand fathoms of line were laid out, in the smallest depth of water, no inaccuracy could arise, as the perpendicular depth, at the point of heaving, would be registered on the index. The only inconvenience experienced would be the additional labour necessary for hauling in the excess of line. The most inexperienced person may use this machine, without risk of error, in the most turbulent sea, and during the night.

The advantages already enumerated would render the sounding machine of great importance; but there are other properties of still more consequence.

To heave a ship to, in order to obtain soundings, on a lee shore, in stormy weather, is a very disagreeable operation, attended with much trouble, and loss of way; also with considerable danger to the ship's sails; indeed, it would often, under such circumstances, be attended with great hazard to the safety of the ship. To avoid these unpleasant consequences, the master sometimes adopts a measure, which he conceives to be the less exceptionable alternative, by running on without sounding at all.

To prove how much inconvenience and danger are avoided by Massey's lead, it is enough to state, that soundings may be taken in depth from 60 to 80 fathoms, while the ship is under way, at the rate of three miles an hour; and as the rate of sailing may be still materially reduced, without entirely stopping the vessel, or altering her course, so may soundings be had, to any depth required, while she is under way.

In order more clearly to show the superiority of this machine, and make it apparent, that the quantity of stray-line veered out does not at all affect the truth of the result: suppose the common lead thrown from the mizen chains of the ship, which may be represented by the point a of the triangle a b c, (fig. 2); and that the ship Fig. 1 has moved forwards through the space equal to the line b c, while the lead has descended through the line a c; it is evident, that it is impossible, in this case, to ascertain the exact depth, as a quantity of line, equal to a b, would be paid out, whereas the true depth is equal only to the line a c, which is much less. But the case is very different when the patent sounding machine is used, as the operation ceases when it has reached the bottom; nor is the stray-line, a b, whatever its length, at all taken into the account.

It has been extremely difficult, and sometimes impossible, to obtain soundings in very deep water with the common lead, which may perhaps be thus accounted for. The common line which is used for sounding, though, if left to itself, it would sink in water, yet its descent would be much slower than that of the lead, separately; it consequently follows, that the lead must be so much impeded by carrying the line with it, that when it does reach the bottom, there will be scarcely any sensible check to enable the seaman to know the precise moment. Indeed, if he can ascertain, even to this a certainty, he still cannot depend upon the truth of his soundings; for if there be the least drift or current, the line itself will assume a curve, similar to that of the line of a kite in the air. These two causes will always ope
rate against the perfection of the common mode of
sound.

"After so fully describing the principle of the patent
sound machine, it is scarcely necessary to prove that
it is liable to neither of the foregoing objections; and it
may be sufficient to say, that, as it will certainly find its
way to the bottom, if a sufficient portion of stray-line
be allowed to guard against its being checked in its
progress, and the certainty of its having reached the
bottom may be ascertained by the sounding, there can be
no doubt of the practical ability of its obtaining soundings,
in any depth, and no reasonable doubt of their correct-
ness when obtained.

"From the construction of this machine, it might be
imagined, that the rotator would impede its motion
through the water, and that it could not descend so
rapidly as the common lead; but during repeated trials,
in thirteen fathoms water, in which the rotator was fre-
fently detached, and the lead suffered to descend alone,
there was no difference perceptible in the time of their
descent, though an excellent quarter-stave stop watch
was used during the experiment, to detect any change.
The following table shows how uniformly the times
of descent corresponded with the depths in fathoms, du-
der a series of trials made on the river Mersey, with
the patent lead, weighing 14 pounds.

The manner of conducting these experiments was
such as is deserving of perfect reliance. Two pilots, of
well-known ability and experience, were employed: one
threw the lead, and the other, the moment he found,
by the slackening of the rope, that the weight had ar-
rived at the bottom, cried 'stop,' to a third person who
held the watch.

"Taken when under sail, at upwards of five knots in
the hour.

"Several captains and masters in the navy have made
trial of the log and sounding machine, and given very
favourable reports of their performance; and it has been
adopted by order of the Navy Board in the British
navy.

SOUP, a strong decoction of flesh or other sub-
stances.

Portable or dry soup is a kind of cake formed by
boiling the gelatinous parts of animal substances till the
watery parts are evaporated. This species of soup is
chiefly used at sea, and has been found of great advan-
tage. The following receipt will show how it is pre-
pared.

Of calves feet take 4; leg of beef 12 lbs.; knuckle
of veal 3 lbs.; and leg of mutton 10 lbs. These are
to be boiled in a sufficient quantity of water, and the
scum taken off as usual; after which the soup is to be
separated from the meat by straining and pressure. The
meat is then to be boiled a second time in other water;
and the two decoctions, being added together, must be
left to cool, in order that the fat may be exactly sepa-
rated. The soup must then be clarified with five or six
whites of eggs, and a sufficient quantity of common salt
added. The liquor is then strained through flannel,
evaporated on the water bath to the consistency of
a very thick paste; after which it is spread rather thin
upon a smooth stone, then cut into cakes, and lastly
dried in a stove until it becomes brittle; these cakes are
kept in well closed bottles. The same process may be
used to make a portable soup of the flesh of poultry;
and aromatic herbs may be used as a seasoning, if thought
proper.

These tablets or cakes may be kept four or five
years. When intended to be used, the quantity of half
an ounce is put into a large glass of boiling water,
which is to be covered, and set upon hot ashes for a
quarter of an hour, or until the whole is entirely dis-
solved. It forms an excellent soup, and requires no
addition but a small quantity of salt.

SOUR-CROUTE. See CROUTE.

SOUR-Gourd, or African Calabash-tree. See ADAN-
sonia, BOTANY INDEX.

SOUTH, Dr Robert, an eminent divine, was the
son of Mr William South a merchant of London, and
was born at Hackney near that city in 1633. He
studied at Westminster school, and afterwards in Chris-
tchurch college, Oxford. In 1654, he wrote a copy of
Latin verses to congratulate Cromwell upon the peace
concluded with the Dutch; and the next year a Latin
poem, entitled Musica Incantata. In 1665 he was elec-
ted public orator of the university; and the next year
became domestic chaplain to Edward Earl of Clarendon,
lord high chancellor of England. In 1665 he was in-
stalled prebendary of Westminster, admitted to the de-
gree of doctor of divinity, and had a sinecure bestowed
on him in Wales by his patron the earl of Clarendon,
after whose retirement into France in 1667 he became
chaplain to the duke of York. In 1670 he was instal-
led canon of Christ church in Oxford; and in 1676 at-
tended as chaplain to Laurence Hyde, Esq. ambassador
extraordinary to the king of Poland. In 1678 he was
presented to the rectory of Islip in Oxfordshire; and
in 1680 rebuilt the chancel of that church, as he after-
wards did the rectory-house belonging to it. After the
revolution he took the oath of allegiance to King Wil-
liam and Queen Mary, though he excused himself from
accepting a great dignity in the church, vacated by the
personal refusal of that oath. His health began to de-
cline several years before his death, which happened in
1716. He was interred in Westminster Abbey, where
a monument is erected to his memory. He published:
1. Animadvertions on Dr Sherlock's Vindication of the
Holy and Ever Blessed Trinity. 2. A Defence of his
Animadvertions. 3. Sermons, 8 vols 8vo. And after
his decease were published his Opera Postuma Latina,
and his posthumous English works. Dr South was ra-
markable for his wit, which abounds in all his writings,
and particularly in his sermons; but at the same time
they equally abound in ill-humour, spleen, and rine.
He was remarkable for being a time-server. During
the life of Cromwell he was a staunch Presbyterian, and
then railed against the Independents: at the Restora-
tion.
tion he exerted his pulpit eloquence against the Presby-
terians; and in the reign of Queen Ann, was a warm
advocate for Sacheverel.

South, one of the four cardinal points from which
the winds blow.

South Sea, or Pacific Ocean, is that vast body of
water interposed between Asia and America. It does
not, however, strictly speaking, reach quite to the
continent of Asia, excepting to the northward of the
peninsula of Malacca: for the water interposed between
the eastern coast of Africa and the peninsula just men-
tioned has the name of the Indian ocean. The South
sea then is bounded on one side by the western coast
of America, through its whole extent, from the unknown
regions in the north to the straits of Magellan and
Terra del Fuego, where it communicates with the sou-
bond part of the Atlantic. On the other side, it is
bounded by the coast of Asia, from the northern pro-
monitory of Tschukotskoi Noss, to the peninsula of Ma-
cassa already mentioned. Thence it is bounded to the
southward by the northern coasts of Borneo, Celebes,
Macassar, New Guinea, New Holland, and the other
islands in that quarter, which divide it from the Indian
ocean. Then, washing the eastern coast of the great
island of New Holland, it communicates with that vast
body of water encompassing the whole southern part of
the globe, and which has the general name of the So-
thern ocean all round. Thus does this vast ocean occu-
py almost the semicircumference of the globe, extend-
ing almost from one pole to the other, and about the
equatorial parts extending almost 180° in longitude, or
12,000 of our miles.

The northern parts of the Pacific ocean are entirely
destitute of land; not a single island having yet been
discovered in it from the latitude of 40° north and up-
wards, excepting such as are very near the coast either
of Asia or America; but in the southern part there
are a great number.

Till very lately the South sea was in a great measure
unknown. From the great extent of ice which covers
the southern part of the globe, it was imagined that
much more land existed there than in the northern re-
regions: but that this could not be justly inferred merel-
ly from that circumstance, is plain from what has been
advanced under the articile AMERICA, No. 3-24; and
the southern continent, long known by the name of
Terra Australis, has eluded the search of the most ex-
pert navigators sent out from Britain and France by
royal authority. See TERRA AUSTRALIS.

South Sea Company. See Company.

Southampton, a sea-port town of Hampshire
in England; is seated on an arm of the sea; is a place
of good trade, and in 1801 contained nearly 9,500
inhabitants. It is surrounded by walls and several watch-
towers, and had a strong castle to defend the harbour,
now in ruins. It is a corporation and a county of itself,
with the title of an earldom, and sends two members to
parliament. W. Long. 1. 24. N. Lat. 50. 54.

Southern, Thomas, an eminent dramatic writer,
was born at Dublin in 1662, and received his
education in the university there. He came young to
London to study law; but instead of that devoted
himself to poetry and the writing of plays. His Per-
sian Prince, or Loyal Brother, was introduced in 1682,
when the Tory interest was triumphant in England;
and the character of the Loyal Brother being intended
to compliment James duke of York, he rewarded the
author when he came to the throne with a commis-
sion in the army. On the Revolution taking place, he
retired to his studies, and wrote several plays, from
which he is supposed to have derived a very hand some
substance, being the first who raised the advantage of
playwriting to a second and third night. The most
finished of all his plays is Oroonoko, or the Royal Slave,
which is built on a true story related in one of Mr.
Behn’s novels. Mr Southern died in 1746, in the 86th year
of his age; the latter part of which he spent in a peaceful
serenity, having by his commission as a soldier, and the
profits of his dramatic works, acquired a handsome for-
tune; and being an exact economist, he improved what
fortune he gained to the best advantage. He enjoyed
the longest life of all our poets; and died the richest
of them, a very few excepted. His plays are printed in
two volumes 12mo.

Sozomenus, Hermias, an ecclesiatical histori-
ain of the 6th century, was born in Bethelia, a town
of Palestine. He was educated for the law, and be-
came a pleader at Constantinople. He wrote an Ar-
bridge ment of Ecclesiastical History, in two books, from
the ascension of our Saviour to the year 323. This
compendium is lost; but a continuation of it in nine
books, written at greater length, down to the year
430, is still extant. He seems to have copied Socrates,
who wrote a history of the same period. The style of
Sozomenus is perhaps more elegant; but in other re-
pects he falls far short of that writer, displaying through-
out his whole book an amazing credulity and a super-
stitious attachment to monks and the monastic life.
The best edition of Sozomenus is that of Robert Step-
en in 1544. It has been translated and published by Va-
lesius, and republished with additional notes by Reading
at London, 1720, in 3 vols folio.

Spa, a town of Germany, in the circle of Westphal-
ia and bishopric of Lige, famous for its mineral wa-
ter, lies in E. Long. 50. N. Lat. 50. 50. about 21
miles south-east from Lige, and 7 south-west from
Lomburg. It is situated at one end of a deep valley,
on the banks of a small rivulet, and is surrounded on all
sides by high mountains. The sides of these mountains
next to Spa are rude and uncultivated, presenting a
rugged appearance as if shattered by the convulsions of
earthquakes; but as they are strewn with tall oaks and
abundance of shrubs, the country around forms a wild,
romantic, and beautiful landscape. The access to the
town
town is very beautiful. The road winds over the
mountains till it descends to their bottom, when it
runs along a smooth valley for a mile or a mile
and a half.

The town consists of four streets in form of a cross,
and contains about 400 inhabitants. Spa has no wealth
to boast of. It can scarcely furnish the necessary life to its own inhabitants during the winter, and almost
all the luxuries which are requisite for the great con-
course of affluent visitors during the summer are car-
cried from Liege by women. Its only source of wealth
is its mineral waters. No sooner does the warm season
commence, than crowds of valetudinarians arrive, as
well as many other persons who are attracted solely by
the love of amusement, and some from less honourable
motives. The inhabitants, who spend seven or eight
months of the year without seeing the face of a stranger,
wait for the return of this period with impatience. The
welcome sound of the carriages brings multitudes from
the town, either to gratify their curiosity, or to offer
their services in the hopes of securing your employment
while you remain at Spa. Immediately after your ar-
ival, your name and designation is added to the printed
list of the annual visitors; for which you pay a stated
sum to the booksellers, who have a patent for this
purpose from the prince bishop of Liege. This list not
only enables one to know at a glance whether any friends
or acquaintance are residing there, but also to distin-
guish persons of rank and fashion from adventurers,
who seldom have the effrontery to insert their names.

There are two different ways of accommodating the
visitors at Spa with lodging and necessaries. People
may either lodge at a hotel, where every thing is furni-
sheh in a splendid and expensive style; or they may
make up their residence in private lodgings, from
which they may send for provisions to a cook's shop.

Among the people who visit Spa, there are many
persons of the first rank and fashion in Europe. Per-
haps indeed there is no place in Europe to which so
many kings and princes resort; but it is also visited by
many self-created nobility, who, under the titles of
counts, barons, marquises, and knights, contrive by
their address, and artifices, to prey upon the rich and
unexperienced.

The manners established at Spa are conducive both
to health and amusement. Every body rises early in
the morning, at six o'clock or before it, when a great
many horses stand ready saddled for those who choose
to drink the Sauveniere or Gerontere waters at a little
distance from Spa. After this healthy exercise a part
of the company generally breakfast together at Vaux-
hall, a magnificent and spacious building. At this
place a number of card-tables are opened every fore-
noon, round which many persons assemble and play for
stakes to a very considerable amount. A ball too is
generally held once a week at Vauxhall, besides two balls
at the assembly rooms near the Poubon in the middle of
the town.

The most remarkable waters at Spa are, 1. The Poub-
on, situated in the middle of the town; 2. The Sau-
veniere, a mile and a half east from it; 3. Grainsbeck,
near to the Sauveniere; 4. Tonnelet, situated a little
to the left of the road which leads to the Sauveniere; 5.
Gerontere, two miles south from Spa; 6. Wartrow,
near to the Tonnelet; 7. Sarts or Niveset, in the dis-
trict of Sarts; 8. Chervon or Brus, in the principality
Gerontere. These four last are near Malmedy.

Dr Brownrigg was the first person who discovered
that fixed air, or, as it is now generally called, carbo-
nic acid gas, forms a principal ingredient in the com-
position of the Spa waters, and actually separated a quan-
tity of this elastic fluid, by exposing it to different de-
grees of heat from 110° to 170° of Fahrenheit. From
22 ounces 7 drams and 14 grains apothecaries weight
of the Poubon water, he obtained 8 ounces 2 drams
and 50 grains. Since June 1765, when Dr Brownrigg
read a paper on this subject before the Royal Society
of London, the waters of Spa have been often analysed,
but perhaps by none with more accuracy than by Dr
Asb, who published a book on the chemical and medi-
cinal properties of these waters in 1788. We shall
present the result of his analysis of the five principal
springs in the following table:

The Poubon spring rises from the hill to the north
of Spa, which consists of argillaceous schistus and fer-
tigenous slate. The other fountains rise from the sur-
rounding hills to the south-east, south, west, and north-
west of the town; and this ridge of mountains is for-
mmed of calcareous earths mixed with siliceous substan-
ces. The surface of the mountains is covered with woods,
terpressed with large boggy swamps filled with mud
and water. The Poubon is considered as the principal
spring at Spa, being impregnated with a greater quan-
tity of iron than any of the rest, and containing more

Vol. XIX. Part II.

fixed air than any except the Tonnelet. It is from this
spring that the Spa water for exportation is bottled;
for which the demand is so great, that, according to
the best information that Mr Thicke of the Journey's
Thick-ness could obtain, the quantity exported amounts
to 200,000 or 250,000 bottles annually. This exported
water is inferior in its qualities to that which is drunk
on the spot; for the vessel into which it is collected are injudiciously exposed
to the sun, rain, wind, and dust, for several hours before
they are corked, by which means a considerable part of
its volatile ingredients must be evaporated; for it has
been
SPAIN.

The kingdom of Spain, which occupies by far the greater portion of the south-western peninsula of Europe, is bounded on the north by the bay of Biscay and Pyrenean mountains, which separate it from France; on the east by the Mediterranean sea; on the south by the straits of Gibraltar, which divide it from the African kingdom of Morocco; and on the west, partly by the Atlantic ocean, but chiefly by the narrow kingdom of Portugal. This last is the only artificial boundary of the Spanish territory, and consists of ideal lines, except in three parts, where the river Minho to the north, and the Douro and the Chanae, till its junction with the Guadiana to the east, form rather more natural limits.

From Cape Ortegal in N. Lat. 43° 44', to the rock of Gibraltar, in N. Lat. 35° 57', the continent of Spain extends through nearly 8° of latitude, while its extent from west to east, viz. from Cape Finisterre in Long. 0° 17 W. from Greenwich to Cape Creus, or Croix, in Long. 3° 30' E. from the same meridian, comprehends nearly 13° of longitude. In British miles, its length from north to south, viz. from Cape Penas to Gibraltar, may be estimated at 570 miles, while its medium breadth may be computed at 440. According to De Laborde, its superficial extent, exclusive of Portugal, is 25,137 square French, leagues, or about 21,000 square English leagues.

Besides the continental part of Spain, this monarchy comprehends several islands in the Mediterranean, especially Majorca, Minorca, and Iviça; the Canary islands, and several places on the north-western coast of Africa; the Philippine and Ladrone islands; together with an immense territory both in North and South America, comprehending Mexico or New Spain, New Mexico, the island of Cuba, Porto Rico, &c. in North America, and in the southern part of that continent, the greatest portion of Terra Firma, Peru, Chili, almost the whole of Paraguay, with an extensive territory lying on the banks of the river Plate.

The usual division of the Spanish continent is into fourteen provinces, viz. those of Catalonia, Aragon, and Navarre, on the confines of France; Biscay, Asturias, and Galicia, on the shores of the Atlantic; Leon and Estremadura, on the side of Portugal; Andalusia chiefly on the straits of Gibraltar; Granada, Murcia, and Valencia, on the shores of the Mediterranean; Old and New Castile in the centre.

The latest writer on the geography of Spain, De Laborde, reckons only 13 provinces, as he includes Granada under Andalusia. In the following table we have brought together the most important circumstances respecting each of these provinces, viz. the subdivisions, extent in square British miles, population at the end of the 18th century, and chief towns; and we have arranged the provinces in the order followed by Laborde.

</table>

Some account of these provinces will be found under the articles Andalusia, Aragon, Asturias, Biscay, Castile, Catalonia, Estremadura, Galicia, Granada, Leon, Murcia, Navarre, Valencia, Ivica, Majorca, and Minorca; but for the best view of their present state, we must refer our readers to D’E. Lawlor’s View of Spain, vols. i. ii. and iii. or to Playfair’s Geography, vol. i.

In its general appearance, Spain presents a pleasing variety of hill and dale, mountain and valley. It must be regarded as a mountainous country, its plains being few in number and of small extent. The most remarkable of these occupies the centre of the kingdom, especially New Castile, which forms the most elevated tract of level country to be found in Europe, having a mean elevation of more than 300 fathoms above the level of the sea. The country is well wooded, and abounds with rivers; but these are often very deficient in water, and...
SPAIN.

Spain, especially on its eastern coast, is remarkable for the dryness of its soil. Notwithstanding this aridity, however, most parts of the kingdom teem with fertility, and native verdure and high cultivation render the scenery delightful. Here and there, indeed, occurs a tract of desert utterly incapable of cultivation; but, in general, nature has done much more for the country than the labour of its inhabitants.

The soil is said to be in general light, and easily wrought; but on many parts of the eastern coast it is composed chiefly of a stiff loam or clay. The most fertile parts of the kingdom are in Valencia, on the coast of Granada, in the kingdom of Old Castile, and in several parts of those of New Castile and Leon. The soil of Catalonia is very discouraging, except in the valleys, and the same may be said of all the provinces bordering on the Pyrenees; the soil of Estremadura, though naturally good, has been so long abandoned to itself, that it has almost ceased to produce, and that of Andalusia has a very mixed character. The soil of Murcia is uncommonly arid; that of the Asturias cold; that of Galicia extremely wet. In the neighbourhood of Carthagena there is an extensive tract, which is so covered with stones as to form a desert as sterile and untameable as any on the sandy plains of Africa or Arabia.

We have said that Spain is a mountainous country. The chain of the Pyrenees, common to it and France, is by no means the most considerable in point either of elevation or extent; though that chain may be regarded as the common root or origin of all the rest. From the western corner of the Pyrenees a vast ridge branches off through Navarre, Biscay, Asturias and Galicia, terminating only at Cape Finisterre, and Cape Ortegal. This ridge is the Cantabrian mountains, and is distinguished into several subordinate groups, denominated from the principal towns situated in their vicinity. Thus we have the mountains of Mondonedo in Galicia. In general, these groups are called Sierras, from the jagged or serrated appearance of their tops; as the Sierra de la Asturias, Sierra d'Auila, &c. The subordinate mountains that extend from the Sierra of the Asturias in the north, to the Alpujarras in the south, run in parallel lines; and the same direction prevails in the mountains of Saint Andro, which join the Pyrenees.

From the mountains of Biscay arises a main ridge, which, after proceeding a little to the south, divides into three or four branches. Of these the most northerly chain separates the provinces of Old Castile and New Castile, extending to the confines of Portugal, and called the mountains of Guadarrama. A second branch divides the principal part of New Castile from the province of La Mancha, running from the north-east to the south-west, as far as Badajos in Estremadura. The most remarkable part of this chain is the Sierra of Guadalupe. South of these runs the Sierra Morena, or Sable mountains, rendered classical by the inimitable pen of Cervantes. This is the last chain till we reach the Alpujarras, that extend through the provinces of Granada and Andalusia.

Of these mountains there are two points, which, in elevation, exceed Mont Perdu, the highest of the Pyrenees, viz. the Pico de Venleta, in the Sierra Nevada, or snowy mountains of Granada, which is elevated more than 1781 fathoms above the level of the ocean, and the peak of Mulahasen, in the same chain, raised above 1824 fathoms, which is within 76 fathoms of the peak of Tenerife.

The principal capes and promontories of the Spanish continent are, Cape Creus, Cape St Antoine, opposite the island of Iviça; Cape Palas, near Carthagena; Cape de Gatte, near Almeria, and the promontory on which stands the town of Gibraltar, all on the coast of the Mediterranean; and Cape Machichaco, Cape Penas, Cape Ortegal, the promontory of Ferrol, Cape Finisterre, and Cape Trafalgar, on the coasts of the Atlantic.

The principal bays and gulfs on the coast of Spain, Bays and pursing the same course, are the following; the bay gulfs of Valencia, the bay of Alican, the gulf of Carthagena, the bay of Almeria, the bay of Gibraltar, the harbour of Cadiz, the bay of Corunna, commonly called the Groyne, and the bay of Biscay.

The rivers of Spain are intimately connected with the rivers mountains from which they derive their source, and between the chains of which they generally flow. The most important are, the Ebro, rising in the mountains of Santillana in the Asturias, and running in a south-eastern direction between the Castiles and Valencia on the one hand, and the provinces of Navarre, Aragon, and Catalonia, on the other, till it reaches the Mediterranean, at a small distance from Tortosa; the Xacar, rising in the Sierra of Cuenca in New Castile, and flowing into the Mediterranean considerably to the southward of Valencia; the Segura, rising in a mountain of the same name, traversing the province of Murcia, and meeting the Mediterranean about midway in the capital of that province, and Alicante. These flow into the Mediterranean, and there are several other rivers of less note, which pour their waters into the same sea, and which we can merely enumerate. These are the Ter at Gerona, the Lobregate at Barcelona, and the Miarees, passing by Segorbe. The rivers which flow into the Atlantic are, the Guadalquivir, rising at the foot of Mount Segura, from the opposite side of which originates the river of the same name, flowing with a sluggish course through the province of Andalusia, and meeting the Atlantic a little to the north-west of Xeres; the Guadiana, rising among some lakes to the north-west of Alcaraz in New Castile, and passing between the Sierra Morena and the Sierra de Guadalupe, till, near Badajos, it enters the kingdom of Portugal, and runs nearly in a southerly direction, till it meets the Atlantic at Ayamonte; the Tagus, rising among the mountains of Alboracin in New Castile, and running westerly till, at Alcantara, it becomes a river of Portugal; the Douro, rising in Old Castile near Soria, and passing by Valladolid and Zamora, near which it forms a part of the boundary of Portugal; the Minho, rising in the mountains of Galicia, and running to the south-west, till it meets the Atlantic to the north of Caminha. The only other river of any importance in this direction is the Lima, supposed to be the Lethe of the poets, which rises in Galicia, and flows into the sea below Viara.

If we except the series of small lakes from which we have said the river Guadiana takes its rise, there are, in Spain, few lakes that merit particular notice. The most remarkable of these is the lake of Albufera, in the province of Valencia. This lake begins near the village of Catarroja, about a league south of the city of Valencia, and extends nearly four leagues as far as Cullera. When it
SPAIN.

From the mean height of the barometer at Madrid, we find that capital to be elevated 309,75 fathoms above the level of the ocean. Madrid, consequently, stands as high as the town of Innsbruck, situated on one of the highest dehis of the Tyrol, while its elevation is 15 times greater than that of Paris, and three times greater than that of Geneva.

According to M. Thalacker, the mineralogist, who has taken several heights with the barometer in the environs of Madrid, the elevation of the king's palace at San Ildefonso is 393 fathoms, which is higher than the edge of the crater of Mount Vesuvius, and is, strictly speaking, in the regions of the clouds, which generally float from 550 to 650 fathoms high.

The height of the plain of the Castiles has an evident effect on its temperature. We are astonished at not finding oranges in the open air under the same latitude as that of Tarentum, part of Calabria, Thessaly, and Asia Minor; but the mean temperature of Madrid is very little superior to that of Marseilles, Paris, and Berlin, and is nearly the same with that of Genoa and Rome. The following table shews the mean temperature at Madrid and at Rome, during the first nine months of the years 1793 and 1807.

Thus, the mean temperature at Madrid appears to be 59° of Fahrenheit, while that of the coasts of Spain, from the 41° to the 36° of Lat. is between 63° and 68° of Fahrenheit. In the former climate we find that orange trees will not flourish in perfection, while in the latter we see banana trees, heliconias, and even sugar canes, growing in situations that are sheltered from the cold winds.

Spain presents few species of animals that are not found in the other parts of southern Europe. Among the quadrupeds, we may remark, as peculiar to Spain, the genet (Genetta genetta). The bear is found in several parts of the great Pyrenean chain, especially on some of the mountains of Aragon, as well as those of Ocar and Reynosa in Old Castile. Wolves are met with in all the higher and mountainous parts of the country, and wild boars on the mountains of Navarre, on the Pin, and the Sierra de Carascoy, in the kingdom of Valencia. The roebuck is found on some of the mountains of Navarre, and the lynx and the ibex on those of Cuenca in New Castile, in the valleys of Auna and Gistau, as well as in the Pyrenees. The glory of Spanish zoology is the horse, for which this kingdom has been famous in all ages. The Spanish horses.

The climate of Spain is as delightful as that of any part of Europe; and though at certain seasons of the year the eastern coast is subject to excessive heat and drought, and the north-western to almost perpetual rains, the temperature is in general mild, and the air salubrious.

The climate of Spain has been admirably depicted by M. A. de Humboldt; and we shall here present to our readers the substance of his remarks, as they are related by De Laborde, in his View of Spain.

No country of Europe presents a configuration so singular as Spain. It is this extraordinary form which accounts for the dryness of the soil in the interior of the Castiles, for the power of evaporation, the want of rivers, and that difference of temperature which is observable between Madrid and Naples, two towns situated under the same degree of latitude.

The interior of Spain is, as we have seen, an elevated plain, which is higher than any of the same kind in Europe, occupying so large an extent of country. The mean height of the barometer at Madrid is 26 inches. It is therefore 4 inches lower than the mean height of the mercury at the level of the ocean. This is the difference of the pressure of the atmosphere that is experienced by all bodies exposed to the air at Madrid, and at Cadiz and Bordeaux. At Madrid the barometer falls as low as 25 inches 6 lines, and sometimes even lower.

The following is a table of the variations in the height of the barometer during the first nine months of the year 1793.

Spain has long been celebrated for the riches of its mineral kingdom, and it may still be considered as the Mexico and Peru of Europe. There are few metals which may not be found in this kingdom; and, till the discovery of America put the Spaniards in possession of mines which far surpass their own in produce, the gold and silver mines of Spain were thought to be nearly the richest in the world. At present, no gold mines are wrought, but grains of that metal are found disseminated in ferruginous quartz, forming a vein that passes through a mountain near the village of San Idefonso in Old Castile. Spannels of gold are found intermixed with emery, in a mine near Alover in Estremadura, and in the territory of Molina in Aragon; and this metal is occasionally found in the sand of two rivers; the Agnera, in the kingdom of Leon, which rises from the mountains of Xalamo, and the Tagus in New Castile, especially in the vicinity of Toledo.

Silver is much more abundant, but most of its mines have also been abandoned. We believe the only silver mine now in work is that of the Sierra de Guadalupe, near the village of Logroño, where the silver is found mixed with micaceous schistus. The most remarkable silver mines formerly worked are those of Albroval del Campo; of Zalamea on the road to Alover in Estremadura; of Almazon near Carthage; three in the Sierra Morena, about a league from Guadalcañal, in the kingdom of Seville, and another about two leagues from Linarex, in the kingdom of Jaén. This last mine was well known both to the Carthaginians and the Romans; while Spain was under the dominion of the former it belonged to Himilea, the wife of Asdrubal. After having been long abandoned, it was again wrought in the 17th century, when a vein of ore five feet in diameter was discovered; at present, however, it is no longer in a state of activity.

Mines of copper are found near Pampeluna in Navarre, near Salva Tierra in Alava; near Escaray, and at the foot of the mountains of Guadarrama in Old Castile; near Lora in Murcia; near the Churriana of the Val de Christo in Valencia; in the Sierra de Guadalupe in Estremadura; in the mountains near Cordova; near Riónto, and at la Canada de los Conejos in Seville.
in the district of Albuladui in Granada, and near Le- 

TORTOSA IN CATALONIA; AT ZAMA, BENAFAQES, AND PLAN IN 

Aragon; near Logrosen and Alocser in Extremadura; 

in the mountain Guadarrama in Old Castile; near los 

Alumbres and Lorca in Murcia; at Alcaniz and Con- 

stantia in Seville, and at the district of Linarex in 

Jaen.

The mines of iron are abundant, and need not be 

enumerated. Of antimony there are two mines, both 
in the district of La Mancha. One of these is at Aten- 
dia, near Almodovar; the other at the foot of the Sierras 

Morena. There is only one mine of coal, viz. in the 
province of Aragon, found in the valley of Geston. 

There are two mines of cinnabar in Valencia; one about 
two leagues from Alicante in the limestone mountains 
of Alcoray; the other between Valencia and San Felipe; 

and two others in the same province, that produce native 
mercury, but none of these are worked. The most a- 

bundant mine of mercury and cinnabar united is in the 
district of La Mancha, on the borders of Cordova. It 
is situated in a hill of sandstone which rests on slate. 
The whole length of the hill is traversed by two principal 
veins, both of which were wrought by the Romans. The 
whole of this mine was lately wrought by the agents 
of the king, and its produce was very abundant.

Plumbago is found in a thick vein intermixed with 
feldspar, about a league from the village of Real Mon- 

astico, in the kingdom of Seville. Mines of sulphur 
occur, both in Aragon and Murcia; yet it has been found 
in the district of Old Colmenar, in Old Castile; and 

there is good evidence of the presence of coal at several 

places in Catalonia, in the Asturias, New Castile, and 

Aragon; but it is said that no coal mines have as yet 
been opened.

The marbles of Spain are very numerous and valuable. 

A black marble, veined with white, is procured near 
Barcelona; many different marbles occur near Tortosa. 

Near the town of Molina, in Aragon, is found a gran- 

ular marble spotted with red, yellow, and white. At 
the village of Salines, in the district of Guipuzcoa, is a 

beautiful blue pyritical marble, containing marine shells.

From Monte Serrall, near Segorbe, in the province of 
Valencia, are procured several fine marbles, which were 

held in great estimation even by the Romans. The pro- 

vince of Granada, however, contains more valuable va-

rieties of this beautiful mineral than all the rest of Spain; 

of these some of the principal are the following. A 
pure white statuary marble, of which the whole moun-
tain of Filabra, near Almeria, is composed; a flesh-co- 
loured marble from a mountain near Antequera; an 
exquisitely beautiful wax-coloured alabaster, from the 

vicinity of the city of Granada; and a finely veined 
marble from the Sierra Nevada.

Of the Spanish mineral waters the following are the 
most celebrated. The principal cold springs are, a he- 
ptic water in the town of Buron, in Valencia; a carbo-
nated water at Geiona, in Catalonia; a saline purgua-
tive water at Vacia-Madrid, three leagues from the ca-
cital, and another of a similar nature near Toledo.

The principal hot springs are, the baths of Abu Zel- 

ena, at Javal-Cohol, near Baza; a hepatic spring used for 
bathing near Alhama de Granada; another near 

Almeria, in the province of Granada, to which are at- 
tached both bathing and vapour baths: all these were 
discovered, or at least brought into general use, by the 

Moors. A very copious hot spring near Merida, in 

Extremadura, made use of by the Romans. The Cala- 
de Bonar, in the neighbourhood of Leon, a spring of 
tepid water frequented by the Romans, and still exhi-

bitiong the ruins of baths and ancient inscriptions. 
A very hot spring near Orense, in Galicia. A spring at 

Alhama, near Calatayud, in Aragon, formerly much 
frequented, but now in a state of neglect. The Fuente 
de Buzot, near Alciant, a saline spring of the tempera-
ture of 125° Fahr. Heat. A very copious and hot 
spring at Archena, near Murcia, where still remain the 

ruins of Roman and Moorish baths. A hepatic spring 
near Arnedillo, in Old Castile.

Among the natural curiosities of Spain, we may particu-
larize the mountain of Montserrat in Catalonia (see curiosities. 

MONTSErrAT); the insulated hill of rock salt near the 
town of Cardona, in Catalonia (see GEOLOGY, No 102); the 
salt-sea lake contained within a cave, in the 
neighbourhood of the Cava Perella, in the island of 
Minorca; the stalactite cave called St Michael's, on 
the west side of the rock of Gibraltar, and the river 
Guadiana, which appears and disappears several times 
in the course of its progress to the sea.

The various groups of islands that are subject to Spain 

have long been distinguished by particular names. Thus islands. 

Majorca, Minorca, Cabrera and Dragonera, were called by the 

ancestors Inisde Balaures, and are still named the 

Balearic Islands; while Iviça and Ventemortura form a 
lesser group, denominated the Pitiusic Islands. Of these 

islands, the latter were taken possession of by the Car-
thaginians nearly 700 years before the Christian era; 

and about 200 years after that enterprising people made 
themselves masters of the Balearic Islands. After the fall 

of Carthage, all these islands long maintained a state of 

piratical independence, and only Majorca was ever 

completely subject to the Romans. In the time of Augustus 
we are told that the Balearic Islands were so infested 

with rabbits, that the inhabitants sent deputies to Rome 
for assistance to destroy these formidable invaders of their 
plntations. In the year 426 of the Christian era, these 
islands came into the possession of the Vandals, from 

whom they were taken at the end of the 8th century 

by the African Moors. At the beginning of the 9th 

century they were seized on by a fleet sent into the Med- 
itteranean by Charlemagne; but they were soon after 

reconquered by the Moors, who maintained the sowe- 

regnity in these islands till, in 1228, they were finally 
dispossessed by Don James grandson of Alphonso II, 

king of Aragon.

Though Spain appears to have been known to the Natas 

of Phcenicians nearly 1000 years before the birth of Christ, 

it seems to have been little regarded by the Greeks till 

after the period when Herodotus composed his history. 

Some part of this country was probably the Tarshish of 

Scripture, from which the Phcenicians imported gold, 
silver, and other precious commodities into Juden. 

When the Greeks had establised a colony at Marseilles, 

they must have been well acquainted with at least the 
northern part of this peninsula, to which they gave the 

names of Iberia and Celtiberia, from two nations who 
then inhabited the country, and of Hesperia, from its 

extreme situation in the west of the then known world. 
The name Hispania, from which its modern appellation
is derived, was bestowed on it by the Romans; but the etymology of this name is uncertain.

The Aborigines of Spain were doubtless a Celtic tribe, which probably passed into this peninsula from the adjoining continent of Gaul, though at a very early period they appear to have been mixed with a colony of Mauritanis, or Moors, from the coast of Africa. The Celtic inhabitants, or Celtiberi, seem to have possessed the northeastern part of the peninsula, while the Mauritanis occupied the southern and south-western districts.

Nothing certain is known respecting the early state of Spain, till the commencement of the first Punic war between the Romans and the Carthaginians, in the middle of the third century before Christ. Not long before this date, probably at the beginning of the century, the latter people had possessed themselves of Catalonia, when their general Hamilcar Barca is said to have founded the city of Barcino, the modern Barcelona. The Carthaginian colony, however, seems to have been rather a mercantile than a warlike settlement, and the Celtiberi were more the allies than the subjects of their African neighbours. Of the contests carried on between the Carthaginians and the Romans, till the final subjugation of the former, and the consequent occupation of all their territories by the Roman republic, we have given an account under the articles CARTHAGE and ROME. We shall here briefly consider the state of Spain at the time of its occupation by the Romans, and relate the events to which that occupation gave rise, and which are less connected with the more immediate transactions of the Punic wars.

At the time of the Roman conquest, Spain, though prodigious quantities of silver had been carried out of it by the Carthaginians and Tyrians, was yet a very rich country. In the most ancient times, indeed, its riches are said to have exceeded what is related of the most wealthy country in America. Aristotle assures us, that when the Phenicians first arrived in Spain, they exchanged their naval commodities for such immense quantities of silver, that their ships could neither contain nor sustain its load, though they used it for ballast, and made their anchors and other implements of silver. When the Carthaginians first came to Spain, they found the quantity of silver nothing lesseued, since the inhabitants at that time made all their utensils, and even mangers, of that precious metal. In the time of the Romans this amazing plenty was very much diminished; however, their gleaning were by no means despicable, since in the space of nine years they carried off 111,542 pounds of silver, and 4959 of gold, besides an immense quantity of coin and other things of value (A). The Spaniards were always remarkable for their bravery, and some of Hannibal's best troops were brought from thence; but as the Romans penetrated farther into the country than the Carthaginians had done, they met with nations whose love of liberty was equal to their valour, and whom the whole strength of their empire was scarcely able to subdue. Of these the most formidable were the Numantines, Cantabrians, and Asturians.

In the time of the third Punic war, one Viriathus, a celebrated hunter, and afterwards the captain of a gang of banditti, took upon him the command of some natives against whom we had been in alliance with Carthage, and ventured to oppose the Roman power in that part of Spain called Lusitania, now Portugal. The praetor named Vetilius, who commanded in those parts marched against him with 10,000 men; but was defeated and killed, with the loss of 4,000 of his troops. The Romans immediately dispatched another praetor with 10,000 foot and 1,700 horse; but Viriathus having first cut off a detachment of 4,000 of them, engaged the rest in a pitched battle; and having entirely defeated them, reduced great part of the country. Another praetor, who was sent with a new army, met with the same fate; so that, after the destruction of Carthage, the Romans thought proper to send a consul named Quintus Fabius, who defeated the Lusitanians in several battles, and regained two important places which had long been in the hands of the rebels. After the expiration of Fabius's consulate, Viriathus continued the war with his usual success, till the senate thought proper to send against him the consuls Q. Cecilius Metellus, an officer of great honour and experience. With him Viriathus did not choose to venture a pitched battle, but contented himself with acting on the defensive; in consequence of which the Romans recovered a great many cities, and the whole of Tarracconian Spain was obliged to submit to their yoke. The other consul, named Servilius, did not meet with the same success; his army was defeated in the field, and his camp was nearly taken by Viriathus. Notwithstanding the good fortune of Metellus, however, he could not withstand the intrigues of his countrymen against him, and he was not allowed to finish the war he had begun with so much success. In resentment for this he took all imaginable pains to weaken the army under his command: he disbanded the flower of his troops, exhausted the magazines, let the elephants die, broke in pieces the arrows which had been provided for the Cretan archers, and threw them into a river. Yet, after all, the army which he gave up to his successor Q. Pompeius, consisting of 30,000 foot and 2,000 horse, was sufficient to have crushed Viriathus if the general had known how to use it. But, instead of opposing Viriathus with success, the imprudent consul procured much more formidable enemies. The Termantines and Numantines, who had hitherto kept themselves independent, offered very advantageous terms of peace and alliance with Rome; but Pompeius insisted on their delivering up their arms. Upon this war was immediately commenced. The consul with great confidence invested Numantia; but being repulsed with considerable loss, he sat down before Ternantia, where he was attended with still worse success. The very first day, the Termantines killed 700 of his legionaries; took a great convoy which was coming to

(A) In this account we must allow something for the exaggerations of fabulous historians. There is no doubt, however, that Spain was at this time immensely rich, and if we may believe Strabo, there was then a mine near Carthage which yielded every day 25,000 drams of silver, or about 300,000l. per annum.
SPAIN.

12 The Romans surrounded all sides, and forced to conclude a peace with Viriathus.

15 Viriathus treacherously murdered.

16 The Romans defeated by the Numantines.

The Roman camp; and having defeated a considerable body of their horse, pushed them from post to post till they came to the edge of a precipice, where they all tumbled down, and were dashed to pieces. In the mean time Servilius, who had been continued in his command with the title of proconsul, managed matters so ill, that Viriathus surrounded him on all sides, and obliged him to sue for peace. The terms offered to the Romans were very moderate; being only that Viriathus should keep the country he at that time possessed, and the Romans remain masters of all the rest. This peace the proconsul was very glad to sign, and afterwards procured its ratification by the senate and people of Rome.

The next year Q. Pompeius was continued in his command against the Numantines in farther Spain, while Q. Servilius Caepio, the new consul, had for his province Hither Spain, where Viriathus had established his new state. Pompeius undertook to reduce Numantia by turning aside the stream of the Durus, now the Douro, by which it was supplied with water; but, in attempting this, such numbers of his men were cut off, that, finding himself unable to contend with the enemy, he was glad to make peace with them on much worse terms than they had offered of their own accord. The peace, however, was ratified at Rome; but in the mean time Caepio, desirous of showing his prowess against the renowned Viriathus, prevailed on the Romans to declare war against him without any provocation. As Caepio commanded an army greatly superior to the Lusitanians, Viriathus thought proper to sue for peace; but finding that Caepio would be satisfied with nothing less than a surrender at discretion, he resolved to stand his ground. In the mean time, the latter having bribed some of the intimate companions of Viriathus to murder him in his sleep, he by that infamous method put an end to a war which had lasted 14 years, very little to the honour of the republic.

After the death of Viriathus, the Romans with like treachery ordered their new consul Popilius to break the treaty with the Numantines. His infamous conduct met with the reward it deserved; the Numantines sallied out, put the whole Roman army to flight with such slaughter, that they were in no condition to act during the whole campaign. Mancinio, who succeeded Popilius, met with still worse success; his great army, consisting of 30,000 men, was utterly defeated by 4000 Numantines, and 20,000 of them killed in the pursuit. The remaining 10,000, with their general, were pent up by the Numantines in such a manner that they could neither advance nor retreat, and would certainly have been all put to the sword or made prisoners, had not the Numantines, with a generosity which their enemies never possessed, offered to let them depart upon condition that a treaty should be concluded with them upon very moderate terms. This the consul very willingly promised, but found himself unable to perform. On the contrary, the people not satisfied with declaring his treaty null and void, ordered him to be delivered up to the Numantines. The latter refused to accept him, unless he be led along with him the 10,000 men whom they had relieved as before related. At last, after the consul had remained a whole day before the city, his successor Furius, thinking this a sufficient recompense to the Numantines for breaking the treaty, ordered him to be received again into the camp. However, Furius did not choose to engage with such a desperate and resolute enemy as the Numantines had showed themselves; and the war with them was discontinued till the year 133 B.C., when Scipio Aemilianus, the destroyer of Carthage, was sent against them. Against this renowned commander the Numantines with all their valor were not able to contend. Scipio, having with the utmost care introduced strict discipline among his troops, and reformed the abuses which his predecessors had suffered in their armies, by degrees brought the Romans to face their enemies, which at their arrival they had absolutely refused to do. Having then ravaged all the country round the town, it was soon blocked up on all sides, and the inhabitants began to feel the want of provisions. At last they resolved to make one desperate attempt for their liberty, and either to break through their enemies, or perish in the attempt. With this view they marched out in good order by two gates, and fell upon the works of the Romans with the utmost fury. The Numantines, unable to stand this desperate shock, were on the point of yielding, when Scipio, hastening to the places attacked, with no fewer than 20,000 men, the unhappy Numantines were at last driven into the city, where they sustained for a little longer the miseries of famine. Finding at last, however, that it was altogether impossible to hold out, it was resolved by the majority to submit to the pleasure of the Roman commander. But this resolution was not universally approved. Miserable Many shut themselves up in their houses, and died of the hunger, while even those who had agreed to surrender repented their offer, and setting fire to their houses, perished in the flames with their wives and children, so that not a single Numantine was left alive to grace the triumph of the conqueror of Carthage.

After the destruction of Numantia, the whole of Spain submitted to the Roman yoke; and nothing remarkable happened till the times of the Cimbri, when a preposterous army was cut off in Spain by the Lusitanians. From this time nothing remarkable occurs in the history of Spain till the civil war between Marius and Sylla. The latter having crushed the Marian faction, as related under the article ROME, proscribed all those that had sided against him, whom he could not immediately destroy.

Among these was Sertorius, a man of consummate valour and experience in war. He had been appointed pretor of Spain by Marius; and upon the overthrow of Marius, retired to that province. Sylla no sooner heard of his arrival in that country, that he sent thither one Caius Annius with a powerful army to drive him out. As Sertorius had but few troops along with him, he dispatched one Julius Salinator with a body of 6000 men to guard the passes of the Pyrenees, and to prevent Annius from entering the country. But Salinator having been treacherously murdered by assassins hired by Annius for that purpose, he no longer met with any obstacle; and Sertorius was obliged to embark for the coast of Africa with 3000 men, being all out, and he had now remaining. With these he landed in Mauretania; but as his men were struggling carelessly about, many hardy great numbers of them were cut off by the Barbarian ships. This new misfortune obliged Sertorius to re-embark for Spain; but finding the whole coast lined with the troops of Annius, he put to sea again, not knowing what course to steer. In this new voyage he met with a small fleet of Cilician pirates; and having prevailed with
with them to join him, he made a descent on the coast of Iviça, overpowered the garrison left there by Annius, and gained a considerable booty. On the news of this victory Annius set sail for Iviça, with a considerable squadron, having 5000 land forces on board. Sertorius, not intimidated by the superiority of the enemy, prepared to give them battle. But a violent storm arising, most of the ships were driven on shore and dashed to pieces, Sertorius himself with great difficulty escaping with the small remains of his fleet. For some time he continued in great danger, being prevented from putting to sea by the fury of the waves, and from landing, by the enemy; at last, the storm abating, he passed the straits of Cadiz, now Gibraltar, and landed near the mouth of the river Baiteis. Here he met with some seamen newly arrived from the Atlantic or Fortunate Islands; and was so charmed with the account which they gave him of those happy regions, that he resolved to retire thither to spend the rest of his life in quiet and happiness. But having communicated this design to the Cilician pirates, they immediately abandoned him, and set sail for Africa, with an intention to assist one of the barbarous kings against his subjects who had rebelled. Upon this Sertorius sailed thither also, but took the opposite side; and having defeated the king named Ascalis, obliged him to shut himself up in the city of Tingis, now Tangier, which he closely besieged. But in the mean time Pacianus, who had been sent by Sylla to assist the king, advanced with a considerable army against Sertorius. Upon this the latter, leaving part of his forces before the city, marched with the rest to meet Pacianus, whose army, though greatly superior to his own in number, he entirely defeated; killed the general, and took all his forces prisoners. The fame of this victory soon reached Spain; and the Lusitanians, being threatened with a new war from Annius, invited Sertorius to head their armies. With this request he readily complied, and soon became very formidable to the Romans. Titus Didius, governor of that part of Spain called Batica, first entered the lists with him; but he being defeated, Sylla next dispatched Metellus, reckoned one of the best commanders in Rome, to stop the progress of this new enemy. But Metellus, notwithstanding all his experience, knew not how to act against Sertorius, who was continually changing his station, putting his army into new forms, and contriving new stratagems. On his arrival he sent for L. Domitius, then praetor of Hither Spain, to his assistance; but Sertorius being informed of his march, detached Hirtuleus, or Herculeus, hisuestor, against him, who gave him a total overthrow. Metellus then dispatched Lucius Lobius praetor of Narbonne Gaul against Hirtuleus; but he met with no better success, being utterly defeated, and his lieutenant-general killed.

The fame of these victories brought to the camp of Sertorius such a number of illustrious Roman citizens of the Marian faction, that he formed a design of erecting Lusitania into a republic in opposition to that of Rome. Sylla was continually sending fresh supplies to Metellus; but Sertorius with a handful of men, accustomed to range about the mountains, to endure hunger and thirst, and live exposed to the inclemencies of the weather, so harassed the Roman army, that Metellus himself began to be quite discouraged. At last, Sertorius hearing that Metellus had spoken disrespectfully of his courage, challenged his antagonist to end the war by single combat; but Metellus very prudently declined the combat, as being advanced in years; yet this refusal brought upon him the contempt of the unthinking multitude, upon which Metellus resolved to retrieve his reputation by some signal exploit; and therefore laid siege to Lacosbriga, a considerable city in those parts. This he hoped to reduce in two days, as siege of Lacosbriga was but one well in the place; but Sertorius having previously removed all those who could be of no service during the siege, and conveyed 6000 skins full of water into the city, Metellus continued a long time before it without making any impression. At last, his provisions being almost spent, he sent out Aquinas at the head of 6000 men to procure a new supply; but Sertorius falling unexpectedly upon them, cut in pieces or took the whole detachment; the commander himself being the only man who escaped to carry the news of the disaster: upon which Metellus was obliged to raise the siege with disgrace.

And now Sertorius, having gained some intervals of ease in consequence of the many advantages he had obtained over the Romans, began to civilize his new subjects. Their savage and furious manner of fighting he changed for the regular order and discipline of a well-formed army; he bestowed liberally upon them gold and silver to adorn their arms, and by conversing familiarly with them, prevailed with them to lay aside their own dress for the Roman toga. He sent for all the children of the principal people, and placed them in the great city of Osca, now Huesca, in the kingdom of Aragon, where he appointed them masters to instruct them in the Roman and Greek learning, that they might, as he pretended, be capable of sharing with him the government of the republic. Thus he made them really hostages for the good behaviour of their parents; however, the latter were greatly pleased with the care he took of their children, and all Lusitania were in the highest degree attached to their new sovereign. This attachment he took care to heighten by the power of superstition; for having procured a young hind of a milk-white colour, he made it so tame that it followed him wherever he went; and Sertorius gave out to the ignorant multitude, that this hind was inspired by Diana, and revealed to him the designs of his enemies, of which he always took care to be well informed by the great number of spies whom he employed.

While Sertorius was thus employed in establishing his authority, the republic of Rome, alarmed at his success, resolved to crush him at all events. Sylla was now dead, and all the eminent generals in Rome solicited this honourable though dangerous employment. After much debate a decree was passed in favour of Pompey the Great, but without recalling Metellus. In the mean time, the troops of one Perpenna, or Perpenna, had in spite of all that their general could do, abandoned him, and taken the oath of allegiance to Sertorius. This was a most signal advantage to Sertorius; for Perpenna commanded an army of 33,000 men, and had come into Spain with a design to settle there as Sertorius had done; but as he was descended from one of the first families of Rome, he thought it below his dignity to serve under any general, however eminent he might be. But the troops of Perpenna were of a different opinion; and therefore declaring that they would serve
SPAIN.

Serve note but a general who could defend himself, they to a man joined Sertorius; upon which Perperna himself, finding he could do no better, consented to serve also as a subaltern.

On the arrival of Pompey in Spain, several of the cities which had hitherto continued faithful to Sertorius began to waver: upon which the latter resolved, by some signal exploit, to convince them that Pompey could no more screen them from his resentment than Metellus. With this view he laid siege to Lauron, now Lirias, a place of considerable strength. Pompey, not doubting but he should be able to raise the siege, marshaled quite up to the enemy’s lines, and found means to inform the garrison that those who besieged them were themselves besieged, and would soon be obliged to retire with loss and disgrace. On hearing this message, “I will teach Sylla’s disciple (said Sertorius), that it is the duty of a general to look behind as well as before him.” Having thus spoken, he sent orders to a detachment of 6000 men, who lay concealed among the mountains, to come down and fall upon his rear if he should offer to force the lines. Pompey, surprised at their sudden appearance, durst not stir out of his camp; and in the mean time the besieged, despairing of relief, surrendered at discretion; upon which Sertorius granted them their lives and liberty, but reduced their city to ashes.

While Sertorius was thus successfully contending with Pompey, his questor Hirtuleius was entirely defeated by Metellus, with the loss of 40,000 men; upon which Sertorius advanced with the utmost expedition to the banks of the Sueco in Tarraconam Spain, with a design to attack Pompey before he could be joined by Metellus. Pompey, on his part, did not decline the combat; but, fearing that Metellus might share the glory of the victory, advanced with the greatest expedition. Sertorius put off the battle till towards the evening; Pompey, though he knew that the night would prove disadvantageous to him, whether victorious or vanquished, because his troops were unacquainted with the country, resolved to venture an engagement, especially as he feared that Metellus might arrive in the mean time, and rob him of part of the glory of conquering so great a commander. Pompey, who commanded his own right wing, soon obliged Perperna, who commanded Sertorius’s left, to give way. Hereupon Sertorius himself, taking upon him the command of that wing, brought back the fugitives to the charge, and obliged Pompey to fly in his turn. In his flight he was overtaken by a gigantic African, who had already lifted up his hand to discharge a blow at him with his broadsword; but Pompey prevented him by cutting off his right hand at one blow. As he still continued his flight, he was wounded and thrown from his horse; so that he would certainly have been taken prisoner, had not the Africans who pursued him quarreled about the rich furniture of his horse. This gave an opportunity to the general to make his escape; so that at length he reached his camp with much difficulty. But in the mean time Afranius, who commanded the left wing of the Roman army, had entirely defeated the wing which Sertorius had left, and even pursued them so close that he entered the camp along with them. Sertorius, returning suddenly, found the Romans busy in plundering the tents; when taking advan-

tage of their situation, he drove them out with great slaughter, and took the camp. Next day he offered battle a second time to Pompey: but Metellus then coming up with all his forces, he thought proper to decline an engagement with both commanders. In a few days, however, Pompey and Metellus agreed to attack the camp of Sertorius. The event was similar to that of the former battle; Metellus defeated Perperna, and Sertorius routed Pompey. Being then informed of Perperna’s misfortune, he hastened to his relief; rallied the fugitives, and repulsed Metellus in his turn, wounded him with his lance, and would certainly have killed him, had not the Romans, ashamed to leave their general in distress, hastened to his assistance, and renewed the fight with great fury. At last Sertorius was obliged to quit the field, and retire to the mountains. Pompey and Metellus hastened to besiege him; but while and Metellus were forming their camp, Sertorius broke through their lines, and escaped into Lusitania. Here he soon by Sertorius—such a powerful army, that the Roman generals, roused with their united forces, did not think proper to venture an engagement with him. They could not, however, resist the perpetual attacks of Sertorius, who now drove them from place to place, till he obliged them to separate; the one went into Gaul, and the other to the foot of the Pyrenees.

Thus did this celebrated commander triumph over all the power of the Romans; and there is little doubt but he would have continued to make head against all the other generals whom the republic could have sent, had he not been assassinated at an entertainment by the infamous treachery of Perperna, in 73 B.C. after he had made head against the Roman forces for almost 10 years. Pompey was no sooner informed of his death, than, without waiting for any new succours, he marched against the traitor, whom he easily defeated and took prisoner; and having caused him to be executed, thus put an end, with very little Glory, to a most dangerous war.

Many of the Spanish nations, however, still continued to bear the Roman yoke with great impatience; and as the civil wars which took place first between Julius Caesar and Pompey, and afterwards between Octavianus and Antony, diverted the attention of the republic from Spain, by the time that Augustus had become sole master of the Roman empire, they were again in a condition to assert their liberty. The Cantabrians and Asturians were the most powerful and valiant nations at that time in Spain; but after incredible efforts, they were obliged to lay down their arms, or rather were almost exterminated by Agrippa, as related under these articles.

When the Romans first became masters of the western peninsula of Europe, to which, as we have said, they der the name of Hispam, it was divided into two provinces, called Citerior and Ulterior, which were governed, sometimes by praetors, and sometimes by consuls. In the distribution of the empire by Augustus, Hispania Citerior contained the modern provinces of Galicia, the Asturias, Biscay, Navarre, Leon, the two Castiles, Aragon, Catalonia, Murcia, and Valencia; and was designated Provincia Tarraconensis, from the city of Tarragona in Catalonia, which was then the seat of government. Hispania Ulterior was subdivided into Bética, including the provinces now called Granada and
Spain, and Andalusia; and Lusitania, comprehending the greatest part of Estremadura, and the modern kingdom of Portugal. The province called Tarraconensis was then inhabited by the following tribes, viz. the Ausetani, occupying the sea-coast, at the north-east, between the Ter and the Lobregat, and having for their capital Germa; the Cerdani, inhabiting the district of Cerdana, at the foot of the Pyrenees, whose capital was Julia, the modern Livia; the Valetani, occupying the sea-coast between the rivers Ter and Lobregat, in the immediate neighbourhood of the Ausetani, and whose capital was Barcelona; the Costeri to the left of the mouth of the Ebro, with Tarragona for their capital; the Locetani, on the left bank of the river Siscor; the Illegetes, extending from that river to the small stream Gallego, which joins the Ebro near Zaragoza, whose capital was Lerida; the Jucetani in the northern extremity of Aragon, having their seat of government at Jaca; the Vascones in Navarre, and the Vardini in the modern Guipuzcoa. These nations occupied the southern and eastern parts of the province. The northern was possessed by the Caristi, the Ostregones, both in Biscay; the Cantabri, cantoned near the source of the Ebro, and along the bay of Biscay; the Astures in Asturias and part of Leon; the Catalani in Galicia; the Vascones along the Douro; the Arbasni in Old Castile; the Celtiberi, between the Ebro and the source of the Tagus, and many others of inferior note.

Lusitania was held by three principal tribes, the Lusitani, occupying the greater part of the province, and having for their capital the modern Lisbon; the Vettiones and the Celtici.

Bética was inhabited by the Tardeutani, the Turduli, the Bastiani, and the Bastuli. All these districts, with their principal towns, are minutely treated of by Dr Playfair, in the first volume of his geography.

When incorporated with the Roman empire, Spain partook of its tranquillity, and received in exchange for her liberty, at least wise laws and a mild government. If she could not prevent herself from falling under the dominion of the masters of the world, she was at least the most powerful, the richest, and the happiest province of their empire. COLUMELLA has left us an interesting account of her agriculture under the first emperors. The tradition of her ancient population is probably exaggerated, but the ruins of several towns prove it to have been considerable. It was increased by a great many Roman families after the conquest; several legions were established in Spain; 25 colonies were distributed in the most fertile parts of the country, and intermarried with the inhabitants. After a while the Spaniards, seeing in their masters only countrymen, were the first to solicit the rights of Roman citizens, by which they were completely consolidated. Some municipal towns went so far as to desire permission to take the title of colonies, though in the change they lost their independence, nearly in the same manner as certain proprietors of lands under the feudal system converted their domains into fiefs, in order to enjoy the honours attached to them. The government was, in general, milder in Spain than in the other Roman provinces. The administration was carried on in the towns by magistrates named by themselves, and the different provinces were under the superintendance of praetors, proconsuls, and legates or deputies, according to the different eras of the Roman empire; those in their respective departments took care of all the works of public utility, the aqueducts, baths, circuses, and highways, whose magnificent ruins are still existing; but they were principally employed in collecting the revenues of the state, which were singularly analogous to those of the present times. They principally arose from dues, fines, or alienations of property, and the produce of the mines. Spain at that time drew from her own mines the same riches she now draws from the new world, and they were distributed in nearly the same manner. One part belonged to the state, and the other to the inhabitants of the country, who paid a certain duty on the metals which they procured from the mines. Their returns went on increasing, and depended entirely on the number of hands which could be devoted to work in the mines. An employment, so laborious, however, which required a numerous population, tended to diminish that population by the excessive fatigue which it occasioned. Agriculture also suffered by the accumulation of estates in the hands of a few wealthy landholders. By the little attention paid to it by the proprietors, and by the defects inseparable from the system of cultivation by means of slaves, commerce and industry languished; and Spain, after having shared in the splendour of the Roman empire, was beginning to participate in its decline, when a new calamity, by completing her ruin, prepared her regeneration.

This calamity was the irruption of the northern hordes, which soon involved Spain in the general attack. This province was invaded first by the Franks, who in the third century had entered Gaul with a formidable force.

The Rhine, though dignified by the title of S LEGUARD of the Provinces, was an imperfect barrier against the daring spirit of enterprise with which the Franks were actuated. Their rapid devastations stretched from the river to the foot of the Pyrenees; nor were they stopped by those mountains. Spain, which had never dreaded, was unable to resist the inroads of the Germans. During 12 years, the greatest part of the reign of Galienus, that opulent country was the theatre of unequal and destructive hostilities. Tarragona, the flourishing capital of a peaceable province, was sacked and almost destroyed; and so late as the days of Orosius, who wrote in the 5th century, wretched cottages, scattered amidst the ruins of magnificent cities, still recorded the rage of the barbarians. When the exhausted country no longer supplied a variety of plunder, the Franks seized on some vessels, and retreated to Mauritania.

The situation of Spain, separated, on all sides, from the enemies of Rome, by the sea, by the mountains, and Sici, Van- by intermediate provinces, had secured the long tranquillity of that remote and sequestered country; and we may observe, as a sure symptom of domestic happiness, that, in a period of 400 years, Spain furnished very few materials to the history of the Roman empire. The footsteps of the Barbarians, who, in the reign of Galienus, had penetrated beyond the Pyrenees, were soon obliterated by the return of peace; and in the 4th century of the Christian era, the cities of Emerita or Merida, of Corduba, Seville, Bracara, and Tarragona, were numbered with the most illustrious of the Roman world.
SPAIN.

The various plenty of the animal, the vegetable, and the mineral kingdoms, was improved and manufactured by the skill of an industrious people; and the peculiar advantages of naval stores contributed to support an extensive and profitable trade. The arts and sciences flourished under the protection of the emperors; and if the character of the Spaniards was enfeebled by peace and servitude, the hostile approach of the Germans, who had spread terror and desolation from the Rhine to the Pyrenees, seemed to rekindle some sparks of military ardour. As long as the defence of the mountains was trusted to the hardy and faithful militia of the country, they successfully repelled the frequent attempts of the Barbarians. But no sooner had the national troops been compelled to resign their post to the Horian bands, in the service of Constantine, than the gates of Spain were treacherously betrayed to the public enemy, about ten months before the sack of Rome by the Goths. The consciousness of guilt, and the thirst of rapine, prompted the mercenary guards of the Pyrenees to desert their station; to invite the arms of the Suevi, the Vandals, and the Alani; and to swell the torrent which was poured with irresistible violence from the frontiers of Gaul to the sea of Africa. The misfortunes of Spain may be described in the language of its most eloquent historian, who has concisely expressed the passionate, and perhaps exaggerated, declamations of contemporary writers. "The irruption of these nations was followed by the most dreadful calamities; as the Barbarians exercised their indiscriminate cruelty on the fortunes of the Romans and the Spaniards; and ravaged with equal fury the cities and the open country. The progress of famine reduced the miserable inhabitants to feed on the flesh of their fellow creatures; and even the wild beasts, who multiplied, without control, in the desert, were exasperated, by the taste of blood, and the impatience of hunger, boldly to attack and devour their human prey. Pestilence soon appeared, the inseparable companion of famine; a large proportion of the people was swept away; and the groans of the dying excited only the envy of their surviving friends. At length the Barbarians satisfied with carnage and rapine, and afflicted by the contagious evil which they themselves had introduced, fixed their permanent seats in the depopulated country. The ancient Galicia, whose limits included the kingdom of Old Castile, was divided between the Suevi and the Vandals; the Alani were scattered over the provinces of Carthagecna and Lusitania, and from the Mediterranean to the Atlantic ocean; and the fruitful territory of Bética was allotted to the Silingi, another branch of the Vandalic nation. After regulating this partition, the conquerors contracted with their new subjects some reciprocal engagements of protection and obedience: the lands were again cultivated; and the towns and villages were again occupied by a captive people. The greatest part of the Spaniards was even disposed to prefer this new condition of poverty and barbarism, to the severe oppressions of the Roman government; yet there were many who still asserted their native freedom, and who refused, more especially in the mountains of Galicia, to submit to the barbarian yoke.*

* "Marcius de rub. Hist. ann. lib. v."

The important present of the heads of Jovinus and Sebastian, had provoked the friendship of Adolphus, and restored Gaul to the obedience of his brother Honorius. Peace was incompatible with the situation and temper of the king of the Goths. He readily accepted the proposal of turning his victorious arms against the barbarians of Spain; the troops of Constantius intercepted his communication with the sea-ports of Gaul, and gently pressed his march towards the Pyrenees. He passed the mountains, and surprised, in the name of the emperor, the city of Barcelona. The fondness of Adolphus for his Roman bride, Placidia, was not abated by time or possession; and the birth of a son, surnamed, from his illustrious gransire, Theodosius, appeared to fix him for ever in the interest of the republic. The loss of that infant, whose remains were deposited in a silver coffin in one of the churches near Barcelona, afflicted his parents; but the grief of the Gothic king was suspended by the labours of the field; and the course of his victories was soon interrupted by domestic treason. He had imprudently received into his service one of the followers of Sarus; a barbarian of a daring spirit, but of a diminutive stature; whose secret desire of revenging the death of his beloved patron, was continually irritated by the sarcasms of his insolent master. Adolphus was assassinated in the palace of Barcelona; the laws of the succession were violated by a tumultuous faction; and a stranger to the royal race, Singeric, the brother of Sarus himself, was seated on the Gothic throne. The first act of his reign was the inhuman murder of the six children of Adolphus, the issue of a former marriage, whom he tore, without pity, from the feeble arms of a venerable bishop. The unfortunate Placidia, instead of the respectful compassion, which she might have excited in the most savage breasts, was treated with cruel and wanton insult. The daughter of the emperor Theodosius, confounded among a crowd of vulgar captives, was compelled to march on foot above 12 miles, before the horse of a barbarian, the assassin of a husband whom Placidia loved and lamented.

But Placidia soon obtained the pleasure of revenge; conquered an indigent people against the tyrant, who was assassinated on the seventh day of his usurpation. After the death of Singeric, the free choice of the nation bestowed the Gothic sceptre on Wallia, whose warlike and ambitious temper appeared, in the beginning of his reign, extremely hostile to the republic. He marched, in arms, from Barcelona to the shores of the Atlantic ocean, which the ancients revered and dreaded as the boundary of the world. But when he reached the southern promontory of Spain, and, from the rock now covered by the fortress of Gibraltar, contemplated the neighbouring and fertile coast of Africa, Wallia resumed the designs of conquest, which had been interrupted by the death of Alaric. The winds and waves disappointed the enterprises of the Goths; and the minds of a superstitious people were deeply affected by the repeated disasters of storms and shipwrecks. In this disposition, the successor of Adolphus no longer refused to listen to a Roman ambassador, whose proposals were enforced by the real, or supposed, approach of a numerous army, under the conduct of the brave Constantius. A solemn treaty was stipulated and observed: Placidia was honourably restored to her brother; 600,000 measures of wheat were delivered to the hungry Goths; and Wallia engaged to draw his sword in the service of the empire. A bloody war was instantly excited among the barbarians of Spain; and the contending princes are said to have
Spain. have addressed their letters, their ambassadors, and their hostages, to the throne of the western emperor, exhorting him to remain a tranquil spectator of their contest; the events of which must be favourable to the Romans, by the mutual slaughter of their common enemies. The Spanish war was obstinately supported, during three campaigns, with desperate valour and various success; and the martial achievements of Wallia diffused through the empire the superior renown of the Gothic hero. He exterminated the Silingi, who had irretrievably ruined the elegant plenty of the province of Bocica. He slew in battle the king of the Alani; and the remains of those Scythian wanderers, who escaped from the field, instead of choosing a new leader humbly sought a refuge under the standard of the Vandals, with whom they were ever afterwards confounded. The Vandals themselves, and the Suevi, yielded to the efforts of the invincible Goths. The promiscuous multitude of barbarians, whose retreat had been intercepted, were driven into the mountains of Gallicia, where they still continued in a narrow compass, and on a barren soil, to exercise their domestic and implacable hostilities. In the pride of victory, Wallia was faithful to his engagements; he restored his Spanish conquests to the obedience of Honorianus; and the tyranny of the imperial officers soon reduced an oppressed people to regret the time of their barbarian servitude. While the event of the war was still doubtful, the first advantages obtained by the arms of Wallia, had encouraged the court of Ravenna to decree the honours of a triumph to their feeble sovereign. He entered Rome like the ancient conquerors of nations, and if the monuments of servile corruption had not long since met with the fate which they deserved, we should probably find that a crowd of poets, and orators, of magistrates and bishops, applauded the fortune, the wisdom, and the invincible courage of the emperor Honorianus.

An. 418. After the retreat of the Goths, the authority of Honorianus had obtained a precarious establishment in Spain; except only in the province of Gallicia, where the Suevi and the Vandals had fortified their camps, in mutual discord, and hostile independence. The Vandals prevailed; and their adversaries were besieged in the Nervanac hills, between Leon and Oviedo, till the approach of Count Asterius compelled, or rather provoked, the victorious barbarians to remove the scene of the war to the plains of Bocica. The rapid progress of the Vandals soon required a more effectual opposition; and the master-general Costinus marched against them with a numerous army of Romans and Goths. Vanquished in battle by an inferior enemy, Costinus fled with dishonour to Tarragona; and this memorable defeat, which has been represented as the punishment, was most probably the effect, of his rash presumption. Seville and Carthagea became the reward, or rather the prey, of the ferocious conquerors; and the vessels which they found in the harbour of Carthagea, might easily transport them to the isles of Majorca and Minorca, where the Spanish fugitives, as in a secure recess, had vainly concealed their families and their fortunes. The experience of navigation, and perhaps the prospect of Africa, encouraged the Vandals to accept the invitation which they received from Count Boniface; and the death of Gonderic served only to forward and animate the bold enterprise. In the room of a prince, not conspicuous for any superior powers of the mind or body, they acquired his bastard brother, the terrible Genseric; a name which, in the destruction of the Roman empire, has deserved an equal rank with the names of Alaric and Attila. Almost in the moment of his departure he was informed, that Hermannic, king of the Suevi, had presumed to ravage the Spanish territories, which he was resolved to abandon. Impatient of the insult, Genseric pursued the hasty retreat of the Suevi as far as Merida; precipitated the king and his army into the river Ana; and calmly returned to the sea shore, to embark his victorious troops. The vessels which transported the Vandals over the modern straits of Gibraltar, a channel only twelve miles in breadth, were furnished by the Spaniards, who anxiously wished their departure; and by the African general, who had implored their formidable assistance.

When Theodoric king of the Visigoths encouraged An. 456. Avitus to assume the purple, he offered his person and his force, as a faithful soldier of the republic. The exploits of Theodoric soon convinced the world, that he had not degenerated from the warlike virtues of his ancestors. After the establishment of the Goths in Aquitain, and the passage of the Vandals into Africa, the Suevi who had fixed their kingdom in Gallicia, aspired to the conquest of Spain, and threatened to extinguish the feeble remains of the Roman dominion. The provincials of Carthagea and Tarragona, afflicted by an hostile invasion, represented their injuries and their apprehensions. Count Fronto was dispatched, in the name of the emperor Avitus, with advantageous offers of peace and alliance; and Theodoric interposed his weighty mediation, to declare that, unless his brother-in-law, the king of the Suevi, immediately retired, he should be obliged to arm in the cause of justice and of Rome. “Tell him,” replied the haughty Rechiarus, “that I despise his friendship and his arms; but that I shall soon try, whether he will dare to expect my arrival under the walls of Toulouse.” Such a challenge urged Theodoric to prevent the bold designs of his enemy: He passed the Pyrenees at the head of the Visigoths; the Franks and Burgundians served under his standard; and though he professed himself the dutiful servant of Avitus, he privately stipulated, for himself and his successors, the absolute possession of his Spanish conquests. The two armies, or rather the two nations, encountered each other on the banks of the river Urgicucus, about 12 miles from Astorga; and the decisive victory of the Goths appeared for a while to have extirpated the name and kingdom of the Suevi. From the field of battle Theodoric advanced to Braga, their metropolis, which still retained the splendid vestiges of its ancient commerce and dignity. His entrance was not polluted with blood, and the Goths respected the chastity of their female captives, more especially of the consecrated virgins; but the greatest part of the clergy and people were made slaves, and even the churches and altars were confounded in the universal pillage. The unfortunate king of the Suevi had escaped to one of the ports of the ocean; but the obstinacy of the winds opposed his flight: he was delivered to his implacable rival; and Rechiarus, who neither desired nor expected mercy, received, with many constancy, the death which he would probably have inflicted. After this bloody sacrifice to policy or resentment, Theodoric carried his victorious
SPAIN.

victorious arms as far as Merida, the principal town of Lusitania, without meeting any resistance, except from the miraculous powers of St Enlalia; but he was stopped in the full career of success, and recalled from Spain, before he could provide for the security of his conquests. In his retreat towards the Pyrenees, he revenged his disappointment on the country through which he passed; and in the sack of Pallentia and Astorga, he showed himself a faithless ally, as well as a cruel enemy.

Recared was the first Catholic king of Spain. He had imbibed the faith of his unfortunate brother, and he supported it with more prudence and success. Instead of revolting against his father, Recared patiently expected the hour of his death. Instead of condemning his memory, he piously supposed, that the dying monarch had abjured the errors of Arianism, and recommended to his son the conversion of the Gothic nation. To accomplish that salutary end, Recared convened an assembly of the Arian clergy and nobles, declared himself a Catholic, and exhorted them to imitate the example of their prince. The laborious interpretation of doubtful texts, or the curious pursuit of metaphysical arguments, would have excited endless controversy; and the monarch discreetly proposed to his illiterate audience, two substantial and visible arguments, the testimony of Earth and of Heaven. The Earth had submitted to the Nicene synod; the Romans, the Barbarians, and the inhabitants of Spain, unanimously professed the same orthodox creed; and the Visigoths resisted, almost alone, the consent of the Christian world. A superstitious age was prepared to reverence, as the testimony of Heaven, the preternatural cures which were performed by the skill or virtue of the Catholic clergy; the baptismal fonts of Ostia in Bética, which were spontaneously replenished each year, on the vigil of Easter; and the miraculous shrine of St Martin of Tours, which had already converted the Suevic prince and people of Gallicia. The Catholic king encountered some difficulties on this important change of the national religion. A conspiracy, secretly fomented by the queen-dowager, was formed against his life; and two counts excited a dangerous revolt in the Narbonnese Gaul. But Recared disarmed the conspirators, defeated the rebels, and executed severe justice; which the Arians, in their turn, might brand with the reproach of persecution. Eight bishops, whose names betray their Barbaric origin, abjured their errors; and all the books of Arian theology were reduced to ashes, with the house in which they had been purposely collected. The whole body of the Visigoths and Suevi were allured or driven into the pale of the Catholic communion; the faith, at least, of the rising generation, was fervent and sincere; and the devout liberality of the Barbarians enriched the churches and monasteries of Spain. Seventy bishops assembled in the council of Toledo, received the submission of their conquerors; and the zeal of the Spaniards improved the Nicene creed, by declaring the procession of the Holy Ghost from the Son, as well as from the Father; a weighty point of doctrine, which produced, long afterwards, the schism of the Greek and Latin churches. The royal proselyte immediately saluted and consulted Pope Gregory, surnamed the Great, a learned and holy prelate, whose reign was distinguished by the conversion of heretics and infidels. The ambassadors of Recared respectfully offered on the threshold of the Vatican his rich present of gold and gems: they accepted, as a lucrative exchange, the hairs of St John the Baptist; a cross, which inclosed a small piece of the true wood; and a key, that contained some particles of iron which had been scraped from the chains of St Peter.*

After their conversion from idolatry or heresy, the Legislative Franks and the Visigoths were disposed to embrace with equal submission, the inherent evils, and the accidental benefits of superstition. But the prelates of Spain in France, long before the extinction of the Merovingian race, had degenerated into fighting and hunting barbarians. They disdained the use of synods, forgot the laws of temperance and chastity, and preferred the indulgence of private ambition and luxury, to the greatest interest of the sacerdotal profession. The bishops of Spain respected themselves, and were respected by the public: their indissoluble union disguised their vices, and confirmed their authority; and the regular discipline of the church introduced peace, order, and stability into the government of the state. From the reign of Recared, the first Catholic king, to that of Witiza, the immediate predecessor of the unfortunate Rodrigo, sixteen national councils were successively convened. The six metropolitans, Toledo, Seville, Merida, Braga, Tarragona and Narbonne, presided according to their respective seniority; the assembly was composed of their suffragan bishops, who appeared in person, or by their proxies; and a place was assigned to the most holy, or opulent, of the Spanish abbots. During the first three days of the convocation, as long as they agitated the ecclesiastical questions of doctrine and discipline, the profane laity was excluded from their debates; which were conducted, however, with decent solemnity. But, on the morning of the fourth day, the doors were thrown open for the entrance of the great officers of the palace, the dukes and counts of the provinces, the judges of the cities, and the Gothic nobles; and the decrees of Heaven were ratified by the consent of the people. The same rules were observed in the provincial assemblies, the annual synods, which were empowered to hear complaints, and to redress grievances; and a legal government was supported by the prevailing influence of the Spanish clergy. The bishops who, in each revolution, were prepared to flatter the victorious, and to inflame the prostrate, laboured, with diligence and success, to kindle the flames of persecution, and to exult the mitre above the crown. Yet the national councils of Toledo, in which the free spirit of the Barbarians was tempered and guided by episcopal policy, have established some prudent laws for the benefit of the king and people. The vacancy of the throne was supplied by the choice of the bishops and palatines; and after the failure of the line of Afaric, the regal dignity was still limited to the pure and noble blood of the Goths. The clergy, who anointed their lawful prince, always recommended, and sometimes practised, the duty of allegiance; and the spiritual censures were denounced on the heads of the impious subjects, who should resist his authority, conspire against his life, or violate, by an indecent union, the chastity even of his widow. But the monarch himself, when he ascended the throne, was bound by a reciprocal oath to God and his people, that he would faithfully execute his important trust. The real or imaginary faults of his administration were subject to
the control of a powerful aristocracy; and the bishops and palatines were guarded by a fundamental privilege that they should not be degraded, imprisoned, tortured, nor punished with death, exile, or confiscation, unless by the free and public judgment of their peers.

One of these legislative councils of Toledo, examined and ratified the code of laws which had been compiled by a succession of Gothic kings, from the fierce Euric, to the devout Egica. As long as the Visigoths themselves were satisfied with the rude customs of their ancestors, they indulged their subjects of Aquitaine and Spain in the enjoyment of the Roman law. Their gradual improvements in arts, in policy, and at length in religion, encouraged them to imitate, and to supersede, these foreign institutions, and to compose a code of civil and criminal jurisprudence, for the use of a great and united people. The same obligations, and the same privileges, were communicated to the nations of the Spanish monarchy; and the conquerors, insensibly renouncing the Teutonic idiom, submitted to the restraints of equity, and ejected the Romans to the participation of freedom. The merit of this impartial policy was enhanced by the situation of Spain, under the reign of the Visigoths. The provincials were long separated from their Arian masters, by the irreconcilable difference of religion. After the conversion of Recared had removed the prejudices of the Catholics, the coasts, both of the ocean and Mediterranean, were still possessed by the Eastern emperors, who secretly excited a discontented people to reject the yoke of the barbarians, and to assert the name and dignity of Roman citizens. The allegiance of doubtful subjects is indeed most effectually secured by their own persuasion, that they hazard more in a revolt, than they can hope to obtain by a revolution; but it has appeared so natural to oppress those whom we hate and fear, that the contrary system well deserves the praise of wisdom and moderation.

The Gothic princes continued to reign over a considerable part of Spain till the beginning of the 8th century, when their empire was overthrown by the Saracens. During this period, they had entirely expelled the eastern emperors from what they possessed in Spain, and even made considerable conquests in Barbary; but towards the end of the 7th century the Saracens overran all that part of the world with a rapidity which nothing could resist; and having soon possessed themselves of the Gothic dominions in Barbary, they made a descent upon Spain about the years 711 or 712. The king of the Goths at that time was called Roderic, and by his bad conduct had occasioned great dissatisfaction among his subjects. He therefore determined to put all to the issue of a battle, knowing that he could not depend upon the fidelity of his own people if he allowed the enemy time to tamper with them. The two armies met in a plain near Xeres in Andalusia. The Goths began the attack with great fury; but though they fought like men in despair, they were at last defeated with excessive slaughter, and their king himself was supposed to have perished in the battle, being never more heard of.

By this battle the Moors in a short time rendered themselves masters of almost all Spain. The poor remains of the Goths were obliged to retire into the mountainous parts of Asturias, Burgos, and Biscay: the inhabitants of Aragon, Catalonia, and Navarre, though they might have made a considerable stand against the enemy, chose for the most part to retire into France. In 718, however, the power of the Goths began again to revive under Don Pelagio or Pelayo, a prince of the royal blood, who headed those that had retired under the mountains after the fatal battle of Xeres, in the province of Liebana, about nine leagues in length and four in breadth. This is the most inland part of the country, full of mountains enormously high, and so much fortified by nature, that its inhabitants are capable of resisting almost any number of invaders. Alakor the Saracen governor was no sooner informed of this revival of the Gothic kingdom, than he sent a powerful army, under the command of one Alechaman, to crush Don Pelagio before he had time to establish his power. The king, however his forces were sufficiently numerous (every one of his subjects arriving at man’s estate being a soldier), did not think proper to venture a general engagement in the open field; but taking post with part of them himself in a cavern in a very high mountain, he concealed the rest among precipices, giving orders to them to fall upon the enemy as soon as they should perceive him attacked by them. These orders were punctually executed, though indeed Don Pelagio himself had repulsed his enemies, but not without a miracle, as the Spanish historians pretend. The slaughter was dreadful; for the troops who lay in ambuscade joining the rest, and rolling down huge stones from the mountains upon the Moors (the name by which the Saracens were known in Spain), no fewer than 124,000 of those unhappy people perished in one day. The remainder fled till they were stopped by a river, and beginning to cross it, part of a mountain suddenly fell down, stopped up the channel of the river, and either crushed or drowned, by the sudden rising of the water, almost every one of that vast army.

The Moors were not so much disheartened by this disaster, but that they made a second attempt against Don Pelagio. Their success was as bad as ever, the greatest part of their army being cut in pieces or taken; in consequence of which, they lost all the Asturias, and never dared to enter the lists with Pelagio afterwards. Indeed, their bad success had in a great measure taken from them the desire of conquering a country where little or nothing was to be gained; and therefore they rather directed their force against France, where they hoped for more plunder. Into this country they poured in prodigious multitudes; but were utterly defeated, in 732, by Charles Martel, with the loss of 300,000 men, as the historians of those times pretend.

The subsequent history of Spain is rendered so confused by the numerous kingdoms that were established either by the Christians or the Moors, that some chronological guide is necessary to make it intelligible. Before pursuing the thread of the narration, we shall lay before our readers the following chronological table of the contemporaneous monarchs from Pelagio to Ferdinand VII.

---

Don Pelagio died in 737; and soon after his death such intestine divisions broke out among the Moors, as greatly favoured the increase of the Christian power. In 745 Don Alonso the Catholic, son-in-law to Pelagio, in conjunction with his brother Froila passed the mountains, and fell upon the northern part of Gallicia; and meeting with little resistance, he recovered almost the whole of that province in a single campaign. Next year he invaded the plains of Leon and Castile; and before the Moors could assemble any force to oppose him, he reduced Astorgas, Leon, Saldagna, Montes de Oca, Amaya, Alava, and all the country at the foot of the mountains. The year following he pushed his conquests as far as the borders of Portugal, and the next campaign ravaged the country as far as Castile. Being sensible, however, that he was yet unable to defend the flat country which he had conquered, he laid the whole of it waste, obliged the Christians to retire to the mountains, and carried off all the Moors for slaves. Thus secured by a desert frontier, he met with no interruption for some years; during which time, as his kingdom advanced in strength, he allowed his subjects gradually to occupy part of the flat country, and to rebuild Leon and Astorgas, which he had demolished. He died in 758, and was succeeded by his son Don Froila. In his time Abdoulrahaman, the khalif's vice. The Saray in Spain, threw off the yoke, and rendered him self independent, fixing the seat of his government at Cordova. Thus the intestine divisions among the Moors of the kha were composed; yet their success seems to have been little better than before; for, soon after, Froila encountered the Moors with such success, that 54,000 of them were killed on the spot, and their general taken prisoner. Soon after he built the city of Oviedo, which he made
the capital of his dominions, in order to be in a better
circumstance to defend the flat country, which he now de-
termined to people.

In the year 850, the power of the Saracens received
another blow by the rise of the kingdom of Navarre.
This kingdom, we are told, took its origin from an ac-
cidental meeting of gentlemen, to the number of 600, at
the tomb of an hermit named John, who had died
among the Pyrenees. At this place, where they had
met on account of the supposed sanctity of the deceas-
ted, they took occasion to convene an enquiry into the
Moors, and the miseries to which the country was exposed,
and the glory that would result from throwing off their
yoke; which, they supposed, might easily be done, by
reason of the strength of their country. On mature
deliberation, the project was approved; one Don Garcia
Ximenes was appointed king, as being of illustrious
birth, and looked upon as a person of great abilities.
He recovered Ainsa, one of the principal towns of the
country, out of the hands of the infidels, and his suc-
cessor Don Garcia Inigas extended his territories as far
as Biscay: however, the Moors still possessed Portugal,
Murcia, Andalusia, Valencia, Granada, Tortosa, with
the interior part of the country as far as the mountains
of Castile and Zaragoza. Their internal dissensions,
which revived after the death of Abdalrahman, con-
tributed greatly to reduce the power of the infidels in
general. In 778, Charles the Great being invited by
some discontented Moorish governors, entered Spain
with two great armies; one passing through Catalonia,
and the other through Navarre, where he pushed his
conquests as far as the Ebro. On his return he was
attacked and defeated by the Moors; though this did
not hinder him from keeping possession of all those
places he had already reduced. At this time he seems
to have been master of Navarre: however, in 831 Count
Azner, revolting from Pepin son to the emperor Louis,
asserted the independence of Navarre; but the sove-
igns did not assume the title of kings till the time of
Don Garcia, who began to reign in 857.

In the mean time, the kingdom founded by Don
Pelagio, now called the kingdom of Leon and Oviedo,
continued to increase rapidly in strength, and many
advantages were gained over the Moors, who having
two enemies to contend with, lost ground every day.
In 921, however, they gained a great victory over the
united forces of Navarre and Leon, by which the whole
force of the Christians in Spain must have been entirely
broken, had not the victors conducted their affairs so
wretchedly, that they suffered themselves to be almost
entirely cut in pieces by the remains of the Christian
army. In short, the Christians became at length so ter-
rible to the Moors, that it is probable they could not
long have kept their footing in Spain, had not a great
general, named Mohammed Ebn Amir Almanzor, ap-
peared, in 979, to support their sinking cause. This
man was visir to the king of Cordova, and being ex-
ceedingly provoked against the Christians on account
of what his countrymen had suffered from them, made war
with the most-impossible fury. He took the city of
Leon, murdered the inhabitants, and reduced the houses
to ashes. Barcelo was burned the same fate; Castile was
reduced to a desert; Gallicia and Portugal ravaged;
and he is said to have overcome the Christians in fifty
different engagements. At last, having taken and
demolished the city of Compostelle, and carried off in
triumph the gates of the church of St James, a flux
happened to break out among his troops, which the
superstitious Christians supposed to be a divine judgment
on account of his sacrilege. Taking it for granted,
therefore, that the Moors were now entirely destitute of
all heavenly aid, they fell upon them with such fury in
He is de-
the next engagement, that all the valour and conduct of
feated, and
Almanzor could not prevent a defeat. Overcome with self
shame and despair at this misfortune, he desired his fol-
lowers to shift for themselves, while he himself retired
to Medina Celi, and put an end to his life by abstinance
in the year 998.

During this period a new Christian principality ap-
Peared in Spain, namely that of Castile, which is now kingdom
of divided into the Old and New Castile. The Old
Castile was recovered long before that called the New.
It was separated from the kingdom of Leon on one side
by some little rivers; on the other, it was bounded by
the Asturias, Biscay, and the province of Rioja. On
the south it had the mountains of Segovia and Avila;
thus lying in the middle between the Christian king-
dom of Leon and Oviedo, and the Moorish kingdom
of Cordova. Hence this district soon became an object
of contention between the kings of Leon and those of
Cordova; and as the former were generally victorious,
some of the principal Castilian nobility retained their
independence under the protection of the Christian
kings, even when the power of the Moors was at its
greatest height. In 854, we first hear of Don Rodri-
guez assuming the title of count of Castile, though it
does not appear that either his territory or title were
given him by the king of Leon. Nevertheless, this
monarch having taken upon him to punish some of the
Castilian lords as rebels, the inhabitants made a formal
reconciliation of their allegiance, and set up a new kind
of government. The supreme power was now vested
in two persons of quality styled judges; however, this
method did not long continue to give satisfaction, and
the sovereignty was once more vested in a single person.
By degrees Castile fell entirely under the power of
the kings of Leon and Oviedo; and, in 1037, Don San-
cho bestowed it on his eldest son Don Ferdinand, with
the title of king; and thus the territories of Castile
were first firmly united to those of Leon and Oviedo,
and the sovereigns were thenceforth styled kings of
Leon and Castile.

Besides all these, another Christian kingdom was set
up in Spain about the beginning of the 11th century. Aragon.
This was the kingdom of Aragon. The inhabitants
were very brave, and lovers of liberty, so that it is pro-
bable they had in some degree maintained their inde-
pendence, even when the power of the Moors was
greatest. The history of Aragon, however, during
its infancy, is much less known than that of any of
the others hitherto mentioned. We are only assured,
that about the year 1035, Don Sancho, surnamed the
Great, king of Navarre, erected Aragon into a king-
dom in the beginning of his rule Don Ramiro, and afterwards
it became very powerful. At this time, we may
imagine the continent of Spain divided into two unequal
parts by a straight line drawn from east to west, from
the coasts of Valencia to a little below the mouth of the
Douro. The country north of this belonged to the
Christians, who, as yet, had the smallest and least valu-
SPAIN.

The Moors were so much alarmed at these conquests, that they not only entered into a general confederacy against the Christians, but invited to their assistance Mahomet Ben Joseph the sovereign of Barbary. He accordingly came, attended by an incredible multitude; but was utterly defeated by the Christians in the defiles of the Black Mountain, or Sierra Morena, on the borders of Andalusia. This victory happened on the 16th of July 1212, and the anniversary is still celebrated at Toledo. This victory was not improved; the Christian army immediately dispersed themselves, while the Moors of Andalusia were strengthened by the remains of the African army; yet, instead of being taught, by their past misfortunes, to unite among themselves, their dissensions became worse than ever, and the conquests of the Christians became daily more rapid. In 1236, Don Ferdinand of Castile and Leon took the celebrated city of Cordova, the residence of the first Moorish kings; at the same time that James I. of Aragon dispossessed them of the island of Majorca, and drove them out of Valencia. Two years after, Ferdinand made himself master of Murcia, and took the city of Seville; and in 1303 Ferdinand IV. reduced Gibraltar.

In the time of Edward III. we find England, for the first time, interfering in the affairs of Spain, on the following occasion. In the year 1284 the kingdom of Navarre had been united to that of France by the marriage of Donna Joanna queen of Navarre with Philip the Fair of France. In 1328, however, the kingdoms were again separated, though the sovereigns of Navarre were still related to those of France. In 1350, Charles, surnamed the Wicked, ascended the throne of Navarre, and married the daughter of John king of France. Notwithstanding this alliance, and that he himself was related to the royal family of France, he secretly entered into a negotiation with England against the French monarch, and even drew into his schemes the dauphin Charles, afterwards surnamed the Wise. The young prince, however, was soon after made fully sensible of the danger and folly of the connections into which he had entered; and, by way of atonement, promised to sacrifice his associates. Accordingly he invited the king of Navarre, and some of the principal nobility of the same party, to a feast at Rouen, where he betrayed them to his father. The most obnoxious were executed, and the king of Navarre was thrown into prison. In this extremity, the party of the king of Navarre had recourse to England. The prince of Wales, surnamed by John the Black Prince, invaded France, defeated King John of Poitiers, and took him prisoner; the unhappy event produced the most violent disturbances in that kingdom. The dauphin, now about 19 years of age, naturally assumed the royal power during his father's captivity: but possessed neither experience nor authority sufficient to remedy the prevailing evils. In order to obtain supplies, he assembled the states of the kingdom: but that assembly, instead of supporting his administration, laid hold of the present opportunity to demand limitations of the prince's power, the punishment of past malversations, and the liberty of the king of Navarre. Marcel, provost of the merchants of Paris, and first magistrate of that city, put himself at the head of the unruly populace, and pushed them to commit the most criminal outrages against the royal authority. They detained the dauphin in a kind of captivity, murdered in his presence Robert de Clermont and John de Conflans, marshals of France; threatened all the other ministers with the like fate; and when Charles, who had been obliged to temporize and dissemble, made his escape from their hands, they levied war against him, and openly rebelled. The other cities of the kingdom, in imitation of the capital, shook off the dauphin's authority, took the government into their own hands, and spread the contagion into every province.

Amidst these disorders, the king of Navarre made his Escapes, escape from prison, and presented a dangerous leader to the furious malcontents. He revived his pretensions to the crown of France: but in all his operations he acted more like a leader of banditti than one who aspired to be the head of a regular government, and who was engaged by his station to endeavour the re-establishment of order in the community. All the French, therefore, who wished to restore peace to their country, turned their eyes towards the dauphin; who, though not remarkable for his military talents, daily gained by his prudence and vigilance the ascendant over his enemies. Marcel, the seditious provost of Paris, was slain in attempting to deliver that city to the king of Navarre. The capital immediately returned to its duty: the most considerable bodies of the mutinous peasants were dispersed or put to the sword; some bands of military robbers underwent the same fate; and France began once more to assume the appearance of civil government.

John was succeeded in the throne of France by his son Charles V. a prince educated in the school of adversity, and well qualified, by his prudence and experience, to repair the losses which the kingdom had sustained from the errors of his predecessors. Contrary to the practice of all the great princes of those times, who held nothing in estimation but military courage, he seems to have laid it down as a maxim, never to appear at the head of his armies; and he was the first European monarch that showed the advantage of policy and foresight over a rash and precipitate valor.

Before Charles could think of counterbalancing so great
great a power as England, it was necessary for him to remedy the many disorders to which his own kingdom was exposed. He accordingly turned his arms against the king of Navarre, the great disturber of France during that age; and he defeated that prince, and reduced him to terms, by the valour and conduct of Bertrand du Guesclin, one of the most accomplished captains of those times, whom Charles had the discernment to choose as the instrument of his victories. He also settled the affairs of Brittany, by acknowledging the title of Mountfort, and receiving homage for his dominions. But much was yet to be done. On the conclusion of the peace of Bretigny, the many military adventurers who had followed the fortunes of Edward, being dispersed into the several provinces, and possessed of strongholds, refused to lay down their arms, or relinquish a course of life to which they were now accustomed, and by which alone they could earn a subsistence. They associated themselves with the banditti, who were already incurred to the habits of rapine and violence; and, under the name of compagnies and compagnies, became a terror to all the peaceable inhabitants. Some English and Gascon gentlemen of character were not ashamed to take the command of these ruffians, whose number amounted to near 40,000, and who bore the appearance of regular armies rather than bands of robbers.

As Charles was not able by power to redress so enormous a grievance, he was led by necessity, as well as by the turn of his character, to correct it by policy; to discover some method of discharging into foreign countries this dangerous and insidious evil; and an occasion now offered.

Alphonso XI. king of Castile, who took the city of Algezira from the Moors, after a famous siege of two years, during which artillery are said first to have been used by the besieged, had been succeeded by his son Pedro I., surnamed the Cruel; a prince equally perfidious, debauched, and bloody. He began his reign with the murder of his father's mistress, Leonora de Gusman: his nobles fell every day the victims of his severity: he put to death his cousin and one of his natural brothers, from groundless jealousy; and he caused his queen Blanche de Bourbon, of the blood of France, to be thrown into prison, and afterwards poisoned, that he might enjoy in quiet the embraces of Mary de Padella, whom he was violently enamoured.

Henry count of Trastamara, the king's natural brother, alarmed at the fate of his family, and dreading his own, took arms against the tyrant; but having failed in the attempt, he fled to France, where he found the minds of men much inflamed against Pedro, on account of the murder of the French princess. He asked permission of Charles to enlist the compagnies in his service, and to lead them to Castile against his brother. The French king, charmed with the project, employed du Guesclin in negotiating with the leaders of these banditti. The treaty was soon concluded; and du Guesclin having completed his levies, led the army first to Avignon, where the pope then resided, and demanded, sword in hand, absolution for his ruffian soldiers, who had been excommunicated, and the sum of 200,000 livres for their subsistence. The first was readily promised him, but some difficulty being made with regard to the second, du Guesclin replied, "My fellows, I believe, may make a shift to do without your absolution, but the money is absolutely necessary." His holiness then extorted from the inhabitants of the city and its neighbourhood the sum of 100,000 livres, and offered it to du Guesclin. "It is not my purpose (cried that generous warrior) to oppress the innocent people. The pope and his cardinals can spare me double the sum from their own pockets. I therefore insist, that this money be restored to the owners; and if I hear they are defrauded of it, I will myself return from the other side of the Pyrenees, and oblige you to make restitution." The pope found the necessity of submitting, and paid from his own treasury the sum demanded.

A body of experienced and hardy soldiers, conducted by so able a general, easily prevailed over the king of Castile, whose subjects were ready to join the enemy. Pedro fled from his dominions, took shelter in Guienne, and craved the protection of Prince the prince of Wales, whom his father had invested with the sovereignty of the ceded provinces, under the title of the principality of Aquitaine. The prince promised his assistance to the deposed monarch; and having obtained his father's consent, he levied an army, and set out on his enterprise.

The first loss which Henry of Trastamara suffered from the interposition of the prince of Wales, was the recalling of the companies from his service; and so much reverence did they pay to the name of Edward, that great numbers of them immediately withdrew from Spain, and enlisted under his standard. Henry, however, beloved by his new subjects, and supported by the king of Aragon, was able to meet the enemy with an army of 100,000 men, three times the number of those commanded by the Black Prince: yet du Guesclin, and all his experienced officers, advised him to delay a decisive action; so high was their opinion of the valour and conduct of the English hero! But Henry, trusting to his numbers, ventured to give Edward battle on the banks of the Ebro, between Najara and Navarette, where the French and Spaniards were defeated, with the loss of above 20,000 men, and du Guesclin and other officers of distinction taken prisoners. All Castile was submitted to the victor; Pedro was restored to the crown, and Edward returned to Guiene with his usual glory; having not only overcome the greatest general of his age, but restrained the most blood-thirsty tyrant from executing vengeance on his prisoners.

This gallant warrior had soon reason to repent of his connection with a man like Pedro, lost to all sense of virtue and honour. The ungrateful monster refused the stipulated pay to the English forces. Edward abandoned him; he treated his subjects with the utmost barbarity; their animosity was roused against him; and du Guesclin having obtained his ransom, returned to Castile with the count of Trastamara, and some forces levied anew in France. They were joined by the Spanish malecontents; and having no longer the Black Prince to encounter, they gained a complete victory over Pedro's again in the neighbourhood of Toledo. The tyrant now took flight, victor, and put to the victors, and taken prisoner in endeavouuring to make his escape. He was conducted to his brother Henry; against whom he is said to have rushed in a transport of rage, disarmed as he was. Henry slew him with his own
the close of the third, the Conde de Benavente wrested the sceptre from his hand; and at the close of the last, Don Diego Lopez de Stuniga tumbled it headlong from the throne. At the same instant, Don Alphonso, Henry's brother, a boy of about twelve years of age, was proclaimed king of Castile and Leon in his stead.

This extraordinary proceeding was followed by a civil war, which did not cease till some time after the death of the young prince, upon whom the nobles had bestowed the kingdom. The archbishop and his party then continued to carry on war in the name of Isabella, the king's sister, to whom they gave the title of Infanta; and Henry could not extricate himself out of these troubles, nor remain quiet upon his throne till he had signed one of the most humiliating treaties ever extorted from a sovereign; he acknowledged his sister Isabel the only lawful heiress of his kingdom, in prejudice to the rights of his reputed daughter Joan, whom the malecontents affirmed to be the offspring of an adulterer of her commerce between the queen and Don la Cueva, heiress to the throne.

The grand object of the malecontent party now was the marriage of the princess Isabella, upon which, it was evident, the security of the crown and the happiness of the people must in a great measure depend. The alliance was sought by several princes: the king of Portugal offered her his hand; the king of France demanded her for his brother, and the king of Aragon for his son Ferdinand. The malecontents very wisely sided in the princess, and espoused the Aragonian prince, and Isabella prudently made the same choice; articles were drawn up; and Aragon were privately married by the archbishop of Toledo.

Henry was enraged at this alliance, which he foresaw would utterly ruin his authority, by furnishing his rebellious subjects with the support of a powerful neighbouring prince. He disinherit his sister, and extinguished the rights of his daughter. A furious civil war desolated the kingdom. The names of Joan and Isabella resounded from every quarter, and were everywhere the summons to arms. But peace was at length brought about. Henry was reconciled to his sister and Ferdinand; though it does not appear that he ever renewed Isabella's right to the succession: for he affirmed in his last moments, that he believed Joan to be his own daughter. The queen swore to the same effect; and Henry left a testamentary deed, transmitting the crown to this princess, who was proclaimed queen of Castile at Placentia. But the superior fortune and superior arms of Ferdinand and Isabella prevailed: the king of Portugal was obliged to abandon his niece and intended ragon and bride, after many ineffectual struggles, and several years Sicily with war. Joan retired into a convent; and the death of Leon and Ferdinand's father, which happened about this time, added the kingdoms of Aragon and Sicily to those of

---

Reign of Henry the Impotent.

An 1450.

This prince, surnamed the Impotent, though continually surrounded with women, began his unhappy reign in 1450. He was totally enervated by his pleasures; and every thing in his court conceived to set the Castilians an example of the most abject flattery and most abandoned licentiousness. The queen, a daughter of Portugal, lived as openly with her parasites and her gallants as the king did with his minions and his mistresses. Pleasure was the only object, and effeminacy is the only recommendation to favour: the affairs of the state went every day into disorder; till the nobility, with the archbishop of Toledo at their head, combining against the weak and ignisfus administration of Henry, resorted to themselves, as one of the privileges of their order, the right of trying and passing sentence on their sovereign, which they executed in a manner unprecedented in history.

All the malecontent nobility were summoned to meet at Avila: a spacious theatre was erected in a plain without the walls of the town: an image, representing the king, was seated on a throne, clad in royal robes, with a crown on its head, a sceptre in its hand, and the sword of justice by its side. The accusation against Henry was read, and the sentence of deposition pronounced, in presence of a numerous assembly. At the close of the first article of the charge, the archbishop of Toledo advanced, tore the crown from the head of the image; at the close of the second, the Conde de Placentia snatched the sword of justice from its side; at
Spain.

Spain. were inseparably united in their common interests; always acting upon the same principles, and forwarding the same ends. Their first object was the regulation of their government, which the civil wars had thrown into the greatest disorder. Rape, outrage, and murder were so common, as not only to interrupt commerce, but in a great measure to suspend all intercourse between one place and another. These evils the joint soveraigns suppressed by their wise policy, at the same time that they extended the royal prerogative.

Institution of the Holy Brotherhood.

About the middle of the 13th century, the cities in the kingdom of Aragon, and after their example those in Castile, had formed themselves into an association, distinguished by the name of the Holy Brotherhood. They exacted a certain contribution from each of the associated towns; they levied a considerable body of troops, in order to protect travellers and pursue criminals; and they appointed judges, who opened courts in various parts of the kingdom. Whoever was guilty of murder, robbery, or any act that violated the public peace, and was seized by the troops of the Brotherhood, was carried before their judges; who, without paying any regard to the exclusive jurisdiction which the lord of the place might claim, who was generally the author or abettor of the injustice, tried, and condemned the criminals. The nobles often murmured against the salutary institution; they complained of it as an encroachment on one of their most valuable privileges, and endeavoured to get it abolished. But Ferdinand and Isabella, sensible of the beneficial effects of the Brotherhood, not only in regard to the police of their kingdom, but in its tendency to abridge, and by degrees annihilate, the territorial jurisdiction of the nobility, countenanced the institution upon every occasion, and supported it with the whole force of royal authority; by which means the prompt and impartial administration of justice was restored, and with it tranquility and order returned.

But at the same time that their Catholic majesties (for such was the title they now bore) were giving vigour to their civil government, and securing their subjects from violence and oppression, an intemperate zeal led them to establish an ecclesiastical tribunal, equally contrary to the natural rights of humanity and the mild spirit of the gospel. This was the court of inquisition; which decides upon the honour, fortune, and even the life, of the unhappy wretch who happens to fall under the suspicion of heresy, or a contempt of any thing prescribed by the church, without his knowing, being confronted with his accusers, or permitted either defence or appeal. Six thousand persons were burnt by order of this sanguinary tribunal within four years after the appointment of Torquemada, the first inquisitor-general; and upwards of 100,000 felt its fury. The same furious and blinded zeal which led to the depopulation of Spain, led also to its aggrandizement.

Conquest of Granada.

The kingdom of Granada now alone remained of all the Mahometan possessions in Spain. Princes equally zealous and ambitious were naturally disposed to turn their eyes to that fertile territory, and to think of increasing their hereditary dominions, by expelling the enemies of Christianity, and extending its doctrines. Every thing conspired to favour their project: the Moorish kingdom was a prey to civil wars; when Ferdinand, having obtained the bull of Sixtus IV. authorizing a crusade, put himself at the head of his troops, and entered Granada. He continued the war with rapid success: Isabella attended him in several expeditions; and they were both in great danger at the siege of Malaga; an important city, which was defended with great courage, and taken in 1487. Baza was reduced in 1489, after the loss of 20,000 men. Gaudix and Almeria were delivered up to them by the Moorish king Alzagal, who had first deposed his brother Alboacen, and afterwards been chased from his capital by his nephew Abdal. That prince engaged in the service of Ferdinand and Isabella; who, after reducing every other place of eminence, undertook the siege of Granada. Abdal made a gallant defence; but all communication with the country being cut off, and all hopes of relief at an end, he capitulated, after a siege of eight months, on condition that he should enjoy the revenues of certain places in the fertile mountains of Alpujarra; that the inhabitants should retain the undisturbed possession of their houses, goods, and inheritances; the use of their laws, and the free exercise of their religion (a). Thus ended the empire of the Arabs in Spain, after it had continued about 800 years. They introduced the arts and sciences into Europe at a time when it was lost in darkness; they possessed many of the luxuries of life, when they were not even known among the neighboring nations; and they seem to have given birth to that romantic gallantry which so eminently prevailed in the ages of chivalry, and which, blending itself with the generation of the northern nations for the softer sex, still particularly distinguishes ancient from modern manners. But the Moors, notwithstanding these advantages, and the eulogies bestowed upon them by some writers, appear always to have been destitute of the essential qualities of a polished people, humanity, generosity, and mutual sympathy.

The overthrow of the last Moorish kingdom was soon followed by the expulsion of the Saracens from Spain. This expulsion did not entirely take place till the 17th century. Vast numbers of the Moors, indeed, oppressed by their conquerors, abandoned a country where they could not reside with comfort and with freedom. From the reign of Ferdinand of Castile, to that of Philip III. of Spain, more than 3,000,000 of those people quitted Spain, and carried with them, not only a great part of their acquired wealth, but that industry and love of labour which are the foundation of national prosperity.

The state of Spain has never been so flourishing at prosperous any period of its civilization, as during the period when it was chiefly possessed by the Moors. The first Saracen invaders, and the twenty successive lieutenants of Moorish the caliph of Damascus, were attended by a numerous dominion train of civil and military followers, who preferred a distant

(a) The particulars of the conquest of Granada are involved in much obscurity. If we were to credit the narrative of Giles Perez, as related by Mr Swinburne, the circumstances which led to that conquest were of a most romantic nature. See Swinburne’s Travels, Letter xxi.
SPAIN.

The private and public interest was promoted by the establishment of faithful colonies, and the cities of Spain were proud to commemorate the tribe or the country of their eastern progenitors. Ten years after the conquest, a map of the province was presented to the caliph, showing the seas, the rivers, and the harbours, the inhabitants and cities, the climate, the soil, and the mineral productions of the earth. In the space of two centuries the gifts of nature were improved by agriculture, the manufactures, and the commerce of an industrious people; though the effects of their diligence have been magnified by the idleness of their fancy. The first of the Ommonades who reigned in Spain solicited the support of the Christians; and in his edict of peace and protection, he contented himself with a modest imposition of 10,000 ounces of gold, 10,000 pounds of silver, 10,000 horses, as many mules, 1000 cuirasses, with an equal number of helmets and lances. The most powerful of his successors derived from the same kingdom the annual tribute of 12,045,000 dinars or pieces of gold, about 6,000,000l. of sterling money; a sum which, in the 10th century, most probably surpassed the united revenues of the Christian monarchs. His royal seat of Cordova contained 600 mosques, 900 baths, and 200,000 houses; he gave laws to 80 cities of the first, to 300 of the second and third order; and the fertile banks of the Guadalquivir were adorned with 12,000 villages and hamlets. The Arabs might exaggerate the truth; but they created, and they describe, the most prosperous era of the riches, the cultivation, and the populousness of Spain (c).

The conquest of Granada was followed by the expulsion, or rather the pillage and banishment, of the Jews, who had engrossed all the wealth and commerce of Spain. The inquisition exhausted its rage against these unhappy people, many of whom pretended to embrace Christianity, in order to preserve their property. About the same time their Catholic majesties concluded an alliance with the emperor Maximilian, and a treaty of marriage for their daughter Joan with his son Philip, archduke of Austria, and sovereign of the Netherlands. About this time also the contract was concluded with Christopher Columbus for the discovery of new countries; and the counties of Roussillon and Cerdagne were agreed to be restored by Charles VIII. of France, before his expedition into Italy. The discovery of America was soon followed by extensive conquests in that quarter, as is related under the articles MEXICO, PERU, CHILI, &c., which tended to raise the Spanish monarchy above any other in Europe.

On the death of Isabella, which happened in 1506, Philip archduke of Austria came to Castile in order to take possession of that kingdom as heir to his mother-in-law; but he dying in a short time after, his son Charles V. afterwards emperor of Germany, became heir to the crown of Spain. His father at his death left the king of France governor to the young prince, and Ferdinand at his death left Cardinal Ximenes sole regent of Castile, till the arrival of his grandson. This man, whose character is no less singular and illustrious, who united the abilities of a great statesman with the abject devotion of a superstitious monk, and the magnificence of a prime minister with the severity of a mendicant, maintained order and tranquillity in Spain, notwithstanding the discontent of a turbulent and high-spirited nobility. When they disputed his right to the regency, he coolly showed them the testament of Ferdinand, and the ratification of that deed by Charles; but those not satisfying them, and argument proving ineffectual, he led them insensibly towards a balcony, whence they had a view of a large body of troops under arms, and

(c) Abdoulrahman III. monarch of Cordova, surpassed all his predecessors in splendour, riches, and expense; and his subjects vied with each other in profusion and magnificence. Some idea may be entertained of the opulence and grandeur of the Moors of Cordova in the 10th century, by perusing the following enumeration of the presents made to Abdoulrahman by Alhunnik his grand vizier, on his appointment to that office. We are told that the minister caused to be brought before the throne, and laid at the feet of his master,

400 lbs. of virgin gold.
1500 lbs. of silver to the value of 420,000 sequins.
400 lbs. of lignum aloes, one piece weighing 140 lbs.
500 oz. of ambergris.
300 oz. of camphor.
30 pieces of gold tissue, so rich that none but the caliph could wear it.
10 suits of Khorassan sables.
100 suits of fur of a less valuable sort.
48 sets of gold and silk long trappings for horses.
4000 lbs. of silk.
30 Persian carpets.
800 iron coats-of-mail for war horses.
1000 shields.
100,000 arrows.
34 led horses of Arabia, as richly caparisoned as those on which the caliph was wont to ride.
100 horses of an inferior price.
20 mules with all their accoutrements.
40 young men, and 20 girls of exquisite beauty, and most sumptuously appareled. This display of riches was accompanied with a most flattering poem, composed by the minister in praise of his sovereign, who in return for his homage, assigned him a pension of 100,000 pieces of gold, about 50,000l. sterling.
Spain.

and a formidable train of artillery. "Behold (said the cardinal) the powers which I have received from his Catholic majesty: by these I govern Castile; and will govern it, till the king, your master and mine, shall come to take possession of his kingdom." A declaration so bold and determined silenced all opposition; and Ximenes maintained his authority till the arrival of Charles in 1517.

The young king was received with universal acclamations of joy; but Ximenes found little cause to rejoice. He was seized with a violent disorder, supposed to be the effect of poison; and when he recovered, Charles prejudiced against him by the Spanish grandees and his Flemish courtiers, slighted his advice, and allowed him every day to sink into neglect. The cardinal did not bear this treatment with his usual fortitude of spirit. He expected a more grateful return from a prince to whom he delivered a kingdom more flourishing than it had been in any former age, and authority more extensive and better established than the most illustrious of his ancestors had ever possessed. Conscious of his own integrity and merit, he could not therefore refrain from giving vent, at times, to indignation and complaint. He lamented the fate of his country, and foretold the calamities to which it would be exposed from the insolence, the rapaciousness, and the ignorance of strangers. But in the mean time he received a letter from the king, dismissing him from his councils, under pretense of easing his age of that burden which he had so long and so ably sustained. This letter proved fatal to the minister; for he expired in a few hours after reading it.

While Charles was taking possession of the throne of Spain, in consequence of the death of one grandfather, another was endeavouring to obtain for him the imperial crown. With this view Maximilian assembled a diet at Augsburg, where he cultivated the favour of the electors by many acts of beneficence, in order to engage them to choose that young prince as his successor. But Maximilian himself never having been crowned by the pope, a ceremony deemed essential in that age, as well as in the preceding, he was considered only as king of the Romans, or emperor elect; and no example occurring in history of any person being chosen successor to a king of the Romans, the Germans, always tenacious of their forms, obstinately refused to confer upon Charles a dignity for which their constitution knew no name.

But though Maximilian could not prevail upon the German electors to choose his grandson of Spain, king of the Romans, he had disposed their minds in favour of that prince; and other circumstances, on the death of the emperor, conspired to the exaltation of Charles. The imperial crown had so long continued in the Austrian line, that it began to be considered as hereditary in that family; and Germany, torn by religious disputes, stood in need of a powerful emperor, not only to preserve its own internal tranquillity, but also to protect against the victorious arms of the Turks, who under Selim I. threatened the liberties of Europe. This fierce and rapid conqueror had already subdued the Mamelukes, and made himself master of Egypt and Syria. The power of Charles appeared necessary to oppose that of Selim. The extensive dominions of the house of Austria, which gave him an interest in the preservation of Germany; the rich sovereignty of the Netherlands and Franche Comté; the entire possession of the great and warlike kingdom of Spain, together with that of Naples and Sicily, all united to hold him up to the first dignity among Christian princes; and the new world seemed only to be called into existence that its treasures might enable him to defend Christianity against the infidels. Such was the language of his partisans.

Francis I., however, no sooner received intelligence of the death of Maximilian, than he declared himself a candidate to the empire; and with no less confidence of the same success than Charles. He trusted to his superior years and experience; his great reputation in arms; and it was farther urged in his favour, that the impetuosity of the French cavalry, added to the firmness of the German infantry, would prove irresistible, and not only be sufficient, under a war-like emperor, to set limits to the ambition of Selim, but to break entirely the Ottoman power, and prevent it from ever becoming dangerous again to Germany.

Both claims were plausible. The dominions of Francis were less extensive, but more united than those of Charles. His subjects were numerous, active, brave, lovers of glory, and lovers of their king. These were strong arguments in favour of his power, so necessary at this juncture: but he had no natural interest in the German body; and the electors, hearing so much of military force on each side, became more alarmed for their own privileges than the common safety. They determined to reject both candidates, and offered the imperial crown to Frederic, surnamed the Wise, duke of Saxony.

But he, dazzled by the splendour of an object courted with so much eagerness, by two mighty monarchs, rejected it with a magnanimity no less singular than great.

"In times of tranquillity (said Frederic), we wish for Speech of an emperor who has no power to invade our liberties; Frederic; at times of danger demand one who is able to secure our safety. The Turkish armies, led by a war-like and victorius monarch, are now assembling: they are ready to pour in upon Germany with a violence unknown in former ages. New conjunctures call for new expedients. The imperial sceptre must be committed to some hand more powerful than mine or that of any other German prince. We possess neither dominions, nor revenues, nor authority, which enable us to encounter such a formidable enemy. Recourse must be had, in this exigency, to one of the rival monarchs. Each of them can bring into the field forces sufficient for our defence. But as the king of Spain is of German extraction, as he is a member and prince of the empire by the territories which descend to him from his grandfather, and as his dominions stretch along that frontier which lies most exposed to the enemy, his claim, in my opinion, is preferable to that of a stranger to our language, to our blood, and to our country." Charles was elected in consequence of this speech in the year 1520.

The two candidates had hitherto conducted their rivalry with emulation, but without enmity. They had even mingled in their competition many expressions of friendship and regard. Francis in particular declared with his usual vivacity, that his brother Charles and he were fairly and openly suitors to the same mistress: "The most assiduous and fortunate (added he) will win her; and the other must rest contented." But the preference was no sooner given to his rival, than Francis discovered
Spain discovered all the passions natural to disappointed ambition. He could not suppress his chagrin and indignation at being baulked in his favourite pursuit, and rejected, in the face of all Europe, for a youth yet unknown to fame. The spirit of Charles resented such contempt; and from this jealousy, as much as from opposition of interests, arose that emulation between those two great monarchs which involved them in almost perpetual hostilities, and kept their whole age in constant agitation.

Charles and Francis had many interfering claims in Italy; and the latter thought himself bound in honour to restore the king of Navarre to his dominions, unjustly seized by the crown of Spain. They immediately began to negotiate; and as Henry VIII. of England was the third prince of the age in power and in dignity, his friendship was eagerly courted by each of the rivals. He was the natural guardian of the liberties of Europe. Sensible of the consequence which his situation gave him, and proud of his pre-eminence, Henry knew it to be his interest to keep the balance even between the contending powers, and to restrain both, by not joining entirely with either: but he was seldom able to reduce his ideas to practice. Vanity and resentment were the great springs of all his undertakings; and his neighbours by touching these, found an easy way to draw him into their measures, and force him upon many rash and inconsiderate enterprises.

All the politic steps in Henry's government must net, however, be imputed to himself; many of them were occasioned by the ambition and avarice of his prime minister and favourite Cardinal Wolsey. This man, who, by his talents and accomplishments, had risen from one of the lowest conditions in life to the highest employments both in church and state, enjoyed a greater degree of power and dignity than any English subject ever possessed, and governed the haughty, presumptuous, and untractable spirit of Henry, with absolute authority. Francis was equally well acquainted with the character of Henry and of his minister. He had successfully flattered Wolsey's pride, by honouring him with particular marks of his confidence, andbestowing upon him the apppellations of Father, Tutor, and Governor; and he had obtained the restitution of Tournay, by adding a pension to those respectful titles. He now solicited an interview with the king of England near Calais; in hopes of being able, by familiar conversation, to attach him to his friendship and interest, while he gratified the cardinal's vanity, by affording him an opportunity of displaying his magnificence in the presence of two courts, and of discovering to the two nations his influence over their monarchs. Charles dreaded the effects of this projected interview between two gallant princes, whose hearts were no less susceptible of friendship than their manners were of inspiring it. Finding it impossible, however, to prevent a visit, in which the vanity of all parties was so much concerned, he endeavoured to defeat its purpose, and to pre-occupy the favour of the English monarch, and of his minister, by an act of complaisance still more flattering and more uncommon. Relying wholly upon Henry's generosity for his safety, he landed at Dover, in his way from Spain to the Low Countries. The king of England, who was on his way to France, charmed with such an instance of confidence, hastened to receive his royal guest; and Charles, during his short stay, had the address not only to give Henry favourable impressions of his character and intentions, but to detach Wolsey entirely from the interest of Francis. The tiara had attracted the eye of that ambitious prelate; and as the emperor knew that the papacy was the sole point of elevation, beyond his present greatness, at which he could aspire, he made him an offer of his interest on the first vacancy.

The day of Charles's departure, Henry went over to Calais with his whole court, in order to meet Francis. Their interview was in an open plain between Guines and Ardes; where the two kings and their attendants displayed their magnificence with such emulation and profuse expense, as procured it the name of the Field of the Cloth of Gold. Here Henry erected a spacious house of wood and canvas, framed in London, on which, under the figure of an English archer, was the following motto, "He prevails whom I favour;" alluding to his own political situation, as holding in his hands the balance of power among the potentates of Europe. Feats of chivalry, however, parties of galantry, and such exercises as were in that age reckoned manly or elegant, rather than serious business, occupied the two courts during the time that they continued together, which was 18 days.

After taking leave of this scene of dissipation, the king of England paid a visit to the emperor and Margaret of Savoy at Gravelines, and engaged them to go along with him to Calais; where the artful and politic Charles completed the impression which he had begun to make on Henry and his favourite, and effaced all the friendship to which the frank and generous nature of Francis had given birth. He renewed his assurances of assisting Wolsey in obtaining the papacy; and he put him in present possession of the revenues belonging to the sees of Badajoz and Palencia in Spain. He flattered Henry's pride, by convincing him of his own importance, and of the justness of the motto which he had chosen; offering to submit to his sole arbitration any difference that might arise between him and Francis.

This important point being secured, Charles repaired to Aix-la-Chapelle, where he was solemnly invested with the crown and sceptre of Charlemagne, in presence of a more splendid and numerous assembly than had ever attended a coronation. About the same time Solyman the Magnificent, one of the most accomplished, enterprising, and victorious of the Turkish princes, and a constant and formidable rival to the emperor, ascended the Ottoman throne.

The first act of Charles's administration was to appoint a diet of the empire, to be held at Worms, in order to concert with the princes proper measures for checking the progress of "those new and dangerous opinions which threatened to disturb the peace of Germany, and to overturn the religion of their ancestors." The opinions propagated by Luther and his followers were here meant. But all his efforts for that purpose were insufficient, as is related under the articles Luther and Reformation.

In 1521, the Spaniards, dissatisfied with the departure of their sovereign, whose election to the empire they foresaw would interfere with the administration of his own kingdom, and incensed at the avarice of the Flemings, to whom the direction of public affairs had been
been committed since the death of Cardinal Ximenes, several grandees, in order to shake off this oppression, entered into an association, to which they gave the name of the Saneta Inueta; and the sword was appealed to as the means of repressing this. This seemed to Francis a favourable juncture for reinstating the family of John d'Albert in the kingdom of Navarre. Charles was at a distance from that part of his dominions, and the troops usually stationed there had been called away to quell the commotions in Spain. A French army, under Andrew de Foix, speedily conquered Navarre; but that young and inexperienced nobleman, pushed on by military ardour, ventured to enter Castile. The Spaniards, though divided among themselves, united against a foreign enemy, routed his forces, took him prisoner, and recovered Navarre in a shorter time than he had spent in subdued it.

Hostilities thus began in one quarter, between the rival monarchs, soon spread to another. The king of France encouraged the duke of Bouillon to make war against the emperor, and to invade Luxembourg. Charles, after humbling the duke, attempted to enter France; but was repelled and worsted before Metziers by the famous Chevalier Bayard, distinguished among his contemporaries by the appellation of The Knight without fear and without reproach; and who united the talents of a great general to the pontifical honour and romantic gallantry of the heroes of chivalry. Francis broke into the Low Countries, where, by an excess of caution, an error not natural to him, he lost an opportunity of cutting off the whole imperial army; and, what was of still more consequence, he disgusts the constable Bourbon, by giving the command of the van to the duke of Atençon.

During these operations in the field, an unsuccessful congress was held at Calais, under the mediation of Henry VIII. It served only to exasperate the parties which it was intended to reconcile. A league was soon after concluded, by the intrigues of Wolsey, between the Pope, Henry, and Charles, against France. Leo had already entered into a separate league with the emperor, and the French were fast losing ground in Italy.

The insolence and exactions of Marshal de Lautrec, governor of Milan, had totally alienated the affections of the Milanese from France. They resolved to expel the troops of that nation, and put themselves under the government of Francis Sforza, brother to Maximilian their late duke. In this resolution they were encouraged by the pope, who excommunicated Lautrec, and took into his pay a considerable body of Swiss. The papal army, commanded by Prosper Colonna, an experienced general, was joined by supplies from Germany and Naples; while Lautrec, neglected by his court, and deserted by the Swiss in its pay, was unable to make head against the enemy. The city of Milan was betrayed by the inhabitants to the confederates; Parma and Piacenza were united to the ecclesiastical state; and of their conquests in Lombardy, only the town of Cremona, the castle of Milan, and a few inconsiderable forts, remained in the hands of the French.

Leo X. received the accounts of this rapid success with such transports of joy, as are said to have brought on a fever, which occasioned his death. The spirit of the confederacy was broken, and its operation suspend-
Spain.

reduced, without being able to make himself master of
one place within the French frontier. Charles was more
fortunate in Spain; he soon quelled the tumults which
had there arisen in his absence.

While the Christian princes were thus wasting each
other’s strength, Solyman the Magnificent entered
Hungary, and made himself master of Belgrade, reckoned
the chief barrier of that kingdom against the Turkish
power. Encouraged by this success, he turned his
victorious arms against the island of Rhodes, at that
time the seat of the knights of St John of Jerusalem;
and though every prince in that age acknowledged
Rhodes to be the great bulwark of Christendom in the
east, so violent was their animosity against each other,
that they suffered Solyman without disturbance to carry
his operations against that city and island. Lisle
Adam, the grand master, made a gallant defence; but,
after incredible efforts of courage, patience, and military
conduct, during a siege of six months, he was obliged to
surrender the place, having obtained an honourable cap-
pitulation from the sultan, who admired and respected
his heroic qualities (see Rhodes and Malta). Charles
and Francis were equally ashamed of having occa-
sioned such a loss to Christendom by their contests;
and the emperor, by way of reparations, granted to
the knights of St John the small island of Malta, where
they fixed their residence, and continued long to retain
their ancient spirit, though much diminished in power
and splendour.

Adrian VI., though the creature of the emperor, and
devoted to his interest, endeavoured to assume the
impartiality which became the common father of Christen-
dom, and laboured to reconcile the contending princes,
that they might unite in a league against Solyman,
whose conquest of Rhodes rendered him more formidable
than ever to Europe. The Italian states were no less
desirous of peace than the pope: and so much reg-
ard was paid by the hostile powers to the exhortations
of his holiness, and to a drill which he issued, requiring
all Christian princes to commit to a truce for three
years, that the imperial, the French, and the English
ambassadors at Rome, were empowered to treat of that
matter; but while they wasted their time in fruitless
negotiations, their masters were continuing their prepara-
tions for war; and other negotiations soon took place.
The confederacy against France became more formidable
than ever.

The Venetians, who had hitherto adhered to the
French interest, formed engagements with the emperor
for securing Francis Sforza in the possession of the
duchy of Milan; and the pope, from a persuasion that
the ambition of the French monarch was the only ob-
stacle to peace, acceded to the same alliance. The
Florentines, the dukes of Ferrara and Mantua, and all
the Italian powers, followed this example. Francis was
left without a single ally, to resist the efforts of a mul-
titude of enemies, whose armies everywhere threatened,
and whose territories encompassed his dominions. The
emperor in person menaced France with an invasion on
the side of Guineu; the forces of England and the Ne-
therlands hovered over Picardy, and a numerous body
of Germans was preparing to ravage Burgundy.

The dread of so many and such powerful adversaries,
it was thought, would have obliged Francis to keep
wholly on the defensive, or at least have prevented him
from entertaining any thoughts of marching into Italy.

But before his enemies were able to strike a blow,
Francis had assembled a great army, with which he
 proposed to discover all the emperor’s schemes, by march-
ing it in person into Italy: and this bold measure, the
more formidable because unexpected, could scarcely have
failed of the desired effect, had it been immediately car-
rried into execution. But the discovery of a domestic
conspiracy, which threatened the destruction of his
own kingdom, obliged Francis to stop short at Lyons.

Charles duke of Bourbon, lord high constable of
France, was a prince of the most shining merit: his
great talents equally fitted him for the council or the
field, while his eminent services to the crown entitled
him to its first favour. But unhappily Louise duchess
of Angouleme, the king’s mother, had contracted a
violent aversion against the house of Bourbon, and had
taught her son, over whom she had acquired an absolute
ascendancy, to view all the constable’s actions with a jea-
ious eye. After repeated affronts he retired from court,
and began to listen to the advances of the emperor’s
ministers. Meantime the duchess of Bourbon died; and
as the constable was no less amiable than accomplished,
the duchess of Angouleme, still susceptible of the tender
passions, favored the scheme of marrying him. But
Bourbon, who might have expected every thing to
which an ambitious mind can aspire, from the abasing
fondness of a woman who governed her son and the
kingdom, incapable of imitating Louise in her sudden
transition from hate to love, or of merely counterfeiting
a passion for one who had so long pursued him with
unprovoked malice, rejected the match with disdain,
and turned the proposal into ridicule. At once despaired
and insulted by the man whom love only could have made
her cease to persecute, Louise was filled with all the
rage of disappointed woman; she resolved to ruin, since
she could not marry Bourbon. For this purpose she
commenced an iniquitous suit against him; and by the
ceremony of Chancellor du Plat, the constable was strip-
ped of his whole family estate. Driven to despair by
so many injuries, he entered into a secret correspond-
ence with the emperor and the king of England; and
he proposed, as soon as Francis should have crossed the
Alps, to raise an insurrection among his numerous vas-
sals, and introduce foreign enemies into the heart of
France.

Happily Francis got intimation of this conspiracy
before he left the kingdom; but not being sufficiently
convinced of the constable’s guilt, he suffered so danger-
ous a foe to escape; and Bourbon entering into the
emperor’s service, employed all the force of his enter-
prising genius, and his great talents for war, to the prej-
dice of his prince and his native country.

In consequence of the discovery of this plot, and the
escape of the powerful conspirator, Francis relinquished
his intention of leading his army in person into Italy.
He was ignorant how far the infection had spread among
his subjects, and afraid that his absence might encourage
them to make some desperate attempt in favour of a man
so much beloved. He did not, however, abandon his

pend,
Spain.
pends, must have fallen into the hands of the French, had not Boniviet, who possessed none of the talents of a general, wasted his time in frivolous enterprises, till the inhabitants recovered from their consternation. The imperial army was reinforced. Colonna died; and Lannoy, viceroy of Naples, succeeded him in the command; but the chief direction of military operations was committed to Bourbon and the marquis de Pescara, the greatest generals of their age. Boniviet, destitute of troops to oppose this new army, and still more of the talents which could render him a match for its leaders, after various movements and encounters, was reduced to the necessity of attempting a retreat into France.

He was followed by the imperial generals, and routed at Biagrossa, where the famous Chevalier Bayard was killed.

The emperor and his allies were less successful in their attempts upon France. They were baffled in every quarter: and Francis, though stripped of his Italian dominions, might still have enjoyed in safety the glory of having defended his native kingdom against one half of Europe, and have bid defiance to all his enemies; but understanding that the king of England, discouraged by his former fruitless enterprises, and disgust ed with the emperor, was making no preparations for any attempt on Picardy, his ancient ardour seized him for the conquest of Milan, and he determined, notwithstanding the advanced season, to march into Italy.

The French army no sooner appeared in Piedmont, than the whole Milanese was thrown into consternation. The capital opened its gates. The forces of the emperor and Sforza retired to Lodi: and had Francis been so fortunate as to pursue them, they must have abandoned that post, and been totally dispersed; but his evil genius led him to besiege Pavia, a town of considerable strength, well garrisoned, and defended by Antonio de Leyva, one of the bravest officers in the Spanish service; before which place he was defeated and taken prisoner on the twenty-fourth day of February 1524.

The captivity of Francis filled all Europe with alarm. Almost the whole French army was cut off; Milan was immediately abandoned; and in a few weeks not a Frenchman was left in Italy. The power of the emperor, and still more his ambition, became an object of universal terror; and resolutions were everywhere taken to set bounds to it. Meanwhile Francis, deeply impressed with a sense of his misfortune, wrote to his mother Louise, whom he had left regent of the kingdom, the following short but expressive letter: "All, Madam, is lost but honour." The same courier that carried this letter carried also dispatches to Charles; who received the news of the signal and unexpected success which had crowned his arms with the most hypocritical moderation. He would not suffer any public rejoicings to be made on account of it; and said, he only valued it, as it would prove the occasion of restoring peace to Christendom. Louise, however, did not trust to those appearances; if she could not preserve what was yet left, she determined at least that nothing should be lost through her negligence or weakness. Instead of giving herself up to such lamentations as were natural to a woman so remarkable for maternal tenderness, she discovered all the foresight, and exerted all the activity, of a consummate politician. She took every possible measure for putting the kingdom in a posture of defence, while she employed all her address to appease the resentment and to gain the friendship of England; and a ray of comfort from that quarter soon broke in upon the French affairs.

Though Henry VIII. had not entered into the war against France from any concerted political views, he had always retained some imperfect idea of that balance of power which it was necessary to maintain between Charles and Francis; and the preservation of which he boasted to be his peculiar office. By his alliance with the emperor, he hoped to recover some part of those territories on the continent which had belonged to his ancestors; and therefore willingly contributed to give him the ascendancy above his rival; but having never dreamt of any event so decisive and fatal as the victory at Pavia, which seemed not only to have broken, but to have annihilated the power of Francis, he now became sensible of his own danger, as well as that of all Europe, from the loss of a proper counterpoise to the power of Charles. Instead of taking advantage of the distressed condition of France, Henry therefore determined to assist her in her present calamities. Some disgusts also had taken place between him and Charles, and still more between Charles and Wolsey. The elevation of the cardinal of Medici to St. Peter's chair, on the death of Adrian, under the name of Clement VII. had made the English minister sensible of the insincerity of the emperor's promises, while it extinguished all his hopes of the papacy; and he resolved on revenge. Charles, too, had so ill supported the appearance of moderation which be assumed, when first informed of his good fortune, that he had already changed his usual style to Henry; and instead of writing to him with his own hand, and subscribing himself "your affectionate son and cousin," he dictated his letters to a secretary, and simply subscribed himself "Charles." Influenced by all these motives, together with the glory of raising a fallen enemy, Henry listened to the flattering submissions of Louise; entered into a defensive alliance with her as regent of France, and engaged to use his best offices in order to procure the deliverance of her son from a state of captivity.

Meanwhile Francis was rigorously confined; and severe conditions being proposed to him as the price of his liberty, he drew his dagger, and, pointing it at his breast, cried, "Were better that a king should die thus!" His hand was witheld: and flattering himself, when he grew cool, that such propositions could not come directly from Charles, he desired that he might be removed to Spain, where the emperor then resided. His request was complied with; but he languished long before he obtained a sight of his conqueror. At last he was favoured with a visit; and the emperor dreading a general combination against him, or that Francis, as he threatened, might, in the obstinacy of his heart, resign his crown to the dauphin, agreed to abate somewhat of his former demands. A treaty was accordingly concluded at Madrid; in consequence of which Francis obtained his liberty. The chief article in this treaty was, that Burgundy should be restored to Charles as the rightful inheritance of his ancestors, and that Francis's two eldest sons should be immediately delivered up as hostages for the performance of the conditions stipulated. The exchange of the captive monarch

---
SPAIN.

narch for his children was made on the borders between France and Spain. The moment that Francis entered his own dominions, he mounted a Turkish horse, and putting it to its speed, waved his hand, and cried aloud several times, "I am yet a king: I am yet a king!"

Francis never meant to execute the treaty of Madrid; he had even left a protest in the hands of notaries before he signed it, that his consent should be considered as an involuntary deed, and be deemed null and void. Accordingly, as soon as he arrived in France, he assembled the states of Burgundy, who protested against the article relative to their province; and Francis coldly replied to the imperial ambassadors, who urged the immediate execution of the treaty, that he would religiously perform the articles relative to himself, but in those affecting the French monarchy, he must be directed by the sense of the nation. He made the highest acknowledgments to the king of England for his friendly interposition, and offered to be entirely guided by his counsels. Charles and his ministers saw that they were over-reached in those very arts of negotiation in which they so much excelled, while the Italian states observed with pleasure, that Francis was resolved not to execute a treaty which they considered as dangerous to the liberties of Europe. Clement absolved him from the oath which he had taken at Madrid; and the kings of France and England, the pope, the Swiss, the Venetians, the Florentines, and the duke of Milan, entered into an alliance, to which they gave the name of the Holy League, because his Holiness was at the head of it, in order to oblige the emperor to deliver up Francis's two sons on the payment of a reasonable ransom, and to re-establish Sicily in the quiet possession of the Milanese.

In consequence of this league, the confederate army took the field, and Italy once more became the scene of war. But Francis, who it was thought would have infused spirit and vigour into the whole body, had gone through such a scene of distress, that he was become diffident of himself, distrustful of his fortune, and desirous of tranquillity. He flattered himself, that the dread alone of such a confederacy would induce Charles to listen to what was equitable, and therefore neglected to send due reinforcements to his allies in Italy. Meanwhile the duke of Bourbon, who commanded the Imperialists, had made himself master of the whole Milanese, of which the emperor had promised him the investiture; and his troops beginning to mutiny for want of pay, he led them to Rome, and promised to enrich them with the spoils of that city. He was as good as his word; for though he himself was slain in planting a scaling ladder against the walls, his soldiers, rather enraged than discouraged by his death, mounted to the assault with the utmost ardour, animated by the greatness of the prize, and, entering the city sword in hand, plundered it for several days.

Never did Rome in any age suffer so many calamities, not even from the Barbarians, by whom she was often subdued, the Hess, Vandals, or Goths, as now from the subjects of a Christian and Catholic monarch. Whatever was respectable in modesty, or sacred in religion, seemed only the more to provoke the rage of the soldiery. Virginns suffered violation in the arms of their parents, and upon those altars to which they had fled for safety. Venerable prelates, after enduring every indignity and every torture, were thrown into dungeons, and menaced with the most cruel death, in order to make them reveal their secret treasures. Clement himself, who had neglected to make his escape in time, was taken prisoner, and found that the sacredness of his character could neither procure him liberty nor respect. He was confined till he should pay an enormous ransom. The pope imposed by the victorious army, and surrender to the confederate emperor all the places of strength belonging to the church.

Charles received the news of this extraordinary event with equal surprise and pleasure; but in order to conceal his joy from his Spanish subjects, who were filled with horror at the insult offered to the sovereign pontiff, and to lessen the indignation of the rest of Europe, he expressed the most profound sorrow for the success of his arms. He put himself and his court into mourning; stopped the rejoicings for the birth of his son Philip, and ordered prayers to be put up in all the churches of Spain for the recovery of the pope's liberty, which he could immediately have procured by a letter to his generals.

The concern expressed by Henry and Francis for the calamity of their ally was more sincere. Alarmed at the progress of the imperial arms, they had, even before the taking of Rome, entered into a closer alliance, and agreed to invade the Low Countries with a powerful army; but no sooner did they hear of the pope's captivity, than they changed, by a new treaty, the scene of the projected war from the Netherlands to Italy, and resolved to take the most vigorous measures for restoring him to liberty. Henry, however, contributed only money. A French army entered Italy, under the command of Marshal Laupere; Clement obtained his freedom, and was for a time carried on by the confederates with success; but the death of Lautrec, and the revolt of Andrew Doria, a Genoese admiral in the service of France, entirely changed the face of affairs. The French army was utterly ruined; and Francis, discouraged and almost exhausted by so many unsuccessful enterprises, began to think of peace, and of obtaining the release of his sons by concessions, not by the terror of his arms.

At the same time Charles, notwithstanding the advantages he had gained, had many reasons to wish for an accommodation. Sultan Solymann having overrun Hungary, was ready to break in upon the Austrian territories with the whole force of the East; and the progress of the Reformation in Germany threatened the tranquillity of the empire. In consequence of this situation of affairs, though pride made both parties conceal or dissemble their real sentiments, two ladies were permitted to restore peace to Europe. Margaret of Peace conciliating Austria, Charles's aunt, and Louisa, Francis's mother, met at Cambrai, and settled the terms of accommodation between the French king and the emperor. Francis agreed to pay two millions of crowns as the ransom of his two sons, to resign the sovereignty of Flanders and Artois, and to forego all his Italian claims; and Charles ceased to demand the restitution of Burgundy.

All the steps of this negotiation had been communicated to the king of England; and Henry was, on that occasion, so generous to his friend and ally Francis, that he sent him an annual of near six hundred thousand crowns, in order to enable him to fulfil his agreement.
with Charles. But Francis's Italian confederates were less satisfied with the treaty of Cambrai. They were almost wholly abandoned to the will of the emperor; and seemed to have no other means of security but his equity and moderation. Of these, from his past conduct, they had not formed the most advantageous idea. But Charles's present circumstances, more especially in regard to the Turks, obliged him to behave with a generosity inconsistent with his character. The Florentines alone, whom he reduced under the dominion of the family of Medici, had reason to complain of his severity. Sforza obtained the investiture of Milan and his pardon; and every other power experienced the lenity of the conqueror.

After having received the imperial crown from the hands of the pope at Bologna, Charles proceeded on his journey to Germany, where his presence was become highly necessary; for although the conduct and valour of his brother Ferdinand, on whom he had conferred the hereditary dominions of the house of Austria, and who had been elected king of Hungary, had obliged Solymans to retire with infamy and loss, his return was to be feared, and the disorders of religion were daily increasing; an account of which, and of the emperor's transactions with the Protestants, is given under the article Reformation.

Charles having exerted himself as much as he could against the reformers, undertook his first expedition against the piratical states of Africa. Barbary, or that part of the African continent lying along the coast of the Mediterranean sea, was then nearly in the same condition which it is at present. Morocco, Algiers, and Tunis, were its principal states; and the two last were nests of pirates. Barbarossa, a famous corsair, had succeeded his brother in the kingdom of Algiers, which he had formerly assisted him to usurp. He regulated with much prudence the interior police of his kingdom, carried on his piracies with great vigour, and extended his conquests on the continent of Africa; but perceiving that the natives submitted to his government with impatience, and fearing that his continual depredations would one day draw upon him a general combination of the Christian powers, he put his dominions under the protection of the grand seignor. Solymans, flattered by such an act of submission, and charmed with the boldness of the man, offered him the command of the Turkish fleet. Proud of this distinction, Barbarossa repaired to Constantinople, and made use of his influence with the sultan to extend his own dominion. Partly by force, partly by treachery, he usurped the kingdom of Tunis; and being now possessed of greater power, he carried on his depredations against the Christian states, more with destructive violence than ever.

Daily complaints of the piracies and ravages committed by the galleys of Barbarossa were brought to the emperor by his subjects, both in Spain and Italy; and all Christendom seemed to look to him, as its greatest and most fortunate prince, for relief from this new and odious species of oppression. At the same time Muley-Hasauen, the exiled king of Tunis, finding none of the African princes able or willing to support him in recovering his throne, applied to Charles for assistance against the usurper. Equally desirous of delivering his dominions from the dangerous neighbourhood of Barbarossa, of appearing as the protector of an unfortunate prince, and of acquiring the glory annexed to the whole of his operations, the emperor readily concluded a treaty with Muley Hasauen, and set sail for Tunis with a formidable armament.

The Goletta, a sea-port town, fortified with 300 pieces of cannon, was taken, together with all Barbarossa's fleet: he was defeated in a pitched battle, and 10,000 Christian slaves, having knocked off their letters, and Tunis made themselves masters of the citadel, Tunis was prepared to surrender. But while Charles was deliberating about the condition of his troops, fearing that they would massacre the inhabitants cruelly on the occasion, his troops broke suddenly into the town, and pillaged and massacred without distinction. Thirty thousand persons perished by the sword, and 10,000 were made prisoners. The sceptre was restored to Muley Hasauen, on condition that he should acknowledge himself a vassal of the crown of Spain, put into the emperor's hands all the fortified sea ports in the kingdom of Tunis, and pay annually 12,000 crowns for the subsistence of the Spanish garrison in the Goletta. These points being settled, and 20,000 Christian slaves freed from bondage either by arms or by treaty, Charles returned to Europe, where his presence was become necessary; while Barbarossa, who had retired to Bona, recovered new strength, and again became the tyrant of the ocean.

The king of France took advantage of the emperor's absence to revive his pretensions in Italy. The treaty of Cambrai had repressed but not extinguished the flames of discord. Francis, in particular, who waited pretensions only for a favourable opportunity of recovering the territories and reputation which he had lost, continued to negotiate against his rival with different courts. But all his negotiations were disconcerted by unforeseen accidents. The death of Clement VII, (whom he had gained by marrying his son the duke of Olenais, afterwards Henry II. to Catherine of Medici, the niece of that pontiff), deprived him of all the support which he hoped to receive from the court of Rome. The king of England, occupied with domestic cares and projects, declined engaging in the affairs of the continent; and the Protestant princes, associated by the league of Smalkalde, to whom Francis had also applied, and who seemed disposed at first to listen to him, filled with indignation and resentment at the cruelty with which some of their reformed brethren had been treated in France, refused to have any connection with the enemy of their religion.

Francis was neither cruel nor bigotted: he was too indolent to concern himself about religious disputes; but his principles becoming suspected, at a time when the emperor was gaining immortal glory by his expedition against the infidels, he found it necessary to vindicate himself by some extraordinary demonstration of reverence for the established faith. The indifferent zeal of some Protestant converts furnished him with the occasion. They had affixed to the gates of the Louvre and other public places papers containing indictment of illicit masses on the rite of the Roman church. Sixty of the persons concerned in this rash action were seized; and the king, pretending to be struck with horror at their blasphemies, appointed a solemn procession, in order to avert the wrath of heaven. The holy sacrament was carried through the city of Paris in great pomp: Francis walked uncovered before it, bearing a torch in his hand.
Spain

land; the princes of the blood supported the canopy over it; the nobles walked behind. In presence of this numerous assembly, the king declared, that if one of his hands were infected with heresy, he would cut it off with the other; "and I would sacrifice (added he) even my own children, if found guilty of that crime."

As an awful proof of his sincerity, the six unhappy persons who had been seized were publicly burnt, before the procession was finished, and in the most cruel manner. They were fixed upon a machine which descended into the flames, and retired alternately, until they expired. -No wonder that the Protestant princes were incensed at such barbarity!

Francis, though unsupported by any ally, commanded his army to advance towards the frontiers of Italy, under pretense of chastising the duke of Milan for a breach of the law of nations, in putting to death his ambassador. The operations of war, however, soon took a new direction. Instead of marching directly to the Milanese, Francis commenced hostilities against the duke of Savoy, whom he had cause to be dissatisfied, and on whom he had some claims; and before the end of the campaign, this feeble prince saw himself stripped of all his dominions, except the province of Piedmont. To complete his misfortunes, the city of Geneva, the sovereignty of which he claimed, and where the reformers had already got footing, threw off its yoke; and its revolt drew along with it the loss of the adjacent territory. Geneva was then an imperial city, and till lately remained entirely free.

In this extremity the duke of Savoy saw no resource but in the emperor's protection; and as his misfortunes were chiefly occasioned by his attachment to the imperial interest, he had a title to immediate assistance. But Charles, who was just returned from his African expedition, was not able to lend him the necessary support. His treasury was entirely drained, and he was obliged to disband his army till he could raise new supplies. Mean time the death of Sforza duke of Milan entirely changed the nature of the war, and afforded the emperor full leisure to prepare for action. The French monarch's pretext for taking up arms was at once cut off; but as the duke died without issue, all Francis's rights to the duchy of Milan, which he had yielded only to Sforza and his descendants, returned to him in full force. He instantly renewed his claim to it; and if he had ordered his army immediately to advance, he might have made himself master of it. But he unfortunately wasted his time in fruitless negotiations, while his more politic rival took possession of the duchy as a vacant Sef of the empire; and though Charles seemed still to admit the equity of Francis's claim, he delayed granting the investiture under various pretences, and as secretly taking every possible measure to prevent him from regaining footing in Italy.

During the time gained in this manner, Charles had recruited his finances, and of course his armies; and finding himself in a condition for war, he at last threw off the mask under which he had so long concealed his designs from the court of France. Entering Rome with great pomp, he pronounced before the pope and cardinals, assembled in full consistory, a violent invective against Francis, by way of reply to his propositions concerning the investiture of Milan. Yet Francis, by an unaccountable fatality, continued to negotiate, as if it had been still possible to terminate their differences in an amicable manner; and Charles, finding him so eager to run into the snare, favoured the deception, and, by seeming to listen to his proposals, gained yet more time for the execution of his ambitious projects.

If misfortunes had rendered Francis too different, success had made Charles too sanguine. He presumed on tempt to nothing less than the subversion of the French monarchy; nay, he considered it as a certain event. Having chased the forces of his rival out of Piedmont and Savoy, he pushed forward at the head of 50,000 men, contrary to the advice of his most experienced ministers and generals, to invade the southern provinces of France; while two other armies were ordered to enter it, the one on the side of Picardy, the other on the side of Champagne.

He thought it impossible that Francis could resist so many unexpected attacks on such different quarters; but he found himself mistaken.

The French monarch fixed on the most effectual but is disapproved and he prudently persevered in following it, though contrary to his own natural temper and to the genius of his people. He determined to remain altogether upon the defensive, and to deprive the enemy of subsistence by laying waste the country before them. The execution of this plan was committed to the mareschal Montmorency its author, a man happily fitted for such a trust by the inflexible severity of his disposition. He made choice of a strong camp, under the walls of Avignon, at the confluence of the Rhone and Durance, where he assembled a considerable army; while the king, with another body of troops, encamped at Valence, higher up the Rhone. Marseilles and Arles were the only towns he thought it necessary to defend; and each of these he furnished with a numerous garrison of his best troops. The inhabitants of the other towns were compelled to abandon their habitations: the fortifications of such places as might have afforded shelter to the enemy were thrown down; corn, forage, and provisions of every kind, were carried off or destroyed; the mills and ovens were ruined, and the wells filled up or rendered useless.

This devastation extended from the Alps to Marseilles, and from the sea to the confines of Dauphiny; so that the emperor, when he arrived with the van of his army on the confines of Provence, instead of that rich and populous country which he expected to enter, beheld nothing but one vast and desert solitude. He did not, however, despair of success, though he saw that he would have many difficulties to encounter; and as an encouragement to his officers, he made them liberal promises of lands and honours in France. But all the land which any of them obtained was a grave, and their master lost much honour by this rash and presumptuous enterprise. After unsuccessfully investing Marseilles and Arles, after attempting in vain to draw Montmorency from his camp at Avignon, and not daring to attack it, Charles having spent two inglorious months in Provence, and lost one half of his troops by disease or by famine, was under the necessity of ordering a retreat; and though he was some time in motion before the enemy suspected his intention, it was conducted with so much precipitation and disorder, as to deserve the name of a flight, since the light troops of France turned it into a perfect rout. The invasion of Picardy
Spain.

Picardy was not more successful: the imperial forces were obliged to retire without seeking any conquest of importance.

Charles had no sooner conducted the shattered remains of his army to the frontiers of Milan, than he set out for Genoa; and unwilling to expose himself to the scorn of the Italians after such a reverse of fortune, he embarked directly for Spain.

Meanwhile Francis gave himself up to that vain resentment which had formerly disgraced the prosperity of his rival. They had frequently, in the course of their quarrels, given each other the lie, and mutual challenges had been sent; which, though productive of no serious consequences between the parties, had a powerful tendency to encourage the pernicious practice of duelling. Charles, in his invective pronounced at Rome, had publicly accused Francis of perfidy and breach of faith; Francis now exceeded Charles in the indecency of his accusations. The dauphin dying suddenly, his death was imputed to poison: Montecuccu his cup-bearer was put to the rack; and that unhappy nobleman, in the agonies of torture, accused the emperor's generals Gonzaga and de Leyva, of instigating him to the detestable act. The emperor himself was suspected; nay, this extorted confession, and some obscure hints, were considered as incontestable proofs of his guilt; though it was evident to all mankind, that neither Charles nor his generals could have any inducement to perpetrate such a crime, as Francis was still in the vigour of life himself, and had two sons besides the dauphin, grown up to a good age.

But the incensed monarch's resentment did not stop here. Francis was not satisfied with endeavouring to blacken the character of his rival by an ambiguous testimony which led to the most injurious suspicions, and upon which the most cruel constructions had been put; he was willing to add rebellion to murder. For this purpose he went to the parliament of Paris; where being seated with the usual solemnities, the advocate-general appeared, and accused Charles of Austria (so he affected to call the emperor) of having violated the treaty of Cambray, by which he was freed from the homage due to the crown of France for the counties of Artois and Flanders; adding, that this treaty being now void, he was still to be considered as a vassal of France, and consequently had been guilty of rebellion in taking arms against his sovereign. The charge was sustained, and Charles was summoned to appear before the parliament of Paris at a day fixed. The term expired; and no person appearing in the emperor's name, the parliament gave judgment, that Charles of Austria had forfeited, by rebellion and contumacy, the counties of Flanders and Artois, and declared these fiefs reunited to the crown of France.

Francis, soon after this vain display of his animosity, marched into the Low Countries, as if he had intended to execute the sentence pronounced by his parliament; but a suspension of arms took place, through the interference of the queens of France and Hungary, before any thing of consequence was effected; and this cessation of hostilities was followed by a truce concluded at Nice, through the mediation of the reigning pontiff Paul III., of the family of Farnese, a man of a venerable character and pacific disposition.

Each of these rival princes had strong reasons to incline them to peace. The finances of both were exhausted; and the emperor, the more powerful of the two, was deeply impressed with the dread of the Turkish arms, which Francis had drawn upon him by a league with Soliman. In consequence of this league, Barbary and the Turks, with a great fleet appeared on the coast of Naples; filled that kingdom with consternation; landed without resistance near Taranto; obliged Castro, a place of some strength, to surrender; plundered the adjacent country; and was taking measures for securing and extending his conquests, when the unexpected arrival of Duria, the famous Genoese admiral, together with the pope's galleys and a squadron of the Venetian fleet, made it prudent for him to retire. The sultan's forces also invaded Hungary, where Mahmet the Turkish general, after gaining several inferior advantages, defeated the Germans in a great battle at Essek on the Drave. Happily for Charles and Europe it was not in Francis's power at this juncture either to join the Turks or assemble an army strong enough to penetrate into the Milanese. The emperor, however, was sensible that he could not long resist the efforts of two such powerful confederates, nor expect that the same fortunate circumstances would concur a second time in his favour; he therefore thought it necessary, both for his safety and reputation, to give his consent to a truce: and Francis chose rather to run the risk of disobliging his new ally the sultan, than to draw on his head the indignation, and perhaps the arms of all Christendom, by obstinately obstructing the re-establishment of tranquility, and contributing to the aggrandizement of the Infidels.

These considerations inclined the contending monarchs to listen to the arguments of the holy father; but he found it impossible to bring about a final accommodation between them, each inflexibly persisted in asserting his own claims. Nor could he prevail on them to see one another, though both came to the place of rendezvous: so great was the remains of distrust and rancour, or such the difficulty of adjusting the ceremonial! Yet, improbable as it may seem, a few days after signing the truce, the emperor, in his passage to Barcelona, being driven on the coast of Provence, Francis invited him to come ashore; frankly visited him on board his galley, and was received and entertained with the warmest demonstrations of esteem and affection. Charles, with an equal degree of confidence, paid the king next day a visit at Aigues-mortes; where these two hostile rivals and vindictive enemies, who had accused each other of every kind of baseness, conversing together with all the cordiality of brothers, seemed to vie with each other in expressions of respect and friendship.

Besides the glory of having restored tranquility to Europe, the pope gained a point of much consequence gained by to his family. He obtained for his grandson, Margaret of Austria, the emperor's natural daughter, formerly the wife of Alexander de Medici, whom Charles had raised to the supreme power in Florence. Laurenein de Medici, the kinsman and intimate companion of Alexander, had assassinated him by one of the blackest treasons recorded in history. Under pretence of having secured him an assignation with a lady of the highest rank, of great beauty, he drew him into a secret apartment of his house, and there stabbed him as he lay carelessly on a couch, expecting the embrace of the lovely fair, whom he had
Spain.

often solicited in vain. Laurencin, however, did not reap the fruits of his crime; for though some of his countrymen extolled him as a third Brutus, and endeavored to seize this occasion for recovering their liberties, the government of Florence passed into the hands of Cosmo II., another kinsman of Alexander. Cosmo was desirous of marrying the widow of his predecessor; but the emperor chose rather to oblige the pope, by bestowing his daughter upon Octavio Farnese, son of the duke of Parma.

Charles had soon farther cause to be sensible of his obligations to the holy father for bringing about the treaty of Nice. His troops everywhere mutinied for want of pay, and the ability of his generals only could have prevented a total revolt. He had depended, as his chief resource for discharging the arrears due to his soldiers, upon the subsidies which he expected from his Castilian subjects. For this purpose he assembled the Cortes of Castile at Toledo; and having represented to them the great expense of his military operations, he proposed to levy such supplies as the present exigency of affairs demanded, by a general excise on commodities; but the Spaniards, who already felt themselves oppressed by a load of taxes unknown to their ancestors, and who had often complained that their country was drained of its wealth and inhabitants, in order to prosecute quarrels in which they had no interest, determined not to add voluntarily to their own burdens. The nobles, in particular, inveighed with great vehemence against the imposition proposed, as an encroachment on the valuable and distinguished privilege of their order, that of being exempted from the payment of any tax. After employing arguments and promises in vain, Charles dismissed the assembly with indignation; and from that period neither the nobles nor the prelates have been called to the Cortes, on pretense that such as pay no part of the public taxes should not claim a vote in laying them on. These assemblies have since consisted merely of the procurators or representatives of 18 cities, two from each; in all 36 members, who are absolutely at the devotion of the crown.

The citizens of Ghent, still more bold, broke out not long after into open rebellion against the emperor’s government, on account of a tax which they judged contrary to their ancient privileges, and a decision of the council of Mechlin in favour of the imperial authority. Enraged at an unjust imposition, and rendered desperate on seeing their rights betrayed by that very court which was bound to protect them, they flew to arms, seized several of the emperor’s officers, and drove such of the nobility as resided among them out of the city. Sensible, however, of their inability to support what their zeal had prompted them to undertake, and desirous of securing a protector against the formidable forces with which they might expect soon to be attacked, they offered to acknowledge the king of France as their sovereign, to put him into immediate possession of their city, and to assist him in recovering those provinces in the Netherlands which had anciently belonged to his crown. True policy directed Francis to comply with this proposal. The counties of Flanders and Artois were more valuable than the duchy of Milan, for which he had so long contended; and their situation in regard to France made it more easy to conquer or to defend them. But Francis over-rated the Milanesa. He had lived in friendship with the emperor ever since their interview at Aigues-mortes, and Charles had promised him the investiture of that duchy. Forgetful, therefore, all his past injuries, and the deceitful promises by which he had been so often duped, the credulous, generous Francis, not only rejected the propositions of the citizens of Ghent, but communicated to the emperor his whole negociation with the malcontents.

Judging of Charles’s heart by his own, Francis hoped by this seemingly disinterested proceeding to obtain at once the investiture of Milan; and the emperor, well acquainted with the weakness of his rival, flattered himself in this apprehension, for his own selfish purposes. His He allowed presence being necessary in the Netherlands, he demanded for Charles to pass a passage through France. It was immediately granted him; and Charles, to whom every moment was precious, set out, notwithstanding the remonstrances of his council and the fears of his Spanish subjects, with a small but splendid train of 300 persons. He was met on the frontiers of France by the dauphin and the duke of Orleans, who offered to go into Spain, and remain there as hostages, till he should reach his own dominions; but Charles replied, that the king’s honour was sufficient for his safety, and prosecuted his journey without any other security. The king entertained him with the utmost magnificence at Paris, and the two young princes did not take leave of him till he entered the Low Countries; yet he still found means to evade his promise, and Francis continued to believe him sincere.

The citizens of Ghent, alarmed at the approach of severity of the emperor, who was joined by three armies, sent ambassadors to implore his mercy, and offered to throw open their gates. Charles only condescended to reply, “That he would appear among them as a sovereign and a judge, with the sceptre and the sword.” He accordingly entered the place of his nativity on the anniversary of his birth; and instead of that lenity which might have been expected, exhibited an awful example of his severity. Twenty-six of the principal citizens were put to death: a greater number was banished: the city was declared to have forfeited its privileges; a new system of laws and political administration was prescribed; and a large fine was imposed on the inhabitants, in order to defray the expense of erecting a citadel, together with an annual tax for the support of a garrison. They were not only despoiled of their ancient immunities, but made to pay, like conquered people, for the means of perpetuating their own slavery.

Having thus re-established his authority in the Low Countries, and being now under no necessity of continuing that scene of falsehood and dissimulation with which he had amused the French monarch, Charles began gradually to throw aside the veil under which he had concealed his intentions with respect to the Milanesa, and at last peremptorily refused to give up a territory of such value, or voluntarily to make such a liberal addition to the strength of an enemy by diminishing his own power. He even denied that he had ever made any promise which could bind him to an action so foolish, and so contrary to his own interest.

This transaction exposed the king of France to as much scorn as it did the emperor to censure. The credulous simplicity of Francis seemed to merit no other return, after experiencing so often the duplicity and artifices of his rival. He remonstrated, however, and expressed
SPAIN.

claimed as if this had been the first circumstance in which the emperor had deceived him. The insult offered to his understanding affected him even more sensibly than the injury done to his interest; and he discovered such resentment as made it obvious that he would seize on the first opportunity of revenge, and that a new war would soon desolate the European continent.

Meanwhile Charles was obliged to turn his attention towards the affairs of Germany. The Protestants having in vain demanded a general council, pressed him earnestly to appoint a conference between a select number of divines of each party, in order to examine the points in dispute. For this purpose a diet was assembled at Ratisbon: and such a conference, notwithstanding the opposition of the pope, was held with great solemnity in the presence of the emperor. But the divines chosen to manage the controversy, though men of learning and moderation, were only able to settle a few speculative opinions, all points relative to worship and jurisdiction serving to inflame the minds of the disputants. Charles, therefore, finding his endeavours to bring about an accommodation ineffectual, and being impatient to close the diet, prevailed on a majority of the members to approve of the following edict of recess; viz. that the articles concerning which the divines had agreed, should be held as points decided; that those about which they had differed, should be referred to the determination of a general council, or if that could not be obtained, to a national synod: and should it prove impracticable also to assemble a synod of Germany, that a general diet of the empire should be called within 18 months, in order to give final judgment on the whole controversy; that, in the mean time, no innovations should be attempted, nor any endeavours employed to gain prosectyes.

This diet gave great offence to the pope. The bare mention of allowing a diet, composed chiefly of laymen, to pass judgment in regard to articles of faith, appeared to him no less criminal and profane than the worst of those heresies which the emperor seemed so zealous to suppress. The Protestants also were dissatisfied with it, as it considerably abridged the liberty which they at that time enjoyed. They murmured loudly against it; and Charles, unwilling to leave any seeds of discontent in the empire, granted them a private declaration, exempting them from whatever they thought injurious or oppressive in the recess, and ascertaining to them the full possession of all their former privileges.

The situation of the emperor’s affairs at this juncture made these extraordinary concessions necessary. He foresaw a rupture with France to be unavoidable, and he was alarmed at the rapid progress of the Turks in Hungary. A great revolution had happened in that kingdom. John Zapoly, Scepus, by the assistance of Soliman, had wrested from the king of the Romans a considerable part of the country. John died, and left an infant son. Ferdinand attempted to take advantage of the minority, in order to repose himself of the whole kingdom; but his ambition was disappointed by the activity and address of George Martinuzzi, bishop of Waradin, who shared the regency with the queen. Sensible that he was unable to oppose the king of the Romans in the field, Martinuzzi satisfied himself with holding out the fortified towns, all of which he provided with every thing necessary for defence; and at the same time he sent ambassadors to Soliman, beseeching him to extend towards the son that imperial protection which had so generously maintained the father on his throne. Ferdinand used his utmost endeavours to thwart this negotiation, and even meanly offered to hold the Hungarian crown on the same ignominious condition by which John had held it, that of paying tribute to the Porte. But the sultan saw such advantages from exposing the interest of the young king, that he instantly marched into Hungary; and the Germans, having formed the siege of Buda, were defeated with great slaughter before that city. Soliman, however, instead of becoming the protector of the infant sovereign whom he had relieved, made use of this success to extend his own dominions: he sent the queen and her son into Transylvania, which province he allotted them, and added Hungary to the Ottoman empire.

Happily for the Protestants, Charles received intelligence of this revolution soon after the diet at Ratisbon; and by the concessions which he made them, he obtained such liberal supplies, both of men and money, as left him under little anxiety about the security of Germany. He therefore hastened to join his fleet and army in Italy, in order to carry into execution a great and favourite enterprise which he had concerted against Algiers: a successful undertaking of which it would certainly have been more consistent with his dignity to have conducted the whole force of the empire against Soliman, the common enemy of Christendom, who was ready to enter his Austrian dominions. But many reasons induced Charles to prefer the African expedition: he wanted strength, or at least money, to combat the Turks in so distant a country as Hungary; and the glory which he had formerly acquired in Barbary led him to hope for the like success, while the cries of his Spanish subjects roused him to take vengeance on their ravagers. But the unfortunate event of this expedition has already been related under the article ALGIERS, No. 14—20.

The loss which the emperor suffered in this calamitous expedition encouraged the king of France to begin hostilities, on which he had been for some time resolved; and Charles and an action dishonourable to civil society furnished him with too good a pretext for taking arms. The marquis del Guasto, governor of the Milanese, having got intelligence of the motions and destination of two ambassadors, Rincon and Fergese, whom Francis had dispatched, the one to the Ottoman Porte, the other to the republic of Venice; knowing how much his master wished to discover the intentions of the French monarch, and of what consequence it was to retard the execution of his measures, he employed some soldiers belonging to the garrison of Ravia to lie in wait for these ambassadors as they sailed down the Po, who murdered them and most of their attendants, and seized their papers. Francis immediately demanded reparation for this barbarous outrage; and as Charles endeavoured to put him off with an evasive answer, he appealed to all the courts of Europe, setting forth the heinousness of the injury, the impiety of the emperor in disregarding his just request, and the necessity of vengeance. But Charles, who was a more profound negotiator, deflected in a great measure the effects of these representations: he secured the fidelity of the Protestant princes in Germany, by granting them new concessions; and he engaged the king of England to espouse his cause, under pretence
SPAIN.

Spain... pretexts of defending Europe against the Infidels; while Francis was only able to form an alliance with the kings of Denmark and Sweden (who for the first time interested themselves in the quarrels of the more potent monarchs of the south), and to renew his treaty with Solyman, which drew on him the indignation of Christendom.

But the activity of Francis supplied all the defects of his negotiation. Five armies were soon ready to take the field, under different generals, and with different destinations. Nor was Charles waiting in his preparations. He and Henry a second time made an ideal division of the kingdom of France. But as the hostilities which followed terminated in nothing decisive, and were distinguished by no remarkable event, except the battle of Cerisoles (gained by Count d’Enguicen over the imperialists, and in which 10,000 of the emperor's best troops fell) at last Francis and Charles, mutually tired of harrying each other, concluded at Crepy a treaty of peace, in which the king of England was not mentioned; and from being implacable enemies, became once more, to appearance, cordial friends, and even allies by the ties of blood.

The chief articles of this treaty were, that all the conquests which either party had made since the truce of Nice should be restored; that the emperor should give in marriage to the duke of Orleans, either his own eldest daughter, with the Low Countries, or the second daughter of his brother Ferdinand, with the investiture of the Milanese; that Francis should renounce all pretensions to the kingdom of Naples, as well as to the sovereignty of Flanders and Artois, and Charles give up his claim to the duchy of Burgundy; and that both should unite in making war against the Turks.

The emperor was chiefly induced to grant conditions so advantageous to France, by a desire of humbling the Protestant princes in Germany. With the papal jurisdiction, he foresaw they would endeavour to throw off the imperial authority; and he determined to make his zeal for the former a pretext for enforcing and extending the latter. However, the death of the duke of Orleans before the consummation of his marriage, disentangled the emperor from the most troublesome stipulation in the treaty of Crepy; and the French monarch, being still engaged in hostilities with England, was unable to obtain any preparation for the loss which he suffered by this unforeseen event. These hostilities, like those between Charles and Francis, terminated in nothing decisive. Equally tired of a struggle attended with no glory or advantage to either, the contending princes concluded, at Campe, near Ardies, a treaty of peace; in which it was stipulated, that France should pay the arrears due by former treaties to England. But these arrears did not exceed one-third of the sums expended by Henry on his military operations; and Francis being in no condition to discharge them, Boulogne (a chargeable pledge) was left in the hands of the English as a security for the debt.

In consequence of the emperor’s resolution to humble the Protestant princes, he concluded a dishonourable peace with the Porte, stipulating that his brother Ferdinand should pay tribute for that part of Hungary which he still possessed; while the sultan enjoyed the imperial and undisturbed possession of all the rest. At the same time he entered into a league with Pope Paul III. for the extirpation of heresy; but in reality with a view to oppress the liberties of Germany. Here, however, his ambition met with a severe check; for though he was successful at first, he was obliged in 1552 to conclude a peace with the Protestants on their own terms; as has been related under the article Reformation, No. 26—32.

By the peace concluded on this occasion the emperor attempted to wheel Metz, Toul, and Verdun, which had formed the barrier of the empire on that quarter; and therefore soon after put himself at the head of an army, in order to recover these three bishoprics. In order to conceal the destination of his army, he gave out, that he intended to lead it into Hungary, to second Maurice in his operations against the Infidels; and as that pretext failed him, when he began to advance towards the Rhine, he propagated a report that he was marching first to chastise Albert of Brandenburg, who had refused to be included in the treaty of Passau, and whose cruel exactions in that part of Germany called loudly for redress.

The French, however, were not deceived by these arts. Isobled Henry immediately guessed the true object of Charles’s to raise the armament, and resolved to defend his conquest with vigour. The defence of Metz, against which it was foreseen the whole weight of the war would be turned, was committed to Francis of Lorraine, duke of Guise, who possessed in an eminent degree all the qualities that render men great in military command. He repaired with joy to the dangerous station; and many of the French nobility, and even princes of the blood, eager to distinguish themselves under such a leader, entered Metz as volunteers. The city was of great extent, ill fortified, and the suburbs large. For all these defects the duke endeavoured to provide a remedy. He repaired the old fortifications with all possible expedition, labouring with his own hands; the officers imitated his example; and the soldiers, thus encouraged, cheerfully submitted to the most severe toils; he erected new works, and he levelled the suburbs with the ground. At the same time he filled the magazines with provisions and military stores, compelled all useless persons to leave the place, and laid waste the neighbouring country; yet such were his popular talents, as well as his arts of acquiring an ascendancy over the minds of men, that the citizens not only refrained from murmuring, but seconded him with no less ardour than the soldiers in all his operations—in the ruin of their estates, and in the havoc of their public and private buildings.

Meanwhile the emperor continued his march towards Lorraine, at the head of 60,000 men. On his approach Albert of Brandenburg, whose army did not exceed 20,000, withdrew into that principality as if he intended to join the French king; and Charles, notwithstanding the advanced season, it being towards the end of October, laid siege to Metz, contrary to the advice of his most experienced officers.

The attention of both the besiegers and the besieged was turned for some time towards the motions of Albert, who still hovered in the neighbourhood, undetermined which side to take, though resolved to sell his service. Charles at last came up to his price, and he joined the imperial army. The emperor now flattered himself that nothing could resist his force; but he found himself deceived. After a siege of almost 60 days, du-
Spanish

When the French sallied out to attack the enemy's rear, the imperial camp was filled with the sick and wounded, with the dead and the dying. All the roads by which the army retired were strewed with the same miserable objects; who, having made an effort beyond their strength to escape, and not being able to proceed, were left to perish without assistance. Happily that, and all the kind offices which their friends had not the power to perform, they received from their enemies. The duke of Guise ordered them all to be taken care of, and supplied with every necessity; he appointed physicians to attend, and direct what treatment was proper for the sick and wounded, and what refreshments for the feeble; and such as recovered lie sent home, under an escort of soldiers, and with money to bear their charges. By these acts of humanity, less common in that age, the duke of Guise completed that heroic character which he had justly acquired by his brave and successful defence of Metz.

His further misfortunes were not confined to Germany. During his residence at Villach, he had been obliged to borrow 200,000 crowns of Cosmo de' Medici; and so low was his credit, that he was obliged to put Cosmo in possession of the principality of Piombino as a security for that considerable sum; by which means he lost the footing he had hitherto maintained in Tuscany. Much about the same time he lost Sienna. The citizens, who had long enjoyed a republican government, rose against the Spanish garrison, which they had admitted as a check upon the tyranny of the nobility, but which they found was meant to enslave them; forgetting their domestic animosities, they recalled the exiled nobles; they demolished the citadel, and put themselves under the protection of France.

To these unfortunate events one still more fatal had almost succeeded. The severe administration of the vicerey of Naples had filled that kingdom with murmuring and dissatisfaction. The prince of Salerno, the head of the malecontents, fled to the court of France. The French monarch, after the example of his father, applied to the grand signior; and Solyman, at that time highly incensed against the house of Austria on account of the proceedings in Hungary, sent a powerful fleet into the Mediterranean, under the command of the corsair Dragut, an officer trained up under Barbarossa, and scarcely inferior to his master in courage, talents, or in good fortune. Dragut appeared on the coast of Calabria at the time appointed; but not being joined by the French fleet according to concert, he returned to Constantinople, after plundering and burning several places, and filling Naples with consternation.

Highly mortified by so many disasters, Charles retired into the Low Countries, breathing vengeance against France: and here the war was carried on with considerable vigour. Impatient to efface the stain which his military reputation had received before Metz, Charles laid siege to Tournai; and the fortifications being in disrepair, that important place was carried by assault. 

Hesdin also was invested, and carried in the same manner. The king of France was too late in assembling his forces to afford relief to either of these places; and the emperor afterwards cautiously avoided an engagement.

The imperial arms were less successful in Italy. The vicerey of Naples failed in an attempt to recover Sienna; in other and the French not only established themselves more firmly in Tuscany, but conquered part of the island of Corsica. Nor did the affairs of the house of Austria go on better in Hungary during the course of this year. Isabella and her son appeared once more in Transylvania, at a time when the people were ready for revolt, in order to revenge the death of Martinuzzi, whose loss they had severely felt. Some noblemen of eminence declared in favour of the young king; and the bashaw of Belgrade, by Solyman's order, espousing his cause, in opposition to Ferdinand, Castaldo, the Austrian general, was obliged to abandon Transylvania to Isabella and the Turks.

In order to counterbalance those and other losses, the emperor, in 1554, concerted a marriage between his son Philip and Mary of England, in hopes of adding Spain and that kingdom to his other dominions. Meanwhile Mary of the war between Henry and Charles was carried on England with various success in the Low Countries, and in Italy, with much to the disadvantage of France. The French, under the command of Strozzi, were defeated in the battle of Merciano; Sienna was reduced by Medicino, the Florentine general, after a siege of ten months; and the gallant Siennese were subjected to the Spanish yoke. Much about the same time a plot was formed by the Franciscans, but happily discovered before it could be carried into execution, to betray Metz to the Imperialists. The father guardian, and twenty other monks, received sentence of death on account of this conspiracy; but the guardian, before the time appointed for his execution, was murdered by his incensed accomplices, whom he had seduced; and six of the youngest were pardoned.

While war thus raged in Italy and the Low Countries, Germany enjoyed such profound tranquillity, as afforded the diet full leisure to confirm and perfect the plan of religious pacification agreed upon at Passan, and referred to the consideration of the next meeting of the Germanic body. During the negociation of this treaty, an event happened which astonished all Europe, and confounded the reasonings of the wisest politicians. The emperor Charles V. though no more than 56, an age when objects of ambition operate with full force on the dominions of the mind, and are generally pursued with the greatest ardour, had for some time formed the resolution of re-signing his hereditary dominions to his son Philip. He now determined to put it into execution. Various have been the opinions of historians concerning a resolution so singular and unexpected; but the most probable seem to be, the disappointment which Charles had met with in his ambitious hopes, and the daily decline of his health. He had early in life been attacked with the gout; and the fits were now become so frequent and severe, that not only the vigour of his constitution was broken, but the faculties of his mind were sensibly impaired. He therefore judged it more decent to conceal his infirmities in some solitude, than to expose them any longer to the public eye; and as he was unwilling to
to forfeit the fame, or lose the acquisitions of his better years, by attempting to guide the reins of government when he was no longer able to hold them with steadiness, he determined to seek in the tranquility of retirement, that happiness which he had in vain pursued amidst the tumults of war and the intrigues of state.

In consequence of this resolution, Charles, who had already ceded to his son Philip the kingdom of Naples and the duchy of Milan, assembled the states of the Low Countries at Brussels; and seating himself for the last time in the chair of state, he explained to his subjects the reasons of his resignation, and solemnly devolved his authority upon Philip. He recounted with dignity, but without ostentation, all the great things which he had undertaken and performed since the commencement of his administration. "I have dedicated (observed he) from the 17th year of my age, all my thoughts and attention to public objects, reserving no portion of my time for the indulgence of ease, and very little for the enjoyment of private pleasure. Either in a pacific or hostile manner, I have visited Germany nine times, Spain six times, France four times, Italy seven times, the Low Countries ten times, England twice, Africa as often; and while my health permitted me to discharge the duty of a sovereign, and the vigour of my constitution was equal in any degree to the arduous office of governing such extensive dominions, I never shunned labour, nor repined under fatigue; but now, when my health is broken, and my vigour exhausted by the rage of an incurable distemper, my growing infirmities admonish me to retire; and am I so fond of reigning, as to retain the sceptre in an impotent hand, which is no longer able to protect my subjects. Instead of a sovereign worn out with diseases (continued he), and scarce half alive, I give you one in the prime of life, already accustomed to govern, and who adds to the vigour of youth all the attention and sagacity of maturer years." Then turning towards Philip, who fell on his knees, and kissed his father's hand, "It is in your power (said Charles), by a wise and virtuous administration, to justify the extraordinary proof which I give you of my paternal affection, and to demonstrate that you are worthy of the extraordinary confidence which I repose in you. Preserve (added he) an inviolable regard for religion; maintain the Catholic faith in its purity; let the laws of your country be sacred in your eyes; encroach not on the rights of your people; and if the time should ever come when you shall wish to enjoy the tranquility of private life, may you have a son to whom you can resign your sceptre with as much satisfaction as I give up mine to you." A few weeks after, he resigned to Philip the sovereignty of Spain and America; reserving nothing to himself out of all these vast possessions but an annual pension of 100,000 crowns.

Charles was now impatient to embark for Spain, where he had fixed on a place of retreat; but by the advice of his physicians, he put off his voyage for some months, on account of the severity of the season; and, by yielding to their judgment, he had the satisfaction before he left the Low Countries of taking a considerable step towards a peace with France. This he ardently longed for; not only on his son's account, whose administration he wished to commence in quietness, but that he might receive the glory, when quitting the world, of restoring to Europe that tranquility which his ambition had diminished out of it almost from the time that he assumed the reins of government.

The great bar to such a pacification, on the part of France, was the treaty which Henry had concluded with the Pope; and the emperor's claims were too numerous to hope for adjusting them suddenly. A truce of five years was therefore proposed by Charles during which term, without discussing their respective pretensions, each should retain what was in his posses- sion; and Henry, through the persuasion of the constant Montmorency, who represented the imprudence of sacrificing the true interests of his kingdom to the rash engagements that he had come under with Paul, authorised his ambassadors to sign at Vaucelles a treaty, which would insure to him for so considerable a period the important conquest which he had made on the German frontier, together with the greater part of the duchy of Savoy's dominions.

The Pope, when informed of this transaction, was no less filled with terror and astonishment than rage and indignation. But he took equal care to conceal his fear and his anger. He affected to approve highly of the truce; and he offered his mediation, as the common father of Christendom, in order to bring about a definite peace. Under this pretext, he appointed Cardinal Reibo his nuncio to the court of Brussels, and his nephew Cardinal Caraffa to that of Paris. The public instructions of both were the same; but Caraffa, besides these, received a private commission, to spare neither intrigues, promises, nor bribes, in order to induce the French monarch to renounce the truce and renew his engagements with the holy see. He flattered Henry with the conquest of Naples; he gained by his address the Guises, the queen, and even the famous Diana of Poictiers, duchess of Valentinois, the king's mistress; and they easily swayed the king himself, who already leaned to that side towards which they wished to incline him. All Montmorency's prudent remonstrances were disregarded; the nuncio (by powers from Rome) absol- ved Henry from his oath of truce; and that weak prince signed a new treaty with the Pope; which rekindled with fresh violence the flames of war, both in Italy and the Low Countries.

No sooner was Paul made acquainted with the suc- cess of this negotiation than he proceeded to the most violent extremites against Philip. He ordered the Spanish ambassador to be imprisoned; he excommuni- cated the Colonnas, because of their attachment to the imperial house; and he considered Philip as guilty of high treason, and to have forfeited his right to the kingdom of Naples, which he was supposed to hold of the holy see, for afterward affording them a retreat in his dominions.

Alarmed at a quarrel with the Pope, whom he had been taught to regard with the most superstitious veneration, as the viceroy of Christ and the common father of Christendom, Philip tried every gentle method before he made use of force. He even consulted some Spanish divines on the lawfulness of taking arms against a person so sacred. They decided in his favour; and Paul continuing inexorable, the duke of Alva, to whom
the negotiations as well as the war had been committed, entered the ecclesiastical state at the head of 10,000 veterans, and carried terror to the gates of Rome.

The haughty pontiff, though still inflexible and undaunted himself, was forced to give way to the fears of the cardinals, and a truce was concluded for 40 days. Mean time the duke of Guise, arriving with a supply of 20,000 French troops, Paul became more arrogant than ever, and banished all thoughts from his mind but those of war and revenge. The duke of Guise, however, who had precipitated his country into this war, chiefly from a desire of gaining a field where he might display his own talents, was able to perform nothing in Italy worthy of his former fame. He was obliged to abandon the siege of Civetella; he could not bring the duke of Alva to a general engagement; his army perished by diseases; and the Pope neglected to furnish the necessary reinforcements. He begged to be recalled; and France stood in need of his abilities.

Philip, though willing to have avoided a rupture, was no sooner informed that Henry had violated the truce of Vaucelles, than he determined to act with such vigour, as should convince Europe that his father had not erred in resigning to him the reins of government. He immediately assembled in the Low Countries a body of 50,000 men, and obtained a supply of 10,000 from England, which he had engaged in his quarrel; and as he was not ambitious of military fame, he gave the command of his army to Emanuel Philibert duke of Savoy, one of the greatest generals of that warlike age.

The duke of Savoy kept the enemy for some time in suspense with regard to his destination; at last he seemed to threaten Champagne; towards which the French drew all their troops; then turning suddenly to the right, he advanced by rapid marches into Picardy, and laid siege to St Quintin. It was deemed in those times a town of considerable strength; but the fortifications had been much neglected, and the garrison did not amount to a fifth part of the number requisite for its defence: it must therefore have surrendered in a few days, if the admiral de Coligny had not taken the gallant resolution of throwing himself into it with such a body of men as could be collected on a sudden. This he effected; in spite of the enemy, breaking through their main body. The place, however, was closely invested; and the constable Montmorency, anxious to extricate his nephew out of that perilous situation, in which his zeal for the public had engendered him, as well as to save a town of such importance, rashly advanced to its relief with forces one half inferior to those of the enemy. His army was cut in pieces, and he himself made prisoner.

The cautious temper of Philip on this occasion saved France from devastation, if not ruin. The duke of Savoy proposed to overlook all inferior objects, and march speedily to Paris, which, in its present constellation, he could not have failed to make himself master of; but Philip, afraid of the consequences of such a bold enterprise, desired him to continue the siege of St Quintin, in order to secure a safe retreat in case of any disastrous event. The town, long and gallantly defended by Coligny, was at last taken by storm; but not till France was in a state of defence.

Philip was now sensible that he had lost an opportunity which could never be recalled, of distressing his enemy, and contented himself with reducing Hon and Spain. Catelet; which petty towns, together with St Quintin, were the sole fruits of one of the most decisive victories gained in the 16th century. The Catholic king, however, continued in high exultation on account of his success; and as all his passions were tinged with superhuman arrogance, he vowed to build a church, a monastery, and a palace, in honour of St Lawrence, on the day sacred to whose memory the battle of St Quintin had been fought. He accordingly laid the foundation of an edifice, in which all these were included, and which he continued to forward at a vast expense, for 22 years. The same principle which dictated the vow directed the building. It was so formed as to resemble a gridiron—on which culinary instruments are placed, according to the legendary tale, St Lawrence had suffered martyrdom. Such is the origin of the famous Escorial near Madrid, the royal residence of the kings of Spain.

The first account of that fatal blow which France had received at St Quintin, was carried to Rome by the courier whom Henry had sent to recall the duke of Guise. Paul strenuously against the departure of the French army; but Guise's orders were peremptory. The arrogant pontiff therefore found it necessary to accommodate his conduct to the exigency of his affairs, and to employ the mediation of the Venetians, and of Cosimo de Medici, in order to obtain peace. The first overtures of this nature were eagerly listened to by the Catholic king, who still doubted the justice of his cause, and considered it as his greatest misfortune to be obliged to contend with the Pope. Paul agreed to renounce his league with France; and Philip stipulated, that the duke of Alva should repair in person to Rome, and after asking pardon of the holy father in his own name and in that of his master, for having invaded the patrimony of the church, should receive absolution from that crime. Thus Paul, through the superstitious timidity of Philip, finished an unprovoked war not only without any detriment to the apostolic see, but saw his conqueror humbled at his feet: and so excessive was the veneration of the Spaniards in that age for the papal character, that the duke of Alva, the proudest man perhaps of his time, and accustomed from his infancy to converse with princes, acknowledged, that when he approached Paul, he was so much overawed, that his voice failed, and his presence of mind forsook him.

But though this war, which at its commencement threatened mighty revolutions, was terminated without occasioning any alteration in those states which were its immediate object, it produced effects of considerable consequence in other parts of Italy. In order to detach Octavio Farnese, duke of Parma from the French interest, Philip restored to him the city of Placentia and its territory, which had been seized by Charles V, and he granted to Cosimo de Medici the investiture of Siena, as an equivalent for the sums due to him. By these treaties, the balance of power among the Italian states was poised with more equality, and rendered less variable than it had been since it received the first violent shock from the invasion of Charles VIII. and Italy henceforth ceased to be the theatre on which the monarchs of Spain, France, and Germany, contended for fame and dominion. Their hostilities, excited by new objects, stained other regions of Europe with blood, and
Spain.

New monarch, Charles II.

Spain.

521

After the death of Charles, the kingdom of Spain soon lost great part of its consequence. Though Charles had used all his interest to get his son Philip elected emperor of Germany, he had been totally disappointed; and thus the grandeur of Philip II. never equalled that of his father. His dominions were also considerably abridged by his tyrannical behaviour in the Netherlands. In consequence of this, the United Provinces revolted; and after a long and bloody war obtained their liberty. Revolt of the United Provinces. See Unit. Philip, which brought on a war with Spain. The great loss he sustained in these wars exhausted the kingdom ed Provin- both of men and money, notwithstanding the great sums 542. imported from America. Indeed the discovery of that country has much impoverished, instead of enriching Spain; for thus the inhabitants have been rendered lazy and averse to every kind of manufacture or traffic, which only can be a durable source of riches and strength to any nation. The ruin of the kingdom in this respect, however, was completed by Philip III. who, at the instigation of the inquisition, and by the advice of his chief prime minister the duke of Lerma, expelled from the kingdom all the Moriscos or Moors, descendants of Spain. The recantists were executed; thirty days only were allowed them to prepare for their departure, and it was death to remain beyond that time. The reason for this barbarous decree was, that these people were still Mahometans in their hearts, though they conformed externally to the rites of Christianity, and thus might corrupt the true faith. The Moriscos, however, chose themselves a king, and attempted to oppose the royal mandate; but, being almost entirely unprovided with arms, they were soon obliged to submit, and were all banished the kingdom. By this violent and impolitic measure, Spain lost almost a million of industrious inhabitants; and as the kingdom was already depopulated by bloody wars, by repeated emigrations to America, and enervated by luxury, it now sank into a state of languor from which it has never recovered.

The reign of Philip IV. the successor of Philip III. commenced in 1621. He had not been long seated on the throne before the expiration of the 12 years truce which Philip III. had concluded with the United Provinces, again involved Spain in the calamities of war. The renewed contest was carried on with vigour by both the contending powers, till in the year 1648 the Spanish monarch was compelled to sign the treaty of Munster, by which the United Provinces were declared free and independent. From this period the power of the Spanish monarchy began to decline, as it had already been Provinces severely shaken by the loss of Portugal. This event took place in 1640, when the Portuguese finally threw off the Spanish yoke, and that country remained an independent kingdom, till the power of Bonaparte compelled its lawful monarch to abandon his European territories. Philip IV. also prosecuted an unsuccessful war with France. This war was terminated in 1659, and Philip died about six years after.

The new monarch, Charles II. was only four years old when he succeeded to the throne. He was of scarce constitution, and a weak capacity. The war which had been occasioned by the revolt of Portugal, continued till the year 1668, when a peace was concluded, and the independence of that kingdom was acknowledged. Hostilities had been renewed with France,
but greatly to the disadvantage of the Spaniards, who lost some of the richest and best fortified towns which they still possessed in Flanders. The Peace of Nim-geven between France and Spain was signed in the year 1678. Charles II. died in 1700, and with him ended the male line of the house of Austria; a dynasty to which Spain owes less than to any other race of its monarachs.

Historians have been fond of representing the dominion of the Austrian princes in Spain as productive of the greatest glory and advantage to that kingdom. The reign of Charles V. may indeed be said to have been a glorious reign; but little of its glory belonged to Spain, and the emperor certainly neglected her interests in advancing those of his more favoured territories. The picture given by the Spanish historians of the state of Spain at the accession and during the reign of Philip II. fully evinces how little that kingdom had profited by the change in the line of its succession. Agriculture was neglected; commerce was fettered by enormous duties, and the people were held in the chains of ignorance and superstition.

Charles II. was succeeded by Philip V. duke of Anjou, and grandson to Louis XIV. of France, who had been nominated heir to the Spanish throne by the late monarch. The transactions of the war which was soon declared against France and Spain, by England, Holland, and the empire, assisted by Savoy, Portugal, and Prussia, have been already related under the article Britain, from No. 345 to No. 371. The treaty of Utrecht, which terminated the differences between the principal contending powers, was signed in 1713, and in 1715 a permanent peace was concluded between Spain and Portugal. Hostilities, however, still continued with Savoy and Sardinia, and in 1715 the island of Sardinia was taken by a Spanish fleet, and the year following another fleet belonging to the same nation invaded Sicily, but was defeated by the British admiral Byng. By a new treaty in 1720, Sardinia was given to the duke of Savoy, and Sicily to the emperor; and by the treaty of Seville, concluded in 1729, the duchies of Tuscany, Parma, and Placentia, were ceded to Spain. In 1731, the Spanish king invaded Naples, took possession of that kingdom, and conferred it on his son Don Carlos, in consequence of which war was declared between Spain and the empire in 1733. At the end of that year the palace of Madrid was consumed by fire, and all the archives relating to the Indies perished in the flames.

In 1739, hostilities were renewed between Spain and Britain, (see Britain, No. 403) but the only successes acquired by the latter power were the capture of Porto Bello by Admiral Vernon, and that of the Manila galleon by Commodore Anson. After a long and turbulent reign, Philip V. died in 1746.

Ferdinand VI. a mild, prudent, and beneficent prince, reformed abuses in the administration of justice, and management of the finances. He revived commerce, established manufactures, and promoted the prosperity of his kingdom. In April A. D. 1755, Quito in South America was destroyed by an earthquake.

Charles III. succeeded Ferdinand in 1759. The famous family compact was concluded at Versailles, A. D. 1761, among the four kings of the house of Bourbon. The English, alarmed by the naval preparations of Spain, declared war in 1762 (see Britain, No. 450), and took Havana in the island of Cuba, and Manila in the East Indies. Notwithstanding this success, peace was hastily concluded at Fontainbleau, in November, by which the Havana was restored. In 1767 the Jesuits were expelled from Spain. An unsuccessful expedition was concerted against Algiers, A. D. 1775, the particulars of which are related in M. Swinburne's Travels, letter v. In the war between Great Britain and her American colonies, Spain, by the intrigues of the French court, was prevailed on to take up arms in support of the latter. At the conclusion of that calamitous war, Great Britain, in a treaty with Spain, ceded to this power, East and West Florida, and the island of Minorca. Charles died in 1788, and was succeeded by his second son Charles Anthony prince of Asturias, the eldest having been declared incapable of inheriting the crown.

Charles IV. had not been long seated on the throne before the portentous revolution in France involved Europe in a general scene of political and military contest. The king of Spain joined the general confederacy against the new republic, and in consequence was numbered among the objects of its resentment, by a declaration of war in 1793. The military operations of Spain, how Engagia the conduct of in her latter campaigns, were extremely languid; and after two campaigns, in which she might be said to carry on rather a defensive than offensive war, against the republican armies of France. (see France, No. 411), she was compelled to conclude a treaty of peace, which was signed at Basel on the 22d July 1795. By this treaty the French republic restored to the king of Spain all the conquests which she had made from him since the commencement of hostilities, and received in exchange all right and property in the Spanish part of St Domingo.

This treaty was soon followed by a rupture with Great Britain. On 5th October 1769, the court of Spain published a manifesto against this country, to which the court of London made a spirited reply; and about the same time was published a treaty of offensive and defensive alliance, which had been concluded about two months before, between the king of Spain and the French republic. In the war which followed between Spain and Great Britain, his Catholic majesty could boast of but little honour or success; and the French republic gained little from its new ally, but the contributions of money, which she from time to time compelled him to advance. On the 14th of February 1797, a Spanish fleet of 27 sail of the line was defeated by Sir John Jervis off Cape St Vincent (see France, No. 482); and four of the Spanish line of battle ships were left in the hands of the victors. From this time till the temporary termination of hostilities by the peace of Amiens in 1803, there is nothing remarkable in the transactions of Spain.

On the renewal of the war in 1803, Spain was again compelled, by the overbearing power of France, to take an active part against Great Britain, and fitted out a formidable fleet, which was united to a consider-derable naval force of the new-made emperor of the French. The Spanish declaration of war against Britain is dated at Madrid on the 21st of December 1804; and on the 21st of October 1805, the combined fleets of France and Spain were nearly annihilated by Lord Nelson's decisive victory off Cape Trafalgar.

After this terrible blow to the naval power of Spain, nothing
nothing of importance took place till 1808, when the designs of Bonaparte against the independence of Spain, which had been long suspected, were openly avowed, in consequence of a domestic dispute, probably fomented by the emissaries of France, which took place between Charles IV. and the prince of Asturias. During the winter of 1807-8 the public mind in Spain had been greatly agitated. Some accused the prince of the Peace, Don Manuel Godoy, (who had long held the helm of state, and was the richest and most powerful subject in the kingdom), of having concerted with the queen to destroy the prince of Asturias. Others accused the prince of Asturias of being at the head of a party to dethrone his father. Solemn councils and long proceedings, followed up by exiles and violent acts, far from calming opinions, served to agitate them still more.

In March 1808, several disturbances happened at Aranjuez. These disturbances were excited by a report that the royal family were about to quit Spain and emigrate to America. In consequence of this report, the populace of the neighbouring villages repaired in crowds to Aranjuez, where they found the attendants of the court packing up the baggage of the royal household; and understood that relays of horses were stationed on the road to Seville, and that every thing was prepared for the departure of the royal fugitives, who were to take shipping at that port. It was suspected that Don Manuel Godoy, or, as he has commonly been called, the prince of the Peace, was the chief instigator of this unpopular measure; and the fury of the people was directed chiefly against that nobleman, whose palace they attacked on the 18th of March. He, however, found means to escape for the present, but was afterwards arrested in a garret of his own house. In the mean time the king issued two decrees with a view to allay the popular ferment; but as this still continued, he on the 19th took the extraordinary resolution of abdicating the throne in favour of the prince of Asturias. This resolution was made known by a royal decree, in which Charles declared that, as his natural infirmities no longer permitted him to support the weight of government, and the re-establishment of his health required a change of climate, he had after the most mature deliberation resolved to abdicate his crown in favour of his heir the prince of Asturias; and this resolution he declared to be the result of his own free will.

The new sovereign was accordingly proclaimed by the title of Ferdinand VII. and issued an edict conferring the effects of Don Manuel Godoy, and announcing the appointment of the duke of Infantado, a nobleman deservedly popular for his talents and virtues, to the presidency of Castile and the command of the royal guards.

These disturbances have commonly been attributed to the machinations of the French emperor, who had gained a complete ascendency over the weak Charles; and had rendered the prince of the Peace entirely subservient to the views which he had formed on the independence and the liberties of Spain. How far this supposition is correct, it is impossible for us at this time to determine; but it is rendered probable by the active measures taken about this time by Napoleon to awe by a French force the Spanish nation. Murat the grand duke of Berg was at this time on his march towards the capital with a body of French troops; and his march was hastened by the information which he had received of the tumults at Aranjuez. This general caused it to be intimated to Ferdinand, that the emperor of the French was on his journey to Spain, and invited him to meet his master on the road. In the mean time he was tampering with the self-deposed monarch, whom he assured of the assistance of Bonaparte in reinstating him on the throne. Charles accordingly addressed a letter to Bonaparte, in which he contradicts the assertion of his decree of the 19th; and declares that his abdication was a measure of compulsion; and throws himself on the protection of that great monarch, his friend and ally, from whom alone he and his subjects can hope to derive tranquillity and happiness.

It appears to have been the design of Murat to draw out of Spain the whole of the royal family, and in this design he completely succeeded. Ferdinand set out to meet Bonaparte, accompanied by the French general Savary, and had advanced as far as Vitoria, where he was left by Savary, and where he found himself surrounded by French troops. He was compelled to remain at Vitoria, until Savary, who had proceeded to Bayonne, where Bonaparte then was, should return and intimate to him the pleasure of his master. When the general returned, he brought with him a letter from Napoleon to Ferdinand. In this letter, which is addressed to Ferdinand as prince of Asturias, and not as king of Spain, Bonaparte assured the prince, that the sole object of his journey into Spain was to make such reforms in that kingdom as would be agreeable to the public feelings. Without pretending to judge respecting the late revolution, he cautions Ferdinand against the danger to be apprehended from sovereigns permitting their subjects to take justice into their own hands. After intimating his own power over the royal family of Spain, and asserting to the tumults that had taken place, in which some of his troops had fallen, he makes use of the following expression, "a few of my soldiers may be murdered; but the subjugation of Spain shall be the consequence of it."

Ferdinand confounded at the conduct of the French emperor, and alarmed for his own personal safety, was compelled to proceed on his journey. When he arrived at Bayonne he was received by the prince of Neufchatel and Duruc, and was conducted to a place by no means suited to his rank or his character as ally of Bonaparte. He however dined with the emperor; but after he had retired, General Savary brought a message from his master, intimating his determination that the present royal family of Spain should give up to him all right and title to the crown of that kingdom, and that they should be succeeded by a branch of his own family. Astonished at this intimation, Ferdinand sent his prime minister Cavallero, to canvas the matter with M. Champagny, the confidential secretary of Napoleon. The conference was held in an apartment adjoining the cabinet of the emperor, and, as it appeared, within his hearing: for when Cavallero was arguing with great warmth and strength of reasoning on the injustice and even impolicy of the proposed measures, both he and Champagny were ordered into the emperor's presence; and the former was reviled in the grossest terms, branded with the appellation of a traitor, accused of having maintained that the recognition of Bonaparte was not necessary to the validity of his master's title to the throne of Spain, and of
But though the nomination of Joseph Bonaparte was easily effected, it was not so easy to place him on the throne in opposition to the almost unanimous will of the Spanish nation. Ferdinand the Seventh was both the darling of the people; and his accession to the crown had been hailed by them, both as placing them under the dominion of the Spain of a beloved monarch, and as removing them from the tyranny of Godoy, who was an object of almost universal detestation. They had hitherto submitted with patience to the influence and power of France, hopeless of rescuing themselves while Charles possessed the throne, and while the prince of the Peace directed his councils; but the accession of Ferdinand, and the consequent disgrace of the favourite, had led them to hope that they should now find a sovereign willing to direct and assist their efforts to regain their independence. Under these expectations, a great part of the nation had come forward to offer their assistance in supporting the claims of the new monarch. The province of Catalonia, the most industrious and the most warlike of the Spanish nation, particularly distinguished itself by the promptitude and extent of its offerings. Soon after Ferdinand had ascended the throne, the captain-general of Catalonia, relying on the well-known resources and dispositions of the inhabitants, had come forward with an offer of a military force of above a hundred thousand men; and other provinces would have followed this example, but Ferdinand had discouraged these military preparations, and appeared willing to submit quietly to French bondage.

The spirit which had animated the Spaniards thus boldly to support their favourite sovereign, was not of a nature to be chilled and depressed by his timidity or example. The hatred which they had conceived against the French daily found fresh sources of nourishment. They saw Ferdinand, who had rejected their proffered services lest he should expose himself to the suspicion or displeasure of Bonaparte, enticed by deceit, or compelled by violence, to relinquish his kingdom and commit himself to the power of his enemy. They anticipated the consequences, and prepared to resist them with vigour and unanimity. The renunciation of the royal family in favour of Bonaparte was no sooner known in Spain, than the northern provinces burst into open insurrection. Asturias and Galicia set the glorious example; and it was soon followed by almost every part of Spain, not immediately occupied or overawed by the armies of France.

One of the first steps taken by the leaders of the insurrection was, to assemble the juntas or general assemblies of the provinces. When these were organized, they issued proclamations, calling on the Spaniards to rise in defence of their sovereign, and in the assertion of their own independence. Besides these proclamations from the provincial juntas, addresses were published in almost every province by the leaders of the popular cause; in particular, the province of Aragon was addressed by Palafox, a name celebrated in the annals of the Spanish revolution, in a bold and spirited manifesto. The junta of Seville, which assembled on the 27th of May, formed itself into a supreme junta of government, caused Ferdinand to be proclaimed king of Spain, took possession of the military stores, and issued an order for all males from 16 to 45, who had not children, to enroll themselves in the national armies.

It was natural that, when entering on so determined

an opposition to the measures of Bonaparte, the Spaniards should turn their eyes towards that nation, by whom alone the ambitious views of that potentate had been successfully combated. A peace and alliance with Britain was evidently not only a measure of policy, but would afford them the most effectual assistance in the formidable struggle in which they were about to engage. Accordingly, deputies were dispatched to Great Britain from several of the provinces, to solicit the aid and friendship of that country, and to concert measures with the British ministry for executing the plans which had been contrived for freeing the kingdom from the French yoke. The junta of Seville issued a declaration of war with France, and declared the Spanish nation on terms of peace and amity with Britain. The Spanish deputies were empowered to solicit supplies of arms, ammunition, clothing and money; but it was thought that a supply of British troops would be unnecessary, the Spanish patriots considering themselves as fully equal to the defence of their country. The cause of the Spanish patriots was eagerly embraced by the court of London, and by the British nation at large, and the most active measures were quickly taken to send them effectual aid.

While these preparations were making on the part of the Spaniards, the French forces were collecting in great numbers, both on the frontiers, and in the neighbourhood of the capital. Above 25,000 men, under the command of Bessieres and Lassoles, threatened the provinces of Asturias and Biscay, or occupied the plains of Castile. Ten thousand men were shut up in the citadel of Barcelona; and, to relieve them a strong body of French troops had marched from the frontiers, and laid siege to Zaragoza. A considerable body under General Moncey attacked the city of Valencia; while the grand duke of Berg, after having detached General Dupont at the head of 20,000 men, to quiet the insurrection of the southern provinces, held Madrid with about 15,000 troops. Junot, with about 25,000 men, had entered Portugal, and taken possession of the capital. The whole French force at this time in Spain cannot be computed at less than 100,000 men. These were opposed by a very numerous, but undisciplined force, commanded by generals of acknowledged bravery, but differing widely from each other in experience and military prudence. General Palafox commanded in Aragon; General Castanos in the southern provinces; and General Blake in the north.

The first exertions of the Spanish patriots were eminently successful, though they have been greatly exaggerated in the newspapers published under authority of the juntas. The harbour of Cadiz, which contained a numerous and well-appointed fleet, was under the command of the marquis de Solano, a man notoriously attached to the French interest; and he lay a French fleet, consisting of five ships of the line and a frigate. One of the first efforts of the patriots was, to obtain possession both of Cadiz and the French fleet, and in this they completely succeeded. Solano was arrested and put to death, and Don Moria was appointed in his room. In the beginning of June the French fleet was summoned to surrender, and on the admiral's refusal, was furiously attacked by the batteries on shore, and obliged to capitulate. The force detached by Murat, under Dupont, was attacked near Baylen on the 22d July by Major-general Reding, second in command under Castanos, and after having been defeated, was compelled to surrender at discretion. The French force besieging Zaragoza was repeatedly attacked by General Palafox, and suffered considerable losses, while that city held out with the most heroic bravery. Perhaps there are few instances in the annals of modern warfare, in which such persevering and successful courage has been displayed, as by the defenders of Zaragoza. All the means of attack which were in possession of the French, directed by the skill with which their long experience and success had supplied them, were made use of. The inhabitants were obliged continually to be upon their guard, and to be prepared to resist the most unexpected and secret, as well as the most open and violent assaults. The city was frequently bombarded in the middle of the night, at the same time that the gates were attempted to be forced under cover of the shells. More than once the French got into some parts of the town; but they were received with so much coolness and bravery, that they were never able to preserve what they had with so much difficulty and loss acquired. The women vied with their husbands, sons, and brothers, in the display of patriotism and contempt of danger; regardless of the fire of the enemy, they rushed into the very middle of the battle, administering support and refreshment to the exhausted and wounded, and animating, by their exhortations and example, all ranks to such a display of firmness and bravery as long secured this important city. When it is recollected, that the attacks of the French were numerous and varied, that they were constantly repeated with fresh, and generally with increasing forces, and that the sole defence of the city rested with its spirited inhabitants and the army of Palafox; some idea may be formed of the difficulties they must have undergone and surmounted, and of the glory to which they are so justly entitled. The patriots gained possession of most of the sea ports in the bay of Biscay, and headed by the bishop of St Andrew, repulsed the French in several attacks. The French force under General Moncey was also repulsed before Valencia, and the patriots were equally successful in several other quarters; so that by the end of July there did not remain above 40,000 French forces within the Spanish territory.

In the mean time preparations were making at Madrid. Arrival and for the reception of the king of Spain and Joseph; and Murat, under pretence of ill health, quitted the capital, to give way to the brother of his master. Joseph Bonaparte arrived at Madrid in the latter end of July, with a guard of 10,000 men; but soon after his arrival the news of the defeat and capitulation of Dupont reached Madrid, and threw the new court into the utmost consternation. They understood that the victorious army of Castanos was on its march towards the capital; and if he did not speedily retire from so dangerous a position, King Joseph dreaded either falling into the hands of the conqueror of Dupont, or of being intercepted in his retreat by the army of General Blake. In this situation he found himself under the necessity of quitting the capital which he had so lately entered, and before the end of the month he had reached Burgos in his precipitate flight towards the frontiers. Thus, within the space of two months, did the people of Spain behold their country almost entirely freed from the presence of the French; and this glorious and happy issue had been brought about by their own intrepidity. At a time when their situation was the most dispiriting and for-
SPAIN.

The successes of the Spanish arms, though brilliant and important, were but transient. The leaders of the insurrection appear to have been but ill calculated to oppose the system of tactics which had been so often practised with success by the conqueror of Marengo, of Jena, and of Austerlitz. Though the conquests of Austria and Prussia had been effected by the same system which the French were now pursuing in Spain, the military men of this kingdom were incapable of analyzing them, or of adopting effectual measures of opposition or defence. In a series of about 30 bulletins, published from the French army of Spain, comprehending from the beginning of November 1808 to the middle of January 1809, we read of nothing but the rapid movements and successes of the French, and the defeat and annihilation of the best appointed armies of the insurgents. In Gallicia, General Blake, after having withstood the duke of Dantzig (Marshal Ney), in several encounters, was at length defeated, and his army dispersed. A division of the army of Estremadura, under Count Belvédere, which had marched from Madrid to support the city of Burgos, was attacked and defeated by a division of the French army under the dukes of Istris and Dalmatin; while the army of General Castanos was in a great measure dispersed, after a severe conflict on the heights of Tadea. According to the French account, the army of Castanos consisted of 45,000 men. It was opposed by the duke of Montebello, and entirely defeated, with the loss of nearly 4000 killed, and 3000 taken prisoners.

In the meantime Bonaparte had entered Spain, and took the command of the French army. He advanced by rapid marches towards Madrid, and at the end of November his advanced guard reached the important pass of Somosierra. This pass was defended by a body of 13,000 Spaniards, with sixteen pieces of cannon. They were attacked by the French under the duke of Belluno, and after making a considerable stand, were entirely defeated. On the 20 of December Bonaparte arrived in the neighbourhood of Madrid, and on the 21st he was master of that capital.

While the Spanish patriots were thus pursuing their plan of opposition to French tyranny with various success, the British cabinet were fitting out formidable expeditions to the coasts of Spain and Portugal. The result of the expedition under Sir Harry Burrard and Sir Arthur Wellesley, the battle of Vimiera, the victory of Cintra, and the consequent evacuation of Portugal by the French, in the month of August 1808, have been already noticed under Portugal, No. 49 and 50. After these transactions, the greater part of the British army under the command of Lieutenant-general Sir John Moore, proceeded on their march to the frontiers of Spain. The progress and operations of this army will be detailed afterwards. About the middle of the same month, a body of 13,000 British troops, under the command of Sir David Baird, arrived at Corunna, and proceeded through the interior of the country, intending to join Sir John Moore in the neighbourhood of Madrid. A brigade of 10,000 men under General Hope, reached that capital, and established themselves at the Escorial; but on the approach of Bonaparte, were under the necessity of retiring.

Experience has shown that in their military campaigns on the continent, British forces have to contend with numerous difficulties, surmountable only by the utmost prudence and vigilance on the part of the commanding officers, and by a considerable degree of skill and foresight on that of the projectors of such undertakings. Never perhaps were these difficulties more severely felt than in the march of Sir John Moore from Portugal to the centre of the Spanish territory. It was found that in whatever direction he might prosecute his march, he would encounter either bad roads or scanty supplies of provisions. In particular, the difficulty of transporting the artillery over the Portuguese mountains was extreme; and the Portuguese at Lisbon were either egregiously ignorant of the state of the roads which led through their own country to the Spanish frontiers, or were unwilling to communicate the information which they really possessed. Under these circumstances it was found necessary to divide the British army; and it was determined to send forward one division consisting of 6000 men under the command of Lieutenant-General Hope, which was directed to march by Elvas, to enter Spain by Badajoz, and to proceed along the Madrid road by way of Espinar. Another division, consisting of two brigades under General Paget, was detached by way of Elvís and Alcantara, where it was to pass the Tagus. Two brigades under General Beresford moved through Portugal by way of Coimbra and Almeida towards Salamanca, while three brigades under General Fraser marched towards the frontiers of Spain by Abrantes and Almeida.

Burgos had been recommended by the Spanish government as the point of union for the British troops, and Madrid and Valladolid were appointed for magazines. The British had been led to expect that they would find between 60,000 and 70,000 Spaniards assembled under General Blake and the marquis de la Romana in the provinces of Asturias and Gallicia, and that a much greater number was ready to co-operate with them under the command of Castanos on the front and left of the principal French position. The Spaniards had been represented as unanimous in their enthusiasm for the cause of liberty, and as ready to treat the British troops as the saviours of their country. How far this information was correct, will be seen presently.

In marching through the Portuguese territory, the troops first encountered difficulties which they were not prepared to expect. The contractor at Lisbon, who had agreed to supply the divisions with rations on the march, failed in his contract, and excessive inconvenience was experienced from the want of money. The divisions under Generals Fraser and Beresford were obliged to halt, and it was some time before they could again set forward. The proceedings of the central junta, on which all the movements both of the British and Spanish armies chiefly depended, were languid, tardy, and irresolute; and before the British troops could assemble in any force in Spain, the principal armies of the patriots had been defeated and dispersed in almost every
every quarter. On the 8th of November Sir John Moore reached Almeida. The weather was at this time extremely unfavourable, and the troops were exposed to almost incessant rain. They entered Spain on the 11th of November, and on the 13th Sir John arrived with his advanced guard at Salamanca, where he halted, intending to assemble there all the troops which were on their march through Portugal. While he remained at Salamanca, he was informed that a considerable French force had assembled and taken possession of Valladolid, at the distance of only twenty leagues, by which one of the places that had been intended for magazines was lost. At this time Sir John had with him only three brigades of infantry without artillery, and it would be at least ten days before the whole of the divisions could come up. He was thus exposed to almost an immediate attack by the French without any effectual support from the boasted patriotism of the Spaniards.

The situation of affairs in Spain had now become extremely critical; and every account sent to Sir John Moore by men of sound judgment, was filled with convincing proofs that the Spanish government had concealed from their ally the very desperate state of their affairs. General Hope, by a long and tiresome march, had reached the neighbourhood of Madrid, whence he wrote a letter to Sir John, stating that every branch was affected by the disjointed and inefficient construction of the government. On the 28th of November Sir John was advertised of the late defeat and dispersion of Castaños, and of the little probability there was of his being able to march forward, so as to effect any thing of advantage. He therefore determined to fall back, though this determination was evidently in opposition to the wishes and advice of his officers. Fresh dispatches, however, from the seat of government, diminishing the losses which had been sustained by the patriots, and exaggerating the ardour with which the people were actuated, induced him to delay his retreat, especially as he had now a complete, though small corps, with cavalry and artillery, and could, by a movement to the left, easily effect a junction with Sir David Baird, while the division under General Hope had, by rapid marches, arrived in the neighbourhood of Salamanca.

In addition to the misrepresentations by which the commanders of the British forces, and the British envoy at Aranjuez, had been deceived, they had now to contend with two designing men, who, it soon appeared, were in the French interest. These were Don Morla, the late governor of Cadiz, and a M. Charmilly. By the machinations of these men, Mr. Freere was led to advise, and Sir John Moore strongly invited to undertake, bringing the whole of the British force to the neighbourhood of Madrid, where they would soon have been completely within the power of the enemy. Though by these arts Sir John was effectually misled, he did not suffer himself to be drawn into so dangerous a snare. He, however, advanced beyond Salamanca, and sent forward the reserve and General Beresford's brigade towards Toro on the Douro, where they were to unite with the cavalry under Lord Paget, who had advanced thither from Astorga. On December 12th, Lord Paget, with the principal part of the cavalry, marched from Toro to Tordesillas, while the brigade under General Stewart moved from Arivolo. In the vicinity of Tordesillas, near the village of Rueda, the British forces were first opposed by the French, a small party of whom were attacked and defeated.

While Sir John Moore was at Toro, he received intelligence that the duke of Dalmatia was at Saldana with a considerable body of French troops, that Junot, duke of Abrantes, was marching with another towards Burgos, and that a third under the duke of Treviño was destined for Zaragoza. He was very desirous that the first of these generals should advance to meet him, and with this view he had come forward to Toro, which he reached on the 16th of December. He had hoped for effectual assistance from the corps commanded by the marquis de la Romanía, but he soon found that this general could render him no support. He had now resolved to threaten the communication between France and Madrid; and, if a favourable opportunity offered, to attack the duke of Dalmatia's corps, or any of the covering divisions that should present themselves. He foresaw that this would necessarily draw upon him a large French force, and of course would prove an important diversion in favour of the Spaniards; who would by this means have the opportunity of collecting in the south, and restoring their affairs. The army was now near the French position. The cavalry under Lord Paget were pushed so forward, that their patrols reached as far as Valladolid, and had frequent successful skirmishes with the enemy. Colonel Otway met a detachment of French cavalry, charged them, and made the whole prisoners.

On the 18th of December, Sir John's head-quarters were at Castro Nuevo, and Sir David Baird's at Benevente, on the road to join him. On the 20th Sir John reached Majorca, where he was joined by Sir David Baird. The united British army now amounted to rather fewer than 26,000 men, of whom about 20,000 were cavalry. The weather was extremely cold, and the ground covered with deep snow. Still the exertions of the troops were indefatigable, and the cavalry in particular attacked and defeated a considerable body of French horse. On the 21st the army reached Sahagun, where Sir John established his head-quarters, and determined to halt for some time, to refresh his troops, after the fatigues which they had undergone.

Sir John had now arrived within a very short distance from Saldana, where the duke of Dalmatia was posted, with the flower of the French army; and preparations were made for an attack, which was waited for with all the ardour and impatience which distinguish British troops. In the mean time, however, repeated couriers arrived at head-quarters, the bearers of unpleasant intelligence. Certain information was received, that a strong French reinforcement had arrived at Carrión, a little to the right of Sahagun, that the French corps, which was marching to the south, had halted at Talsa, and that the enemy were advancing from Madrid in considerable force. Sir John now saw that his motions had been watched by Bonaparte, and that all the arts of this experienced general had been preparing to entrap him. To advance was madness; to retreat, almost in the face of an enemy, was a measure of the utmost danger, but it was the only alternative.

On the 24th of December Sir John began silently his retreat, and secretly to prepare for his retreat, and to provide, as far as possible, for the defence of those parts of the country
country which were still held by the patriots. With this latter view, he directed Sir David Baird to take the route towards Valencia de Don Juan, while the rest of the army was to proceed by Castro Gonzalo. By this division the magazines and stores which had been deposited at Benevente and Zamora, were also effectually secured.

According to the arrangement made, General Fraser, followed by General Hope, marched with their divisions on the 24th December to Valderos and Majorga, and Sir David Baird proceeded with his to Valencia. To conceal this movement, Lord Paget was ordered to push on strong patrols of cavalry close to the advanced posts of the enemy. The reserve, with two light corps, did not retire from Sagazun till the morning of the 25th, following General Hope. Lord Paget was ordered to remain with the cavalry until evening, and then follow the reserve. These last were accompanied by Sir John. The retreat commenced in this deliberate manner. On the 26th of December, Sir David Baird reached the Eslar, and passed the ferry with less difficulty than was expected. He took post, according to his orders, at Valencia, and wrote to the marquis of Romana, urging him to blow up the bridge of Mansilla. The other divisions of infantry proceeded unmolested to Castro Gonzalo. On the 24th the advanced guard of Bonaparte's army marched from Tordesillas, 120 miles from Madrid, and strong detachments of cavalry had been pushed forward to Villalpando and Majorga. On the 26th, Lord Paget fell in with one of those detachments at the latter place. His lordship immediately ordered Colonel Leigh, with two squadrons of the 10th hussars, to attack this corps, which had halted on the summit of a steep hill. One of Colonel Leigh's squadrons was kept in reserve; the other rode briskly up the hill; on approaching the top, where the ground was rugged, the colonel judiciously reined-in to refresh the horses, though exposed to a severe fire from the enemy. When he had nearly gained the summit, and the horses had recovered their breath, he charged boldly and overthrew the enemy; many of whom were killed and wounded, and above 100 surrendered prisoners. Nothing could exceed the coolness and gallantry displayed by the British cavalry on this occasion. The 18th dragoons had signalized themselves in several former skirmishes; they were successful in six different attacks. Captain Jones, when at Palencia, had even ventured to charge 100 French dragoons with only 30 British; 14 of the enemy were killed, and six taken prisoners. The cavalry, the horse-artillery, and a light corps, remained on the night of the 26th, at Castro Gonzalo; and the divisions under Generals Hope and Fraser marched to Benevente. On the 27th, the rear-guard crossed the Eslar, and followed the same route, after completely blowing up the bridge.

We shall not attempt any farther detail of this dangerous and calamitous retreat, in which our army suffered extremely, from the fatigues of constant marching; from the badness of the weather, and even from the brutality of the Spaniards, in whose cause they had embarked. Before they reached Astorga, it was found necessary to divide the army: a body of 3000 men, under Brigadier-general Crawford, was detached on the road to Orense towards Vigo, while the main body, under the command of Sir John Moore, marched by Astorga and Lugo, on the road to Corunna. They left Astorga on the 30th of December, and on the 11th of January came in sight of Corunna. The army had now reached the sea port from which they were to embark, but adverse winds had detained the transports, or the whole of the troops would have been speedily and safely on board. Only a few ships lay in the harbour, and in these some sick men and a few stragglers, under pretence of sickness, had immediately embarked.

During the whole march from Sagazun to Corunna, the British army was closely followed by the French, who, under Bonaparte and the duke of Dalmatia, and the two armies were often so near each other, that the French patrols fell in, during the night, with the cavalry piquets of the British. The duke of Dalmatia had joined Bonaparte at Astorga, and had increased his force to nearly 70,000 men, while the whole force of the British did not exceed 26,000. When Sir John's army reached Lugo, it was found that three divisions of the French were arranged in front, and it was thought advisable, on the 8th of January, to offer the enemy battle. This offer, however, the French thought proper to decline, and the duke of Dalmatia stirred not from his post. When the army reached Corunna, the French were far in the rear, and it was hoped that the transports might arrive before the enemy could come up.

The retreat of the British, considering the circumstances under which it was effected, was a brilliant and successful achievement. Two hundred and fifty miles of country had been traversed in 11 days, during the worst season of the year, through bad roads, over mountains, defiles, and rivers, and in almost daily contact with an enemy nearly three times their numbers. Though often engaged, the rear-guard of the British had never been beaten, nor even thrown into confusion.

Many losses had indeed been sustained, in baggage, artillery, and horses, and many stragglers had fallen into the hands of the enemy; but neither Napoleon nor the duke of Dalmatia could boast of a single military trophy taken from the retreating army. The greatest danger was still to be incurred; the position of Corunna was found to be extremely unfavourable; the transports had not arrived, and the enemy began to appear upon the heights. The situation of the army was by most of the officers thought so desperate, that they advised the general to propose terms to the duke of Dalmatia, that they might be suffered to embark unmolested; but this advice Sir John, without hesitation, rejected.

On the 12th of January, the French were seen moving in considerable force on the opposite side of the river Mero. They took up a position near the village of Perillo, on the left flank of the British, and occupied the houses along the river. In the mean time Sir John was incessantly occupied in preparing for the defence of his post, and in making every arrangement for the embarkation of the troops.

On the 13th, Sir David Baird marched out of Corunna with his division, and took post on a rising ground, where he determined to remain all night. A division under General Hope was sent to occupy a hill on the left, which remained behind the town. A body of 3000 men, under Brigadier-general Crawford, was detached on the road to Vigo, about half a mile from Corunna, and communicated
Spanish communication with that under Sir David Baird, by means of the rifle corps attached to the latter, which formed a chain across the valley. The rear officer, Major Paget, occupied a village on the Betanzos road, about half a mile from the rear of General Hope. The higher grounds on the rear and flanks of the British were possessed by the French, a situation which gave the latter a considerable advantage.

On the 16th, the French were observed to be getting under arms, and this was immediately succeeded by a rapid and determined attack on the division under Sir David Baird, which formed the right wing, and was the weakest part of the line. The first effort of the enemy was met by Sir John Moore and Sir David Baird at the head of the 42d regiment, and the brigade under Lord William Bentinck. The village on the right became an object of obstinate contest, but the enemy was at last repelled. While leading on his division to support this position, Sir David had his arm shattered with a grape shot. Not long after, while Sir John Moore was riding from post to post, everywhere encouraging his troops, and pointing out the most advantageous opportunities for attack or defence, his conspicuous situation had exposed him to the fire of the enemy. A cannon-ball struck his left shoulder, and beat him to the ground. He raised himself, and sat up with an unaltered countenance, looking intently at the Highlanders, who were warmly engaged. Captain Hardinge threw himself from his horse, and took him by the hand; then, observing his anxiety, he told him the 42d were advancing, upon which his countenance immediately brightened. His friend Colonel Graham now dismounted to assist him; and, from the composure of his features, entertained hopes that he was not even wounded; but observing the horrid laceration and effusion of blood, he rode off for surgeons. The general was carried from the field on a blanket, by a sergeant of the 42d, and some soldiers.

The enemy finding himself foiled in every attempt to force the right of the position, endeavoured by numbers to turn it. A judicious and well-timed movement, which was made by Major-general Paget, with the reserve, which corps had moved out of its cantonments to support the right of the army, by a vigorous attack, defeated this intention. His efforts were, however, more forcibly directed towards the centre, where they were again successfully resisted by the brigade under Major-general Manningham, forming the left of Sir David Baird’s division, and a part of that under Major-general Leith, forming the right of the division under General Hope. Finding his efforts unsatisfying on the right and centre, he seemed determined to render the attack on the left more serious, and had succeeded in obtaining possession of the village through which the great road to Madrid passes, and which was situated in front of that part of the line. From this point, however, he was soon expelled with considerable loss, by a gallant attack of some companies of the 2d battalion of the 14th regiment under Lieutenant-colonel Nicholls. Before five in the evening, the British had not successfully repelled every attack made upon the position, but had gained ground in almost all points. At six the firing ceased.

Notwithstanding this advantage, General Hope did not, on reviewing all circumstances, conceive that he should be warranted in departing from what he knew

was the previous and fixed determination of the late commander of the forces, to withdraw the army on the evening of the 13th, for the purpose of embarkation. The troops quitted their position about 11 o’clock at night, with a degree of order that did them credit.

By the unremitting exertion of the captains of the royal navy, who had been entrusted with the service of embarking the army, and in consequence of the arrangements made by the agents for transports, the whole of the forces were embarked with an expedition which has been seldom equalled.

Notwithstanding the ill success which had thus attended the expedition under Sir John Moore, the spirit of patriotism which appeared still to actuate the southern provinces of Spain, and the hope that the common cause might there be supported to greater advantage, induced the British ministry to send another military force to the western peninsula of Europe, to co-operate with the patriots who still continued in arms. Accordingly a body of about 15,000 forces, under the command of Sir Arthur Wellesley, whose bravery and good conduct in the battle of Vimeira had recommended him, in a particular manner, both to the ministry and the nation, was dispatched toward the coast of Portugal, where Marshal Beresford still maintained a British force; while General Hill, with about 3,000 infantry, and 400 cavalry, sailed from Ireland with the same destination. General Hill arrived at Lisbon on the 4th of April, and soon after Sir Arthur landed with the main body. On the 7th of April the army moved forward towards the Douro, and crossed that river during the night of the 11th, a little above Oporto. Here they fell in with a French detachment from the army of the duke of Dalmatia, which they routed and put to flight, after a short but well-contested action. After this action the duke of Dalmatia found it necessary to retreat.

Sir Arthur Wellesley, after having remained for some time in the Portuguese territory, to refresh his men after the fatigues which they had undergone, advanced into Spain, and effected a junction with General Cuesta, who then commanded a considerable part of the remains of the patriotic army. In the latter end of July, the allied army had advanced to Talavera de la Reina, in the neighbourhood of which they were encountered by a formidable French force, consisting of a corps commanded by Marshal Victor, another under General Sebastiani, the guards of Joseph Bonaparte, amounting to 8,000 men, and the garrison of Madrid. This large force was commanded by Joseph Bonaparte in person, assisted by Marshals Jourdan and Victor, and General Sebastiani. On the 27th of July, an attack was made by the French army on that of the allies, who had taken up their position at Talavera. The attack was vigorous, but was repelled with great spirit and success by the British. The defeat of this attempt was followed by a general attack of the enemy’s whole force, on the whole of that part of the position which was occupied by the British army. The general attack began by the march of several columns of infantry into the valley, with a view to attack the height occupied by Major-general Hill. These columns were immediately charged by the 1st German light dragoons, and 23d dragoons, under the command of General Anson, and supported by General Fane’s bri-

Spain.
In the end of February 1811, about 4000 British troops under General Graham, with 7000 Spaniards under General Penns, were embarked at Cadiz, and landed at Algeciras, with the view of joining the Spanish forces at St Roque, and making an attack on the rear of the French, to compel them to raise the blockade of Cadiz. The united corps advanced to Barrosa on the 6th March. Here the British general was compelled, by an unexpected movement of the enemy, to attack a force twice that of his own army. The victory was brilliant and decisive. The French were overthrown with the bayonet, with the loss of 3000 or 4000 killed or made prisoners. The British loss was 1243. Strong complaints were made of the conduct of the Spanish general, who made no exertions to support the British in their attack, or to improve the victory when it was gained.

In Estremadura the French obtained possession of Badajos. In the province of Salamanca Marshal Massena made a bloody but unsuccessful attack on the position of Fuentes d' Honor, and shortly after retired beyond the Agueda; in consequence of which Almeida was evacuated, and fell into the hands of the allies. With the view of relieving Badajos, which the allies were now besieging, Soult advanced from Seville; but Marshal Beresford, apprised of his object, suspended the siege, and met him at Albuera on the 16th of May. Here a bloody and obstinate but undecided battle was fought, which ended in Marshal Soult, who was the assailant, re-occupying his original position, and the next day retreating to Seville. The force under Marshal Beresford, which made a very gallant resistance, suffered a heavy loss. The French loss was estimated at 9000 men. Shortly after, however, the allies found it necessary to raise the siege of Badajos as well as Ciudad Rodrigo; the former after two unsuccessful assaults. In the east of Spain, the French took Tarragona by storm, sacked the town, and massacred a vast number of the inhabitants in cold blood. This conquest gave them the entire command of the coast of Catalonia.

On the 8th January 1812 Valencia surrendered to Marshal Suchet, with a garrison of 18,000 men; but this loss was balanced by the capture of Ciudad Rodrigo on the 10th January, and of Badajos on the 6th April, by the allies. Both these towns were carried by storm, at a great expense of blood; the loss of the British and Portuguese, in the siege of Badajos, was 4850 men. Bonaparte had now entered on his Russian campaign, and the great number of troops he had withdrawn from Spain, cramped the operations of his armies in that country. The Spaniards resumed their activity; and in July the British army advanced northwards to meet the French, who crossed the Douro under Marshal Marmont. On the 22d July the British general found a favourable opportunity for attacking the enemy near Salamanca. Marmont, though not expecting an attack, made an able and obstinate defence; but at length the rout became general, and darkness alone saved the French army from still greater destruction. About 7000 were made prisoners; and the number killed was much greater. The British and Portuguese loss amounted to 6500 men in killed and wounded.

This brilliant victory had a favourable effect on the state of the campaign in every part of Spain. In the end of August the French raised the siege of Cadiz, and began to withdraw their troops from the south of the peninsula. Bilbao and some other towns in the north were evacuated. Joseph Bonaparte left Madrid, which was occupied by two divisions of the British army on the 12th August. The arrival of reinforcements, however, enabled Sonneth, who succeeded Marmont, to advance again, and relieve the castle of Burgos, which Lord Wellington had made several fruitless attempts to storm. From this period the French continued to concentrate their troops. They reoccupied Madrid, and held it till June 1813, when they began to prepare for the evacuation of the country. In their retreat northwards the British came up with them at Vittoria, and gained a splendid victory. Never was success more complete. The victors, besides a vast number of prisoners, took 151 pieces of cannon, 415 ammunition wagons, with all the baggage of the French army. The British loss amounted to 700 killed, and 4000 wounded. Jourdan, who commanded the French in this battle, was replaced by Soult, who made an able and persevering defence, but could not long arrest the British army in its career of conquest. On the 31st July St Sebastian was taken by a very daring assault by the troops under General Graham, though with the loss of 2300 in killed and wounded. The check which the British troops, under Lord William Bentinck, received in Catalonia, produced little effect. Napoleon's power was now declining rapidly; and the battle of Leipzig, fought on the 18th October, shook his empire to its foundations. But even before this the British and Spanish army had entered France. After driving the French from a strong position at Barre, the allies established themselves in the French territory, but waited for the cessation of the heavy rains before they advanced.

The cortes, in the meantime, was agitated by fierce party contests. It had displaced the members of the regency several times, and appointed new ones; and amidst these repeated changes, the government could not acquire any stability. A new subject had occurred to perplex its proceedings. Though the American colonies had felt a warm interest in the fortunes of the mother country at the beginning of the present contest; yet, when they saw the French in possession of the capital, and apparently masters of the whole peninsula, it was natural they should think of providing for their own security. Accordingly, in 1810, simultaneous movements were made in La Plata, in Venezuela, and in Mexico. In the latter country the revolutionary attempt was put down; but in the other two the authority of the parent state was thrown off almost without a struggle. Though the cortes endeavored to attach the Americans to their cause, by allowing them to elect deputies to that body, it was soon found, that this privilege was entirely illusory, and that no disposition existed to remedy the gross abuses under which they suffered. The cortes tried to temporize, but the colonists saw through their intentions, while they, at the same time, despised their feebleness. The consequence has been the entire loss of Buenos Ayres to Spain, while the lone resistance of the independents in Chili and Venezuela will certainly lead at last to the same result. In January 1814, the cortes held its first sittings in Madrid.

On the 23d February 1814, the allied army crossed
the Adour, and on the 27th defeated the French at Orthes. Bourdeaux was occupied on the 12th March; and the brilliant victory obtained by the duke of Wellington at Toulouse on the 10th April, put an end to the war. The next day intelligence was received of the deposition of Napoleon, which led to an armistice, and the armistice to a peace. Ferdinand, now liberated, returned to Spain, and made his public entry into Madrid on the 13th May 1814. Nothing could exceed the enthusiastic joy with which he was received by all ranks. One of his first acts was to disavow the constitution promulgated by the cortes, and to declare that body an illegal assembly; and so little was freedom understood among the people, that these acts were, to all appearance, extremely popular. Not satisfied with this, he threw the most distinguished members both of the cortes and the regency into prison; and, about two months after his return, he issued a decree re-establishing the inquisition. The monstrous ingratitude of this worthless prince has driven several of those heroic men who sustained his cause against the French, to take up arms against him. Mina made an attempt in November 1814, and Portier, in 1815, but, from the apathy of the people, both failed. The former escaped into France, the latter was taken and executed. Several other movements of the same kind proved equally unsuccessful.

It was plain, however, to discerning persons, that some great change was at hand. The incorrigible folly, as well as wickedness of Ferdinand's conduct, disgusted even the friends of monarchy, and discontent continued to spread rapidly among the body of the people. Every month brought forth a new list of proscriptions, and among the sufferers were included almost every man whom the nation had reason to esteem and honour. The extreme disorder of the finances increased the difficulties of the court; and repeated charges of ministers showed that the royal councils were in a state of extreme embarrassment and constant fluctuation. At length, on the 1st January 1820, a body of troops stationed near Cadiz, partly irritated by want of pay, and partly actuated by the spirit of discontent which was spreading throughout the army, proclaimed the constitution of the cortes. Other troops brought to reduce them to obedience, instead of acting against them, espoused their cause. Colonel Quiroga, the leader of the insurrection, published a spirited address to the nation in the name of the army, setting forth the calamities which Spain had suffered from arbitrary power, and calling on the people to support the generous effort of the army. From the want of a periodical press, however, it was some time before the nature and objects of the revolutionary movement were widely known. Seville and other towns in Andalusia were the first to declare in favour of the army; these were followed by Barcelona and other places in Catalonia, where the patriotic spirit has always been very strong. At length the popular cause began to show its head in Madrid; and Ferdinand finding that all his means of resistance were exhausted, issued a proclamation on the 6th of March, promising to convokve the cortes. The people of Madrid, however, justly suspicious of Ferdinand's intentions, were not satisfied with this concession; and demanded the immediate establishment of the constitution of 1812. Accordingly, on the 9th a junta was formed to conduct public measures till the cortes should meet; and in presence of this junta Ferdinand took an oath to maintain the constitution. This great revolution had nearly been accomplished without bloodshed, when an unhappy catastrophe occurred in Cadiz on the 10th March. The inhabitants of this city had met to celebrate, by public rejoicings, the establishment of the constitution, when, owing to some treachery, which has never been fully explained, they were assaulted by a regiment of soldiers, and massacred without mercy. No less than 436 persons were killed in this affair, and a vast number were wounded.

The cortes met on the 9th July. All persons confined for state crimes had previously been liberated, and the opening of this representative body excited the most lively satisfaction in the kingdom. Its labours did not disappoint the public expectations. During the first session it abolished the inquisition, reduced a vast number of monasteries, and applied the funds arising from their suppression to the public service. It made new regulations for improving the administration of justice, abolished many useless offices, put an end to the monstrous abuse of entails, and introduced order and economy into the finances. Quiroga, Riego, and other leaders of the revolution, received promotion in the army, and votes of thanks for their services. In short, the cortes conducted its plans with a wise moderation, neither sparing abuses on the one hand, nor yielding to a rash spirit of innovation on the other.

From the reports laid before the cortes by the different ministers, it appeared that all the departments of the government were in the utmost disorder. The army was stated to consist of 87,779 infantry, including militia; and of 6338 cavalry: requiring an annual expense of 352,607,000 reals, or 3,500,000l. sterling. A great proportion of the officers had been for years on half pay, though in active service. Both infantry and cavalry were miserably clothed, and very badly armed and equipped. Since 1815 no less than 42,177 men had been sent out to America. The troops in Cuba, including militia, amounted to 10,995 men; those in North America to 41,556 infantry and cavalry. And the whole force in the colonies, including the Philippine islands, amounted to 96,578 men and 8419 horses.

The budget for the financial year, commencing 1st July, was fixed as follows:

It was fixed, that the army in time of peace should consist of 66,828 men; viz. of 48,553 infantry, 12,475 cavalry, 5000 artillery, and 1000 sappers. In a per...
SPAIN.

12. To fix the expenses of the public administration.
13. To establish annually the taxes.
19. To determine the value, the weight, the standard, the figure, and description of money.
22. To establish a general plan of public instruction in the whole monarchy, and approve that which is intended for the education of the prince of Asturias.
24. To protect the political liberty of the press.
25. To render real and effective the responsibility of the secretaries of state, and other persons in public employ.
26. Lastly, It belongs to the cortes to grant or refuse its consent in all those cases and acts which the constitution points out as necessary.

The king enjoys the following powers under art. 171.
He watches over the prompt and perfect administration of justice throughout the kingdom; declares war and ratifies peace, subject to the approval of the cortes; nominates magistrates; presents to ecclesiastical dignities; is the fountain of honour; has the command of the army both by sea and land; regulates all diplomatic and commercial relations with other states; appoints ambassadors, ministers, and consuls; can pardon criminals, except in certain cases; proposes to the cortes such projects of laws as he may think necessary, but it is for the cortes to deliberate or not upon such propositions: has the power of appointing ministers. The king cannot, under any pretence, prevent the convocation of the cortes; nor when assembled can he suspend or dissolve them, nor in any manner interfere with their sittings or deliberations; and all persons who shall advise him to act contrary to this article shall be deemed traitors to the country. The king cannot leave the kingdom without the consent of the cortes; nor can he, without their consent, form any offensive treaty; nor private treaty of commerce with any foreign power; nor furnish subsidies to a foreign power; nor impose any taxes or duties; nor can he of his own authority deprive any individual of personal liberty, or of property, without due course of law. Here he contracts marriage, he shall communicate his intention to the cortes, for the purpose of obtaining their consent, without which he shall be considered to have abdicated his throne. Should a law have passed the cortes, and fail on three successive applications to obtain the royal consent; on the third refusal, the sanction of the king shall be supposed to have been obtained, and the law shall be in full force. A permanent committee is to be nominated before the close of each session, and to continue sitting in vigilant attention to the proceedings of the government, until the next assembly of the cortes. This committee has the prerogative of summoning an extraordinary meeting of the cortes, when the crown shall become vacant, or the king incompetent, or when his majesty may be desirous of convoking them.

At the close of the 14th century, the population of Spain is stated by most Spanish writers to have been of 21,700,000; but this is evidently a gross exaggeration.

According to the table of the provinces, collected chiefly from De Laborde, it amounted, at the end of the 18th century, to 10,308,503; and the latest writ-
ERS do not suppose the population at present to exceed this amount.

Of the number above stated, the clergy are reckoned at least 47,722: viz. of secular clergy, 60,240; of monks, 49,270; of nuns and friars, 22,537, and of subaltern ministers of the church, 15,875. The numbers of the clergy have indeed diminished by more than 27,000 during the last 30 years of the 18th century, as in the year 1768 they amounted to 176,057.

According to a calculation in the year 1776, the cities, towns, villages, and hamlets, amounted to 34,459, and public edifices and temples to 30,495.

The money of Spain is either real or imaginary, the former serving for the purposes of exchange, the latter for keeping accounts and transacting business. Both these are common throughout the whole kingdom; but several kinds of both are to be found in the different provinces.

Two kinds of real money, both in gold and silver, are distinguished in Spain; the old, that is, such as were coined before the year 1772, and those coined subsequent to that period. None of the former are uniform, but consist of small pieces of different sizes unequally cut, and their currency is only by weight. The latter uniformly bear the head of the sovereign on the obverse, and on the reverse side the arms of Spain; the ancient gold coins are more intrinsically valuable than the modern. The last only will be here described.

The Spanish weights and measures vary considerably in different parts of the kingdom, as almost every province has both peculiar to itself. The pound generally consists of 15 ounces in that part of the kingdom formerly belonging to the crown of Castile, and of 12 ounces in those annexed to the crown of Aragon; viz. in Aragon, in the kingdom of Valencia, and in Cata-

The measures are still more complicated than the weights; and especially the measures of capacity will require to be considered rather more in detail. We shall, as usual, distinguish them into long measure, superficial or land measure, and measures of capacity.

### Long Measure.

The standard lineal measure in Spain is the royal foot, consisting of 153.47 inches; and bearing to the English foot the proportion of about 1.53 to 1.44, or of 17 to 16. This foot, however, is not in general use, almost every province having its own foot, which is generally rather less than the royal foot. Thus, the foot in Castile is 18 inches less, and that of Valencia about 9 inches less than the standard.

Of royal feet 100 are equivalent to 102 feet 7 inches of Catalonia, to 107 feet of Valencia, to 115 feet 10 inches and 4 lines of Castile.

One hundred feet of Catalonia are equal to 92 feet 2 inches 3 lines of the royal foot, to 97 feet 5 inches of Valencia, and 104 feet 11 inches 11 lines of Castile.

In Valencia 100 feet are equal to 93 feet 4 inches 10 lines of the royal foot, to 98 feet 9 inches of Catalonia; and 107 feet 2 inches 6 lines of Castile.

In Castile, 100 feet are equal to 86 feet 1 inch 3 lines of the royal foot; to 93 feet 4 inches 95 lines of Valencia; and 92 feet 2 inches 3 lines of Catalonia.

### Land Measure.

Land in the provinces belonging to the crown of Castile is measured by ungadas, fanegas, estadales, brazas, varas, pas, and aranazadas. Of these the ungada contains 50 fanegas, about 202.5 feet; the fanega 40 estadales = about 4.55 feet; the estadale two brazas = about ten feet; the brass two varas, or about 5 feet 1 inch 4 lines; the pas about 13 of a vara, and the aranazada about 73 varas. This last is only used for measuring vineyards.

### Measures of Capacity.

Corn is measured in the provinces belonging to the crown of Castile by cahizas, fanegas, celemines, and quartillos; and in Biscay the same measures are used, with the exception of the cahiza. The cahiza contains 12 fanegas, and is about 15 lb. French; the fanega contains 12 celemines = 124 lb.; the celemine 4 quartillos = 10 lb. 5¼ ounces, and the quartillo = 2 lb. 7½ ounces.

In Catalonia grain is measured by salmas, charges, quarteras, cortanas, and picotes. The salma contains 2 charges or 6 quintals = 546 lb.; the charge contains 2 quarteras or 3 quintals = 273 lb.; and the quartera 12 cortanas or 5 quintals = 138 ¼ lb. 8 oz.: the cortana contains 4 picotes or 13 lb. of 12 oz. = 11 lb. 6 oz.; and the picote 3½ lb. of 12 oz. = 2 lb. 13½ oz.

Wine in New Castile is measured by moyos, an imaginary
Spain.

glossary measure, cantarás, azimuths, quarters, and secretaries. The moyo contains 16 cantarás, the cantara 12 azimuths, the azimuth 4 quarters, each equal to 1 lb. At Cadiz wine is measured by tonneau, araba, azimuths, and quarters. The tonneau contains 30 araba, the araba 8 azimuths, the azimuth 4 quarters, each of which is equal to 1 lb. 1 oz. At Seville the measures for wine are cantarás, azimuths, and quarters. The cantara contains 8 azimuths, the araba the same, the azimuth 4 quarters, each of which is equal to 17 ounces.

In Valencia these measures are, botas or tonneau, charges, araba, or cantarás, and azimuths or cuestas; and in Catalonia, pies, charges, quintals, araba, quarters, and quartos, of which the pie contains 4 charges, the quarter 3 quintals, the quintal 4 araba, the araba 22 quarters, the quartero 4 quartos, and the quarto is equal to nearly 3 ounces of Catalonian measure.

The laws of Spain, which for a long time varied greatly in the different states of the monarchy, are at present reduced to a considerable degree of uniformity. Navarre and Biscay have retained their ancient laws and constitution; but the revolution which took place in Spain at the beginning of the 18th century, enabled Philip V. to introduce into Catalonia and the kingdoms of Aragon and Valencia the laws of Castile; which, excepting a few alterations, rendered necessary by local peculiarities, still continue in full effect.

The laws of Castile, which are thus become those of almost all Spain, are contained in the codes known by the titles of the Fuero juzgo, Ley de las siete partidas, Ordenamiento real, Fuero real, and Recepción; from these last is a collection of occasional edicts of the kings of Spain, and enjoys the highest authority.

The Roman law has no validity in Spain; and though it may be studied by a few lawyers, as containing first principles universally applicable, yet it is never quoted in the courts, and is expressly excepted against by some of the old laws of Castile.

The conducting of a law suit in Spain is subject to very complicated forms; whence necessarily results a slowness of progress. The whole business is carried on by writers, a peculiar branch of the legal profession. In the superior tribunals, the management of causes is in such manner committed to a kind of subaltern magistrates, called reporters (relores), who contrive to render their own department a situation of much greater emolument than that of the judge.

In all the branches of civil, military, ecclesiastical, and judicial administration, in Spain, is evident a spirit of mildness and paternal indulgence, which often degenerates into great abuse. By multiplying courts for the administration of justice, and by establishing the long series of appeals from jurisdiction to jurisdiction, in order that each case may be heard and re-heard, and receive an equitable sentence, the still more important advantages of prompt decision are sacrificed, and a door is opened for chicane.

It is universally acknowledged that the courts of exception are far too numerous; they enfeeble the authority of the established judges, and withdraw a number of individuals from the superintendence of magistrates who reside among them, and are readily accessible, to consign them to the care of distant and dilatory tribunals.

A considerable degree of jealousy and opposition also subsists among many of the tribunals; hence they mutually weaken each other's authority, and the clients are consigned over from court to court; so that lawsuits become intolerably protracted, and a family is held in suspense for two or three generations. The consequence of this is, that the rich wear out those of inferior fortune.

Even the ordinary and regular forms of civil process are slow and complicated. The husbandman is called from his labour, the merchant from his commercial concerns, the artist from his work, and all from their domestic affairs. Nearly an equal tardiness takes place in criminal processes, so that witnesses die, and means of proof are lost, while the guilty often escape unpunished; and those who have been formerly acquitted, are still subject to a long detention in prison, whence they are at length dismissed without indemnity, and irretrievably ruined.

In consequence of the great number of courts, the facility of appeal from one to the other, and the tediousness of law suits; the multitude of judges, advocates, writers, and other subordinate officers employed in the administration of justice, is prodigious. The number of persons employed in the different law establishments has been estimated at 100,000, which is nearly an hundredth part of the population of the country; and the very last general enumeration of the inhabitants of Spain makes the number of advocates amount to 5675, and of writers to 9351; besides the judges and their secretaries, the attorneys and their clerks, and the innumerable host of alguazils and inferior officers.

Another serious inconvenience in the administration of Spanish law, is the necessity of reposing entire and blind confidence in a class of subaltern officers of the courts, called writers. This appears to be a branch of the profession wholly peculiar to Spain; the writer exercising at the same time the functions of secretary, solicitor, notifer, registrar, and being the sole medium of communication between the client and the judge.

It is not customary in Spain to allow either of the parties concerned any copy of the documents requisite for carrying on a suit, except by the express order of the judge. All the writings on both sides are collected together and bound up into a volume, which remains stated in the profession of the writer, who intrusts it for a certain time to the attorneys of the parties for the instruction of advocates. The writer, to whose care the documents of any suit are committed, also registers the decrees and sentences of the judges on the case, and notifies to the parties concerned, each step of the process, by reading to them the proper instrument; without, however, allowing them to have a copy of it.

The union of so many important functions in the same person, necessarily affords various opportunities for dishonesty; and the chance of being imposed upon is still further increased by an unwise regulation which obliges the defendant, in any action, to choose the same writer as is employed by the plaintiff.

It may be remarked that scarcely any other persons are under equal temptations to dishonesty, on account of the almost total impunity that they enjoy in consequence of the following regulation. In all those districts where there are either a corregerador and superior alcalde, or two superior alcaldes; each of these officers has an independent tribunal for the decision of law suits; and the right of pronouncing sentence in any particular case belongs to
SPAIN.

The archbishoprics before the late revolution were eight in number; and the bishoprics 46. The most opulent see was that of Toledo, supposed to yield annually about 90,000l. The Mozarabic Missal, composed by St Isidora for the Gothic church, after the conversion from Arianism to the Catholic faith, continued to be used in Spain till the Moors were subdued, when the Roman form was introduced.

The Spanish clergy, in proportion to the population of the country, is less numerous than was the clergy of France prior to the revolution; even their wealth is less considerable, but better administered; and their contribution to the public revenue is much greater. As to the general conduct of the Spanish church, and its influence on the state, we may remark that after all the perverted and malicious industry that has been exerted in the examination of this question, the result has turned out highly favourable to the superior orders of the Spanish clergy, who are for the most part, free from those irregularities which are charged on the clergy of other countries. The conspicuous situations in the Spanish church are by no means considered as the patrimony of the rich and noble, but, as the well-merited reward of irreproachable conduct. Whatever may be the rank of an ecclesiastic in the sacerdotal hierarchy, he never habitually absents himself from his proper place of residence, where he expends the revenue of his benefice in alms or public works. From the period of the reconquest of Spain from the Moors, most of the public establishments owe their foundation to the clergy, by whom also whole towns have been rebuilt and raised from their ruins. The most beautiful aqueducts, fountains, and public walks in the cities, have been constructed at the expense of their bishops; from them also the poor have received the most effectual relief in times of scarcity, epidemic disease, and war. The bishop of Orense converted his episcopal palace into his almshouse, where were lodged and supported 300 French ecclesiastics, condemned to transportation during the furies of the revolution; the prelate himself took his place at their table, and refused to partake of any indulgence that he could not also procure for his guests. Cardinal Orense, archbishop of Toledo, converted the alcazar of that city into an establishment wherein are received 200 children, and 700 poor persons of all ages. The bishop of Cordova, during the scarcity of 1804, and for a long time afterwards, made a daily distribution of 1200 rations of bread to the poor inhabitants of his diocese. The aqueduct which conveys water to the city of Tarragona is the work of their archbishop, who has thus conferred upon the place the inappreciable benefits of cleanliness and health; to both of which it was long a stranger. Similar instances of public merit may be found in almost every diocese.

With regard to the religious orders, their conduct is certainly less exemplary, though by no means meriting the reproaches that have been so liberally cast upon them.
The reforms that have taken place at various periods have stopped the progress of the abuses introduced by length of time; and as the numbers of the monks have diminished, their pernicious influence on public opinion has proportionally declined. Some progress has been made in the desirable policy of uniting the different orders of the same rule into a single order; and from the present prohibition to receive novices, it is probable that several orders are about to be totally suppressed.

The Spanish language is one of the great southern dialects which spring from the Roman; but many of the words become difficult to the French or Italian student, because they are derived from the Arabic used by the Moors. The speech is grave, sonorous, and of exquisite melody, containing much of the flow and formal manner of the orientals.

The Spanish language, in some respects, very rich; it abounds in compound words, insuperlatives, derivatives, augmentatives, diminutives, and frequentative verbs; it has many quite synonymous words, and others which well express the different shades of meaning. In the technical terms of arts and sciences it is, however, extremely poor; a few of these it has borrowed from the Latin; and almost all the rest from the French.

On the whole, the Spanish is one of the finest of the European languages. It is dignified, harmonious, energetic, and expressive; and abounds in grand and sonorous expressions, which unite into measured periods, whose cadence is very agreeable to the ear. It is a language well adapted to poetry; but it also inclines to exaggeration, and its vehemence easily degenerates into bombast. Though naturally grave, it easily admits of pleasantry. In the mouth of well educated men it is noble and expressive; lively and pointed in that of the common people; sweet, seductive, and persuasive, when uttered by a female. Amongst the orators it is touching and imposing, though rather diffuse; at the bar and in the schools it is barbarous, and is spoken about the court in a concise and agreeable manner.

The literature of Spain is highly reputable, though little known to the other countries of Europe since the decline of Spanish power. The Bibliotheca Hispanica of Antonio will completely satisfy the curious reader on this subject. Among the fathers of literature in this country must be named Isidore of Seville, many of whose works are extant, and inferior in merit to few of that epoch. Lives of saints, and chronicles, are also found among the earliest productions; and successive writers may be traced to the 11th century, when they became numerous; but before mentioning some Spanish authorities posterior to that period, it will be proper to recollect that Arabian learning flourished under the caliph of Cordova, and produced many illustrious names well known to the oriental scholar, as Aben Zac, or Averroes, Aben Zuar, Rhazes, &c. nor must it be forgotten that Aben Nazan wrote a book on the learning and authors of Spain. On this subject the inquisitive are referred to the work of Casiri.

In the 11th century, the Spanish authors began to increase in number, and the native language begins to appear. This was the epoch of the famous Cid, Roderic Didac de Bivar, whose actions against the Moors were celebrated in contemporary songs, and by a long poem

written in the following century. After the 13th century, it would be idle to attempt enumerating all the Spanish authors, among whom are Alphonso the Wise, who wrote the Libro del Tereso, a treatise on the Three Parts of Philosophy; and at whose command were compiled the famous Alphonseine Tables of Astronomy. Raymond Lully is said to have written not fewer than 317 books, full of metaphysical froth. In the 15th century appeared Juan de Mena, a poet of surprising powers, since which time a department of literature can scarcely be mentioned in which the Spaniards have not excelled. It would be unnecessary to repeat the well-known names of Cervantes, Quevedo, Lopez de Vega, and others, whose works are known to all Europe. The history of Mexico has been celebrated as a composition; but in fact it is defective and erroneous. The name of Bayer in learning, and of Peyjos in general knowledge, have recently attracted deserved respect; nor has the Pinner's line of royal authors failed, an elegant translation of Sallust having been published by the heir apparent to the Spanish monarchy, the present Ferdinand VII.

As the rudiments of education are in Spain generally imparted by the monks, it can scarcely be expected that useful knowledge should be communicated by them. The accounts given on this subject by travellers, have thrown so little light on the state of education in Spain, that it can be generally understood only by comparison with other Catholic countries. In this comparison Spain will be found inferior to France and Italy, but in many respects superior to Austria and the German states.

The number of universities in Spain was formerly Universities 24, but only the following 17 now remain, viz. that of Pampelona, in Navarre; of Oviedo, in the Asturias; of San Jago, in Galicia; of Seville, and of Granada, in the provinces of the same name; of Huesca and Zaragoza, in Aragon; of Avila, Osma, and Valladolid, in Old Castile; of Toledo, Sigenzua, and Alcala de Hanez, in New Castile; of Cervera, in Catalonia; of Oribuela and Valencia, in Valencia; and of Salamanca, in the province of Leon. Of these the most celebrated, are the universities of Zaragoza, Toledo, Alcala, Cervera, and Salamanca.

The university of Zaragoza has 22 professors, and that of Toledo has 24; about 900 students attend the classes of the former, and nearly 3000 those of the latter; yet neither of these establishments is known in Europe, or regarded as of high reputation even in Spain.

The university of Alcala, established at a prodigious expense by Cardinal Ximenes, answered for nearly a century the views of its illustrious founder. This splendid institution consists of 31 general professors, and 13 colleges, each of which has its particular establishment of masters and professors, and of students, who receive gratuitous support and instruction. At present, however, this university is gone so entirely to decay, that scarcely a vestige of its ancient splendour remains, and the whole number of students scarcely amounts to 500.

The university of Cervera, founded at the commencement of the 18th century, with a magnificence truly royal, possesses 43 professors, five colleges, about 900 students; but it partakes of the radical fault of all the Spanish universities; the course of study is incomplete and antiquated, and the very name of the institution is scarcely known beyond the boundaries of Catalonia.
The university of Salamanca, the most ancient of any in Spain, has enjoyed a degree of celebrity which entitles it to a particular description.

It was founded by Alphonso IX. between the years 1230 and 1244, and was considerably enlarged by Ferdinand III. his grandson. But its most magnificent patron was Alphonso X. surnamed the Wise, son and successor of the last-mentioned sovereign. This prince richly endowed it, and drew up a set of statutes for its government. He established a professorship of civil law, with a salary of 500 maravedies; a professorship of canon law, with a salary of 300 maravedies; two professorships of decretals with salaries of 500 maravedies; two professors of natural philosophy, and as many of logic, with salaries of 200 maravedies each; and two masters of grammar, with salaries of 300 maravedies. It experienced also the liberality of many succeeding sovereigns, and received from the popes a vast extent of privileges.

For many years this university enjoyed a high reputation; its fame extended over all Europe; it was consulted by kings and by popes, and its deputies were received into the general councils, where they well sustained the character of the body which they represented. Students flocked to it not only from all the provinces of Spain and Portugal, and from the islands of Majorca and the Canaries, but also from the West Indies and New Spain, and even from France, Flanders, and England. The number of students who attended the classes amounted nearly to 15,000. The whole of this vast establishment consisted of 25 colleges, a library, and an hospital, called Del Estudio, intended for the amelioration of poor scholars.

The celebrity of Salamanca continued in full vigour during many ages; but, at length, as rival institutions sprang up, declined by slow degrees, so that by the year 1595, the number of students did not exceed 7000.

After the evacuation of Spain by the Romans, theatrical representations were discontinued till they were restored by the Moors, and from them adopted by the Gothic Spaniards, who soon became passionately fond of the stage, a taste which they have ever since preserved.

They had at first neither theatres nor a stage, their dramas were acted in a court, a garden, or the open fields; the actors and spectators were mingled, and were equally exposed to the injuries of the weather.

At a subsequent period the stage was marked out by a kind of bearded platform, and was surrounded by old clothes, drawn back, on occasion, by means of cords, which formed the only decorations, and behind which the actors dressed. Their properties consisted only of crooks, some wigs and false beards, and a few white shaws, trimmed with gold fringe.

Theatrical exhibitions became more regular and decent towards the end of the 16th century, when a new form was given to them by the exertions of Bartholomew Naharro, a middling dramatic poet. Theatres were then erected, but the greatest part were upon tressels, and two parallel pieces of canvas formed their scenes, which were sometimes decked with various colours, sometimes covered with miserable paintings, or adorned with foliage, trees, or flowers.

During all these periods, the prompter, with a candle in his hand, stationed himself on the stage by the side of the performers who were speaking, and jumped from side to side whenever the actors changed their places.

This custom prevailed at the end of the 17th century, and even still prevails among the strolling companies of small towns.

Theatres have at length, however, assumed a handsomer appearance in this country, and customs more conformable to the rest of Europe. Handsome theatres have been multiplied, and their stages are now well arranged and decorated; all the great cities are well provided with them, and many of the smaller towns may boast of elegant and not ill furnished playhouses.

The prompter no longer runs from one side of the stage to the other; he is placed in the middle before the scenes, in a kind of well, where he no longer offends the sight and taste of the spectator: but an old custom which is still observed, greatly injures the interest and effect of the representation. The prompter, who has the piece before him, does not wait till the actor is at a loss to prompt him, but recites the whole drama aloud, so that the actor appears to follow him in his declamation. By this means two voices are heard in the theatre pronounced the same words, which are confounded, and often produce a discord, and the spectator who has first heard the piece recited, no longer takes an equal interest in the same verses, phrases, and words, which the actor afterwards declaims. The Spanish theatres are divided into a patio, or area, and boxes called balco and aposentos. The orchestra, where the musicians are stationed, adjoins the stage; an inclosure between it and the pit is set round with arm chairs, and destined for the reception of the higher class: the patio, or pit, is placed behind, and filled with benches, and the gradas consist of two rows of benches disposed amphitheatrically on each side below the boxes, and sometimes also across the lower end of the theatre. This last division is found only in a few theatres; in the others, the space beneath the boxes is empty, and persons stand in it. The patio and the gradas contain the common people, the most numerous, most noisy, and most imperious part of the public.

There are commonly only two tiers of boxes, sometimes three; they extend on each side from the stage to the end of the theatre. The form is the usual one, but they are divided from each other by partitions, which completely shut them up on each side, a circumstance which greatly injures the beauty of the general effect.

There is commonly at the end of the theatre fronting the stage, a large box with seats placed semicircularly behind one another, which is called the cazuela. No man is allowed to enter it, and only women muffled up in their monetes are admitted.

There are several things very singular and amusing in this cazuela. Women of every age and condition are there united; the married are confounded with the single; the wives of the common people with those of tradesmen and the ladies of the court; the poor woman with the rich one who would not be at the trouble of dressing to appear in her box. Their appearance is most curious; they are all covered with their monetes, a kind of white or black veil, and give the idea of a choir of nuns. It is the place for chattering, and between the acts there proceeds from the cazuela a confused noise like the hum of bees, which astonishes and diverts all who hear it for the first time. Scarcely is the performance ended, when the door of this box, its galleries, passages, and the staircase leading to it, are all
Spain.

all besieged by a great crowd of men of every condition; some attracted by curiosity; others coming to wait upon the women who are in it.

Notwithstanding all that has been done for its improvement, the Spanish stage is still far from the celebrity which it once possessed; and the people do not see second the efforts of their best writers. The acting is in a still lower state. The performers possess neither that dignity which characterizes great personages, and enables a subject without injuring its interest; nor that sweet expression of voice and gesture which goes to the heart, and awakens the sentiments it expresses. In their acting every thing is trivial or inanimate; every thing departs from nature. Their recitation is most of strength, and is performed at the sole expense of the lungs. Cries and shrieks are its most impressive part, and the most applauded by the majority of the audience. They put nothing in its proper place: all their action is exaggerated; when they threaten they roar; when they command they thunder; when they sigh, it is with an effort which completely exhausts the breath. They substitute anger for dignity, violence for spirit, insipidity for gallantry. Their gestures rarely correspond with the sentiments they ought to express; but resemble their recitation; and are usually monotonous, capricious, ignoble, and almost always violent. The women, in their bursts of passion, become furies; warriors become villains; generals robbers; and heroes bravos. Nothing, as they manage it, is pathetic; nothing makes any impression on the audience. The spectators, equally unmoved at the end of the piece, as at the beginning, see it, without having experienced a single moment of interest or emotion.

As labour and culture are reckoned derogatory to the Spanish character, a sufficient quantity of grain for the support of the inhabitants is not raised, though societies for the encouragement of agriculture have been established in different parts of the kingdom. The principal produce is wine, delicious fruits, oil, silk, honey, and wax. A considerable proportion of the mountains and valleys is pastured by immense flocks of sheep, whose wool is extremely fine and valuable. Estremadura is noted for its excellent pastures; and the wool in Old Castile is reputed the finest in the kingdom. In Catalonia the hills are covered with forest and fruit trees. Valencia is celebrated for its silk, and for the exquisite flavour of its melons. Murcia abounds in mulberry trees; and the southern provinces yield the most delicious wines and fruits. Upon the whole, it has been observed of Spain, that few countries owe more to nature, and less to industry.

The soil in general repose on beds of gypsum, which is an excellent manure. The common course of husbandry about Barcelona begins with wheat; which being ripe in June, is immediately succeeded by Indian corn, hemp, millet, cabbage, kidney beans, or lettuce. The second year the same crops succeed each other as before. The next year they take barley, beans, or vetches; which coming off the ground before midsummer, are followed, as in the former years, by other crops, only changing them according to the season, so as to have on the same spot the greatest possible variety. Near Carthagena the course is wheat, barley, and fallows. For wheat they plough three, and sow from the middle of November to the beginning of December; in July they reap from 10 to 100 for one, as the seasons happen to be humid. The rich vale of Alicant yields a perpetual succession of crops. Barley is sown in September, reaped in April; succeeded by maize, reaped in September; and by a mixed crop of esculents which follow. Wheat is sown in November, and reaped in June; flax in September, pulled in May. In the vale of Valencia wheat yields from 20 to 40; barley from 18 to 24; oats from 20 to 30; maize 100; rice 40. The Spanish plough is generally light; and is drawn by oxen with the yoke over the horns; the most proper and natural mode, as the chief strength of the animal centres in the head. For a very minute account of agriculture in Spain, see De Laborde’s View, vol. iv. chap. 2.

That prejudice which regards the mechanic arts as State of base, is not yet extinguished in Spain: hence it happens the arts that these arts are either neglected, or abandoned to such unskillful hands, as in general to render the Spaniards much behind their neighbours in the useful arts of life. The influence of this prejudice is least in the province of Catalonia, where the laws, customs, and opinions are favourable to artisans; and it is accordingly in this province that the mechanic arts have made the greatest progress. Foreign artists experience great difficulties in this country. They are not allowed to practice without gaining admission into some incorporation or company, and this has almost always been refused them.

Some arts have, however, made considerable progress in Spain, especially those of gilding leather, and printing, which has lately acquired a great degree of perfection.

The fabrication of articles of gold and silver might become an important object in a country where these metals abound; but it is neglected, and the demand is almost entirely supplied from foreign markets. What little they perform in this way at home is usually very ill executed, and exorbitantly dear. Madrid, however, begins to possess some good workmen in this way; encouragement would increase their number, and facilitate the means of improvement; but manual labour is these excessively dear. Hence the Spaniards prefer foreign articles of this kind, which, notwithstanding the expense of carriage, the enormous duties which are paid on these articles, and the profits of the merchants, are still cheaper than those made at home.

The liberal arts are cultivated in this country with more assiduity and success. The 16th century was the most brilliant period of the arts in Spain, as well as of the sciences, of literature, and of the power and grandeur of the monarchy. A crowd of able architects appeared at once under Charles V. and Philip II. They erected numerous edifices, which will immortalize the reigns of these princes and the names of the artists. John de Herrera and Cepedes displayed the highest talents; Pedro de Uría constructed the magnificent bridge of Almaráz, in Estremadura; John-Baptist Monegro of Toledo, assisted in the building of the Escorial, and of the church of St Peter at Rome.

The structures of that age are the finest in Spain, and perhaps the only ones in the country which deserve to fix the attention of the skilful spectator. There are some among them which, in regularity, solidity, and magnificence, deserve to be compared with the fine buildings of the Romans. The bridges of Badajoz, over the Guadiana, and of Toledo, over the Manzanares, are of this period; as are also the grand house or palace, now the
Spain now possesses an academy of painting, at Seville, and two academies of the fine arts, one at Madrid, and the other at Valencia. The first owes its origin to an association of the painters of Sevilla formed by themselves, about the year 1660; Charles III. revived it, and established there a school of the fine arts. That of Madrid was founded by Philip V. The last was established by the exertions of some private persons, assisted by the benefaction of Andrew Majoral, archbishop of Valencia, and the protection of the municipal body. Charles III. came to its assistance 26 years after its establishment, with an annual gift of nearly 700l. These academies have for their object the study and improvement of painting, sculpture, and architecture; they give public lessons on these three arts, and distribute annual prizes among their pupils. That of Madrid, or San-Fernando, sends its pupils to Rome at the expense of government, to complete their studies.

Public and gratuitous schools for drawing have been established within the last 20 years in different places at Madrid, Cordova, Valencia, Seville, Zaragoza, Barcelona, &c. The last of these is supported by the merchants; that of Vergara was founded by the patriotic society of Biscay; and those of Zaragoza and Cordova owe their birth to the zeal and generosity of two individuals; the first to Don Martin Noy Cochea, the last to Don Antonio Cavallerio, the present bishop of Cordova. Those of Madrid, Seville, and Valencia, depend on the academies of these cities.

The manufactures of Spain are more flourishing during the government of the Moors in that country, than they have been at any subsequent period. So completely had the kingdom declined in this respect at the end of the 16th century, when Philip V. ascended the throne, that it is said by De Laborde to have been absolutely destitute of trade. The intestine wars which ravaged the kingdom during the first 14 years of that reign, and the low state to which the national finances were reduced, prevented the government from paying attention to manufactures; and it was not till after tranquillity had been restored, and regulations adopted with respect to the public revenue, that the nations were induced to wear articles of their own manufacture. Since the reigns of Ferdinand VI. and Charles III. this part of the internal trade of the kingdom has greatly improved, and the manufactures of Spain are now once more on a respectable footing.

The Spanish manufactures enumerated by De Laborde, in his View of Spain, are those of cloth and other woollen goods; silks; brocaded stuffs in gold and silver; linens and other articles formed from flax or hemp; cottons; leather and other articles manufactured from skins and hides; paper; china and delft ware; brandy; beer; aqua fortis; salt of lead; shears for the woollen trade; copper, iron, and brass goods; glass and mirrors; soap; hair; articles for the marine; military implements; arms and ammunition; tobacco and snuff. Of these, the most important are, the woollen and silk manufactures; leather; brandy; military weapons; soap and tobacco.

The principal places for the woollen manufactures are, Auelot, Arens, Vich, and the convent of Gironne in Catalonia; Jaca, and the district of Cincavilla in Aragon, and Burgos in Old Castile, for woollen stockings; Barcelona, Zaragoza, and Burgos, for blankets; Junquera, Segovia, Burgos, and many others, for baizes and...
Spain has long been famous for its manufacture of military weapons; and it is well known that the swords, sabres, bangers, and bayonets, made at Toledo and Barcelona, are of a very superior temper. Large manufactories for fire-arms occur in the district of Guipuscoa, and two royal founderies for brass cannon, are established at Barcelona and Seville.

There is only one manufactury for tobacco and snuff in Spain, viz. at Seville; but this is on a most extensive scale, and is supposed to yield of annual profits about 800,000. sterling. Here are employed 202 mills, turned by 300 horses or mules; and the various operations call for the daily labour of above 1400 persons.

Considering the extent of sea coast belonging to the commerce, kingdom of Spain, its commerce is but inconsiderable, and principally takes place between the mother-country and the American colonies. Spain, indeed, carries on a foreign trade with every country in Europe; but its principal transactions are, with England, Holland, Italy, and France. Its exports to these countries consist almost entirely of raw produce, as, if we except oil, wine, brandy, shoes, salt, and a few coarse cloths and silken articles, the trade in manufactured goods is almost wholly confined to the interior of the country. Its chief exports, and the amount yielded by each for the several provinces, as well as the whole amount of the export trade of Spain, to the rest of Europe, will be seen in the following table.

The above table is confined almost entirely to the European exports. To these must be added the amount of Spanish exports to the American colonies, in order to acquire a just view of the total amount of the export commerce. The following table will show the amount of the exports, both of home and foreign produce, from Spain to America in 1784, as estimated by Mr Townsend in pounds sterling.

</table>

Of these exports we are to regard chiefly those of Spanish produce, and these Mr Townsend has probably estimated too high. M. de Laborde, on whose authority we are more disposed to rely, states the value of Spanish domestic merchandise exported to America in the year 1788, as amounting to 1,633,651l. sterling, while in 1792, it amounted to 2,812,500l. sterling, and on an average of five years, from 1788 to 1792, it amounted to 1,833,333l. sterling. The amount of foreign merchandise exported in 1788, was 1,484,315l. sterling. Adding the average to this last sum, we have 3,317,965l. sterling for the whole export trade to America. This added to 4,908,324l. sterling, makes a grand total of 8,225,929l. sterling for the whole export trade of Spain.

The Spanish imports are much more considerable than the exports. Before the present troubles, Spain imported from Holland, tapes, linen drapery, common lace, cutlery goods and paper; from Silesia linen drapery; from Germany, more particularly from Hamburg, quantities of haberdashery; from England, calicoes, iron and steel goods, fine cloth, quantities of cod fish and ling; the value of the last articles is estimated at three millions of duros, five millions livres tournois, (208,333l. 13s. 4d.) from France, calicoes, linen drapery, silk stockings, silks, camlets, and other kinds of worsted stuffs, fine cloths, gilded articles, jewellery, iron goods, haberdashery, steel goods, and perfumery.

We have not satisfactory documents sufficient to ascertain the amount of these imports, but it was certainly much less than that of the imports from the American colonies. These latter, according to Mr Townsend's statement, amounted in 1784 to 12,635,175l. sterling; to which, if we add nearly half a million for duty, we shall have a total of above thirteen millions sterling for American imports alone. De Laborde estimates the total amount of American imports for the year 1788 at 8,382,432l. sterling, of which Cadiz alone imported 6,619,873l. sterling. If to the above amount we add 577,579l. for the duty at the same period, we shall have a total of 8,960,009l. sterling against the mother coun-

try, deducting from this 3,317,648l. for the average exports, we have 5,642,361l. as the balance of trade in favour of the Spanish colonies.

Though there are in Spain many navigable rivers, inland as well as few canals of communication have been constructed to improve the internal navigation of the country. The canal of Aragon, completed during the reign of Charles IV, must be highly beneficial to that province. Two canals, viz. that of Tuenstru, and the imperial canal, both of which begin at Navarre, run in various windings through Aragon, by turns receding from or approaching the river Ebro, where at length they terminate. Besides the dykes, banks, sluices, and bridges necessary in the course of these canals, an aqueduct has been constructed in the valley of Riozalen, 710 fathoms in length, and 17 feet thick at the base, in which the canal runs.

The canal of Castile, projected and begun in the last reign, has been almost abandoned. It was to commence at Segovia, sixteen leagues north of Madrid, to follow the course of the Eresma, that falls into the Douro, and to be continued as far north as Reynosa; which is twenty leagues from St Ander, a sea port. At Reynosa is the communication with the canal of Aragon, that unites the Mediterranean to the bay of Biscaia. Above Palencia, a branch goes westward through Rio-Seeo and Benevento to Zamora; making the canal of Castile, in its whole extent 140 leagues; where it is completed, viz. between Reynosa and Rio-Seeo, its width at top is 36 feet, at bottom 20, and nine in depth.

In 1784, a canal was planned, which, from the foot of the mountains of Guadaluma near the Courish, would proceed southward to the Tagus; afterwards to the Guadiana, and terminate at the Guadalquivir above Andaxar. Some other attempts to improve the inland navigation of the country have been unsuccessful.

There is no nation in Europe which displays such a general variety of national character as Spain. In no two people are the manners and characters exactly alike. It is therefore difficult to collect traits on which to found the national character of the Spaniards; and this character has been variously represented by different writers. From the transactions which have lately taken place between that people and the British nation, we confess ourselves prejudiced against them; and we shall therefore, instead of sketching their character according to our own preconceived notions, endeavour to delineate it as concisely as possible from De Laborde, who is probably a sufficiently competent judge.

The national pride, says this author, is everywhere the same. The Spaniard has the highest opinion of his nation and himself, and this he expresses with energy, in his gestures, words, and actions. This opinion is discovered among all ranks in life, and all classes of society. Its result is a kind of haughtiness, sometimes repulsive to him who is its object, but useful in giving to the mind a sentiment of national pride and self-esteem which fortifies it against all meanness.

In later times the Spaniards have not degenerated from the valour of their ancestors. The Spanish soldier is still one of the best in Europe, when placed under an experienced general, and brave and intelligent officers. He possesses a cool and steady valour; he long endures fatigue and hunger, and easily endures himself to labour.

The Spaniards are very reserved, and rather wait for,
than court the advances of a stranger. Yet in spite of their apparent gravity, they possess an inward gaiety, which frequently shines out when proper occasions call it forth.

The Spaniard is very slow in all his operations; he often deliberates when he ought to act, and spoils affairs as much by temporising as the natives of other countries do by precipitation. This tardiness would be but a slight defect, did it not proceed from a serious radical want, from the invincible indolence and hatred of labour which prevails among all ranks of society.

That jealousy which was formerly proverbial among the Spaniards, is now greatly diminished; husbands are much less suspicious, and women much more accessible. Lattices have disappeared; doors exist only in romances; veils are exchanged for mantelas; houses are thrown open, and the women have recovered a liberty by which they are less tempted to go astray than when their virtue was entrusted to locks and grates, and to the superintendence of guards often faithless and easily corrupted.

In fine, the Spaniards are sober, discreet, adroit, frank, patient in adversity, slow in decision, but wise in deliberation; ardent in enterprise, and constant in pursuit. They are attached to their religion, faithful to their king, hospitable, charitable, noble in their dealings, generous, liberal, magnificent; good friends, and full of honour. They are grave in carriage, serious in discourse, gentle and agreeable in conversation, and enemies to falsehood and evil speaking.

Such is the Spanish character as drawn by De La Borde. Its varieties in the several provinces are thus stated by the same author. The Old Castilians are silent, gloomy, and indolent, and are the most severely grave of all the Spaniards; but they possess a steady prudence, an admirable constancy under adversity, an elevation of soul, and an unalterable probity and uprightness. The character of the natives of New Castile is nearly the same, but more open, and less grave and taciturn. Indolence and conceit make part of the character of the people of Navarre; they are distinguished by lightness and adroitness. The Biscayans are proud, impetuous, and irritable; abrupt in discourse and in action; haughty and independent, but industrious, diligent, faithful, hospitable, and sociable. The Galicians are gloomy, and live very little in society; but they are bold, courageous, laborious, very sober, and distinguished for their fidelity. The Asturians partake of the character of the Galicians and Biscayans; but they are less industrious than the former, less civilized, less sociable, less amiable, and more haughty than the latter. The people of Estremadura are proud, haughty, vain, serious, indolent; but remarkably sober, honourable, and much attached to their own province, which they seldom quit. The Murcians are lazy, listless, plotting, and suspicious; attached neither to sciences, arts, commerce, navigation, nor a military life. The Valencians are light, inconstant, and indiscriminate; gay, fond of pleasure, little attached to each other, and still less to strangers, but affable, agreeable, and diligent. The Catalans are proud, haughty, violent in their passions, rude in discourse and in action, turbulent, untractable, and passionately fond of independence; they are not particularly liberal, but active, industrious, and indefatigable; they are sailors, husbandmen, and builders, and resort to all corners of the world to seek their fortunes. They are brave, intrepid, sometimes rash, obstinate in adhering to their schemes, and often successful in vanquishing, by their steady perseverance, obstacles which would appear insurmountable to others.

The natives of almost every province have some distinguishing peculiarity in their dress, manners, and pursuits. Before the accession of the house of Bourbon to the throne, the usual dress of a Spanish nobleman consisted of a slouched hat, a long black or brown cloak, short jerkin, and street breeches, with a long Toledo sword; but French dresses are now introduced at court. The higher classes wear their hats under their arm. The common people wrap themselves up to the eyes in a brown cloak, called alecopa, that reaches to the ground, and conceal their hair beneath a cotton cap, and a broad hat called sombrero. When a lady walks abroad, her head and upper part of her body are covered with a mantela; that is, a white or black veil, so that it is impossible she should be known. At home, the dress is a jacket and a petticoat of silk or cotton. The hair is generally a fine black; and powder is rare.

In romance, the ladies are celebrated for beauty, and some of them deserve that character; yet beauty is not their general character. They are of a slender make, but with great art they supply the defects of nature. By an indiscriminate use of paint, they disfigure their complexion and shrieve their skin.

Several of the Spanish customs and habits, which seem ridiculous to foreigners, are gradually wearing out, and in process of time will no doubt be corrected. The higher classes at breakfast use chocolate, and seldom tea. Dinner generally consists of beef, veal, pork, mutton, and beans, boiled together. They are fond of garlic; and it is proverbial that olives, salad, and radishes, are food for gentlemen. The men drink little wine, and the women use water or chocolate. Both sexes sleep after dinner, and air themselves in the cool of the evening. Their repasts are composed of sweetmeats, biscuits, coffee and fruit, which servants distribute to the company; who keep their seats, and have little conversation.

Dancing and cards are favourite amusements. Theatrical exhibitions are generally insipid or ridiculous bombast, low wit, absurdity, and buffoonery. The combats of the cavalleros, and bull fights, are almost peculiar to this country. On these occasions young gentlemen were used to show their courage to their mistresses; and were honoured and rewarded according to their success. But these exhibitions were lately conducted with greater economy and parsimony; and mercenary champions studied in the most secure and graceful manner to destroy the devoted animal. See Bull-Fighting.

The chief defect in all ranks is an aversion to labour and industry. The higher orders bestow no attention on agriculture and commerce; they reside for the most part at court and in the metropolis, reckoning it beneath their dignity to live in villas on their estates among their tenants. In their estimation, a labouring man quits the dignity of the Spanish character, and renders himself an object of contempt. Hence a listless indolence prevails. Thousands waste their time in total want of every incitement to action. Their intellectual powers lie dormant, and their views and exertions are confined within the narrow sphere of mere existence. The common people have no encouragement to industry; and must feel little concern
concern for the welfare of a country where a few overgrown families engross every thing valuable, and never think of the condition of their vassals. The indigent Spaniard does not bestir himself unless impelled by want, because he perceives no advantage to be derived from industry. A stranger to intemperance and excess, his scanty fare is easily procured; and under a climate so propitious, few clothes are required. The hovel which he occupies, together with all its contents, has a mean, filthy, despicable appearance; and all that relates to him bears the impression of wretchedness and misery. There are certain customs which may be regarded as peculiar to the Spaniards, or which at least are scarcely found in any other European country. The number of servants retained in the families of the higher ranks is prodigious; and even a tradesman’s wife, in narrow circumstances, will frequently have four maid servants, though she cannot, with propriety, employ more than two. The houses of gentlemen, and especially of grandees, swarm with them; and, not infrequently, all the principal servants will have their wives and children lodged with them, and supported by their master. We have heard of one nobleman who was at the daily expense of 340 l. merely for the maintenance of his numerous domestics.

The Spaniards are fond of meeting in the evening in parties, which are often very numerous. On these occasions, the ladies as they arrive place themselves in one room, and the gentlemen in another; or else the ladies range themselves in a line along the side of the room, the lady of the house always taking the lowest place next to the door, whilst the men remain standing, or seat themselves on the opposite side. They remain separated in this manner till the card parties are introduced. They play at loo, loto, and other games of a similar kind. Those who do not play, either look on, or embrace the opportunity of chatting with the person most interesting to them. Others form little circles, where the conversation is usually very animated. These parties very much resemble the French evening, and the English rout.

A refresco sometimes makes part of these entertainments, but only on particular occasions, when the company is more than usually numerous. But orgeat, lemonade, orangeade, ices of different kinds, sweetmeats, and biscuits, are distributed with uncommon profusion; and chocolate ends the function, as all these entertainments are called.

Many precautions are taken in Spain against the heat. The rooms are watered several times a-day, and the windows are shaded on the outside with sashings of cloth or ticking, or on the inside by large and full curtains. In some places, as at Valencia, the glass is taken out of the windows at the approach of summer, and the doors of the apartments are all set open.

The beds in Spain are hard, being made of mattresses, laid on paillasses, resting on a wooden bottom. The furniture of the houses is usually very simple, and the floors are covered with matting or printed cloth. The chairs have rush bottoms, and are usually of different heights, those for the ladies being one-third lower than those for the gentlemen.

Among the principal amusements of the Spaniards must be reckoned music and dancing. Though the Spaniards have a taste for music, they are by no means proficient in that accomplishment. Their principal instrument is the guitar, which is in the hands of every body. Different provinces have also their peculiar instruments. Thus the Gallicians use a dull and heavy bagpipe; the Catalonians a large flageolet, and a little drum or tambor; and the Biscayans a short flute, with four holes. Castanettes are also extremely common, and are employed with great dexterity and address in the national dances.

The Spaniards are passionately fond of dancing, and they have certain dances which are peculiar to Spain. Of these the fandango is the most celebrated, and appears to be the most ancient. It is a very extraordinary dance, in which the whole body is thrown into a regular and harmonious convulsion, expressive of the most insidious ideas.

The passion of the Spaniards for these dances is carried to a height which can scarcely be imagined. No sooner are the guitar and the singing to which they are danced heard in a ball room or theatre, than a murmur of delight arises on all sides; all faces become animated; the feet, hands, and eyes of all present are put in motion: it is impossible to describe the effect produced. Mr Townend, an English traveller, affirms, that if a person were to come suddenly into a church or a court of justice playing the fanfare, or the corder, priests, judges, lawyers, criminals, auditors, one and all, grave and gay, young or old, would quit their functions, forget all distinctions, and all set themselves a dancing.

The Spanish balls are directed by two persons chosen among the visitors, who are called bastoneras, and with the hat under the arm, and the cane in the hand, perform the office of masters of the ceremonies. One is for the gentlemen, the other for the ladies. It is their business to appoint who is to dance, whether minuets or country dances: they are in general very attentive to the observance of precedence and etiquette, and have usually the complaisance to contrive that those shall dance together to whom it is peculiarly agreeable to meet.

A singular custom is observed at these balls, which appears new and strange to a foreigner. The lady chosen to dance rises, crosses the room alone, and places herself where she is to begin dancing, without waiting for her partner to lead her out; and after the dance is over, her partner makes his bow to her again in the middle of the room without taking any further concern about her, or handing her back to her place. But this custom prevails only in the provinces.

The bull-fights noticed above were once not only a favourite but a fashionable spectacle in Spain. Every city, and almost every small town, had a place set apart for these daring combats; and hither all ranks and ages resorted with the greatest avidity, and witnessed the prowess of the combatants, and the torture of the wretched animals, whom they were hired to butcher, with the most savage expressions of delight. These fights made a part of every festival, and, as soon as they were announced, the housewife left her family, the tradesman forsook his shop, the artist his work-room, the labourer his field, and joy and expectation were painted on every countenance. To the honour of the nation, these cruel sports are at length abolished, and Spain has thus set an example of humanity, which Britain, with all her civilization and refinement, need not blush to copy.
il Systema di Needham e Buffon, in 1765, in which he establishes, by a number of the most ingenious and solid experiments, the animality of microscopic animals. This work was sent by the author to Bonnet, who drew from it a prediction respecting the future celebrity of Spallanzani, which he lived to see accomplished. This circumstance gave birth to the most intimate friendship, which lasted to the close of life, and constituted their chief happiness. During the same year he published a truly original work, entitled De Lapidibus ab aqua resiliendis, in which he proves, in opposition to the commonly received opinion, by the most satisfactory experiments, that what are called ducks and drakes, are not produced by the elasticity of the water, but by the effect naturally resulting from the change of direction experienced by the stone in its movement, after it has struck the water, and that it has been carried over the hollow of the cup formed by the concussion.

When the university of Padua was re-established upon a larger scale, the Count de Firmian was directed by the empress Maria Theresa, to invite Spallanzani to be professor of natural history, to which his great reputation made him competent, although it was solicited by many celebrated characters; and he merited it by his success, as immense crowds of students thronged to his lectures. He had a fine genius, and his knowledge was of vast extent; his method was simple, but rigorous in its nature, and what he knew he connected with principles firmly established. He acquired the valuable art of interpreting nature by herself, which diffused such a light over his lectures, that every thing became perspicuous, which could be said to afford any instruction. His discourses were plain and animated, and the elegance and purity of his style charmed every hearer. He prepared his lectures a year before-hand, and it was his chief aim to render them useful in an eminent degree. His new observations made them always new and engaging. Many learned persons who attended his lectures were not above becoming his scholars, in order to acquire a more extensive knowledge of what they knew before, and to learn that which otherwise they might probably never have known. The Contemplation de la Nature of Bonnet was his text book, the vacancies of which he ably filled up, fully explained the ideas, and established the theories by his own experiments. This work was translated by him into the Italian language, and he added much to its value by notes of his own, the first volume of which he published in 1769, and the second the following year.

His connection with Bonnet tended, in a great measure, to influence his genius, which yielded to the severe method of investigation adopted by the philosopher of Geneva. He was proud of being the pupil of such an illustrious character, upon whose writings he incessantly bestowed every leisure moment, and thus became anxious to learn from Nature herself the proofs of Bonnet's sentiments respecting the generation of organized bodies, the pleasing nature of which research captivated his attention for a considerable time.

The first two volumes of this work, entitled Opuscoli di Fisica Animale e Vegetabile, were published in the year 1776, containing the explanation of part of the microscopic observations which were previously given to the world.

If it must be admitted that the art of accurate observation
tion is by far the most difficult, it cannot be denied that it is at the same time the most necessary, and requires the most brilliant talents and abilities, which were possessed by Spallanzani in a remarkable degree, as is fully evinced by all his researches and all his admirable writings.

The polite manner in which he conducted his dispute with Needham respecting the phenomena of generation, secured for him a high degree of applause. On this occasion he treated of the influence of cold upon animals, and proved that the torpidity of some during winter, does not depend on the impression the blood may receive from it, since a frog deprived of blood, becomes torpid when reduced to the same cold state by being immersed in ice, and swims as formerly when restored to a proper degree of warmth.

Spallanzani travelled through Switzerland and the Grisons in the year 1779, after which he went to Geneva, spending a month with his friends, by whom his conversation was as much admired as his masterly writings. From this place he returned to Pavia, and in 1780 published two more volumes of his _Dissertazione di Fisica Animale e Vegetale_, wherein he unfolded the secrets of the interpretation of two very intricate phenomena, concerning the economy of animals and vegetables. He was led to this study from some experiments made by him upon digestion, for his lectures; and he repeated the experiments of Beaumur on gallinaceous birds, remarking that the trituration which in this case is favourable to digestion, could not be a very powerful means. He perceived that the gizzard of those birds, by which the stones of fruit are pulverized, did not digest the powder thus formed, it being necessary that it should undergo a new operation in the stomach, previous to its becoming chyle for the production of the blood and other humours.

This subject may be regarded as one of the most difficult in physiology, because the observer is always under the necessity of acting and looking in the midst of darkness; the animal must be managed with care, that the arrangement of the operations may be avoided; and when the experiments are completed with great labour, it is requisite that the consequences be well distinguished. Spallanzani in this work is truly enchanting, analysing facts with scrupulosity, in order to ascertain their causes with certainty; comparing Nature with his experiments, in order to form a correct judgment respecting them; laying hold of every thing essential to them in his observations, and measuring their solidity by the increase or diminution of supposed causes.

Mr John Hunter appears to have been greatly hurt by this work, which led him to publish, in the year 1785, _Some Observations upon Digestion_, in which he threw out some bitter sarcasms against the Italian naturalist, who took ample revenge by publishing this work in the Italian language, and addressing to Caldani in 1788, _Una Lettera Apologetica in Risposta alle Osservazioni del Signor Giovanni Hunter_. In this he exposed with great moderation, but at the same time with logic which nothing could resist, the mistakes and errors of the British physiologist, leaving the power of a reply altogether hopeless.

The generation of animals and plants is treated of in the second volume of this last-mentioned work, in which he proves the pre-existence of germs to fecundation, by experiments as satisfactory as surprising; shewing also the existence of tadpoles in the females of five different species of frogs, in salamanders, and toads, before their fecundation. He likewise recounts the success of some artificial fecundations upon the tadpoles of those five species, and even upon a quadruped.

In the year 1781, he took the advantage of the academical vacation, for the purpose of making a journey, in order to add to the cabinet of Pavia. He set out for Marseilles in the month of July that year, where he began a new history of the sea, which presented him with many new and curious facts on numerous genera of the natives of the ocean. He went also to Finale, Genoa, Massa, and Carrara, to make observations on the quarries of marble, held by statuaries in such estimation. He then returned to Spezzia, and brought from thence to Pavia a vast number of fishes, which he deposited in the cabinet of that city, wholly collected by himself. With the same view and success he visited the coasts of Istria in 1782, and the Apennine mountains the subsequent year, taking notice of the dreadful hurricanes, and the astonishing vapours by which that year became so noted in meteorology. The emperor Joseph, on examining this cabinet, presented Spallanzani with a gold medal. In 1785, he was offered the chair of natural history by the university of Padua, vacant by the death of Anthony Valisaniere; but in order to prevent his acceptance of it, his salary was doubled by the archduke, and he went to Constantinople with Chiavari Zuliani, who had been appointed ambassador from the Venetian republic. He set out on the 21st of August, and reached the Turkish metropolis on the 11th of October, where he remained during eleven months. His attention was fixed by the physical and moral phenomena of this country, which were new even to Spallanzani. He strayed along the borders of the two seas, and ascended the mountains in the vicinity; he paid a visit to the island of Chalki, discovering to the Turks a copper mine, the existence of which they had never once conjectured. He discovered an iron mine not far from Constantinople, in the island of Principi, of which the Turks were equally ignorant, and prepared to return for Italy on the 15th of August 1786.

A voyage by sea was undoubtedly the safest, but the dangers to which he would be exposed by land were regarded as nothing when contrasted with the idea of being beneficial to science and to man. Having reached Bucharest, Mauroceni the friend of science, received Spallanzani with marks of distinction, presented him with many rarities which the country produced, and gave him horses for travelling, with an escort of 30 troopers, to the utmost confines of his own dominions. Our philosopher passed by Hermannstadt in Transylvania, and reached Vienna on the 7th of December, where he remained during five days, and had two long conferences with the emperor Joseph II. was much esteemed by the nobility of that city, and respectfully visited by many literary characters. When he arrived at Pavia, the students went out of the city gates to meet him, and testified their joy at his return by repeated acclamations. He was almost instantly drawn to the auditorium, and compelled to ascend the chair from which he had been accustomed to deliver his fascinating lectures; but their demonstrations of joy and shouts of applause made him request of them to give over, and indulge him with
that repose in his own house which was now so absolutely necessary. His students this year exceeded 500.

So extensive was the fame of Spallanzani become by this time, that envy was determined, if possible, to wound his reputation. If his discoveries were too new, solid, and original, to be successfully disputed, that vile passion, or rather feend, began to question his integrity and uprightness respecting the administration of the cabinet of Pavia; but this iniquitous attempt to tarnish his honour, only made it shine forth with redoubled splendour. The judicial examination of the tribunal made his integrity appear even purer than before; and it must be mentioned to his honour, that he had the fortitude to forget this event; his enemies in general confessed their mistake, renounced their unprovoked animosity, and still hoped to regain a friendship of which they had proved themselves so unworthy.

In the voyage of Spallanzani we meet with what may be denominated a new volcanology. We are there instructed how to measure the intensity of volcanic fires, and in his analysis of the lava, almost to touch the particular gas which tears those torrents of stone in fusion from the bowels of the earth, and raises them to the top of Mount Etna. This delightful work is closed by some important enquiries into the nature of swallows, the mildness of their dispositions, the rapidity of their flight; discussing the celebrated problem respecting their remaining torpid during the winter season; proving that artificial cold, much more intense than what is ever naturally experienced in our climates, does not reduce these birds to the torpid state.

Things apparently impossible were often discovered by Spallanzani. In the year 1795 he made one of this description, which he gave to the world in his Lettere sopra il sorpeto d'un nuovo sesso nei Pippistrelli. In that work we are informed that bats, if deprived of sight, act with the same precision in every instance as those which have their eyes; that they slum in the same manner the most trivial obstacles, and also know where to fix themselves when their flight is terminated. Several philosophers confirmed these astonishing experiments, from which a suspicion arose, that these animals must have a new sense, as it appeared to Spallanzani that the other known senses could not compensate for the want of sight; but he was afterwards inclined to think, in consequence of Professor Jurine's experiments on the organ of hearing in bats, that in this particular instance the sense of hearing might possibly supply the want of sight.

The literary career of this celebrated naturalist was terminated by a letter to Giobert, entitled Sopra la piante chiuse ne vasi dentro l'acqua e l'atmosfera, esposto a l'immobili lume solare e l'ombra. These numerous works, which met with the highest approbation, do not comprehend the whole of his multiform labours; for the phenomena of respiration had occupied his attention a considerable time; their points of resemblance and dissimilitude in many species of animals; and he had nearly finished his voyage to Constantinople, as well as collected many valuable materials for a history of the sea, when his life and labours were unfortunately terminated.

He was seized with a retention of urine on the 4th of February 1799, and next morning was deprived of the regular use of his faculties, only enjoying a sound mind during very short intervals. Tourdes and Professor Scarpa did every thing to save him, which could be produced by the joint exertions of genius, experience, and friendship, but in vain. He died on the 17th; but we know not what credit is due to the assertion, that he edified those around him during his last moments by his piety. Be that as it may, while his works exist to speak for themselves, impartial posterity will regard him as a very extraordinary man. These works have been translated into almost every European language, and he was admitted a member of the academies and learned societies of London, Stockholm, Gottingen, Holland, Lyons, Bologna, Turin, Padua, Munich, and Geneva, and he received from Frederick the Great the diploma of member of the academy of Berlin.

SPAN, a measure taken from the space between the thumb and the tip of the little finger when both are stretched out. The span is estimated at three handbreadths or nine inches.

SPANDRELL, the solid work on each branch of an arch, to keep it from spreading.

SPANHEIM, EZEKIEL, a learned writer in the 17th century, was born at Geneva in 1629; and in 1642 went to Leyden to study. Here he distinguished himself to great advantage; and his reputation spreading, Charles Louis elector palatine sent for him to be tutor to his only son. This task our author discharged to the entire satisfaction of the elector; by whom he was also employed in divers negotiations at foreign courts. He afterwards entered into the service of the elector of Brandenburg, who in 1650 sent him envoy extraordinary to the court of France, and soon afterwards made him a minister of state. After the peace of Bicowie, he was again sent on an embassy to France, where he continued from the year 1697 to 1702. The elector of Brandenburg having during that interval assumed the title of King of Prussia, conferred on him the title and dignity of a baron. In 1702 he left France, and went ambassador to England, where he had been several times. Here he died in 1710, aged 81 years. It is surprising, that in discharging the duties of a public minister with so much exactness, and amidst so many different journeys, he could find time enough to write the several books published by him. It may be said of him, that he acquitted himself in his negotiations like a person who had nothing else in his thoughts; and that he wrote like a man who had spent his whole time in his study. The principal of his works are, 1. De praestantia et usus numismatum antiquorum; the best edition of which is in two volumes folio. 2. Several letters or dissertations on scarce and curious medals. 3. A preface and notes to the edition of the emperor Julian's works, printed at Leipsic in 1696, folio. See CANIS, MAMMALIA Index.

SPAR, in Mineralogy, a name given chiefly to some of the crystallized combinations of lime, as the carbonate and the fluoride; the former being called simply lime spar, the latter fluor spar, or Derbyshire spar, from the name of the place where it is found in greatest abundance. See MINERALOGY.

SPARGANII, BUR-REEED, a genus of plants belonging to the class of monocoty, and to the order of triandria; and in the natural system ranged under the 3d order, Calamari. See BOTANY INDEX.
SPARLING, or STIRLING, a small fish belonging to the genus Salmo. See Ichthyology, p. 99.

SPARMANNIA, a genus of plants belonging to the class of polyandria, and to the order of monogynia. See Botany Index.

SPARROW. See Fringilla, Ornithology Index.

SPARROW-Hawk. See Falco, Ornithology Index.

SPARROW-Grass. See Asparagus, Botany and Gardening Index.

SPARRY ACID. See Fluoric Acid, Chemistry Index.

SPARTA, or LACEDEMON, the capital of the country of Laconia in Greece, an ancient and most renowned state, the inhabitants of which have been in all ages celebrated for the singularity of their laws and character. The history of Sparta for many ages is entirely fabulous; and the authentic accounts commence only with the celebrated lawyer Lycurgus, who flourished about 870 B.C. See the article Lycurgus.

After his death, the first important transaction which we find mentioned in the Spartan history is the Messenian war, which commenced in the year 752 B.C. and ended in the total reduction of the Messenian territory, as related under the article Messenia. During this period, according to some authors, a great change took place in the government of Sparta. This was the creation of the ephors, which is ascribed to one of the kings named Theopompus. This man perceived that there was a necessity for leaving magistrates to execute the laws, when the kings were obliged to be in the field, appointed the magistrates above mentioned, who afterwards made so great a figure in the state (see Ephors). One great privilege of the ephors was, that they did not rise up at the presence of the kings, as all other magistrates did; another was, that if the kings offended against the laws, the ephors took cognizance of the offence, and inflicted a suitable punishment. From the first election of the ephors, the year was denominated, as at Athens from the first election of the archons.

The conquest of Messenia gave Sparta the superiority over the rest of the states, excepting only that of Athens, which for a long time continued to be a very troublesome rival: but the contests between these two rival states have been so fully related under the article Attica, that nothing more is requisite to be added in this place. In the time of the Persian war, Leonidas the Spartan king, distinguished himself in such a manner as to become the admiration not only of that but of every succeeding age. It being resolved in a general council to defend the straits of Thermopylae against the Persians, 7000 foot were put under the command of Leonidas; of whom, however, only 300 were Spartans. Leonidas did not think it practicable to defend the pass against such multitudes as the Persian king commanded; and therefore privately told his friends, that his design was to devote himself to death for his country.

Xerxes advancing near the straits, was strangely surprised to find that the Greeks were resolved to dispute his passage; for he had always flattered himself, that on his approach they would betake themselves to flight, and not attempt to oppose his innumerable forces. However, Xerxes still entertaining some hopes of their flight, waited four days without undertaking any thing, on purpose to give them time to retreat. During this time, he used his utmost endeavours to gain and corrupt some Greeks, promising to make him master of all Greece if he would come over to his interest. His offers being rejected with contempt and indignation, the king ordered him by a herald to deliver up his arms. Leonidas, in a style and with a spirit truly laconical, answered, "Come thyself, and take them." Xerxes, at this reply, transported with rage, commanded the Medes and Carians to march against them, take them all alive, and bring them to him in fetters. The Medes, not able to stand the shock of the Greeks, soon betook themselves to flight, and in their room Hydarnes was ordered to advance with that body which was called Immortal, and consisted of 10,000 chosen men; but when these came to close with the Greeks, they succeeded no better than the Medes and Carians, being obliged to retire with great slaughter. The next day the Persians, reflecting on the small number of their enemies, and supposing so many of them to be wounded that they could not possibly maintain a second fight, resolved to make another attempt; but could not by any efforts make the Greeks give way: on the contrary, they were themselves put to a shameful flight. The valour of the Greeks exerted itself on this occasion in a manner so extraordinary, that Xerxes is said to have three times leaped from his throne, apprehending the entire destruction of his army.

Xerxes having lost all hopes of forcing his way through troops that were determined to conquer or die, was extremely perplexed and doubtful what measures he should take in this posture of affairs; when one Epialtes, in expectation of a great reward, came to him, and discovered a secret passage to the top of the hill which overlooked and commanded the Spartan forces. The king immediately ordered Hydarnes thither with his select body of 10,000 Persians; who marching all night, arrived at break of day, and possessed themselves of that advantageous post. The Phocceans, who defended this pass, being overpowered by the enemy's numbers, retired with precipitation to the very top of the mountain, prepared to die gallantly. But Hydarnes, neglecting to pursue them, marched down the mountain with all possible expedition, in order to attack those who defended the straits in the rear. Leonidas being now apprised that it was impossible to bear up against the enemy, obliged the rest of his allies to retire: but he stated himself, with the Thespians, Thebans, and 700 Laccdemians, all resolved to die with their leader; who being told by the oracle, that either Sparta should be destroyed or the king lose his life, determined without the least hesitation to sacrifice himself for his country. The Thebans indeed remained against their inclination, being detained by Leonidas as hostages; for they were suspected to favour the Persians. The Thespians, with their leader Demosthenes, could not by any means be prevailed upon to abandon Leonidas and the Spartans. The augur Megistias, who had foretold the event of this enterprise, being pressed by Leonidas to retire, sent home his only son; but remained himself, and died by Leonidas. Those who staid did not feed themselves with any hopes of conquering or escaping, but looked upon Thermopylae as their graves; and when Leonidas, exhorting them to take some nourishment, said, that they should
should all sup together with Plato, with one accord they set up a shout of joy, as if they had been invited to a banquet.

Leontidas killed with all his men, as he had been advised by Epialtes. Upon their approach, Leontidas advanced to the broadest part of the passage, and fell upon the enemy with such undaunted courage and resolution, that the Persian officers were obliged to stand behind the divisions they commanded, in order to prevent the flight of their men. Great numbers of the enemy falling into the sea, were drowned; others were trampled under foot by their own men, and a great many killed by the Greeks; who knowing they could not avoid death upon the arrival of those who were advancing to fall upon their rear, exerted their utmost efforts. In this action fell the brave Leontidas, which Abrocomes and Hyperanthes, two of the brothers of Xerxes, observing, advanced with great resolution to seize his body, and carry it in triumph to Xerxes. But the Lacedæmonians, more eager to defend it than their own lives, repulsed the enemy four times, killed both the brothers of Xerxes, with many other commanders of distinction, and rescued the body of their beloved general out of the enemy's hands. But in the mean time, the army that was led by the treacherous Epialtes, advancing to attack their rear, they retired to the narrowest place of the passage, and drawing altogether, except the Thebans, posted themselves on a rising ground. In this place they made head against the Persians, who poured in upon them on all sides, till at length, not vanquished, but oppressed and overwhelmed by numbers, they all fell, except one who escaped to Sparta, where he was treated as a coward and traitor to his country; but afterwards made a glorious reparation in the battle of Plataea, where he distinguished himself in an extraordinary manner. Some time after, a magnificent monument was erected at Thermopylae, in honour of those brave defenders of Greece, with two inscriptions; one the general, and relating to all those who died on this occasion, importing, that the Greeks of Peloponnesus to the number only of 4000, made head against the Persian army, consisting of 3,000,000. The other related to the Spartans in particular, and was composed by the poet Simonides, to this purport: "Go, passenger, and acquaint the Spartans that we died here in obedience to their just commands." At those tombs a funeral oration was yearly pronounced in honour of the dead heroes, and public games performed with great solemnity, wherein none but the Lacedæmonians and Thespians had any share, to show that they alone were concerned in the glorious defence of Thermopylae.

At the end of the 77th Olympiad, a most dreadful earthquake happened at Sparta, in which, according to Diodorus, 20,000 persons lost their lives; and Plutarch tells us, that only five houses were left standing in the whole city. On this occasion the Helotes or slaves, whom the Spartans had all along treated with the utmost cruelty, attempted to revenge themselves, by taking up arms, and marching directly to the ruins of the city, in hopes of cutting off at once those who had escaped from the earthquake. But in this they were prevented by the prudence of the Spartan king Archidamus; for he, observing that the citizens were more desirous of preserving their effects than taking care of their own lives, caused an alarm to be sounded, as if he had known that an enemy was at hand. On this the citizens armed themselves in haste with such weapons as they could come at; and having marched a little way from the city, met the Helotes, whom they soon compelled to retire. The latter, however, knowing that they had now no mercy to expect from those who had already treated them with such cruelty, resolved to too. Hence they fortified themselves in the field, but took shelter in their fortified places, the war was protracted for ten years and upwards. At last the Helotes were reduced to their former misery; and the Messenians were obliged to leave Peloponnesus, on pain of being made slaves also. These poor people were then received by the Athenians, who granted them Naupactus for their residence, and afterwards brought them back to a part of their own country, from whence in the course of the Peloponnesian war they had driven the Spartans.

In the year 431 B.C. the Peloponnesian war commenced; of which a full account has been given under Athenians the article ATTICA, No. 116—165. It ended most unfortunately for the Athenians; their city being taken and dismantled, as related in the article above mentioned. Thus were the Spartans raised to the highest pitch of glory; and in the reign of Agesilaus, they seemed to be on the point of subverting the Persian empire, as related under the article PERSIA, No. 34. But here their good fortune and their views of empire were suddenly checked. Agesilaus had carried on the war in Asia with the greatest success; and as he would reckoned to no terms of accommodation, a Persian governor named Tisslouses, having first attempted in vain to bribe the king, dispatched Timocrates the Rhodian with 50 talents into Greece, in order to try whether he could there meet with any person less incorruptible than the Spartan monarch. This agent found many who inclined to accept his offers; particularly in Thebes, Corinth, and Argos. By distributing the money in a proper manner, he inflamed the inhabitants of these three cities against the Spartans; and of all others the Thebans combined with the Lacedæmonians, and formed a union against the Spartans; and of all others the Thebans combined with the Lacedæmonians, and formed a union against the Spartans. A great breach was made between Sparta and the other states of Greece, and did not choose to begin the war themselves, because the chief of the Persian faction were unwilling to be accountable for the event. For this reason they persuaded the Locrions to invade a small district which lay in dispute betwixt the Piocian and themselves. On this the Phocians invaded Locris; the Locrions applied to the Thebans, and the Phocians to the Spartans. The latter were glad of an opportunity of breaking with the Thebans; but met with a much warmer reception than they expected. Their old general Lysander, who had reduced
reduced Athens, was defeated and killed, with the loss of 1000 men: on which disaster Agesilaus was recalled, and obliged to relinquish all hopes of conquering the Persians. His return changed the fortune of the war so much, that all the states began to grow weary of a contest from which nobody derived any advantage except the king of Persia. In a short time a treaty was concluded, known in history by the name of the peace of Antalcidas. The terms of this treaty were highly disadvantageous and dishonourable to the Greeks; for even the Spartans, though successful in Greece, had lost a great battle at sea with the Persian fleet under Conon the Athenian, which entirely broke their power in Asia.

By the peace of Antalcidas, the government of Boeotia was taken from the Thebans, which they had for a long time enjoyed; and by this they were so much provoked, that at first they absolutely refused to accede to the treaty; but as Agesilaus made great preparations to invade them, they thought proper at last to comply. However, it was not long before a new war commenced, which threatened the total subversion of the Spartan state. As, by the peace of Antalcidas, the king of Persia had in a manner guaranteed the sovereignty of Greece to Sparta, this republic very soon began to exercise its power to the utmost extent. The Mantinians were the first who felt the weight of their resentment, although they had been their allies and confederates. In order to have a pretence for making war against them, they commanded them to quit their city, and to retire into five old villages which, they said, had served their forefathers, and where they would live in peace themselves, and give no umbrage to their neighbours. This being refused, an army was sent against them to besiege their city. The siege was continued through the summer with very little success on the part of the Spartans; but having during the winter season dammed up the river on which the city stood, the water rose to such a height, as either to overflow or throw down the houses; which compelled the Mantinians to submit to the terms prescribed to them, and to retire into the old villages. The Spartan vengeance fell next on the Phliusians and Olynthians, whom they forced to come into such measures as they thought proper. After this they fell on the Thebans, and, by attempting to seize on the Pireum, drew the Athenians also into the quarrel. But here their career was stopped: the Thebans had been taught the art of war by Chabrias the Athenian; so that even Agesilaus himself took the command of the Spartan army in vain. At sea they were defeated by Timotheus the son of Conon; and by land the battle of Leuctra put an end to the superiority which Sparta had held over Greece for near 500 years. See LEUCTRA.

After this dreadful defeat, the Spartans had occasion to exert all their courage and resolution. The women and nearest relations of those who were killed in battle, instead of spending their time in lamentations, shook each other by the hand, while the relations of those who had escaped from the battle hid themselves among the women; or if they were obliged to go abroad, they appeared in tattered clothes, with their arms folded, and their eyes fixed on the ground. It was a law among the Spartans, that such as fled from battle should be degraded from their honours, should be constrained to appear in garments patched with divers colours, to wear their beards half-shaved, and to suffer any to beat them who pleased, without resistance. At present, however, this law was dispensed with; and Agesilaus by his prudent conduct kept up the spirits of the people, at the same time that by his skill in military affairs he checked the progress of the enemy. Yet, during the lifetime of Epaminondas the Theban general, the war went on greatly to the disadvantage of the Spartans; but he being killed at the battle of Mantinea, all parties became quickly desirous of peace. Agesilaus did not long survive; and with him, we may say, perished the glory of Sparta. Soon after this all the states of Greece fell under the power of Alexander the Great; and the Spartans, as well as the rest, having become corrupt, and lost their martial spirit, became a prey to domestic tyrants, and to foreign invaders. They maintained their ground, however, with great resolution against the celebrated Pyrrhus king of Epirus; whom they repulsed for three days successively, though not without assistance from one of the captains of Antigonus. Soon after this, one of the kings of Sparta named Agis, perceiving the universal degeneracy that had taken place, made an attempt to restore the laws and discipline of Lycurgus, by which he supposed the state would be restored to its former glory. But though at first he met with some appearance of success, he was in a short time tried and condemned by the ephors as a traitor to his country. Cleomenes, however, who ascended the throne vain to re-store it in 216 B.C. accomplished the reformation which Agis had attempted in vain. He suppressed the ephors; cancelled all debts; divided the lands equally; and they had been in the time of Lycurgus; and put an end to the luxury which prevailed among the citizens. But at last he was overborne by the number of enemies which surrounded him; and being defeated in battle by Antigonus, he fled to Egypt, where he put an end to his own life. With him perished every hope of retrieving the affairs of Sparta: the city for the present fell into the hands of Antigonus; after which a succession of tyrants took place; till at last all disturbances were ended by the Romans, who reduced Macedon and Greece to provinces of their empire, as has been related under these articles.

It remains now only to say something concerning the institutions character, manners, and customs of the Spartans, which, as they were founded on the laws of Lycurgus, may best be learned from a view of these laws. The institutions of Lycurgus were divided into 12 His laws tables. The first comprehended such of the Spartan laws as regarded religion. The statues of all the gods and goddesses were represented in armour, even to Venus herself; the reason of which was, that the people might conceive a military life the most noble and honourable, and not attribute, as other nations did, sloth and luxury to the god. As to sacrifices, they consisted of things of very small value; for which Lycurgus himself gave this reason, That want might never hinder them from worshipping the gods. They were forbidden to make long or rash prayers to the heavenly powers, and were enjoined to ask no more than that they might live honestly and discharge their duty. Graves were permitted to be made within the bounds of the city, contrary to the custom of most of the Greek nations: nay, they buried close by their temples, that all degree of
of people might be made familiar with death, and not conceive it such a dreadful thing as it was generally esteemed elsewhere: on the same account, the touching dead bodies, or assisting at funerals, made none unclean, but were held to be as innocent and honourable duties as any other. There was nothing thrown into the grave with the dead body; magnificent sepulchres were forbidden; neither was there so much as an inscription, however plain or modest, permitted. Tears, sighs, outcries, were not allowed in public, because they were thought dishonourable in Spartans, whom their lawyer would have to bear all things with equanimity. Mourning was limited to 11 days; on the 12th the mourner sacrificed to Ceres, and threw aside his weeds. In favour of such as were slain in the wars, however, and of women who devoted themselves to a religious life, there was an exception allowed as to the rules before mentioned; for such had a short and decent inscription on their tombs. When a number of Spartans fell in battle, at a distance from their country, many of them were buried together under one common tomb; but if they fell on the frontiers of their own state, then their bodies were carefully carried back to Sparta, and interred in their family sepulchres.

II. Lycurgus divided all the country of Lacedaemon into 30,000 equal shares: the city of Sparta he divided into 6000 as some say; into 6000, as others say; and as a third party will have it, into 4500. The intent of the legislator was, that property should be equally divided among his citizens, so that none might be powerful enough to oppress his fellows, or any in such necessity, as to be therefrom in danger of corruption. With the same view he forbade the buying or selling these possessions. If a stranger acquired a right to any of these shares, he might quietly enjoy it, provided he submitted to the laws of the republic. The city of Sparta was unswalled; Lycurgus trusting it rather to the virtue of its citizens than to the art of masons. As to the houses, they were very plain; for their ceilings could only be wrought by the axe, and their gates and doors only by the saw; and their utensils were to be of a like stamp, that luxury might have no instruments among them.

III. The citizens were to be neither more nor less than the number of city lots; and if at any time there happened to be more, they were to be led out in colonies. As to children, their laws were equally harsh and unreasonable; for a father was directed to carry his new-born infant to a certain place, where the gravest men of his tribe looked upon the infant; and if they perceived its limbs straight, and thought it had a wholesome look, they then returned it to its parents to be educated; otherwise it was thrown into a deep cavern at the foot of the mountain Taygetus. This law seems to have had one very good effect, viz. making women very careful, when they were with child, of either eating, drinking or exercising, to excess; it made them also excellent nurses; for which they were in mighty request throughout Greece. Strangers were not allowed to reside long in the city, that they might not corrupt the Spartans by teaching them new customs. Citizens were also forbidden to travel, for the same reason, unless the good of the state required it. Such as were not bred up in their youth according to the law, were not allowed the liberty of the city, because they held it unreasonable, that one who had not submitted to the laws in his youth should receive the benefit of them when a man. They never preferred any stranger to a public office; but if at any time they had occasion for a person not born a Spartan, they first made him a citizen, and then preferred him.

IV. Celibacy in men was infamous, and punished in a most extraordinary manner; for the old bachelor was constrained to walk naked, in the depth of winter, through the market-place: while he did this, he was obliged to sing a song in desparagement of himself; and he had none of the honours paid him which otherwise belonged to old age, it being held unreasonable, that the youth should venerate him who was resolved to leave none of his progeny behind him, to reverence them when they grew old in their turn. The time of marriage was also fixed; and if a man did not marry when he was of full age, he was liable to an action; as were such also as married above or below themselves. Such as had three children had great immunities; such as had four were free from all taxes whatsoever. Virgins were married without portions; because neither want should hinder a man, nor riches induce him, to marry contrary to his inclinations. When a marriage was agreed on, the husband committed a kind of rape upon his bride. Husband went for a long time, secretly and by stealth, to the beds of their wives, that their love might not be quickly and easily extinguished. Husbands were allowed to lend their wives; but the kings were forbidden to take this liberty. Some other laws of the like nature there were, which as they were evidently against modesty, so they were far from producing the end for which Lycurgus designed them; since, though the men of Sparta were generally remarkable for their virtue, the Spartan women were as generally decried for their boldness and contempt of decency.

V. It was the care of Lycurgus, that, from their very birth, the Lacedaemonians should be inured to their conquests appetites: for this reason he directed, that nurses should accustom their children to spare meals, and now and then to fasting; that they should carry them, when 12 or 13 years old, to those who should examine their education, and who should carefully observe whether they were able to be in the dark alone, and whether they had got over all other follies and weaknesses incident to children. He directed, that children of all ranks should be brought up in the same way; and that none should be more favoured in food than another, that they might not, even in their infancy, perceive any difference between poverty and riches, but consider each other as equals, and even as brethren, to whom the same portions were assigned, and who, through the course of their lives, were to fare alike: the youths alone were allowed to eat flesh: older men ate their black broth and pulse; the lads slept together in chambers, and after a manner somewhat resembling that still in use in Turkey for the Janizaries: their beds, in the summer, were very hard, being composed of the reeds plucked by the hand from the banks of the Evros; in winter their beds were softer, but by no means downy, or fit to indulge immoderate sleep. They ate altogether in public, and in case any abstained from coming to the tables, they were fined. It was likewise strictly forbidden for any to eat or drink at home before they came to the common meal; even then...
each had his proper portion, that every thing might be
done there with gravity and decency. The black broth
was the great rarity of the Spartans, which was com-
pounded of salt, vinegar, blood, &c. so that in our tim-
er, it would be esteemed a very unsavoury soup. If they
were moderate in their eating, they were so in their
drinking also; thirst was the sole measure thereof; and
never any Lacedaemonian thought of drinking for plea-
sure: as for drunkenness, it was both infamous and se-
verely punished; and, that young men might perceive
the reason, slaves were compelled to drink to excess, so
that the beastliness of the vice might appear. When
they retired from the public meal, they were not slow-
ed any torches or lights, because it was expected, that
men who were perfectly sober should be able to find
their way in the dark; and besides, it gave them a fa-
cility of marching without light; a thing wonderfully
useful to them in time of war.

VI. As the poor ate as well as the rich, so the rich
could wear nothing better than the poor: they neither
changed their fashion nor the materials of their gar-
ments; they were made for warmth and strength, not
for gaiety and show: and to this custom even their
kings conformed, who were nothing gaudy in right of
their dignity, but were contented that their virtue
should distinguish them rather than their clothes. The
youths wore a tunic till they were twelve years old;
afterwards they had a cloak given them, which was to
serve them a year; and their clothing was, in general,
so thin, that a Lacedaemonian vest became proverbial.
Boys were always used to go without shoes; but when
they grew up, they were indulged with them, if the
manner of life they led required it; but they were al-
ways inured to run without them, as also to climb up
and slip down steep places with bare feet: nay, the very
shoe they used was of a particular form, plain and
strong. Boys were not permitted to wear their hair;
but when they arrived at the age of twenty, they suf-
f ered their hair and beard to grow. Baths and anoint-
ing were not much in use among the Lacedaemonians;
the river Eurotas supplied the former, and exercise the
latter. In the field, however, their sumptuary laws
did not take place so strictly as in the city; for when they
went to war, they wore purple habits; they put on
crowns when they were about to engage the enemy;
they had also rings, but they were of iron; which met-
als was most esteemed by this nation. Young women
wore their vests or jerkins only to their knees, or, as
some think, not quite so low; a custom which both
Greek and Roman authors censure as indecent. Gold,
precious stones, and other costly ornaments, were per-
mitted only to common women; which permission was
the strongest prohibition to women of virtue, or who af-
fected to be thought virtuous. Virgins went abroad
without veils, with which married women, on the con-
trary were always covered. In certain public exercises,
in which girls were admitted as well as boys, they were
both obliged to perform naked. Plutarch apologizes
for this custom, urging, that there could be no danger
from nakedness to the morals of youths whose minds
were fortified and habituated to virtue. One of Ly-
curgus’s principal views in his institutions, was to er-
cdiate the very seeds of civil dissension in his republic.
Hence proceeded the equal division of estates enjoined
by him; hence the contempt of wealth, and the neglect
of other distinctions, as particularly birth, being con-
sidering the people of his whole state as one great family;
distinctions which, in other commonwealths, frequently
produce tumults and confusions that shake their very
foundation.

VII. Though the Spartans were always free, yet it Obedi-
ence was with this restriction, that they were subservient to their
their own laws, which bound them as strictly in the city,
as soldiers, in other states, were bound by the rules of
war in the camp. In the first place, strict obedience to
their superiors was the great thing required in Sparta.
This they looked upon as the very basis of government;
without which neither laws nor magistrates availed much.
Old age was an indubitable title to honour in Sparta:
to the old men the youth rose up whenever they came
into any public place; they gave way to them when
they met them in the streets, and were silent whenever
their elders spoke. As all children were looked upon
as the children of the state, so all the old men had the
authority of parents: they repressed whatever they
saw amiss, not only in their own, but in other people’s
children: and by this method Lycurgus provided, that
as youth are everywhere apt to offend, they might be
nowhere without a monitor. The laws went still far-
ther: if an old man was present where a young one
committed a fault, and did not reprove him, he was
punished equally with the delinquent. Amongst the
youths there was one of their own body, or at most
two years older than the rest, who was styled are
he had authority to question all their actions, to look
strictly to their behaviour, and to punish them if they
did amiss; neither were their punishments light, but,
on the contrary, very severe; whereby the youth were
made hardy, and accustomed to bear stripes and rough
usage. Silence was a thing highly commended at Spar-
ta, where modesty was held to be a most becoming vi-
tue in young people; nor was it restrained only to their
words and actions, but to their very looks and gestures;
Lycurgus having particularly directed, that they should
look forward, or on the ground, and that they should
always keep their hands within their robes. A stupid
inconsiderate person, one who would not listen to in-
struction, but was careless of whatever the world might
say of him, the Lacedaemonians treated as a scandal to
human nature; with such a one they would not con-
verse, but threw him off as a rotten branch and worth-
less member of society.

VIII. The plainness of their manners, and their be-
Learning so very much addicted to war, made the Lacedae-
monians less fond of the sciences than the rest of the
Greeks. A soldier was the only reputable profession
in Sparta; a mechanic or husbandman was thought a
low fellow. The reason of this was, that they imagi-
ned professions which required much labour, some con-
stant posture, being continually in the house, or always
about a fire, weakened the body and depressed the
mind: whereas a man brought up hardly, was equally
fit to attend the service of the republic in time of
peace, and to fight its battles when engaged in war.
Such occupations as were necessary to be followed for
the benefit of the whole, as husbandry, agriculture,
and the like, were left to their slaves the helots; but
for curious arts, and such as served only to luxury, they
would not so much as suffer them to be introduced in
their city; in consequence of which, rhetoricians, au-
gurs,
S P A

SP A

Sparta.

gurs, bankers, and dealers in money, were shut out.

The Spartans admitted not any of the theatrical diversions among them; they would not hear the representation of evil even to produce good; but other kinds of poetry were admitted, provided the magistrates had the perusal of pieces before they were handed to the public.

Above all things, they affected brevity of speech, and accustomed their children, from their very infancy, never to express themselves in more words than were strictly necessary; whence a concise and sententious oratory is to this day styled 

Laconic. In writing they used the some conciseness; of which we have a signal instance in a letter of Archidamus to the Eleans, when he understood that they had some thoughts of assisting the Arcadians. It ran thus: “Archidamus to the Eleans: It is good to be quiet.”

And therefore Epaminondas thought that he had reason to glory in having forced the Spartans to abandon their monosyllables, and to lengthen their discourses.

The greatest part of their education consisted in giving their youth right ideas of men and things: the ten or master proposed questions, and either commended the answers that were made him, or reproved such as answered weakly. In these questions, all matters, either of a trivial or abstruse nature, were equally avoided; and they were confined to such points as were of the highest importance in civil life; such as, Who was the best man in the city? wherein lay the merit of such an action? and, Whether this or that hero’s fame was well-founded? Harsh and raillery was greatly encouraged; and this, joined to their short manner of speaking, rendered laconic replies universally admired.

Music was much encouraged; but in this, as in other things, they adhered to that which had been in favour with their ancestors; nay, they were so strict therein, that they would not permit their slaves to learn either the tune or the words of their most admired odes; or, which is all one, they would not permit them to sing them if they had learned them. Though the youth of the male sex were much cherished and beloved, as those that were to build up and continue the future glory of the state, yet in Sparta it was a virtuous and modest affection, untinged with that sensuality which was so scandalous at Athens. The good effects of this part of Lycurgus’s institutions were seen in the union that reigned among his citizens; and which was so extraordinary, that even in cases of competition, it was hardly known that rivals bore ill-will to each other; but, on the contrary, their love to the same person begat a secondary friendship among themselves, and united them in all things which might be for the benefit of the person beloved.

Some authors have accused this great lawgiver of encouraging theft in his institutions; which, they say, was not held scandalous among the Spartans, if it were so dexterously managed as that the person was not detected in it. But this is certain, and seems to be a strong contradiction of the heinous charge, that when a theft was discovered, it was punished with the utmost severity: a person even suspected of it would endure the heaviest punishments rather than acknowledge it, and be branded with so base a crime.

IX. The exercises instituted by law fall under the ninth table. In these all the Greeks were extremely careful, but the Lacedaemonians in a degree beyond the rest; for if a youth, by his corpulence, or any other means, became unfit for these exercises, he underwent public contempt at least, if not banishment. Hunting was the usual diversion of their children; nay, it was made a part of their education, because it had a tendency to strengthen their limbs, and to render those who practised it supple and fleet: they likewise bred up dogs for hunting with great care. They had a kind of public dances, in which they exceedingly delighted, and which were common alike to virgins and young men: indeed, in all their sports, girls were allowed to divert themselves with the youths: insomuch, that, at darting, throwing the quoit, pitching the bar, and such like robust diversions, the women were as dexterous as the men. For the manifest oddity of this proceeding, Lycurgus assigned no other reason, than that he sought to render women, as well as men, strong and healthy, that the children they brought forth might be so too. Violent exercises, and a laborious kind of life, were only enjoined the youth; for when they were grown up to men’s estate, that is, were upwards of 30 years old, they were exempted from all kinds of labour, and employed themselves wholly either in affairs of state or in war.

They had a method of whipping, at a certain time, young men in the temple of Diana, and about her altar; which, however palliated, was certainly unnatural and cruel. It was esteemed a great honour to sustain these flagellations without weeping, mourning, or showing any sense of pain; and the thirst of glory was so strong in these young minds, that they very frequently suffered death without shedding a tear or breathing a sigh. A desire of overcoming all the weaknesses of human nature, and thereby rendering his Spartans not only superior to their neighbours, but to their species, runs through many of the institutions of Lycurgus; which principle, if well attended to, thoroughly explains them, and without attending to which it is impossible to give any account of them at all.

X. Gold and silver were, by the constitutions of Money, well apprized of the danger of riches, that he made the very possession of them venal; but as there was no living without some sort of money, that is, some common measure or standard of the worth of things, he directed an iron coinage, whereby the Spartans were supplied with the useful money, and at the same time had no temptation to covetousness afforded them; for a very small sum was sufficient to load a couple of horses, and a great one must have been kept in a barn or warehouse. The introduction of all foreign money was also prohibited, that corruption might not enter under the name of commerce. The most ancient method of dealing, viz, by barter, or exchange of one commodity for another, was preserved by law in Sparta long after it had gone into disuse everywhere else. Interest was a thing forbidden in the Spartan commonwealth; where they had also a law against alienation of lands, accepting presents from foreigners, even without the limits of their own country, and when their authority and character might well seem to excuse them.

XI. Such of the laws of Sparta as related to courts of justice may be brought under the 11th table. Thirty years must have passed over the head of him who had a right to concern himself in juridical proceedings.

4 A

Young
Spa.

Young men were thought unfit for them; and it was even held indecent, and of ill report, for a man to have any fondness for law-suits, or to be busying himself at the tribunals, when he had no affairs there of his own. By these rules Lycurgus thought to shut out litigiousness, and to prevent that multiplicity of suits which is always scandalous in a state. As young people were not permitted to inquire about the laws of other countries, and as they were hindered from hearing judicial proceedings in their courts, so they were likewise forbidden to ask any questions about, or to endeavour to discover, the reasons of the laws by which themselves were governed. Obedience was their duty; and to that alone they would have them kept. Men of abandoned characters, or who were notoriously of ill fame, lost all right of giving their votes in respect of public affairs, or of speaking in public assemblies; for they would not believe that an ill man in private life could mean his country better than he did his neighbour.

XII. Till a man was 30 years old, he was not capable of serving in the army, as the best authors agree: though some think that the military age is not well ascertained by ancient writers. They were forbidden to march at any time before the full moon; the reason of which law is very hard to be discovered, if indeed it had any reason at all, or was not rather founded on some superstitious opinion, that this was a more lucky conjuncture than any other. They likewise forbidden to fight often against the same enemy; which was one of the wisest maxims in the political system of Lycurgus: and Agesilaus, by offending against it, destroyed the power of his country, and lost her that authority which for so many ages she maintained over the rest of Greece; for, by continually warring against the Thibrans, to whom he had an inveterate hatred, he at last beat them into the knowledge of the art of war, and enabled them, under the command of Epaminondas, to maintain for a time the principality of Greece. Maritime affairs they were forbidden to meddle with, though the necessity of things compelled them, in process of time, to transgress this institution, and by degrees to transfer to themselves the dominion of the sea as well as of the land: but, after the Peloponnesian war, they again neglected naval affairs, from a persuasion that sailors and strangers corrupted those with whom they conversed. As they never fortified Sparta, they were not ready to undertake sieges: fighting in the field was their proper province, and, while they could overcome their enemies there, they rightly conceived that nothing could hurt them at home. In time of war they relaxed somewhat of their strict manner of living, in which they were singular. The true reason for this was, in all probability, that war might be less burdensome to them; for, as we have more than once observed, a strong desire to render them bold and warlike was the reigning passion of their legislators. They were forbidden to remain long encamped in the same place, as well to hinder their being surprised, as that they might be more troublesome to their enemies, by wasting every corner of their country. They slept all night in their armour; but their outguards were not allowed their shields, that, being unprovided of defence, they might not dare to sleep. In all expeditions they were careful in the performance of religious rites; and, after their evening meal was over, the soldiers sung together hymns to their gods. When they were about to engage, the king sacrificed to the muses, that, by their assistance, they might be enabled to perform deeds worthy of being recorded to latest times. Then the army advanced in order to the sound of flutes, which played the hymn of Castor. The king himself sung the psalm, which was the signal to charge. This was done with all the solemnity imaginable; and the soldiers were sure either to conquer or die: indeed they had no other choice; for if they fled they were infamous, and in danger of being slain, even by their own mothers, for disgracing their families. In this consisted all the excellency of the Spartan women, who, if possible, exceeded in bravery the men, never lamenting over husbands or sons, if they died honourably in the field; but deploring the shame brought on their house, if either the one or the other escaped by flight. The throwing away a shield also induced infancy; and, with respect to this, mothers, when they embraced their departing sons, were wont to caution them, that they should either return armed as they were; or be brought back so when they were dead; or, as we have observed, such as were slain in battle were nevertheless buried in their own country. When they made their enemies fly, they pursued no longer than till victory was certain; because they would seem to fight rather for the honour of conquering, than of putting their enemies to death. According to their excellent rules of war, they were bound not to spoil the dead bodies of their enemies; but in process of time, this, and indeed many other of their most excellent regulations, fell into desuetude. He who overcame by stratagem, offered up an ox to Mars; whereas he who conquered by force, offered up only a cock; the former being esteemed more manly than the latter. After 40 years' service, a man was, by law, no longer required to go into the field; and consequently, if the military age was 30, the Spartans were not held invalids till they were 70.

SPARTANUS, AElius, a Latin historian, who wrote the lives of Adrian, Caracalla, and four other Roman emperors. He lived under the reign of Dioclesian, about the year 290.

SPARTIUM, Broom, a genus of plants belonging to the class of diadelphia, and order of decandria; and in the natural system arranged under the 32d order, Papilionaceæ. See BOTANY INDEX.

The flower buds are in some countries pickled, and eaten as capers; and the seeds have been used as a bad substitute for coffee. The branches are used for making besoms, and tanning leather. They are also used instead of thatch to cover houses. The old wood furnishes the cabinet-maker with beautiful materials for varnishing. The tender branches are in some places mixed with hops for brewing, and the macerated bark may be manufactured into cloth.

The junceum, or Spanish broom, grows naturally in the southern provinces of France, as well as in other parts of the south of Europe. It grows in the poorest soils, on the steepest declivities of the hills, in a stony soil, where hardly any other plant could vegetate. In a few years it makes a vigorous shrub; insinuating its roots between the interstices of the stones, it binds the soil, and retains the small portion of vegetable earth scattered over these hills, which the autumnal rains would otherwise...
Spartium. wise wash away. It is most easily raised from seed, which is usually sown in January, after the ground has received a slight dressing.

The shrub serves two useful purposes. Its branches yield a thread of which linen is made, and in winter supports sheep and goats.

In manufacturing thread from broom, the youngest plants are cut in the month of August, or after harvest, and gathered together in bundles, which at first are laid in the sun to dry; they are then beaten with a piece of wood, washed in a river or pond, and left to steep in the water for about four hours. The bundles thus prepared are taken to a little distance from the water, and laid in a hollow place made for them, where they are covered with fern or straw, and remain thus to steep for eight or nine days; during which time, all that is necessary, is to throw a little water once a day on the heap, without uncovering the broom. After this, the bundles are well washed, the green rind of the plant or epidermis comes off, and the fibrous part remains; each bundle is then beaten with a wooden hammer upon a stone, to detach all the threads, which are at the same time carefully drawn to the extremity of the branches.

After this operation, the faggots are untied, and spread upon stones or rocks till they are dry. The twigs must not be peeled till they are perfectly dry; they are then dressed with the comb, and the threads are separated according to the fineness, and spun upon a wheel.

The linen made of this thread serves various purposes in rural economy. The coarsest is employed in making sacks and other strong cloths for carrying grain or seeds. Of the finest is made bed, table, and body linen. The peasants in several places use no other, for they are unaccustomed with the culture of hemp or flax, their soil being too dry and too barren for raising them. The cloth made with the thread of the broom is very useful; it is as soft as that made of hemp; and it would perhaps look as well as that made of flax if it was more carefully spun. It becomes white in proportion as it is steeped. The price of the finest thread, when it is sold, which seldom happens, is generally about a shilling a pound.

The use to which this broom is applied, is to maintain sheep and goats during winter. In the mountains of Lower Languedoc these animals have no other food from November to April, except the leaves of trees preserved. The branches of this broom therefore are a resource the more precious, that it is only fresh nourishment which at that season the flocks can procure, and they prefer it at all times to every other plant. In fine weather the sheep are led out to feed on the broom where it grows; but in bad weather the shepherds cut the branches and bring them to the sheep folds. There is, however, an inconvenience attending the continued use of this food. It generally produces inflammation in the urinary passages. But this inconvenience is easily removed by cooling drink, or a change of food, or by mixing the broom with something else.

It is perhaps needless to add, that it differs much from the broom that is common everywhere in the north of Europe, though not all, in many places, is used for food to cattle. Both of them produce flowers that are very much resorted to by bees, as they contain a great quantity of honey juice. And this should be another inducement to the cultivation of the Spanish broom.

SPARUS, Gilthead, a genus of fishes belonging to the order of thoracii. See Ichthyology Index.

The sparus auratus, or gilthead, was well known to the Romans, who did not esteem them unless they were fed with Lucrine oysters, as Martial informs us,

Non omnis laudem pretiumque Aurata mercetur,
Se qui solus erit concha Lucrina cibus.

SPASM, a convulsion. See Medicine, No 278.

SPATHACAE (from spatha, "a sheath"), the name of the ninth order in Linnaeus's Fragments of a Natural Method, consisting of plants whose flowers are protruded from a spatha or sheath. See Botany Index.

SPATHELIA, a genus of plants belonging to the class of pentandria, and to the order of trigynia. See Botany Index.

SPAW. See Spa.

SPAWN, in Natural History, the eggs of fishes or frogs.

SPAVENTO. See Scanto.

SPAVIN, in the manège, a disease in horses, being a swelling or stiffness, usually in the ham, occasioning a lameness. See Farriery Index.

SPAYING, or SPADING, the operation of castrating the females of several kinds of animals, as sows, bitches, &c. to prevent any further conception, and promote their fattening. It is performed by cutting them in the mid flank, on the left side, with a sharp knife or lancet, taking out the ovaries, and cutting them off, and so stitching up the wound, anointing the part with tar, and keeping the animal warm for two or three days. The usual way is to make the incision a slope, two inches and half long; that the fore-finger may be put in towards the back, to feel for the ovaries, which are two kernels as big as acorns on both sides of the uterus, one of which is drawn to the wound, and thus both taken out.

SPEAKER of the House of Commons, a member of the house elected by a majority of votes thereof to act as chairman or president in putting questions, reading briefs, or bills, keeping order, reprimanding the refractory, adjourning the house, &c. See Parliament.

SPEAKING, the art or act of expressing one's thoughts in articulate sounds or words. See Grammar, Language, Reading, and Oratory, Part iv. Speaking-Trumpet. See Trumpet.

SPEAR-MINT. See Mentha, Botany Index.

SPEAR-WORT. See Ranunculus, Botany Index.

SPECIAL, something that is particular, or has a particular designation; from the Latin species, in opposition to the general, from genus.

SPECIES, in Logic, a relative term, expressing an idea which is comprised under some general one called a genus. See Logic, No 68.

SPECIES, in Commerce, the several pieces of gold, silver, copper, &c. which having passed their full preparation.
preparation and coinage, are current in public. See Money.

Species, in Algebra, are the letters, symbols, marks, or characters, which represent the quantities in any operation or equation. This short and advantageous way of notation was chiefly introduced by Vieta, about the year 1593; and by means of it he made many discoveries in algebra, not before taken notice of.

Species, in Optics, the image painted on the retina by the rays of light reflected from the several points of the surface of an object, received by the pupil, and collected in their passage through the crystalline, &c.

It has been a matter of dispute among philosophers, whether the species of objects which give the soul an occasion of seeing, be an effusion of the substance of the body; a mere impression which they make on all bodies under certain circumstances; or whether they are not some more subtle body, such as light. The moderns have decided this point by the invention of artificial eyes, in which the species of objects are received on paper, in the same manner as in the natural eye.

Specific, in Philosophy, that which is peculiar to any thing, and distinguishes it from all others.

Specific, in Medicine. By species is not meant such as isibility and in all patients produce salutary effects. Such medicines are not to be expected, because the operations and effects of remedies are not formally inherent in them, but depend upon the mutual action and reaction of the body and medicine upon each other; hence the various effects of the same medicine in the same kind of disorders in different patients, and in the same patient at different times. By specific medicines we understand such medicines as are found to be more uniform in their effects than others in any particular disorder.

Specific Gravity, is a term much employed in the discussions of modern physics. It expresses the weight of any particular kind of matter, as compared with the weight of the same bulk of some other body of which the weight is supposed to be familiarly known, and is therefore taken for the standard of comparison. The body generally made use of for this purpose is pure water.

The specific gravity of bodies is a very interesting question both to the philosopher and to the man of business. The philosopher considers the weights of bodies as measures of the number of material atoms, or the quantity of matter which they contain. This he does on the supposition that every atom of matter is of the same weight, whatever may be its sensible form. This supposition, however, is made by him with caution, and he has recourse to specific gravity for ascertaining its truth in various ways. This shall be considered by and by. The man of business entertains no doubt of the matter, and proceeds on it as a sure guide in his most interesting transactions. We measure commodities of various kinds by tons, pounds, and ounces, in the same manner as we measure them by yards, feet, and inches, or by bushels, gallons, and pints; nay, we do this with much greater confidence, and prefer this measurement to all others, whenever we are much interested to know the exact proportions of matter that bodies contain. The weight of a quantity of grain is allowed to inform as much more exactly of its real quantity of useful matter than the most accurate measure of its bulk. We see many circumstances which can vary the bulk of a quantity of matter, and these are frequently such as we cannot regulate or prevent; but we know very few indeed that can make any sensible change in this weight without the addition or abstraction of other matter. Even taking it to the summit of a high mountain, or from the equator to the polar region, will make no change in its weight as it is ascertained by the balance, because there is the same real diminution of weight in the pounds and ounces used in the examination.

Notwithstanding the unavoidable change which heat and cold make in the bulk of bodies, and the permanent varieties of the same kind of matter which are caused by different circumstances of growth, texture, &c, most kinds of matter have a certain constancy in the density of their particles, and therefore in the weight of a given bulk. Thus the purity of gold, and its degree of adulteration, may be inferred from its weight, it being purer in proportion as it is more dense. The density, therefore, of different kinds of tangible matter becomes characteristic of the kind, and a test of its purity; it marks a particular appearance in which matter exists, and may therefore be called, with propriety, Specific.

But this density cannot be directly observed. It is not by comparing the distances between the atoms of matter in gold and in water that we say the first is 19 times denser than the last, and that an inch of gold contains 19 times as many material atoms as an inch of water; we reckon on the equal gravitation of every atom of matter whether of gold or of water; therefore the weight of any body becomes the indication of its material density, and the weight of a given bulk becomes specific of that kind of matter, marking its kind, and even ascertaining its purity in this form.

It is evident that, in order to make this comparison of general use, the standard must be familiarly known, and must be very uniform in its density, and the comparison of bulk and density must be easy and accurate. The most obvious method would be to form, with all nicety, a piece of the standard matter of some convenient bulk, and to weigh it very exactly, and keep a note of its weight: then, to make the comparison of any other substance, it must be made into a mass of the same precise bulk, and weighed with equal care; and the most convenient way of expressing the specific gravity would be to consider the weight of the standard as unity, and then the number expressing the specific gravity is the number of times that the weight of the standard is contained in that of the other substance. This comparison is most easily and accurately made in fluids. We have only to make a vessel of known dimensions equal to that of the standard which we employ, and to weigh it when empty, and then when filled with the fluid. Nay, the most difficult part of the process, the making a vessel of the precise dimensions of the standard, may be avoided, by using some fluid substance for a standard. Any vessel will then do; and we may ensure very great accuracy by using a vessel with a slender neck, such as a phial or matras; for when this is filled to a certain mark in the neck, any error in the estimation by the eye will bear a very small proportion to the whole. The weight of the standard fluid which fills it to this mark being carefully ascertained, is kept in remembrance. The specific gravity of any other fluid is had by weighing the contents of this vessel when filled with it, and dividing
of any other body is the real weight in pounds and ounces, when of the bulk of one pound or one ounce of water. It is therefore of the first importance, in all discussions respecting the specific gravity of bodies, to have the precise weight of some known bulk of pure water. We have taken some pains to examine and compare the experiments on this subject, and shall endeavour to ascertain this point with the precision which it deserves. We shall reduce all to the English cubic foot and avoirdupois ounce of the Exchequer standard, on account of a very convenient circumstance peculiar to this unit, viz., that a cubic foot contains almost precisely a thousand ounces of pure water, so that the specific gravity of bodies expresses the number of such ounces contained in a cubic foot.

We begin with a trial made before the house of commons in 1696 by Mr Everard. He weighed 2145.6 cubic inches of water by a balance, which turned sensibly with 6 grains, when there were 30 pounds in each scale. The weights employed were the troy weights, in the deposit of the Court of Exchequer, which are still preserved, and have been most scrupulously examined and compared with each other. The weight was 1132 ounces 14 pennyweights. This wants just 11 grains of a thousand avoirdupois ounces for 1728 cubic inches, or a cubic foot; and it would have amounted to that weight had it been a degree or two colder. The temperature indeed is not mentioned; but as the trial was made in a comfortable room, we may presume the temperature to have been about 55° of Fahrenheit’s thermometer. The dimensions of the vessel were as accurate as the nice hand of Mr Abraham Sharp, Mr Flamsteed’s assistant at Greenwich, could execute, and it was made by the Exchequer standard of length.

This is confirmed by the naturalists of Europe as a very accurate standard experiment, and it is confirmed by many others both private and public. The standards of weight and capacity employed in the experiment are still in existence, and publicly known, by the report of the Royal Society to parliament in 1742, and by the report of a committee of the house of commons in 1758. This gives it a superiority over all the measures which have come to our knowledge.

The first experiment, made with proper attention, that we meet with, is by the celebrated Snellius, about the year 1615, and related in his Eratosthenes Batavus. He weighed a Rhinland cubic foot of distilled water, and found it 62.79 Amsterdam pounds. If this was the ordinary weight of the shops, containing 7626 English troy grains, the English cubic foot must be 62 pounds 9 ounces, only one ounce more than by Everard’s experiment. If it was the Mint pound, the weight was 62 pounds 6 ounces. The only other trials which can come into competition with Mr Everard’s are some made by the Academy of Sciences at Paris. Picart, in 1694, found the Paris cubic foot of water of the fountain d’Arcueil to weigh 60.588 pounds, poids de Paris. Du Hamel obtained the very same result; but Mr Monge, in 1782, says that filtered rain-water of the temperature 15° (Reaumur) weighs 60.392. Both these measures are considerably below Mr Everard’s, which is 62.5, the former giving 62.053, and the latter 61.868. M. Lavoisier states the Paris cubic foot at 70 pounds, which makes the English foot 62.47. But there is an inconsistency.

Those gentlemen observed the expansion of water to be very anomalous between 32° and 45°. This is distinctly seen during the gradual cooling of water to the point of freezing. It contracts for a while, and then suddenly expands. But we seldom have occasion to measure specific gravities in such temperature.

The reader is now sufficiently acquainted with the principles of this hydrostatical method of determining the specific gravity of bodies, and can judge of the propriety of the forms which may be proposed for the experiment.

The specific gravity of a fluid may be determined either by filling with it a vessel with a narrow neck, or by weighing a solid body that is immersed in it. It is hard to say which is the best way. The last is not subject to any error in filling, because we may suspend the solid by a fine wire, which will not displace any sensible quantity of the fluid; and if the solid is but a little heavier than the fluid, the balance being loaded only with the excess, will be very sensible to the smallest want of equilibrium. But this advantage is perhaps compensated by an obstruction to the motion of the solid up or down in the fluid, arising from viscosity. When the weight in the opposite scale is yet too small, we slowly add more, and at last grain by grain, which gradually brings the beam to the level. When it is exactly level, the weight in the scale is somewhat too great; for it not only balances the preponderance of the solid, but also the viscosity of the fluid. But we may get rid of this error. Add a small quantity more; this will bring the beam over to the other side. Now put as much into the scale on the same side with the solid; this will not restore the beam to its level. We must add more till this be accomplished; and this addition is the measure of the viscosity of the fluid, and must be subtracted from the weight that was in the other scale when the beam came first to a level. This effect of viscosity is not insensible, with nice apparatus, even in the purest water, and in many fluids it is very considerable—and what is worse, it is very changeable. It is greatly diminished by heat; and this is an additional reason for making
making those trials in pretty warm temperatures. But for fluids of which the viscosity is considerable, this method is by no means proper; and we must take the other, and weigh them in a vessel with a narrow neck. Mercury must also be treated in this way, because we have no solid that will sink in it but gold and platinum.

It is not so easy as one would imagine to fill a vessel precisely to the same degree upon every trial. But if we do not operate on too small quantities, the unavoidable error may be made altogether insignificant, by having the neck of the vessel very small. If the vessel hold a pound of water, and the neck do not exceed a quarter of an inch (and it will not greatly retard the operation to have it half this size), the examinator must be very careful indeed to err one part in two thousand; and this is perhaps as near as we can come with a balance. We must always recollect that the capacity of the vessel changes by heat, and we must know this variation, and take it into the account. But it is affectation to regard (as Mr Iomberg would make us believe that he did) the distension of the vessel by the pressure of the fluid. His experiments of this kind have by no means the consistency with each other that should convince us that he did not commit much greater errors than what arose from distension.

In examining either solids or fluids, we must be careful to free their surface, or that of the vessel in which the fluid is to be weighed, from air, which frequently adheres to it in a peculiar manner, and, by forming a bubble, increases the apparent bulk of the solid, or diminishes the capacity of the vessel. The greatest part of what appears on those occasions seems to have existed in the fluid in a state of chemical union, and to be set at liberty by the superior attraction of the fluid for the contiguous solid body. These air bubbles must be carefully brushed off by hand. All greasy matters must be cleared off for the same reason: they prevent the fluid from coming into contact.

We must be no less careful that no water is imbibed by the solid, which would increase its weight without increasing its bulk. In some cases, however, a very long maceration and imbibition is necessary. Thus, in examining the specific gravity of the fibrous part of vegetables, we should err exceedingly if we imagined it as small as appears at first. We believe that in most plants it is at least as great as water, for after long maceration they sink in it.

It is almost needless to say that the nicest and most sensible balances are necessary for this examination. Balances are even constructed on purpose, and fitted with several pieces of apparatus, which make the examination easy and neat. We have described (see Balance) Mr Gravesande's as one of the most convenient of any. His contrivance for observing the fractions of a grain is extremely ingenious and expeditious, especially for detecting the effect of viscosity.

The hydrometer, or arecrometer, is another instrument for ascertaining the specific gravity of fluids. This very pretty instrument is the invention of a lady, as eminent for intellectual accomplishments as she was admired for her beauty. Hypatia, the learned daughter of the celebrated mathematician Theon of Alexandria, became so eminent for her mathematical knowledge, that she was made public professor of the science in the first school in the world. She wrote a commentary on the works of Apollonius and of Diophantus, and composed Astronomical Tables; all of which are lost. These rare accomplishments, however, could not save her from the fury of the fanatics of Alexandria, who cut her in pieces for having taken an offensive part in the dispute between the governor and patriarch.—We have described some of the most approved of these instruments in the article HYDROMETER, and shall in this place make a few observations on the principles of their construction, not as they are usually made, accommodated to the examination of particular liquors, but as indicators of pure specific gravity. And we must premise, that this would, for many reasons, be the best way of constructing them. The very ingenious contrivances for accommodating them to particular purposes are unavoidably attended with many sources of error, both in their adjustment by the maker and in their use; and all that is gained by a very expensive instrument is the saving the trouble of inspecting a table. A simple scale of specific gravity would expose to no error in construction, because all the weights but one, or all the points of the scale but one, are to be obtained by calculation, which is incomparably more exact than any manual operation, and the table can always be more exact than any complex observation. But a still greater advantage is, that the instruments would by this means be fitted for examining all liquors whatever, whereas at present they are almost useless for any but the one for which they are constructed.

Hydrometers are of two kinds. The most simple and the most delicate are just a substitute for the hydrostatical balance. They consist of a ball (or rather an egg or pear-shaped vessel, which moves more easily through the fluid) A (fig. 1.) having a foot projecting down from it, terminated by another ball B, and a slender stalk or wire above, carrying a little dish C. The whole is made so light as to float in the lightest fluid we are acquainted with, such as vitriolic or muriatic ether, whose specific gravity is only 0.73. This number should be marked on the dish, indicating that this is the specific gravity of the fluid in which the instrument floats, sinking to the point D of the stem. The ball B is made heavy, and the foot is of some length, that the instrument may have stability, and swim erect, even if considerably loaded above; and, for the same reason, it must be made very round, otherwise it will lean to a side. When put into a heavier liquor, its buoyancy will cause it to float with a part of the ball above the surface. Weights are now put into the scale C, till the instrument sinks to D. The weight put into the scale, added to the weight of the instrument, is the weight of the displaced fluid. This, compared with the weight of the whole when the instrument is swimming in pure water, gives the specific gravity of the fluid. All trouble of calculation may be avoided by marking the weights with such numbers as shall indicate the specific gravity at once. Thus having loaded the instrument so as to sink it to D in pure water, call the whole weight 1000; then weigh the instrument itself, and say, "as the weight when swimming in water is to its present weight, so is 1000 to a 4th proportional." This is the specific gravity of the liquor which would float the unloaded instrument. Suppose this to be 730. The hydrometer would just float in muriatic ether, and this should be marked on the side. Now make a set of small weights,
weights, and mark them, not by their weights in grains, but in such units that 230 of them shall be equal to the weight which fits the instrument for pure water.

Suppose that, in order to float this instrument in a certain brandy, there are required 186 in these small weights. This added to 730 gives 916 for the specific gravity, and shows it to be precisely excise proof spirit. Nine weights, viz. 256, 128, 64, 32, 16, 8, 4, 2, 1, will suffice for all liquors from ether to the strongest wort. And that the trouble in changing the weights may be greatly lessened, let a few circles $a, b, c, d, e$ be marked on the top of the ball. When we see it float unloaded at the circle $e$ for instance, we know it will require at least 128 to sink it to $D$ on the stem.

If the weights to be added above are considerable, it raises the centre of gravity so much, that a small want of equilibrium, by laying the weights on one side, will produce a great inclination of the instrument, which is unsightly. Instead therefore of making them loose weights, it is proper to make them round plates, with a small hole in the middle, to go on a pin in the middle of the scale. This will keep the instrument always upright. But unless the hydrometer is of a considerable size, it can hardly be made so as to extend from the lightest to the heaviest fluid which we may have occasion to examine, even though we except mercury. Some of the mineral acids are considerably more than twice the weight of ether. When there is such a load at top, the hydrometer is very apt to overset, and inclines with the smallest want of equilibrium. Great size is inconvenient even to the philosopher, because it is not always in his power to operate on a quantity of fluid sufficient to float the instrument. Therefore two, or perhaps three, are necessary for general examination. One may reach from ether to water; another may serve for all liquors of a specific gravity between one and one and a half; and the third, for the mineral acids, may reach from this to two. If each of these be about two solid inches in capacity, we may easily and expeditiously determine the specific gravity within one ten thousandth part of the truth: and this is precision enough for most purposes of science or business.

The chief questions are, 1. To ascertain the specific gravity of an unknown fluid. This needs no farther explanation. 2. To ascertain the proportion of two fluids which are known to be in a mixture. This is done by discovering the specific gravity of the mixture by means of the hydrometer, and then deducing the proportion from a comparison of this with the specific gravities of the ingredients.

In this mode of examination the bulk is always the same; for the hydrometer is immersed in the different fluids to the same depth. Now if an inch, for example, of this bulk is made up of the heaviest fluid, there is an inch wanting of the lightest; and the change made in the weights of the mixture is the difference between the weight of an inch of the heaviest, and of an inch of the lightest ingredients. The number of inches therefore of the heaviest fluid is proportional to the addition made to the weight of the mixture. Therefore let $B$ and $b$ be the bulks of the heaviest and lightest fluids in the bulk $\beta$ of the mixture; and let $D, d'$ and $\beta$ be the densities, or the weights, or the specific gravities (for they are in one ratio) of the heavy fluid, the light fluid, and the mixture (their bulk being that of the hydrometer). We have $\beta = B + b$. The addition which would have been made to the bulk $\beta$, if the lightest fluid were changed entirely for the heaviest, would be $D - d'$; and the change which is really made is $D - d$. Therefore $\beta = B = D - d$: $D - d$. For similar reasons we should have $B = D - d = D - d$; or, in words, "the difference between the specific gravities of the two fluids, is to the difference between the specific gravities of the mixture and of the lightest fluid, as the bulk of the whole to the bulk of the heaviest contained in the mixture," and "the difference of the specific gravities of the two fluids, is to the difference of the specific gravities of the mixture and of the heaviest fluids, as the bulk of the whole to that of the lightest contained in the mixture." This is the form in which the ordinary business of life requires the answer to be expressed, because we generally reckon the quantity of liquors by bulk, in gallons, pints, quarts. But it would have been equally easy to have obtained the answer in pounds and ounces; or it may be had from their bulk, since we know their specific gravities.

The hydrometer more commonly used is the ancient one of Hypatia, consisting of a ball $A$ (fig. 2) made steady by an addition $B$ below it like the former, but having a long stem $C F$, above. It is so loaded that it sinks to the top $F$ of the stem in the lightest of all the fluids which we propose to measure with it, and to sink only to $C$ in the heaviest. In a fluid of intermediate specific gravity it will sink to some point between $C$ and $F$.

In this form of the hydrometer the weight is always the same, and the immediate information given by the instrument is that of different bulks with equal weight. Because the instrument sinks till the bulk of the displaced fluid equals it in weight, and the additions to the displaced fluid are all made by the stem, it is evident that equal bulks of the stem indicate equal additions of volume. Thus the stem becomes a scale of bulks to the same weight.

The only form in which the stem can be made with sufficient accuracy is cylindrical or prismatical. Such a stem may be made in the most accurate manner by wire-drawing, that is, passing it through a hole made in a hardened steel plate. If such a stem be divided into equal parts, it becomes a scale of bulks in arithmetical progression. This is the easiest and most natural division of the scale; but it will not indicate densities, specific gravities, or weights of the same bulk in arithmetical progression. The specific gravity is as the weight divided by the bulk. Now as series of divisors (the bulks), in arithmetical progression, applied to the same dividend (the bulk and weight of the hydrometer as it floats in water), will not give a series of quotients (the specific gravities) in arithmetical progression: they will be in what is called harmonic progression, their differences continually diminishing. This will appear even when physically considered. When the hydrometer sinks a tenth of an inch near the top of the stem, it displaces one tenth of an inch of a light fluid, compared with that displaced by it when it is floating with all the stem above the surface. In order therefore that the divisions of the stem may indicate equal changes of specific gravity, they must be in a series of harmonic progressions increasing. The point at which the instrument floats in pure water should be marked 1000, and those above it 999, 998, 997, &c.; and
the whole stem will emerge; for the bulk of the displaced fluid is now \(\frac{7}{10}\)th of the whole less, and the weight is the same as before, and therefore the specific gravity is \(\frac{7}{10}\)th greater.

Thus we have obtained a hydrometer which will indicate, by means of divisions marked on the stem, all specific gravities from 0.73 to 0.803; for 0.803 in \(\frac{7}{10}\)th greater than 0.73. These divisions must be made in harmonic progression, as before directed for an entire scale, placing 0.73 at the top of the stem and 0.803 at the bottom.

When it floats at the lowest division, a weight may be put to the top of the stem, which will again sink it to the top. This weight must evidently be 0.073, or \(\frac{7}{10}\)th of the weight of the fluid displaced by the unloaded instrument. The hydrometer, thus loaded, indicates the same specific gravity, by the top of the stem, that the unloaded instrument indicates by the lowest division. Therefore, when loaded, it will indicate another series of specific gravities, from 0.803 to 0.8833 (0.803 + 0.0803), and will float in a liquor of the specific gravity 0.8833 with the whole stem above the surface.

In like manner, if we take off this weight, and put on 1 = 0.0803, it will sink the hydrometer to the top of the stem; and with this new weight it will indicate another series of specific gravities from 0.8833 to 0.97163 (=0.8833 + 0.08833). And, in the same manner, a third weight = 0.8833 will again sink it to the top of the stem, and fit it for another series of specific gravities up to 1.06893. And thus, with three weights, we have procured a hydrometer fitted for all liquors from ether to a wort for a malt liquor of two barrels per quarter. Another weight, in the same progression, will extend the instrument to the strongest wort that is brewed.

This is a very commodious form of the instrument, and is now in very general use for examining spirituous liquors, worts, ales, brines, and many such articles of commerce. But the divisions of the scale are generally adapted to the questions which naturally occur in the business. Thus, in the commerce of strong liquors, it is usual to estimate the article by the quantity of spirit of a certain strength which the liquor contains.—This we have been accustomed to call proof spirit, and it is such a wine gallon weighs 7 pounds 12 ounces; and it is by this strength that the excise duties are levied. Therefore the divisions on the scale, and the weights which connect the successive repetitions of the scale, are made to express at once the number of gallons or parts of a gallon of proof spirits contained in a gallon of the liquor. Such instruments save all trouble of calculation to the exciseman or dealer; but they limit the use of a very delicate and expensive instrument to a very narrow employment. It would be much better to adhere to the expression either of specific gravity, or of bulk; and then a very small table, which could be comprised in the smallest case for the instrument, might render it applicable to every kind of fluid.

The reader cannot but have observed that the successive weights, by which the short scale of the instrument is extended to a great range of specific gravities, do not increase by equal quantities. Each difference is the weight of the liquor displaced by the graduated stem of the instrument when it is sunk to the top of
the scale. It is a determined aliquot part of the whole
weight of the instrument so loaded, (in our example it
is always 1/6th of it.) It increases therefore in the same
proportion with the preceding weight of the loaded
instrument. In short, both the successive additions, and
the whole weights of the loaded instrument, are quan-
tities in geometrical progressions; and in like manner,
the divisions on the scale, if they correspond to equal
differences of specific gravity, must also be unequal.—
This is not sufficiently attended to by the makers; and
they commit an error here, which is very considerable
when the whole range of the instrument is great. For
the value of one division of the scale, when the largest
weight is on, is as much greater than its value when
the instrument is not loaded at all, as the full loaded
instrument is heavier than the instrument unloaded. No
manner whatever of dividing the scale will correspond
to equal differences of specific gravity through the
whole range with different weights; but if the divi-
sions are made to indicate equal proportions of gravity
when the instrument is used without a weight, they
will indicate equal proportions throughout. This is
evident from what have been just now saying; for the
proportion of the specific gravities corresponding to
any two immediately succeeding weights is always the
same.

The best way, therefore, of constructing the instru-
ment, so that the same divisions of the scale may be ac-
curate in all its successive repetitions with the different
weights, is to make these divisions in geometrical pro-
gression. The corresponding specific gravities will al-
so be in geometric proportion. These being all inserted
in a table, we obtain them with no more trouble than
by inspecting the scale which usually accompanies the
hydrometer. This table is of the most easy construc-
tion; for the ratio of the successive bulk and specific
 gravities being all equal, the differences of the logarithms
are equal.

This will be illustrated by applying it to the exam-
ple already given of a hydrometer extending from 0.73
to 1.068793 with three weights. This gives four re-
petitions of the scale on the stem. Suppose this scale
divided into 15 parts, we have 40 specific gravities.—
Let these be indicated by the numbers 0, 1, 2, 3, &c.
to 40. The mark 0 is affixed to the top of the stem,
and the divisions downward are marked 1, 2, 3, &c.
the lowest being 10. These divisions are easily deter-
mined. The stem, which we may suppose 5 inches
long, was supposed to be 1/6th of the capacity of the
ball. It may therefore be considered as the extremity
of a rod of 11 times its length, or 55 inches, and we
must find nine mean proportions between 50 and 55
inches. Subtract each of these from 55 inches, and
the remainder are the distances of the points of divi-
sion from 0, the top of the scale. The smallest weight
is marked 10, the next 20, and the third 30. If the
instrument loaded with the weight 20 sinks in some li-
quor to the mark 7, it indicates the specific gravity 27,
that is, the 27th of 40 mean proportions between
0.73 and 1.068793, or 0.944242. To obtain all these
intermediate specific gravities, we have only to subtract

Nay, the trouble of inspecting a table may be avoid-
ed, by forming on a scale the logarithms of the num-
ers between 7300 and 1068.793, and placing along
side of it a scale of the same length divided into 400
equal parts, numbered from 0 to 400. Then, looking
for the mark shown by the hydrometer on this scale
equal parts, we see opposite to it the specific gravity.

We have been thus particular in the illustration of
this mode of construction, because it is really a beau-
tiful and commodious instrument, which may be of great
use both to the naturalist and to the man of business.—
A table may be comprised in 20 octavo pages, which
will contain the specific gravities of every fluid which
can interest either, and answer every question relative
to their admixture with as much precision as the ob-
servations can be made. We therefore recommend it
to our readers, and we recommend the very example
which we have given as one of the most convenient.
The instrument need not exceed eight inches in length,
and may be contained in a pocket case of two inches
broad and as many deep, which will also contain the
scale, a thermometer, and even the table for applying it
to all fluids which have been examined.

It is unfortunate that no graduated hydrometer can
be made so easily for the examination of the corrosive
mineral acids (A). These must be made of glass, and
we cannot depend on the accurate cylindric form of any
glass stem. But if any such can be procured, the con-
struction is the same. The divided scale may either be
on thin paper pasted on the inside of the stem, or it may
be printed on the stem itself from a plate, with ink made
of a metallic calc, which will attach itself to the glass
with a very moderate heat. We would recommend
common white enamel, or arsenical glass, as the fittest
material for the whole instrument; and the ink used, in
taking the impression of the scale, may be the same that
is used for the low-priced printing on Delft ware pot-
tery.—First form the scale on the stem. Then, having
measured the solid contents of the graduated part as ex-
actly as possible, and determined on the general shape

(A) It would be worth while to try copper enamelled. See note at page 599. of this volume.
of the ball and counterpoise below, calculate its size, so
that it may be a little less than ten times that of the
stem. The glass-blower can copy this very nearly, and
join it to the stem. Then make two brines or other li-
quors, which shall have specific gravities in the ratio of
10 to 1. Load the instrument so that it may sink to
0 in the lightest. When put into the heaviest, it should
rise to 10. If it does not rise so high, the immersed part
is too small. Let the glass-blower enlarge the ball of
the counterpoise a little. Repeat this trial till it be ex-
act. Nothing now remains but to form the weights:
And here we observe, that when the instrument is to
have a very great range, as for examining all states of
the vitriolic acid, it has a chance of being very tot-
tering when loaded with the greatest weight on the
top of so long a scale. To avoid this, Mr Quin and
others have added some of their weights below.
But this will not suit the present construction, because
it will alter the proportion between the bulks of the
stem and immersed part. Therefore let these weights
consist of cylinders of metal small enough to go into
the stem, and let them be soldered to the end of long
wires, which will let them go to the bottom, and leave
a small hook or ring at top. These can lie alongside
of the instrument in case. This is indeed the best
construction for every hydrometer, because it makes it
incomparably more steady. The instrument is poised
by small shot or mercury. But it will be much better
to do it with Newton's fusible metal (three parts of tin,
five parts of lead, and eight parts of bismuth) in coarse
flings. When the exact quantity has been put in, the
instrument may be set in a vessel of oil, and this kept
on the fire till all is completely melted. It soon freezes
again, and remains fast. If this metal is not to be had,
let a few bits of sealing-wax be added to the mercury
or shot, to make up the counterpoise. When heated,
it will float a-top, and when it freezes again it will
keep all fast. Thus we shall make a very complete and
cheap instrument.

There is yet another method of examining the spe-
cific gravities of fluids, first proposed by Dr Wilson,
date professor of astronomy in the university of Glasgow.
This is by a series of small glass bubbles, differing equal-
ly, or according to some rule, from each other in spe-
cific gravity, and each marked with its proper number.
When these are thrown into a fluid which is to be ex-
amined, all those which are heavier than the fluid will fall
to the bottom. Then holding the vessel in the hand,
or near a fire or candle, the fluid expands, and one of
the floating bubbles begins to sink. Its specific gravity,
therefore, was either equal to, or a little less than, that
of the fluid; and the degree of the thermometer, when
it began to sink, will inform us how much it was def-
cient, if we know the law of expansion of the liquor.
Sets of these bubbles fitted for the examination of spi-
rituous liquors, with a little treatise showing the manner
of using them, and calculating by the thermometer, are
made by Mr Brown, an ingenious artist of Glasgow,
and are often used by the dealers in spirits, being found
both accurate and expeditious.

Also, though a bubble or two should be broken, the
strength of spirits may easily be had by means of the
remainder, unless two or three in immediate succession
be wanting: for a liquor which answers to No. 4. will
sink No. 2. by heating it a few degrees, and therefore

N° 3. may be spared. This is a great advantage in or-
dinary business. A nice hydrometer is not only an ex-
pensive instrument, but exceedingly delicate, being so
very thin. If broken or even bruised, it is useless, and
can hardly be repaired except by the very maker.

As the only question here is, to determine how many
gallons of excise proof spirits is contained in a quantity
of liquor, the artist has constructed this series of bubbles
in the simplest manner possible, by previously making
40 or 50 mixtures of spirits and water, and then adjust-
ing the bubbles to these mixtures. In some sets the
number on each bubble is the number of gallons of
proof spirits contained in 100 gallons of the liquor. In
other sets the number on each bubble expresses the
gallons of water which will make a liquor of this strength,
if added to 14 gallons of alcohol. Thus, if a liquor an-
swers to N° 4, then 4 gallons of water added to 14
gallons of alcohol will make a liquor of this strength.
The first is the best method; for we should be mistaken
in supposing that 18 gallons, which answer to N° 2,
contains exactly 14 gallons of alcohol: it contains more
than 14, for a reason to be given and explained by
examining the specific gravity of bodies, the philos-
osopher has made some very curious discoveries. The
most remarkable of these is the change which the densi-
ty of bodies suffers by mixture. It is a most reasonable
expectation, that when a cubic foot of one substance is
mixed any how with a cubic foot of another, the bulk
of the mixture will be two cubic feet; and that 18 gal-
ions of water joined to 18 gallons of oil will fill a vessel
of 36 gallons. Accordingly this was never doubted;
and even Archimedes, the most scrupulous of mathema-
ticians, proceeded on this supposition in the solution of
his famous problem, the discovery of the proportion of
silver and gold in a mixture of both. He does not even
mention it as a postulate that may be granted him, so
much did he conceive it to be an axiom. Yet a little
reflection seems sufficient to make it doubtful and to
require examination. A box filled with musket balls
will receive a considerable quantity of small shot, and
after this a considerable quantity of fine sand, and after
this a considerable quantity of water. Something like
this might happen in the admixture of bodies of porous
texture. But such substances as metals, glass, and
fluids, where no discontinuity of parts can be perceived,
or was suspected, seem free from every chance of this
kind of introduction. Lord Bacon, however, with-
out being a naturalist or mathematician ex professo, in-
ferred from the mobility of fluids that they consisted of
discrete particles, which must have pores interposed,
whatever be their figure. And if we ascribe the differ-
ent densities, or other sensible qualities, to difference
in size or figure of those particles, it must frequently hap-
pen that the smaller particles will be lodged in the in-
terstices between the larger, and thus contribute to the
weight of the sensible mass without increasing its bulk.
He therefore suspects that mixtures will be in general
less bulky than the sum of their ingredients.

Accordingly, the examination of this question was
one of the first employments of the Royal Society of
London, and long before its institution had occupied
the attention of the gentlemen who afterwards com-
posed it. The register of the Society's early meetings
contains many experiments on this subject, with mix-
tures of gold and silver, of other metals, and of various
fluids, examined by the hydrostatical balance of Mr Boyle. Dr Hooke made a prodigious number, chiefly on articles of commerce, which were unfortunately lost in the fire of London.

It was soon found, however, that Lord Bacon's conjecture had been well founded, and that bodies changed their density very sensibly in many cases. In general, it was found that bodies which had a strong chemical affinity increased in density, and that their admixture was accompanied with heat.

By this discovery it is manifest that Archimedes had not solved the problem of detecting the quantity of silver mixed with the gold in King Hiero's crown, and that the physical solution of it requires experiments made on all the kinds of matter that are mixed together. We do not find that this has been done to this day, although we may affirm that there are few questions of more importance. It is a very curious fact in chemistry, and it would be most desirable to be able to reduce it to some general laws: For instance, to ascertain what is the proportion of two ingredients which produces the greatest change of density. This is important in the science of physics, because it gives us considerable information as to the mode of action of those natural powers or forces by which the particles of tangible matter are united. If this intrusion, concentration, penetration, or by whatever name it be called, were a mere reception of the particles of one substance into the interstices of those of another, it is evident that the greatest concentration would be observed when a small quantity of the recipient is mixed with, or disseminated through, a great quantity of the other. It is thus that a small quantity of fine sand will be received into the interstices of a quantity of small shot, and will increase the weight of the bagful without increasing its bulk. The case is nowise different when a piece of freestone has grown heavier by imbibing or absorbing a quantity of water. If more than a certain quantity of sand has been added to the small shot, it is no longer concealed. In like manner, various quantities of water may combine with a mass of clay, and increase its size and weight alike. All this is very conceivable, occasioning no difficulty.

But this is not the case in any of the mixtures we are now considering. In all these, the first additions of either of the two substances produce but an inconvenient change of general density; and it is in general most remarkable, whether it be condensation or rarefaction, when the two ingredients are nearly of equal bulks. We can illustrate even this difference, by reflecting on the imbibition of water by vegetable solids, such as timber. Some kinds of wood have their weight much more increased than their bulks: other kinds of wood are more enlarged in bulk than in weight. The like happens in grains. This is curious, and shows in the most unquestionable manner that the particles of bodies are not in contact, but are kept together by forces which act at a distance. For this distance between the centres of the particles is most evidently susceptible of variation; and this variation is occasioned by the introduction of another substance, which, by acting on the particles by attraction or repulsion, diminishes or increases their mutual actions, and makes new distances necessary for bringing all things again into equilibrium. We refer the curious reader to the ingenious theory of the abbé Boscowich for an excellent illustration of this subject (Theor. Phil. Nat. § de Solutions Chemica).

This question is no less important to the man of business. Till we know the condensation of those metals by mixture, we cannot tell the quantity of alloy in gold and silver by means of their specific gravity; nor can we tell the quantity of pure alcohol in any spirituous liquor, or that of the valuable salt in any solution of it. For want of this knowledge, the dealers in gold and silver are obliged to have recourse to the tedious and difficult test of the assay, which cannot be made in all places or by all men. It is therefore much to be wished, that some persons would institute a series of experiments in the most interesting cases: for it must be observed, that this change of density is not always a small matter; it is sometimes very considerable and paradoxical. A remarkable instance may be given of it in the mixture of brass and tin for bells, great guns, optical speculums, &c. The specific gravity of cast brass is nearly 8.06, and that of tin is nearly 7.363. If two parts of brass be mixed with one of tin, the specific gravity is 8.917; whereas, if each had retained its former bulk, the sp. grav. would have been only 7.793. The mixture of equal parts should have the specific gravity 7.684; but it is 8.441. A mixture of two parts tin with one part brass, instead of being 7.577 is 8.027.

In all these cases there is a great increase of specific gravity, and consequently a great condensation of parts or contraction of bulk. The first mixture of eight cubic inches of brass, for instance, with four cubic inches of tin, does not produce 12 cubic inches of bell-metal, but only 10-¾ nearly, having shrunken ¾. It would appear that the distances of the brass particles are most affected, or perhaps it is the brass that receives the tin into its pores; for we find that the condensations in these mixtures are nearly proportional to the quantities of the brass in the mixtures. It is remarkable that this mixture with the lightest of all metals has made a composition more heavy and dense than brass can be made by any hammering.

The most remarkable instance occurs in mixing iron with platina. If ten cubic inches of iron are mixed with ⅓ of platina, the bulk of the compound is only 9¾ inches. The iron therefore has not simply received the platina into its pores: its own particles are brought nearer together. There are similar results in the solution of turbeth mineral, and of some other salts, in water. The water, instead of rising in the neck of the vessel, when a small quantity of the salt has been added to it, sinks considerably, and the two ingredients occupy less room than the water did alone.

The same thing happens in the mixture of water with other fluids and different fluids with each other: But we are not able to trace any general rule that is observed with absolute precision. In most cases of fluids the greatest condensation happens when the bulks of the ingredients are nearly equal. Thus, in the mixture of alcohol and water, we have the greatest condensation when 16½ ounces of alcohol are mixed with 20 ounces of water, and the condensation is about 7¾ of the whole bulk of the ingredients. It is extremely various in different substances, and no classification of them can be made in this respect.

A dissertation has been published on this subject by Dr
Dr Hahn of Vienna, intitled De Efficacia Mixtions in mutandis Corporum Voluminis, in which all the remarkable instances of the variation of density have been collected. All that we can do (as we have no directing principle) is to record such instances as are of chief importance, being articles of commerce.

The first that occurs to us is the mixtures of alcohol and water in the composition of spirituous liquors. This has been considered by many with great care. The most scrupulous examination of this, or perhaps of any mixture, has been lately made by Dr Blagden (now Sir Charles Blagden) of the Royal Society, on the requisition of the Board of Excise. He has published an account of the examination in the Philosophical Transactions of London in 1791 and 1792. We shall give an account of it under the article Spirituous Liquors; and at present only select one column, in order to show the condensation. The alcohol was almost the strongest that can be produced, and its specific gravity, when of the temperature 60°, was 0.825. The whole mixtures were of the same temperature.

Column 1. contains the pounds, ounces, or other measures by weight, of alcohol in the mixture. Column 2. contains the pounds or ounces of water. Column 3. is the sum of the bulbs of the ingredients, the bulk of a pound or ounce of water being accounted 1. Column 4. is the observed specific gravity of the mixture, taken from Dr Blagden's dissertation. Column 5. is the specific gravity which would have been observed if the ingredients had each retained its own specific gravity. This we calculated by dividing the sum of the two numbers of the first and second columns by the corresponding number of the third. Column 6. is the difference of column 4. and column 5. and exhibits the condensation.

</table>

It is to be remarked, that the condensation is greatest when 161/3 ounces of alcohol have been added to 20 of water, and the condensation is 99.31, or nearly 1/100th of the computed density. Since the specific gravity of alcohol is 0.825, it is evident that 161/3 ounces of alcohol and 20 ounces of water have equal bulbs. So that the condensation is greatest when the substances are mixed in equal volumes; and 18 gallons of alcohol mixed with 18 gallons of water will produce not 36 gallons of spirits, but 35 only.

We may also observe, that this is the mixture to which our revenue laws refer, declaring it to be one to six or one in seven under proof, and to weigh 7 pounds 13 ounces per gallon. This proportion was probably selected as the most easily composed, viz. by mixing equal measures of water and of the strongest spirit which the known processes of distillation could produce. Its specific gravity is 0.939 very nearly.

We must consider this elaborate examination of the mixture of water and alcohol as a standard series of experiments, to which appeal may always be made, whether for the purposes of science or of trade. The regularity of the progression is so great, that in the column which we have examined, viz. that for temperature 60°, the greatest anomaly does not amount to one part in six thousand. The form of the series is also very judiciously chosen for the purposes of science. It would perhaps have been more directly stereometrical had the proportions of the ingredients been stated in bulbs, which are more immediately connected with density. But the author has assigned a very cogent reason for his choice, viz. that the proportion of bulbs varies by a change of temperature, because the water and spirits follow different laws in their expansion by heat.

This is a proper opportunity for taking notice of a mistake which is very generally made in the conclusions drawn from experiments of this kind. Equal additions of the spirit or water produce a series of specific gravi-

---

It is to be remarked, that the condensation is greatest when 161/3 ounces of alcohol have been added to 20 of water, and the condensation is 99.31, or nearly 1/100th of the computed density. Since the specific gravity of alcohol is 0.825, it is evident that 161/3 ounces of alcohol and 20 ounces of water have equal bulbs. So that the condensation is greatest when the substances are mixed in equal volumes; and 18 gallons of alcohol mixed with 18 gallons of water will produce not 36 gallons of spirits, but 35 only.

We may also observe, that this is the mixture to which our revenue laws refer, declaring it to be one to six or one in seven under proof, and to weigh 7 pounds 13 ounces per gallon. This proportion was probably selected as the most easily composed, viz. by mixing equal measures of water and of the strongest spirit which the known processes of distillation could produce. Its specific gravity is 0.939 very nearly.

We must consider this elaborate examination of the mixture of water and alcohol as a standard series of experiments, to which appeal may always be made, whether for the purposes of science or of trade. The regularity of the progression is so great, that in the column which we have examined, viz. that for temperature 60°, the greatest anomaly does not amount to one part in six thousand. The form of the series is also very judiciously chosen for the purposes of science. It would perhaps have been more directly stereometrical had the proportions of the ingredients been stated in bulbs, which are more immediately connected with density. But the author has assigned a very cogent reason for his choice, viz. that the proportion of bulbs varies by a change of temperature, because the water and spirits follow different laws in their expansion by heat.

This is a proper opportunity for taking notice of a mistake which is very generally made in the conclusions drawn from experiments of this kind. Equal additions of the spirit or water produce a series of specific gravities, which decrease or increase by differences continually diminishing. Hence it is inferred that there is a contraction of bulk. Even Dr Lewis, one of our most acc.
complished naturalists, advances this position, in a dissertation on the potash of America; and it considerably affects his method for estimating the strength of the potash leys. But that it is a mistake, appears plainly from this, that although we add for ever equal quantities of the spirits, we shall never produce a mixture which has as small a specific gravity as alcohol. Therefore the series of successive gravities must approximate to this without end, like the ordinates of a hyperbolic curve referred to its asymptote.

That this may appear in the most general terms, let \( w \) represent the weight of the constant quantity of water in the mixture, and let \( a \) be the weight of the small addition of spirits. Also let \( w \) represent the bulk of this quantity of water, and \( b \) the bulk of the small addition of alcohol. The weight of the mixture is \( w + a \), and its bulk is \( w + b \), and its specific gravity is \( \frac{w + a}{w + b} \).

If now we add a second equal quantity of spirits, the weight will be \( w + 2a \), and if the spirit retains its density unchanged, the bulk will be \( w + 2b \), and the specific gravity is \( \frac{w + 2a}{w + 2b} \); and after any number \( m \) of such equal additions of spirits, the specific gravity will be \( \frac{w + ma}{w + mb} \). Divide the numerator of this fraction by its denominator, and the quotient or specific gravity will be \( 1 + \frac{ma}{w + mb} \). This consists of the constant part \( \frac{a}{w + mb} \), and the variable part \( \frac{ma}{w + mb} \). We need attend only to this part. If its denominator were constant, it is plain that the successive specific gravities would have equal differences, each being \( \frac{a}{w + mb} \), because \( m \) increases by the continual addition of an unit, and \( a - b \) is a constant quantity. But the denominator \( w + mb \) continually increases, and therefore the value of the fraction \( \frac{a - b}{w + mb} \) continually diminishes.

Therefore the gradual diminution of the increments or decrements of specific gravity, by equal additions of one ingredient to a constant measure of the other, is not of itself an indication of a change of density of either of the ingredients; nor proves that in every diluted mixtures a greater proportion of one ingredient is absorbed or lodged in the interstices of the other, as is generally imagined. This must be ascertained by comparing each specific gravity with the gravity expressed by \( 1 + \frac{w + ma - b}{w + mb} \).

This series of specific gravities resembles such a numerical series as the following, \( 1, 1, 1, \ldots \); \( 1.56; 1.60; \) &c. the terms of which also consist of the constant integer \( 1 \), and the decimal fractions \( 0.156; \) \( 0.163; 0.169; \) &c. The fraction \( \frac{ma - b}{w + mb} \) expresses this decimal part. Call this \( d \), or make \( d = \frac{ma - b}{w + mb} \).

This will give us \( b = \frac{ma - wd}{m(1 + d)} \). Now \( a \) is the weight of the added ingredient, and \( d \) is the variable part of the specific gravity observed; and thus we learn whether \( b \), the bulk of the added ingredient, suffers any change. We shall have occasion by and by to resume the consideration of this question, which is of the first moment in the theory of specific gravities, and has great influence in many transactions of commerce.

This series of specific gravities is not so well fitted for commercial transactions. In these the usual question is, how many gallons of alcohol is there in a cask, or some number of gallons of spirit? and it is more directly answered by means of a table, formed by mixing the ingredients in aliquant parts of one constant bulk. The following table, constructed from the experiments of Mr Brisson of the academy of Paris, and published in the Memoirs for 1769, is therefore inserted.

</table>

In this table the whole quantity of spirituous liquor is always the same. The first column is the number of measures (gallons, pints, inches, &c.) of water in the mixture: and column 2d gives the measures of alcohol. Column 3d is the specific gravity which was observed by Mr Brisson. Column 4th is the specific gravity which would have been observed if the spirits, or water, or both, had retained their specific density unchanged. And the 5th column marks the augmentation of specific gravity or density in parts of 10,000. A 6th column is added, showing the bulk of the 16 cubic measures of the two ingredients. Each measure may be conceived as the 16th part of 10,000, or 625; and we may suppose them cubic inches, pints, gallons, or any solid measure.

This table scarcely differs from Sir Charles Blagden's; and the very small difference that may be observed, arises from Mr Brisson's having used an alcohol not so completely rectified. Its specific gravity is 0.8371, whereas the other was only 0.8270.

Here it appears more distinctly that the condensation is greatest when the two ingredients are of equal bulk.

Perhaps this series of specific gravities is as declarative as the other, whether or not there is a change of density induced in either of the ingredients. The whole
temperature of $55^\circ$ when diluted by the successive addition of parts of water by weight.

Here is observed a much greater condensation than in the mixture of alcohol and water. But we cannot assign the proportion of ingredients, which produces the greatest condensation; because we cannot, in any case, say what is the proportion of the saline and watery ingredients. The strongest oil of vitriol is already a watery solution; and it is by a considerable and uncertain detour that Mr Kirwan has assigned the proportion of 612 and 388 nearly. If this be the true ratio, it is unlike every other solution that we are acquainted with; for in all solutions of salts, the salt occupies less room in its liquid form than it did when solid; and here it would be greatly the reverse.

This solution is remarkable also for the copious emergence of heat, in its dilutions with more water. This has been ascribed to the great superiority of water in its capacity of heat; but there are facts which render this very doubtful. A vessel of water, and another of oil of vitriol, being brought from a cold room into a warm one, they both imbibe heat, and rise in their temperature; and the water employs nearly the same time to attain the temperature of the room.

Aquafortis or nitrous acid is another fluid very much employed in commerce; so that it is of importance to ascertain the relation between its saline strength and its specific gravity. We owe also to Mr Kirwan a table for this purpose.

The most concentrated state into which it can easily be brought is such, that 1000 grains of it consists of 563 grains of water and 437 of dry acid. In this state its specific gravity is 1.557. Let this be called nitrous acid.

There is not the same uniformity in the densities of this acid in its different states of dilution. This seems owing.

The vitriolic or sulphric acid is of extensive use in manufactures under the name of oil of vitriol. Its value depends entirely on the saline ingredient, and the water is merely a vehicle for the acid. This, being much denser than water, affects its specific gravity, and thus gives us a method of ascertaining its strength.

The strongest oil of vitriol that can be easily manufactured contains $612\frac{7}{10}$ grains of dry acid, united with $387\frac{3}{10}$ grains of water, which cannot be separated from it by distillation, making 1000 grains of OIL OF VITRIOL. Its specific gravity in this state is 1.877.

The following table shows its specific gravity at the
owing to the variable proportion of the deleterious and vital air which compose this acid. It is more dense in proportion as it contains more of the latter ingredient.

The proportions of the aeriiform ingredients of the muriatic acid are so very variable, and so little under our command, that we cannot frame tables of its specific gravity which would enable us to judge of its strength.

It is a general property of these acids, that they are more expansible by heat as they are more concentrated.

There is another class of fluids which it would be of great consequence to reduce to some rules with respect to specific gravity, namely, the solutions of salts, gums, and resins. It is interesting to the philosopher to know in what manner salts are contained in these watery solutions, and to discover the relation between their strength and density; and to the man of business it would be a most desirable thing to have a criterion of the quantity of salt in any brine, or of extractable matter in a decoction. It would be equally desirable to those who are to purchase them as to those who manufacture or employ them. Perhaps we might ascertain in this way the value of sugar, depending on the quantity of sweetening matter which it contains; a thing which at present rests on the vague determination of the eye or palate. It would therefore be doing a great service to the public, if some intelligent person would undertake a train of experiments with this view. Accuracy alone is required; and it may be left to the philosophers to compare the facts, and draw the consequences respecting the internal arrangement of the particles.

One circumstance in the solution of salts is very general; and we are inclined, for serious reasons, to think it universal: this is a diminution of bulk. This indeed in some salts is inconsiderable. Sedative salt, for instance, hardly shows any diminution, and might be considered as an exception, were it not the single instance. This circumstance, and some considerations connected with our notions of this kind of solution, dispose us to think that this salt differs in contraction from others only in degree, and that there is some, though it was not sensible, in the experiments hitherto made.

These experiments, indeed, have not been numerous. Those of Mr Achard of Berlin, and of Dr Richard Watson of Cambridge, are perhaps the only ones of which we have a descriptive narration, by which we can judge of the validity of the inferences drawn from them. The subject is not susceptible of much accuracy; for salts in their solid form are seldom free from cavities and shivery interstices, which do not admit the water on their first immersion, and thereby appear of greater bulk when we attempt to measure their specific gravity by weighing them in fluids which do not dissolve them, such as spirits of turpentine. They also attach to themselves, with considerable tenacity, a quantity of atmospheric air, which merely adheres, but makes no part of their composition. This escapes in the act of solution, being set at liberty by the stronger affinity of the water. Sal gem, however, and a few others, may be very accurately measured; and in these instances the degree of contraction is very constant.

The following experiments of Dr Watson appear to us the most instructive as to this circumstance. A glass vessel was used, having a slender cylindrical neck, and holding 67 ounces of pure water when filled to a certain mark. The neck above this mark had a scale of equal parts pasted on it. It was filled to the mark with water. Twenty-four pennyweights of salt were thrown into it as speedily as possible, and the bulk of the salt was measured by the elevation of the water. Every thing was attended to which could retard the immediate solution, that the error arising from the solution of the first particles, before the rest could be put in, might be as small as possible; and in order to that both the absolute bulk and its variations might be obtained by some known scale, 24 pennyweights of water were put in. This raised the surface 58 parts of the scale. Now we know exactly the bulk of 24 pennyweights of pure water. It is 2.275 cubic inches; and thus we obtain every thing in absolute measures: And by comparing the bulk of each salt, both at its first immersion and after its complete solution, we obtain its specific gravity, and the change made on it in passing from a solid to a fluid form.

The following table is an abstract of these experiments. The first column of numbers is the elevation of the surface immediately after immersion; the second gives the elevation when the salt is completely dissolved; and the third and fourth columns are the specific gravities of the salts in these two states.

</table>

The inspection of this list naturally suggests two states of the case as particularly interesting to the philosopher studying the theory of solution. The first state is when the lixivium approaches to saturation. In the very point of saturation any addition of salt retains its bulk unchanged. In diluted brines, we shall see that the density...
are seldom considered as sources of original information; and it is thought sufficient when the knowledge already diffused is judiciously compiled. But a due respect for the public, and gratitude for the very honourable reception hitherto given to our labours, induced us to exert ourselves with honest zeal to merit the continuance of public favour. We assure our readers that the experiments were made with care, and on quantities sufficiently large to make the unavoidable irregularities in such cases quite insignificant. The law of density was ascertained in each substance in two ways. We dissolved different portions of salt in the same quantity of water, and examined the specific gravity of the brine by weighing it in a vessel with a narrow neck. The portions of salt were each of them one-eighth of what would make a nearly saturated solution of the temperature 55°. We did not make the brine stronger, that there might be no risk of a precipitation in form of crystals. We considered the specific gravities as the ordinates of a curve, of which the abscissae were the numbers of ounces of dry salt contained in a cubic foot of the brine. Having thus obtained eight ordinates corresponding to 1, 2, 3, 4, 5, 6, 7, and 8 portions of salt, the ordinates or specific gravities for every other proportion of salt were laid by the usual methods of interpolation.

The other method was, by first making a brine nearly saturated, in which the proportion of salt and water was exactly determined. We then took one eighth of the brine, and filled up the vessel with water, taking care that the mixture should be complete; for which purpose, besides agitation, the diluted brine was allowed to remain 24 hours before weighing. Taking out one-eighth of the brine also takes out one-eighth of the salt; so that the proportion of salt and water in the diluted brine was known. It was now weighed, and thus we determined the specific gravity for a new proportion of salt and water.

We then took one-seventh of the brine. It is evident that this takes one-eighth of the original quantity of salt; an abstraction equal to the former.

We filled the vessel with water with the same precautions; and in the same manner we proceeded till there remained only one-eighth of the original quantity of salt.

The specific gravities by these two methods agreed extremely well. In the very deliquescent salts the first method exhibited some small irregularities, arising from the unequal quantities of water which they had imbibed from the atmosphere. We therefore confided most in the experiments made with diluted brines.

That the reader may judge of the authority of the tables which we shall insert, we submit to his inspection one series of experiments.

Two thousand one hundred and eighty-eight grains of very pure and dry (but not decrepitated) common salt, prepared in large crystals, were dissolved in 6562 grains of distilled water of the temperature 55°. A small matras with a narrow neck, which held 4200 grains of distilled water, was filled with this brine. Its contents weighed 5027 grains. Now 6562 + 2188 = 8750 = 5027 : 1256.75. Therefore the bottle of brine contained 1256.75 grains of salt dissolved in 3772.25 grains of water. Its specific gravity is $\frac{5027}{1256.75}$ or $1.196925$; and a cubic foot of brine weighs 4200, or 1.196925; and a cubic foot of brine weighs 4200...
cubic foot are made the abscissae, and the weights of the cubic foot of brine are the corresponding ordinates, the curve will be found to be extremely regular, resembling a hyperbolic arch whose asymptote makes an angle of 30° with the axis. Ordinates were then interpolated analytically for every 10 ounces of contained salt, and thus the table was constructed. We did not, however, rest it on one series alone; but made others, in which one-fourth of the salt was repeatedly abstracted. They agreed, in the case of common salt, with great exactness, and in some others there were some very inconsiderable irregularities.

To show the authority of the tables of strength was by no means our only motive for giving an example of the process. It may be of use as a pattern for similar experiments. But, besides, it is very instructive. We see, in the first place, that there is a very sensible change of density in one or both of the ingredients. For the series is of that nature (as we have formerly explained), that if the ingredients retained their densities in every proportion of commixture, the specific gravities would have been in arithmetical progression; whereas we see that their differences continually diminish as the brines grow more dense. We can form some notion of this by comparing the different brines. Thus in the first brine, weighing 5027 grains, there are 3770 grains of water in a vessel holding 4200. If the density of the water remains the same, there is left for the salt only as much space as would hold 430 grains of water. In this space are lodged 1257 grains of salt, and its specific gravity, in its liquid form, is \( \frac{1257}{430} \approx 2.9392 \) nearly. But in the 8th brine the quantity of water is 4156, the space left for 157 grains of salt is only the bulk of 44 grains of water, and the density of the salt is \( \frac{157}{356} \approx 3.568 \), considerably greater than before.

This induced us to continue the dilution of the brine as follows, beginning with the 8th brine.

</table>

Thus, by repeated abstraction of brine, so as always to take out \( \frac{1}{5} \)th of the salt contained in one constant bulk, we have obtained a brine consisting of 157 grains of salt united with 4313—157, or 4156 grains of water. Its specific gravity is \( \frac{4313}{4156} \approx 1.0279 \), and a cubic foot of it weighs 1028 ounces, and contains 37.5 ounces of dry salt. In like manner may the specific gravity, the weight of a cubic foot, and the salt it contains, be estimated for the intermediate brines.

When these eight quantities of salt contained in a
single grain of excess or defect in taking out the brine and replacing it with water has a sensible proportion to the whole variation. But we see with sufficient evidence, that from the strong to the weak brines the space left for the portion of salt is continually diminishing. In the first dilution 527 grains of water were added to fill up the vessel; but one-eighth of its contents of pure water is only 525: so that here is a diminution of two grains and a half in the space occupied by the remaining salt. The subsequent additions are 600.7; 766.5; 947; 1504.5; 1405; 2102; 2105; 2102; instead of 600; 700; 800; 1000; 1400; 2100; 2100; 2100. Nothing can more plainly show the condensation in general, though we do not learn whether it happens in one or both of the ingredients; nor do the experiments show with sufficient accuracy the progression of this diminution. The excesses of the added water being only six or seven grains, we cannot expect a nice repartition. When the brine is taken out, the upper part of the vessel remains lined with a briny film containing a portion of salt and water, perhaps equal or superior to the differences. Had our time permitted, we should have examined this matter with scrupulous attention, using a vessel with a still narrower neck, and in each dilution abstracting one half of the brine. The curve, whose ascissae and ordinates represent the weight of the contained salt and the weight of a constant bulk of the brine, exhibits the best and most synoptical view of the law of condensation, because the position of the tangent in any point, or the value of the symbol $\frac{x}{y}$, always shows the rate at which the specific gravity increases or diminishes. We are inclined to think that the curve in all cases is of the hyperbolic kind, and complete; that is, having the tangent perpendicular to the axis at the beginning of the curve. The mathematical reader will easily guess the physical notions which incline us to this opinion; and will also see that it is hardly possible to discover this experimentally, because the mistake of a single grain in the very small ordinates will change the position of the tangent many degrees. It was for this reason that we thought it useless to prosecute the dilution any farther. But we think that it may be prosecuted much farther in Dr Watson's or Mr Achard's method, viz. by dissolving equal weights of salt in two vessels, of very different capacities, having tubular necks, in which the change of bulk may be very accurately observed. We can only conclude, that the condensation is greatest in the strongest brines, and probably attains its maximum when the quantities of true saline matter and water are nearly equal, as in the case of vitriolic acid, &c.

We consider these experiments as abundantly sufficient for deciding the question, "Whether the salt can be received into the pores of the water, or the water into the pores of the salt, so as to increase its weight without increasing its bulk?" and we must grant that it may. We do not mean that it is simply lodged in the pores as sand is lodged in the interstices of small shot; but the two together occupy less room than when separate. The experiments of Mr Achard were insufficient for a decision, because made on so small a quantity as 600 grains of water. Dr Watson's experiments have, for the most part the same defect. Some of them, however, are of great value in this question, and are very fit for ascertaining the specific gravity of dissolved salts. In one of them (not particularly narrated) he found that a quantity of dissolved salt occupied the same bulk in two very different states of dilution. We cannot pretend to reconcile this with our experiments. We have given these as they stood; and we think them conclusive, because they were so numerous and so perfectly consistent with each other; and their result is so general, that we have not found an exception. Common salt is by no means the most remarkable instance of condensation. Vegetable alkalis, salt ammonia, and some others, exhibit much condensation.

We thought this a proper opportunity of considering this question, which is intimately connected with the principles of chemical solution, and was not perhaps considered in sufficient detail under the article Chemistry. We learn from it in general, that the quantities of salt in brines increase at somewhat a greater rate than their specific gravities. This difference is in many cases of sensible importance in a commercial view. Thus an alkaline lixivium for the purposes of bleaching or soap-making, whose specific gravity is 1.234, or exceeds that of water by 234, contains 361 ounces of salt in a cubic foot; a ley which exceeds the weight of water twice as much, or 468 ounces per cubic foot, contains 777 ounces of salt, which exceeds the double of 361 by 55 ounces, more than seven per cent. Hence we learn, that hydrometers for discovering the strength of brines, having equal divisions on a cylindrical stem, are very erroneous; for even if the increments of specific gravity were proportional to the quantities of salt in a gallon of brine, the divisions at the bottom of the stem ought to be smaller than those above.

The construction of the following table of strengths from the above narrated series of brines is sufficiently obvious. Column first is the specific gravity as discovered by the balance or hydrometer, and also is the number of ounces in a cubic foot of the brine. Col. 2d is the ounces of the dry salt contained in it.

The
The table differs considerably from Mr. Lambert's. The quantities of salt corresponding to any specific gravity are about 45 less than in his table. But the reader will see that they correspond with the series of experiments above narrated; and these were but a few of many which all corresponded within an hundredth part. The cause of the difference seems to be, that most kinds of common salt contain magnesia salts, which contain a very great proportion of water necessary for their crystallization. The salt which we used was of the purest kind, but such as may be had from every salt work, by Lord Dundonald's very easy process, viz. by passing through it a saturated solution boiling hot, which carries off with it about four-fifths of all the bitter salts. Our aim being to ascertain the quantities of pure sea-salt, and to learn by the bye its relation to water in respect of density, we thought it necessary to use the purest salt. We also dried it for several days in a stove, so that it contained no water not absolutely necessary for its crystallization. An ounce of such salt will communicate a greater specific gravity to water than an ounce of a salt that is less pure, or that contains extraneous water.

The specific gravity 1.650 is that of ordinary pickles, which are estimated as to strength by floating an egg. We cannot raise the specific gravity higher than 1.206 by simply dissolving salt in cold water. But it will become much denser, and will even attain the specific gravity 1.240 by boiling, then holding about 336 ounces in the cubic foot of hot brine. But it will deposit by cooling, and when of the temperature 55° or 60° hardly exceeds 1.206. We obtained a brine by boiling till the salt grained very rapidly. When it cooled to 60°, its specific gravity was 1.2063; for a vessel which held 3365 ounces of distilled water held 4229 of this brine. This was evaporated to dryness, and there were obtained 1344 grains of salt. By this was computed the number interposed between 310 and 320 in the table. We have, however, raised the specific gravity to 1.217, by putting in no more salt than was necessary for this density, and using heat. It then cooled down to 60° without quitting any salt; but if a few grains of salt be thrown into this brine, it will quickly deposit a great deal more, and its density will decrease to 1.206. We find this to hold in all salts; and it is a very instructive fact in the theory of crystallization; it resembles the effect which a magnet produces upon iron filings in its neighbourhood. It makes them temporary magnets, and causes them to arrange themselves as if they had been really made permanent magnets. Just so a crystal already formed disposes the rest to crystallize. We imagine that this analogy is complete, and that the forces are similar in both cases.

The above table is computed for the temperature 55°; but in other temperatures the strength will be different on two accounts, viz. the expansion of the brine and the dissolving power of the water. Water expands about 49 parts in 1000 when heated from 62° to 212°. Saturated brine expands about 48 parts, or one-fifth more than water; and this excess of expansion is nearly proportional to the quantity of salt in the brine. If therefore any circumstance should oblige us to examine a brine in a temperature much above 62°, allowance should be made for this. Thus, should the specific gravity of brine of the temperature 130° (which is nearly half way between 60° and 212°) be 1.140, we must increase it by 20 (half of 40); and having found the strength 240 corresponding to this corrected specific gravity, we must correct it again by adding 1 to the specific gravity for every 45 ounces of salt.

But a much greater and more uncertain correction is necessary on account of the variation of the dissolving power of water by heat. This indeed is very small in the case of sea-salt in comparison with other salts. We presume that our readers are apprised of this peculiarity of sea-salt, that it dissolves nearly in equal quantities in hot or in cold water. But although water of the temperature 60° will not dissolve more than 320 or 325 ounces of the purest and dryest sea-salt, it will take up above 20 ounces more by boiling on it. When thus saturated to the utmost, and allowed to cool, it does not quit any of it till it is far cooled, viz. near to 60°. It then deposits this redundant salt, and holds the rest till it is just going to freeze, when it lets it go in the instant of freezing. If evaporated in the state in which it continues to hold the salt, it will yield above 400 ounces per cubic foot of brine, in good crystals, but rather overcharged with water. And since in this state the cubic foot of brine weighs about 1220 ounces it follows, that 820 ounces of water will, by boiling, dissolve 400 of crystallized salt.

The table shows how much any brine must be boiled down in order to obtain. Having observed its specific gravity, find in the table the quantity of salt corresponding. Call this s. Then, since a boiling hot graining or saturated solution contains 340 ounces in the cubic foot of brine, say 340:1000::s:1000, this is the bulk of brine to which every cubic foot (valued at 1000) must be boiled down. Thus suppose the brine has the specific gravity 1109. It holds 160 ounces per foot, and we must boil it down to $\frac{160}{1000} = 0.16$ or 471; that is, we must boil off $\frac{120}{1000}$ of every cubic foot or gallon.

These remarks are of importance in the manufacture of common salt; they enable us to appreciate the value of salt springs, and to know how far it may be prudent to engage in the manufacture. For the doctrine of latent heat assures us, that in order to boil off a certain quantity of water, a certain quantity of heat is indispensably necessary. After the most judicious application of this heat, the consumption of fuel may be too expensive.

The specific gravity of sea-water in these climates does not exceed 1.03, or the cubic foot weighs 1020 ounces, and it contains about 42 ounces of salt. The brine pits in England are vastly richer; in many parts of the world brines are boiled for salt which do not contain above 10 or 20 ounces in the cubic foot.

In buying salt by weight, it is of importance to know the degree of humidity. A salt will appear pretty dry (if free from magnesia salts) though moistened with one per cent. of water; and it is found that incipient humidity exposes it much to further deliquescence. A much smaller degree of humidity may be discovered by the specific gravity of a brine made with a few ounces of the salt. And the inspection of the table informs us, that
that the brine should be weak; for the differences of specific gravity go on diminishing in the stronger brines; 320 ounces of dry salt dissolved in 897 ounces of water should give the specific gravity 1.197. Suppose it be but 1.190, the quantity of salt corresponding is only 290; but when mixed with 897 ounces of water, the weight is 1.197, although the weight of the cubic foot is only 1.190. There is therefore more than a cubic foot of the brine, and there is as much salt as will make more than a cubic foot of the weight 1.190. There is

\[290 \times \frac{1.197}{1.190},\] or 291.7 ounces, and there is 81 ounces of water attached to the salt.

The various informations which we have pointed out as deducible from a knowledge of the specific gravity of the brines of common salt, will serve to suggest several advantages of the knowledge of this circumstance in other lithiasis. We shall not therefore resume them, but simply give another table or two of such as are most interesting. Of those, alkaline leys are the chief, being of extensive use in bleaching, soap-making, glass making, &c.

We therefore made a very strong ley of the purest vegetable alkali that is ever used in the manufactories, not thinking it necessary, or even proper, to take it in its state of utmost purity, as obtained from cubic nitre and the like. We took salt of tartar from the apothecary, perfectly dry, of which 3583 grains were dissolved in 3340 grains of distilled water and after agitation for several days, and then standing to deposit sediment, the clear ley was decanted. It was again agitated; because, when of this strength, it becomes, in a very short time, rarer above and denser at the bottom. A flask containing 4200 grains of water held 5165 of this ley when the temperature was 55°. Its specific gravity was therefore 1.4678, and the 6165 grains of ley contained 3264 grains of salt. We examined its specific gravity in different states of dilution, till we came to a brine containing 51 grains of salt, and 4189 grains of water, and the content of the flask weighed 4240 grains: its specific gravity was therefore 1.0695. In this train of experiments the progress was most regular and satisfactory; so that when we constructed the curve of specific gravities geometrically, none of the points deviated from a most regular curve. It was considerably more inculcated near its commencement than the curve for sea-salt, indicating a much greater condensation in the diluted brines. We think that the following table, constructed in the same manner as that for common salt, may be depended on as very exact.

</tbody>
</table>

We see the same augmentation of the density of the salt in the diluted brines here as in the case of common salt. Thus a brine, of which the cubic foot weighs 1482 ounces, or which has the specific gravity 1.482, contains 850 ounces of dry alkali and 632 of water. Therefore, if we suppose the density of the water unchanged, there remains the bulk of 318 ounces of water to receive 840 ounces of salt: its density is therefore \(\frac{318}{840}\) = 2.512 nearly. But in the brine whose weight per foot is only 1016 there are 20 ounces of salt, and therefore 996 of water; and there is only four ounce-measures of water, that is, the bulk of four ounces of water, to receive 20 ounces of salt. Its specific gravity therefore is \(\frac{20}{4}\) = 5, almost twice as great as in the strong brine. Accordingly Mr Achard is disposed to admit the absorption (as it is carelessly termed) in the case of salt tartar. But it is a general (we think an universal) fact in the solution of salts. It must be carefully distinguished from the first contraction of bulk which salts undergo in passing from a solid to a fluid form. The contraction now under consideration is analogous to the contraction of oil of vitriol when diluted with water; for oil of vitriol must be considered as a very strong brine which we cannot depurate by distillation, and therefore cannot obtain the dry saline ingredient in a separate form, so as to observe its solid density, and say how much it contracts in first becoming fluid. The way of conceiving the first contraction in the act of solution as a lodging of the particles of the one ingredient on the interstices of the other, "qui se n'incrit, en augmentant lo poids sans effetre le volume de la saumure," as Euler and Lambert express themselves, is impossible here, when both are fluids. Indeed it is but a slowly way of thinking.
thinking in either case, and should be avoided, because inadvertent persons are apt to use as a physical principle what is merely a mode of speech.

We learn from the table, that a hydrometer with equidistant divisions on a cylindrical or prismatical stem is still more erroneous than in the brines of common salt.

We learn from the experiments of Kirwan, Lavoisier, and others, that dry salt of tartar contains about one-fourth of its weight of fixed air. In many applications of this salt to the purposes of manufacture, this ingredient is of no use. In some it is hurtful, and must be abstracted by lime. Soap-maker's lea consists of the pure alkaline salt dissolved in water. It is therefore of importance to ascertain its quantity by means of the specific gravity of the brine. For this purpose we took a lea of sal tart, whose specific gravity was 1.20417, containing 314 ounces of mild alkali in a cubic foot of lea, and we rendered it nearly caustic by lime. The specific gravity was then 1.1897. This is a very unexpected result. Nothing is employed with more success than quicklime for dephlegmating any watery fluid. We should rather have expected an increase of specific gravity by the abstraction of some of the water of the crystallization, and perhaps the water of the crystallization, and the aerial part of the salt. But we must ascribe this to the great density in which the fixed air exists in the mild alkali.

It is unnecessary to give similar tables for all the salts, unless we were writing a dissertation on the theory of their solution. We shall only observe, that we examined with particular attention sal ammoniac, because Mr Achard, who denies what is called the absorption of salts, finds himself obliged to allow something like it in this salt. It does not, however, differ from those of which we have given an account in any other respect than this, that the changes of fluid density are much less than in others (instead of being greater, as Achard's experiments seem to indicate) in all brines of moderate strength. But in the very weak brines there is indeed a remarkable difference; and if we have not committed an error in our examination, the addition of one part of sal ammoniac to 64 of water occupies less room than the water alone. We think that we have met with this as an accidental remark by some author, whose work we do not recollect. But we do not choose to rest so much on our form of the experiment in such weak brines. The following mixtures will abundantly serve for constructing the table of its strength: Sal ammoniac 1061 grains was dissolved in 4466 grains of water, making a brine of 4466 grains. A phial which held 1600 grains water held 1698 of this brine. It contained

\[
\frac{1698 \times 960}{4466}, \text{ or } 365 \text{ grains of salt. The specific gravity was } \frac{1698}{1600} = 1.061, \text{ and the cubic foot weighed } 1061 \text{ ounces. It also contained } \frac{1061 \times 365}{1698}, \text{ or } 288 \text{ ounces of salt. By repeated abstraction of brine, and replacing with water, we had the following series:}

This series is extremely regular, and the progress of density may be confidently deduced from it.

From the whole of this disquisition on the relation between the specific gravities of brines and the quantities of salt contained, we see in general that it may be guessed at, with a degree of useful precision, from the density or specific gravity of saturated solutions. We therefore conclude with a list of the specific gravities of several saturated solutions, made with great care by the bishop of Landaff.—The temperature was 42°. The first numerical column is the density of saturated brine, and the next is the density of a brine consisting of 12 parts (by weight) of water and one of salt. From this may be inferred the quantity in the saturated solution, and from this again may be inferred the quantity corresponding to inferior densities.

SPECTACLES, in Dioptrics, a machine consisting of two lenses set in silver, horn, &c. to assist the defects of the organ of sight. Old people, and others who have flat eyes, use convex spectacles, which cause the rays of light to converge so as to meet upon the retina: whereas myopes, or short-sighted people, use concave lenses for spectacles, which cause the rays to diverge, and prevent their meeting ere they reach the retina. See OPTICS.

Some cases of a peculiar nature have been met with where the sight receives no assistance from the use of either convex or concave glasses. To remedy this, the following method was contrived and successfully adopted. A man about sixty years of age having almost entirely lost his sight, could see nothing but a kind of thick mist with little black specks in it which seemed to float in the air. He could neither read, walk the streets, nor distinguish his friends who were most familiar to him. In this deplorable situation he procured some spectacles with large range; and having taken out the glasses,
to consult the witch at Endor, he asked her to bring up the person whom he should name unto her; a proof that he considered his demand as easy to be performed, and therefore that he probably acted under the influence of popular opinion. The same opinions had been generally entertained at a much earlier period; for necromancy and witchcraft, the arts by which the dead were supposed to be raised, had been prohibited while the Israelites were in the wilderness, and yet untainted with the vices of the Canaanites. They must therefore have derived them from Egypt, the cradle of superstition, as well as of the arts and sciences.

Among the Greeks and Romans the apparition of spectres was generally believed. On innumerable occasions the gods are said to have discovered themselves to the eyes of mortals, to have held conferences, and to have interposed their aid. The ghosts of the dead, too, are said to have appeared. When Aeneas, amidst the distraction and confusion of his mind in flying from the destruction of Troy, had lost his wife by the way, he returned in search of her. Her shade appeared to him (for she herself had been slain) with the same aspect as before, but her figure was larger. She endeavoured to assuage the grief of her unhappy husband, by ascribing her death to the appointment of the gods, and by foretelling the illustrious honours which yet awaited him. But when Aeneas attempted to clasp her in his arms, the phantom immediately vanished into air. From this story we may observe, that the ancients believed that the umbrae or shades, retained nearly the same appearance after death as before; that they had so far the resemblance of a body as to be visible; that they could think and speak as formerly, but could not be touched. This description applies equally well to those shades which had passed the river Styx, and taken up their residence in the infernal regions. Such were the shades of Biba, of Drupholus, and all those which Æneas met with in his journey through the subterraneous world.

It appears from the writings of modern travellers who have visited rude and savage nations, that the belief of spectres is no less common among them. Mr. Bruce tells us, that the priest of the Nile affirmed, that he had more than once seen the spirit of the river in the form of an old man with a white beard. Among the Mahometans the doctrine of spectres seems to be reduced to a regular system, by the accounts which they give of genii. Whoever has read the Arabian Nights Entertainments must have furnished his memory with a thousand instances of this kind. Their opinions concerning genii seem to be a corrupted mixture of the doctrines of the Jews and ancient Persians. In Christian countries, too, notwithstanding the additional light which their religion has spread, and the great improvement in the sciences to which it has been subservient, the belief of ghosts and apparitions is very general, especially among the lower ranks. They believe that evil spirits sometimes make their appearance in order to terrify wicked men, especially those who have committed murder. They suppose that the spirits of dead men assume a corporeal appearance, hover about church-yards and the houses of the deceased, or haunt the places where murders have been committed. (See GHOST). In some places it is believed that beings have been seen bearing a perfect resemblance to men alive. In the Highlands of Scotland, what is called the second sight is still believed
S P E [ 576 ]

S P E

lieved by many (see Second Sight) viz. that future events are foretold by certain individuals by means of spectral representation.

So general has the belief of spectres been, that this circumstance alone may be thought by some sufficient to prove that it must have its foundation in human nature, or must rest upon rational evidence. When any doctrine has been universally received by all nations, by generations living several thousand years from one another, and by people in all the different stages of society, there is certainly the strongest presumption to conclude that such a doctrine has its foundation in reason and in truth. In this way we argue in favour of the existence of a God, concerning moral distinction, and the doctrine of a future state: and certainly so far we argue well. But if the same argument be applied to idolatry, to sacrifices, or to apparitions, we shall find that it is applied improperly. Idolatry was very general among ancient nations; so was the offering of sacrifices, so was polytheism; but they were by no means universal. Should we allow, for the sake of shortening the argument, that all ancient nations were polytheists and idolaters, and presented oblations to their imaginary deities, all that could be concluded from this concession is, that they fell into these mistakes from their ignorance and from the rude state of society, from which their imperfect knowledge of theology and moral philosophy was never able to rescue them. These erroneous notions fled before the brightness of the Christian system; while the doctrines of the existence of God, of moral distinction, and of a future state, have been more thoroughly confirmed and ascertained. The same thing may be said of the belief of spectres. However generally it has been adopted in the first stages of society, or by civilized nations who had made but little progress in the study of divine things, it has been rejected, we may say invariably, wherever theology and philosophy have gone hand in hand.

As all popular and long established opinions are objects of curiosity and research for the philosopher, we think the belief of spectres worthy of some attention even in this light. It will therefore, we hope, give some satisfaction to the philosophical reader to see a short account of the sources or principles from which this belief is derived. But as the belief of spectres is connected with other opinions which appear to us high

a rious to religion; opinions which have been supported by many learned men, and which are still believed by some men of literary education—it will also be proper, in the first place, to consider the evidence on which this belief rests, in which we must consider both their probability and credibility.

In the present investigation we mean to set aside altogether the celestial appearances recorded in Scripture, as being founded on unquestionable evidence, and perfectly agreeable to those rules by which the Deity acts in the usual course of his Providence. The Israelites, during the existence of their state, were immediately under the authority of God, not only as the moral governor of the world, but as the king of Israel; in the influence of the world, men were rude and unenlightened, and entirely under the influence of idolatry, many revelations were necessary to preserve in their minds pure ideas of the nature of God, and of the worship due to him. They were necessary also to pave the way for that illustrious dispensation which the Lord Je-

s

a

ian came from Heaven to diffuse over the world. Every celestial appearance recorded in Scripture was exhibited for some wise and important purpose, which must be apparent to every person who considers these appearances with attention. But when the Scriptures were written and published, and the Christian religion fully established, revelation ceased, and miracles and heavenly messages were no longer requisite. What credit then ought we to give to those marvelous stories related in ancient authors concerning prodigies in the heavens, and the apparition of angels both good and bad?

It is not pretended that any of these prodigies and appearances were exhibited for purposes equally great and important with those which are described in Scripture: And can we suppose that the all wise Governor of the world would permit his angels to render themselves visible to the eye of man for no purpose at all, or for a purpose which might have been equally well accomplished without their interposition? Would this be consistent with perfect wisdom, or would it be consistent even with the excellence and superiority of understanding which we are taught to ascribe to these elevated beings? The whole will of God is revealed to us in the Scriptures; what further use for the visible interposition of angels? It may be objected, Are they not all ministering spirits, sent forth to minister for them who shall be heirs of salvation? We answer, that angels may animate and * Heb. 1

14 support good men by an invisible interposition. But 14

the Apostle is not speaking of celestial spirits. The 14

word angel signifies *"a messenger"; and in Scripture often refers to men. In the passage which we are now reviewing it certainly is applied with much more propriety to men than to angels: for the Apostle is stating a comparison between the prophets, by whom God, at sundry times and in divers manners, spake in time past to the fathers, and *the Son, by whom he spake in these last days.

And if God has given no commission to his angels to deliver to men since the publication of the Christian religion, is there any probability that he would give any commission or any licence to evil spirits? It will be said, that this doctrine is clearly taught in the New Testament, in these words, "The devil goeth about as a roaring lion seeking whom he may devour." We will not avail ourselves of the interpretation of some, who say that the word devil, which in the Greek language signifies an adversary, or slanderer, refers here to some human being, who was a violent enemy of the Christians. All that can be deduced from these words, upon the supposition that they refer to a malignant spirit, is merely that he goeth about seducing men to vice. But it is not by assuming a hideous form, and presenting himself to the midnight traveller, that such a purpose is to be accomplished. A spirit may probably have direct access to our minds without the intervention of any thing corporeal; and by exciting our passions may plunge us into vice, which is the only object such a being is supposed to have in view. None of the marvelous and prodigious stories which we have considered concerning the apparition of evil spirits lead us to conclude that they appear to entice men to commit crimes. We never heard of any evil spirits that required men to steal, to perpetrate robbery or murder. They only appeared to terrify some crazy timorous individuals, who have whims and fancies...
enow of their own to agitate their minds, though no preternatural vision should ever appear to them. It is not consistent, therefore, with the character of God, and what he has revealed to us of his will, to believe that he would commission good angels, or permit evil angels, to appear to men since the propagation of the gospel, or indeed at any former period of the world, unless some great and mighty purpose was to be fulfilled. It is not consistent with what we know of the nature of good or bad angels to suppose, that though permission were granted them occasionally to show themselves to men, that they would appear in that way which story-tellers describe.

It is equally improbable that the spirits of the dead who have removed from this world should again be permitted to visit it. At death men undergo as great, perhaps a greater change, than when they came first into the light of the sun. Is it not therefore as improbable that a man should return in a visible corporeal form after death, as that, after having arrived at manhood, he should return to the state in which he was before his birth? Such changes as these are evidently made permanent by the invariable laws of nature. But suppose it were possible, for what purpose should they return? To describe to us what is passing in the other world, to animate us to virtue, by informing us of the rewards which there await the good: or to alarm us, by describing the punishment of the wicked. These seem important reasons. But Divine Providence has wisely thrown a veil over futurity. We know every thing of the other world from the scripture which it is proper for us to present to know. And as to incentives to virtue, we are already blessed with a number sufficiently great and powerful for moral beings, who are to act from rational motives, and not from compulsion. “He that will not hear Moses and the prophets, will not be persuaded though one rose from the dead.”

There is one strong objection against the probability of spectres, which is sufficient to prove that they are not intelligent creatures; or at least that they possess so small a degree of intelligence, that they are unqualified to act with prudence, to propose any end to themselves, or use the proper means to accomplish that end. Ghosts often appear in order to discover some crime that has been committed: but they never appear to a magistrate, or person in authority, but to some illiterate clown, who happens to live near the place where the crime was perpetrated; to some person who has no connection with the affair at all, and who in general is the most improper in the world for making the discovery. For instance, in Glanville’s Suiducius triumphatna (a book written in the last century by a chaplain of Charles II. in support of the common opinions respecting witchcraft and apparitions), we have the following story: James Haddock, a farmer, was married to Eleanor Welsh, by whom he had a son. After the death of Haddock, his wife married one Davis; and both agreed to defraud the son by the former marriage of a lease bequeathed to him by his father. Upon this the ghost of Haddock appeared to one Francis Taverner the servant of Lord Chichester, and desired him to go to Eleanor Welsh, and to inform her that it was the will of her former husband that their son should enjoy the lease. Taverner did not at first execute this commission; but he was continually haunted by the apparition in the most hideous shapes, which even threatened to tear him in pieces, till at last he delivered the message. Now, had this spectre had the least common sense, it would have appeared first to Eleanor Welsh and her husband Davis, and frightened them into compliance at once, and not have kept poor Taverner in such constant disquietude, who had no concern in the matter.

Another very odd circumstance respecting apparitions in general must not be omitted, which is, that they have no power to speak till they are addressed. In the 27th of Glanville’s Relations we read of an old woman that appeared often to David Hunter, a neat-herd, at the house of the bishop of Down and Conner. Whenever she appeared, he found himself obliged to follow her; and for three quarters of a year poor David spent the whole of almost every night in scampering up and down through the woods after this old woman. How long this extraordinary employment might have continued, it is impossible to guess, had not David’s violent fatigue made him one night exclaim, “Lord bless me! would I were dead!—shall I never be delivered from this misery?” On which the phantom replied, “Lord bless me too! It was happy you spoke first, for till then I had no power to speak, though I have followed you so long.” Then she gave him a message to her two sons, though David told her he remembered nothing about her. David, it seems, neglected to deliver the message; at which the old beldam was so much provoked, that she returned and hit him a hearty blow on the shoulder, which made him cry out, and then spoke to her. Now if she could not speak till David addressed her, why might she not have applied this oriental medicine the first time she appeared to him? It would have saved both herself and him many a weary journey; and certainly David would much rather have had even half a dozen of blows from her choppy fists than have wanted so many nights sleep. To complete the story, we must add, that when David’s wife found it impossible to keep him from following the troublesome visitor, she trudged after him, but never was gratified with a sight of the enchantress. David’s little dog too was a dutiful attendant on his master during his pilgrimage.

It is remarked by Glanville, that ghosts are generally very eager to be gone. Indeed they are often so much so, that they do not stay to tell their errand. One would be induced from this, as well as the circumstances already mentioned, to think that they are the stupidest and dullest of the dead that assume the appearance of ghosts; unless we adopt the ingenious solution of Glanville, “that it is a very bad and painful thing for them to force their thin and tenuous bodics into a visible consistence; that their bodies must needs be excessively compressed; and that therefore they must be in haste to be delivered from the unnatural pressure.”

With respect to the evidence in favour of spectres, if examined ever so slightly, it will be found very defective. They only appear to one person at a time; they are seen only in the night; they are visible only to ignorant, illiterate, and credulous persons, and never present themselves before men of education and learning.

That spectres only appear to one person at a time, even though there are more in company, is an objection against the credibility of their appearance quite insurmountable.
mountable. How is it possible that two men of eyesight equally good, directing their eyes to the same spot, should not see so large an object as that of a man or woman at a small distance equally well? Some will tell us that a mist is cast over the eyes of the one, while the view of the other is free from obstruction. But how is this to be proved? and besides, what purpose would it serve? Ghosts have seldom any secrets to disclose; they might be proclaimed to a multitude with as much propriety as confined to one person. Shall we be told, that the spectre has the power of becoming visible to some, and of remaining invisible to others? This cannot be allowed without adopting opinions destructive to revealed religion; for it would be a miracle: and we cannot be persuaded, without evidence, that God would empower any inferior being to control at pleasure the wise laws which he has ordained for governing the world.

To him who is of a different opinion, we would recommend Farmer on Miracles; a book in which this question is fully examined. Spectres appear only in the night. But why should they shun the light of the sun? Those mischievous ghosts that Glanville mentions might indeed have some reason to choose midnight for the execution of their pranks, as they would be more easily detected in open day. Such was the roguish drummer that haunted Mr Mompesson's house, who beat his drum all night, threw the old gentlewoman's clothes about the room, hid her Bible in the ashes, plucked the clothes off the bed, and amused himself with tossing about Mr Mompesson's shoes. But why should a grave serious ghost appear at midnight? Might it not deliver its message with as much ease and more success in the day-time? In the day-time it would not excite much fear; it would be listened to therefore with more attention; and did it choose to exhibit itself before a number of witnesses, its grievances would be more speedily redressed, because more persons would interest themselves in seeing justice done to the injured ghost.

Spectres not only choose the most improper time, but the most improper persons. To render the testimony of any person credible, he must not only be a man of veracity, but he must have sufficient ability to judge of the subject to which he is to bear witness. It is not on the evidence of an ignorant illiterate person, who has more fancy and fear than judgment, that we are to rest our belief of what is supernatural. It is also worthy of remark, that we have never heard of a ghost appearing to any person who did not previously believe their existence. A man must be prejudiced in favour of this opinion, or he will never see a ghost. But sensible men know, that he who has been accustomed to hear frightful stories of ghosts and apparitions gliding through a churchyard, or haunting some particular place, can scarcely pass through a churchyard, or haunted spot without conjuring up in his imagination the hideous phantoms which he has been accustomed to associate with such places. Is it strange, then, that an ignorant man, with a mind uncultivated and uninform ed, with all the prejudices of the nursery about him, should imagine he sees ghosts in those places where he believes they hover, especially in the dead hour of midnight, when, with the slightest aid of the imagination, a cow may be turned into a monstrous phantom, and the reflection of the beams of the moon from a little water be converted into a ghost with a winding-sheet? But why should apparitions shun men of understanding and learning? Why should learning be formidable to them (A)?

It was not so with the celestial messengers mentioned in the Scriptures: they appeared to the patriarchs and prophets; and the miracles there recorded were performed in the most public places, before the eyes of Rabbis, of Scribes, and Pharisees. Indeed this circumstance is sufficient to destroy the evidence of spectres. They have never been seen by any but men of weak or disturbed minds, or by men who have previously believed in them.

Having now considered the evidence on which the belief of spectres rests, we will endeavour to give some account of the foundation of it. To trace an opinion, that has prevailed so generally in the world to its source, is a labour not unworthy of the philosopher, even though the opinion be false. It is always gratifying to detect the causes of error: it is no less useful; for in order to refute error, it is often sufficient to point out the sources from which it has sprung. To reach the origin of the belief of spectres is not more difficult than to account for idolatry or polytheism. In the infant state of the intellectual powers every thing is considered as possessing life and intelligence. The child beats the stool.

---

(A) The celebrated historian De Thou had a very singular adventure at Saumur, in the year 1598. One night, having retired to rest very much fatigued, while he was enjoying a sound sleep, he felt a very extraordinary weight upon his feet, which, having made him turn suddenly, fell down and awakened him. At first he imagined that it had been only a dream, but hearing soon after some noise in his chamber, he drew aside the curtains, and saw, by help of the moon, which at that time shone very bright, a large white figure walking up and down, and at the same time observed upon a chair some rags, which he thought belonged to thieves who had come to rob him. The figure then approaching his bed, he had the courage to ask it what it was. "I am (said it) the Queen of Heaven." Had such a figure appeared to any credulous ignorant man in the dead of night, and made such a speech, would he not have trembled with fear, and have frightened the whole neighbourhood with a marvellous description of it? But De Thou had too much understanding to be so imposed upon. Upon hearing the words which dropped from the figure, he immediately concluded that it was some mad woman, got up, called his servants, and ordered them to turn her out of doors; after which he returned to bed and fell asleep. Next morning he found that he had not been deceived in his conjecture, and that having forgot to shut his door, this female figure had escaped from her keepers, and entered his apartment. The brave Schomberg, to whom De Thou related his adventure some days after, confessed that in such a case he would not have shown so much courage. The king also, who was informed of it by Schomberg, made the same acknowledgement.

Spectre.

stood over which he has fallen with the same passion that he would treat his companion: The young girl talks to her doll as if it understood her: The savages ascribe every change which they observe on the face of nature to the action of some animated being. As knowledge advances, they single out those beings which seem to produce the most striking effects, arrange them into some kind of order, and divide the government of the world among them. Unable, at the same time, to conceive any notion of a pure spirit, they imagine those divinities are corporeal beings. This is the foundation of idolatry. The belief of spectres is but another step. That these animated corporeal beings, to whom they address their prayers, and who preside over the world, should on particular occasions display themselves to the human eye, is what they must be previously disposed to expect. Hence the numberless appearances of the heathen gods, of the Persian and Mahometan genii. The belief of ghosts may be easily deduced from the opinions entertained respecting a future state. These opinions are founded on that essential doctrine of natural religion, that there is another world in which men shall exist when death has removed them hence. This doctrine has been universally received both by savage and civilized nations; but, as might be expected, men have formed very different sentiments concerning the nature of a future state, of the situation and employments of departed spirits, according to the degree of knowledge which they possessed. But the general opinion in ancient and rude nations was, that departed spirits retained the same external appearance, the same passions and principles as before. Nothing therefore was more natural than the opinion, that they might occasionally revisit this world, from an anxious desire to alleviate the sufferings of those beloved friends and relations whom they had left behind them, or to communicate from the unseen world what might be important to their welfare. Upon such an errand did Cerusa appear to Enervas. The apparition of the ghosts of murderers is easily explained upon the same general principles. The remorse and horror of mind which the murderer feels are supposed to haunt him in the other world, and to render his situation there intolerable (especially if the murder was never detected and punished), till he return and give information against himself. In this way, then, we think it highly probable the belief of spectres has originated. But many other causes concur to confirm and propagate this belief. These are imperfect vision united with fear, dreams, opium, diseases, drunkenness, and artifice.

1. Indistinct vision is one source of apparitions, especially when the mind is under the influence of fear. It is well known, that the sense of seeing conveys no idea of distance till improved by experience and observation; and how we come at length to distinguish objects at a distance from those that are near, has been explained in another place (see Metaphysics, No. 50.).

In the daytime we seldom commit mistakes, because we know the object at which we look; but at night, when we see objects obscurely, and know not what they are, we have no distinct idea either of their distances or of their magnitude. We may mistake a bush that is near us for a tree at a distance; or if the imagination be under the influence of fear, it will easily convert it into a gigantic figure. "It is generally asserted (says Buffon) that these figures exist only in the imagination; yet they may have a real existence in the eye; for whenever we have no other mode of judging of an unknown object but by the angle it forms in the eye, its magnitude will uniformly increase in proportion to its propinquity. If it appears, when at the distance of 20 or 30 paces, to be only a few feet high, its height, when within two or three feet of the eye, will be many fathoms. An object of this kind must naturally excite terror and astonishment in the spectator, till he approaches and recognises it by actual feeling; for the moment a man knows an object, the gigantic appearance it assumed in the eye instantly diminishes, and its apparent magnitude is reduced to its real dimensions. But if, instead of approaching such an object, the spectator flies from it, he can have no other idea of it but from the image which it formed in his eye; and, in this case, he may affirm with truth that he saw an object terrible in its aspect, and enormous in its size. Thus the notions concerning spectres are founded in nature, and depend not, as some philosophers affirm, upon the imagination alone."

In addition to these observations of Buffon, we may take notice, that objects are always magnified in a fog; so that when a fog happens in the night-time, objects may be magnified to an enormous size. But, at any rate, whether there be a fog in the night or not, there is such a great analogy between darkness and a fog, that if the latter deceive us with respect to the size of objects, the former will also deceive us. The writer of this article was passing the Frith of Forth at Queensferry, near Edinburgh, one morning which was extremely foggy. Though the water be only two miles broad, the boat did not get within sight of the southern shore till it approached very near it. He then saw to his great surprise a large perpendicular rock, where he knew the shore was low and almost flat. As the boat advanced a little nearer, the rock seemed to split perpendicularly into portions, which separated at a little distance from one another. He next saw these perpendicular divisions move; and upon approaching a little nearer, found it was a number of people standing on the beach, waiting the arrival of the ferry-boat.

2. Dreams are another fertile source of apparitions. It is well known to every person, that while the mind is under the influence of a dream it considers it as much a reality as it does any particular action while awake. Now if a person of a weak superstitious mind should have a very lively dream, which interests his passions, particularly the passion of fear, it may make so deep an impression, that he may be firmly convinced that he has actually seen with his eyes what has only passed before his imagination (see Apparition) (b). We shall here tell a story, by way of illustration, which we have

(b) When the thoughts are much troubled, and when a person sleeps without the circumstances of going to bed, or putting off his clothes, as when he nods in his chair, it is very difficult, as Hobbes remarks, to distinguish a dream from a reality. On the contrary, he that composes himself to sleep, in case of any uncouth or absurd fancy, easily suspects it to have been a dream.—Leviathan, par. 1. c. 1.
have received on unquestionable authority. An East India captain had an honest, faithful servant named John, for whom he had a great regard. John died, if we recollect right, on a voyage from England to the East Indies during a French war. As the ship approached the place of its destination the captain had a dream, in which John appeared to him, and earnestly besought him not to sail to the port for which he was bound, as it was in the hands of the French. The captain, though not addicted to superstition, thought it prudent to follow this admonition; and after landing at a different port, he was informed that the place to which he had intended to steer was, according to the information of the dream, captured by the French. On the voyage home, the captain had a second dream, in which John again appeared to him, and gave him notice that he should soon die, and that the ship should be taken in the mouth of the Channel by the French. Next morning the captain called his first mate, told him his dream, which he believed was prophetic, and delivered his papers, that he might take proper care of them after his decease. Every thing happened exactly as the dream had foretold; the captain died, and the vessel was taken by a French man of war in the mouth of the Channel. This dream, wonderful as it appears, is easily explained. In the voyage out to India, nothing was more natural than that the captain should sometimes be thinking, that amidst the various chances of war, the port to which he was bound might be taken; perhaps it was a place of consequence, which the French might be eager to possess. The captain being accustomed to revolve these thoughts in the day-time, they would naturally return at night; the regret which he felt for the loss of a faithful servant might mingle with his apprehensions, and thus produce the dream. Perhaps the advice was such as John would have given had he been alive. It is equally easy to explain the cause of the dream in the passage home. The captain, we are told, was very ill, and thought himself dying, at the very time he had the second dream, and therefore did not expect to reach England. This part of the dream, then, was only his own thoughts, delivered by his servant. As to the other part, that his ship should be taken in the mouth of the Channel, it might be thought unaccountable how the very place should be foreseen. But we must recollect, that the mouth of the Channel, being over against the coast of France, was by far the most dangerous place in the whole passage; and that, therefore, the captain had more reason to be afraid of losing his ship there than in any other place. The use which we mean to make of this story is this: Had the captain been a man of a weak mind, he would certainly have considered the dream as a reality, and believed that, instead of having dreamed of the things on which his imagination dwelt, he had actually seen his servant return from the dead, and heard him deliver the message. But on the other hand, the captain, though he believed the dream was prophetic, mentioned it without any signs of fear; and no man of courage and reflection ever sees an apparition. This sight is reserved for the weak, the timid, and the superstitious. Of this many instances might be mentioned.

3. Spectres are also sometimes occasioned by opium. Gassendi the philosopher found a number of people going to put a man to death for having intercourse with the devil; a crime which the poor wretch readily acknowledged. Gassendi begged of the people that they would permit him first to examine the wizard before putting him to death. They did so; and Gassendi, upon examination, found that the man firmly believed himself guilty of this impossible crime. He even offered to Gassendi to introduce him to the devil. The philosopher agreed; and when midnight came, the man gave him a pill, which he said it was necessary to swallow before setting off. Gassendi took the pill, but gave it to his dog. The man having swallowed his, fell into a profound sleep; during which he seemed much agitated by dreams. The dog was affected in a similar manner. When the man awoke, he congratulated Gassendi on the favourable reception he had met with from his sable highness. It was with difficulty Gassendi convinced him that the whole was a dream, the effect of soporific medicines, and that he had never stirred from one spot during the whole night.

4. That diseases, especially the night-mare, the hypochondria, hysterical passion, and madness, are another source of spectres, we have the strongest reason to affirm. Persons subject to the night-mare often imagine that they see spectres. This is still more the case with hypochondriac and hysterical persons, and those who are in any degree deranged in their intellects. A fact which fell within the observation of the writer of this article will both prove and illustrate this assertion. In a village in one of the midland counties of Scotland, lived a widow distinguished among her neighbours for decency of manners, integrity, and respect for religion. She affirmed, that for several nights together she had heard a supernatural voice exclaiming aloud, Murder! murder! This was immediately reported through the neighbourhood; all were alarmed, and looked around them with solicitude for the detection of the murder which they supposed to have been committed; and it was not long till a discovery seemed actually to be made. It was reported, that a gentleman, who had relations at no great distance, and had been residing in the West Indies, had lately arrived with a considerable fortune; that he had lodged in an inn about three miles off; and that he had afterwards been seen entering a house in the village where the widow lived, from which he had never returned. It was next affirmed, that a tradesman passing the churchyard about twelve at midnight had seen four men carry a dead corpse into that cemetery. These three facts being joined together seemed perfectly to agree and to confirm one another, and all believed some horrible murder had been committed. The relations of the gentleman thought they were called upon to make inquiry into the truth of these allegations: they accordingly came first to the churchyard, where, in company with the sexton, they examined all the graves with great care, in order to discover whether any of them had been lately dug, or had the appearance of containing more than one coffin. But this search was to no purpose, for no alteration had been made upon the graves. It was next reported that the murdered man had been buried in a plantation about a mile distant from the village. As the alarm was now very general, a number of the inhabitants proposed of their own accord to explore it. They accordingly spread themselves over the wood; and searched it with care, but no grave nor new dug earth was found. The writer of this article, who was then a boy at school, was along with them. The matter
S P E S

S P E

Spectre did not rest here: The person who was said to have seen four men carry a dead corpse into the churchyard at midnight was summoned to appear before a meeting of the justices of the peace. Upon examination he denied any knowledge of the affair, but referred the court to another person from whom he had received his information. This person was examined, and the result was the same as the former. In short, one person had heard it from another, who had received it from a third, who had heard it from a fourth; but it had received a little embellishment from every person who repeated it. It turned out to be the same with Smollett's story of the three black crows, which some body was said to have vomited.

Upon inquiry at the inn where the West Indian gentleman had lodged, no such gentleman had been seen there. It was found afterwards he had never left the West Indies. Still, however, the veracity of the widow was not disputed; and some dark and secret transaction was suspected. But the whole affair was at length explained by discovering that she was somewhat deranged by melancholy. And the cries which she had at first imagined she had heard were afterwards imitated by some Roguish person, who was highly amused with spreading terror among the credulous.

5. Drunkenness also has the power of creating spectres. Its natural effect in most cases is to derange the understanding, to throw it off its guard, and to give full scope to that passion which has a natural disposition to gain an ascendency; and sometimes excites passions which scarcely seem to exist at any other time. It makes some men licentious, some furious, some all benevolence and kindness, some from being cowards it renders undaunted heroes. It seldom, if ever, excites fear; and therefore it may be thought strange that men should imagine they see ghosts when intoxicated. But it must be remarked, that the ghosts which the drunkard sees, he sees not with the same alarm and terror as men who are sober. He is not afraid of them. He has the courage to converse with them, and even to fight with them, if they give him provocation. A man returning home intoxicated, affirmed that he had met with the devil, and that after a severe encounter, he had vanquished him and brought him to the ground, to which he had nailed him fast by driving his staff through his body. Next morning the staff was found stuck with great violence into a heap of turf.

6. Many apparitions of spectres have no other origin than the artifices of the waggish or self-interested. Dr Plot, in his Natural History of Oxfordshire, relates a marvellous story, which will illustrate this assertion. Soon after the murder of King Charles I., a commission was appointed to survey the king's house at Woodstock, with the manor, park, woods, and other demesnes to that manor belonging; and one Callins, under a feigned name, hired himself as secretary to the commissioners, who, upon the 13th of October 1649, met, and took up their residence in the king's own rooms. His majesty's bed-chamber they made their kitchen, the council hall their pantry, and the presence-chamber was the place where they sat for the dispatch of business. His majesty's dining-room they made their wood yard, and stored it with the wood of the famous royal-oak from the High Park, which, that nothing might be left with the name of king about it, they had dug up by the roots, and split and bundled up into faggots for their firing. Things being thus prepared, they sat on the 15th of the same month for the dispatch of business; and in the midst of their first debate there entered a large black dog (as they thought), which made a dreadful barking, overturned two or three of their chairs, and then crept under a bed and vanished. This gave them the greater surprise, as the doors were kept constantly locked, so that no real dog could get in or out. The next day their surprise was increased, when sitting at dinner in a lower room, they heard plainly the noise of persons walking over her heads, though they well knew the doors were all locked, and there could be no body there. Presently after they heard also all the wood of the king's oak brought by parcels from the dining-room, and thrown with great violence into the presence chamber; as also all the chairs, stools, tables, and other furniture, forcibly hurried about the room; their papers, containing the minutes of their transactions were torn, and the ink-glass broken. When all this noise had ceased, Giles Sharp, their secretary, proposed to enter first into these rooms; and in presence of the commissioners, from whom he received the key, he opened the doors, and found the wood spread about the room, the chairs tossed about and broken, the papers torn, the ink-glass broken (as has been said, but not the least track of any human creature, nor the least reason to suspect one, as the doors were all fast, and the keys in the custody of the commissioners. It was therefore unanimously agreed, that the power who did this mischief must have entered the room at the key-hole. The night following, Sharp the secretary, with two of the commissioners' servants, as they were in bed in the same room, which room was contiguous to that where the commissioners lay, had their bed's feet lifted up so much higher than their heads that they expected to have their necks broken, and then they were let fall at once with so much violence as shook the whole house, and more than ever terrified the commissioners. On the night of the 19th, as all were in bed in the same room for greater safety, and lights burning by them, the candles in an instant went out with a sulphureous smell, and that moment many terrors of wood were hurled about the room, which next morning were found to be the same their honours had eaten on the day before, which were all removed from the pantry, though not a lock was found opened in the whole house. The next night they fared still worse; the candles went out as before, the curtains of their honours beds were rattled to and fro with great violence; their honours received many cruel blows and bruises, by eight great pewter-dishes and a number of wooden terrors being thrown on their beds, which being heard off, were heard rolling about the room, though in the morning none of these were to be seen. This night likewise they were afraid with the tumbling down of oaken billets about their beds, and other frightful noises; but all was clear in the morning, as if no such thing happened. The next night the keeper of the king's house and his dog lay in the commissioners room, and then they had no disturbance. But on the night of the 22d, though the dog lay in the room as before, yet the candles went out, a number of brick-bats fell from the chimney into the room, the dog howled piteously, their bed-clothes were all stripped off, and their terror increased. On the 24th,
24th they thought all the wood of the king's oak was violently thrown down by their bed sides; they counted 64 billets that fell, and some hit and shook the beds in which they lay; but in the morning none were found there, nor had the door been opened where the billet wood was kept. The next night the candles were put out, the curtains rattled, and a dreadful crack like thunder was heard; and one of the servants running in haste, thinking his master was killed, found three dozen of trenchers laid smoothly under the quilt by him. But all this was nothing to what succeeded afterwards: The 29th, about midnight, the candles went out, something walked majestically through the room, and opened and shut the windows; great stones were thrown violently into the room, some of which fell on the beds, others on the floor; and at about a quarter after one a noise was heard as of forty cannon discharged together, and again repeated at about eight minutes distance. This alarmed and raised all the neighbourhood, who coming into their honours room, gathered up the great stones, fourscore in number, and laid them by in the corner of a field, where, in Dr Plot's time, who reports this story, they were to be seen. This noise, like the discharge of cannon, was heard through all the country for 16 miles round. During these noises, which were heard in both rooms together, the commissioners and their servants gave one another over for lost, and cried out for help; and Giles Sharp, snatching up a sword, had well nigh killed one of their honours, mistaking him for the spirit, as he came in his shirt from his own room to theirs. While they were together, the noise was continued, and part of the tiling of the house was stript off, and all the windows of an upper room were taken away with it. On the 30th at midnight something walked into the chamber treading like a bear; it walked many times about, then threw the warming-pan violently on the floor; at the same time a large quantity of broken glass, accompanied with great stones and horses bones, came pouring into the room with uncommon force. These were all found in the morning to the astonishment and terror of the commissioners, who were yet determined to go on with their business. But on the first of November the most dreadful scene of all ensued: Candles in every part of the room were lighted up and great fires made; at midnight, the candles all yet burning, a noise like the bursting of a cannon was heard in the room, and the burning billets were tossed about by it even into their honours beds; who called Giles and his companions to their relief, otherwise the house had been burnt to the ground; about an hour after the candles went out as usual, the crack as if many cannon was heard, and many patills of green stinking water were thrown upon their honours beds; great stones were also thrown in as before, the bed curtains and bedsteads torn and broken, the windows shattered, and the whole neighbourhood alarmed with the most dreadful noises; nay, the very rabbit-stealers that were abroad that night in the warren were so terrified, that they fled for fear and left their ferrets behind them. One of their honours this night spoke, and, in the name of God, asked what it was, and why it disturbed them so? No answer was given to this; but the noise ceased for a while, when the spirit came again; and, as they all agreed, brought with it seven devils worse than itself. One of the servants now lighted a large candle, and set it in the door-way between the two chambers, to see what passed; and as he watched it, he plainly saw a hoof striking the candle and candlestick into the middle of the room, and afterwards making three scrapes over the stuff, scraped it out. Upon this the same person was so bold as to draw a sword; but he had scarce got it out when he felt another invisible hand holding it too, and pulling it from him; and at length prevailing, struck him so violently on the head with the pummel, that he fell down for dead with the blow. At this instant was heard another burst like the discharge of the broadside of a ship of war, and at about a minute or two's distance each no less than 19 more such: these shook the house so violently, that they expected every moment it would fall upon their heads. The neighbours, on this, as has been said, being all alarmed, flocked to the house in great numbers, and all joined in prayer and psalm singing; during which the noise still continued in the other rooms, and the discharge of cannons was heard as from without, though no visible agency was seen to discharge them. But what was the most alarming of all, and put an end to their proceedings effectually, happened the next day as they were all at dinner, when a paper, in which they had signed a mutual agreement to reserve a part of the premises out of the general survey, and afterwards to share it equally amongst themselves, (which paper they had hid for the present under the earth in a pot in one corner of the room, and in which an orange-tree grew), was consumed in a wonderful manner, by the earth's taking fire with which the pot was filled, and burning violently with a blue fume, and an intolerable stench; so that they were all driven out of the house, to which they could never again be prevailed upon to return.

This wonderful contrivance was all the invention of the memorable Joseph Collins of Oxford, otherwise called Funny Joe, who having hired himself as secretary, under the name of Giles Sharp, by knowing the private traps belonging to the house, and the help of pulvis fulminans and other chemical preparations, and letting his fellow-servants into the scheme, carried on the deceit without discovery to the very last; insomuch that the Dr Plot, in his Natural History, relates the whole for fact, with the name of Natural in this grave manner, "That though tricks have been often played in affairs of this kind, many of the things above related are not reconcileable with juggling; such as the loud noises, beyond the power of man to make without such instruments as were not there; the tearing and breaking the beds; the throwing about the fire; the hoof treading out the candle; and the striving for the sword, and the blow the man received from the pummel of it."

Spectre of the Broken, a singular phenomenon observed on the top of the Broken, one of the Hartz mountains in Hanover, of which M. Haue has given the following account. "After having been here (says he) for the thirtieth time, and having procured information respecting the above-mentioned atmospheric phenomenon, I was at length, on the 23rd of May 1797, so fortunate as to have the pleasure of seeing it; and perhaps my description may afford satisfaction to others who visit the Broken through curiosity. The sun rose about four o'clock, and, the atmosphere being quite serene towards the east, his rays could pass without any obstruction over the Heinrichslohe. In the south-west, however,
ever, towards Achtermannshöhe, a brisk west wind carried before it thin transparent vapours, which were not yet condensed into thick heavy clouds.

"About a quarter past four I went towards the inn, and looked round to see whether the atmosphere would permit me to have a free prospect to the south-west; when I observed, at a very great distance towards Achtermannshöhe, a human figure of a monstrous size. A violent gust of wind having almost carried away my hat, I clapped my hand to it by moving my arm towards my head, and the colossal figure did the same.

"The pleasure which I felt on this discovery can hardly be described; for I had already walked many a weary step in the hopes of seeing this shadowy image, without being able to gratify my curiosity. I immediately made another movement by bending my body, and the colossal figure before me repeated it. I was desirous of doing the same thing once more—but my colossal had vanished. I remained in the same position, waiting to see whether it would return; and in a few minutes it again made its appearance on the Achtermannshöhe. I paid my respects to it a second time, and it did the same to me. I then called the landlord of the Broken; and having both taken the same position which I had taken alone, we looked towards the Achtermannshohe, but saw nothing. We had not, however, stood long, when two such colossal figures were formed over the above eminence, which repeated our compliments by bending their bodies as we did; after which they vanished. We retained our position; kept our eyes fixed on the same spot, and in a little the two figures again stood before us, and were joined by a third. Every movement that we made by bending our bodies these figures imitated—but with this difference, that the phenomenon was sometimes weak and faint, sometimes strong and well defined. Having thus had an opportunity of discovering the whole secret of this phenomenon, I can give the following information to such of my readers as may be desirous of seeing it themselves. When the rising sun, and according to analogy the case will be the same at the setting sun, throws his rays over the Broken upon the body of a man standing opposite to fine light clouds floating around or hovering past him, he needs only fix his eyes steadily upon them, and, in all probability, he will see the same far spectacle of his own shadow extending to the length of five or six hundred feet, at the distance of about two miles before him."

**SPECULARIS LAPIS**, composed of large plates of extreme thinness. (See Talc, Mineralogy Index).

The white variety with large and broad leaves, commonly called isinglass and Muscovy glass, is imported in great quantities; the miniature-painters cover their pictures with it; the lantern-makers sometimes use it instead of horn; and minute objects are usually preserved between two plates of it, for examination by the microscope.

**SPECULATIVE**, something relating to the theory of some art or science, in contradistinction to practical.

**SPECULUM** for reflecting telescopes, is made of a kind of white copper consisting of 32 parts fine red copper, one of brass, 15 of grain-tin, and three of white arsenic. The process given by the late J. Edwards, who was rewarded by the Board of Longitude for disclosing it to the public, was published in the Speculum. Nautical Almanack for 1787, and is as follows: Melt the copper in a large crucible, employing some black flux, composed of two parts of tartar and one of nitre: when melted, add to it the brass and the silver. Let the pure tin be melted in another crucible, also with some black flux. Take them both from the fire, and pour the melted tin into the fused mass in the large crucible. Stir the whole well with a dry spatula of birch, and pour off the fused metal immediately into a large quantity of cold water. The sudden chill of the water will cause the fluid metal to divide into an infinite number of small particles, which will cool instantly.

If the copper be completely saturated, the fracture of one piece of this mixed metal will appear bright, and of a glossy look, resembling the face of pure quicksilver. But if it is of a brown reddish colour, it wants a little more tin. To ascertain the required proportion, melt a small quantity, known by weight, of the mixed metal, with a known very small part of tin; and, if necessary, repeat the trial with different doses, till the fracture of the new mixture looks as already described. Having now ascertained the necessary addition of tin that is required, proceed to the last melting of the whole metal, together with the additional proportional dose of tin; fuse the whole, observing the same caution as before; and you will find that the mixture will melt with a much less heat than that for the first fusion. Have ready as many ounces of white arsenic in coarse powder as there are pounds in the weight of the metal; wrap up the arsenic in a small paper, and put it, with a pair of tongs, into the crucible; stir it well with the spatula, retaining the breath to avoid the arsenical fumes or vapours (which however are not found to be hurtful to the lungs) till they disappear; take the crucible off the fire, clear away the dross from the top of the metal, pour in about one ounce of powdered resin, with as much nitre, in order to give the metal a clean surface, and pour out the metal into the moulded flasks.

The speculum should be moulded with the concave surface downwards, and many small holes should be made through the sand upwards, to discharge the air. The moulding sand from Higgin's near London, used by the founders, is as good as any for casting these metallic mirrors. The cast metal should be taken out from the sand of the flasks whilst it is hot, or else it may happen to crack if left to cool within. See Telescope.

But in addition to what has now been said, we must notice some other information relative to the grinding, polishing, and other important circumstances connected with the method of preparing the most perfect speculum for telescopes. The metal being taken out of the flask, as already noticed, and this should be done as soon as it has become solid, and while it is yet red hot, care must be taken to keep the face downwards to prevent it from sinking. Holding it in that position by the girt, force out the sand from the hole in the middle of the mirror with a piece of wood or iron, and place the speculum in an iron pot, with a large quantity of hot ashes or small coals, so as to bury the speculum in them a sufficient depth. If the sand is not forced out of the hole in the manner above directed, the metal, by sinking as it cools,
will embrace the sand in the middle of the speculum so
tight, as to cause it to crack before it becomes entirely
cold. And if the metal be not taken out of the sand,
and put in a pot with hot ashes or coals to anneal it, the
moisture from the sand will always break the metal. Let
the speculum remain in the ashes till the whole is be-
come quite cold. The grit may be easily taken off by
marking it round with a common fine half round file,
and giving it then a gentle blow. The metal is then to
be rough ground and figured.

But before we proceed to describe that process,
it may be proper to give an account of another com-
position for the speculum of a reflecting telescope,
which has been employed with great success, by Rochon
director of the marine observatory at Brest. Of this
composition the principal ingredient is platina; which,
in grains, must be purified in a strong fire by means of
nitre and the salt of glass, or that flux which in the
English glass-houses is called by the workmen sandifer.
To the platina, when purified, add the eighth part
of the metal employed in the composition of common
specula; for tin without red copper would not produce
a good effect. This mixture is then to be exposed to
the most violent heat, which must be still excited by
the oxygen gas that dissolves itself from nitre when
thrown into the fire. One melting would be insuffi-
cient: five or six are requisite to bring the mixture to
perfection. It is necessary that the metal should be in
a state of complete fusion at the moment when it is
poured into the mould. By this process I have been
enabled (says the author) to construct a telescope with
platina, which magnifies the diameters of objects five
hundred times, with a degree of clearness and distinct-
ness requisite for the nicest observations. The large
speculum of platina weighs fourteen pounds: it is eight
inches in diameter, and its focus is six feet. Though
the high price of platina will, in all probability, for
ever prevent it from coming into general use for the
specula of telescopes, we thought it proper to notice
this discovery, and shall now proceed to the grinding of
the speculum.

For accomplishing this object, a very complicated
process is recommended in Smith's Optics, and one not
much more simple, by Mr Mudge in the 6th volume
of the Philosophical Transactions; but according to
Mr Edwards, whose specula are confessedly the best,
neither of these is necessary. Besides a common grind-
stone, all the tools that he made use of are a rough
grinder, which serves also as a polisher, and a bed of
hones. When the speculum was cold, he grinds its
surface bright on a common grindstone, previously
brought to the form of the gage; and then took it to
the rough grinder.

The tool is composed of a mixture of lead and tin,
or of pewter, and is made of an elliptical form, of such
dimensions, that the shortest diameter of the ellipse is
equal to the diameter of the mirror or speculum, and
the longest diameter is to the shortest in the proportion
of ten to nine. This rough grinder may be fixed upon
a block of wood, in order to raise it higher from the
bench; and as the metal is ground upon it with fine
emery, Mr Mudge, with whom, in this particular, Mr
Edwards agrees, directs a hole or pit to be made in
the middle of it as a lodgement for the emery, and deep
grooves to be cut out across its surface with a graver

for the same purpose. By means of a handle fixed on
Speculum,
the back of the metal with soft cement, the speculum
can be whirled round upon this grinder so rapidly, that
a common labourer has been known to give a piece
of metal, four inches in diameter, so good a face and figure
as to fit it for the horns in the space of two hours. The
emery, however fine, will break up the metal very much;
but that is remedied by the subsequent process of hon-
ing and polishing.

When the metal is brought to a true figure, it must
be taken to a convex tool, formed of some stones from
a place called Edgedon in Shropshire, situated between
Ludlow and Bishop's Castle. The common blue hones,
used by many opticians for this purpose, will scarcely
touch the metal of Mr. Edwards's specula; but where
they must be employed for want of the others, as little
water should be used as possible when the metal is put
upon them; because it is found by experience that they
cut better when but barely wet, than when drenched
with water. The stones, however, from Edgedon are
greatly preferable; for they cut the metal more easi-
ly, and having a very fine grain, they bring it to a smooth
face. These stones are directed by Mr Mudge to be
cemented in small pieces upon a thick round piece of
marble, or of metal made of tin and lead like the former
composition, in such a manner, that the lines between
the stones may run straight from one side to the other;
so that placing the teeth of a very fine saw in each of
these divisions, they may be cleared from one end to
the other of the cement which rises between the stones.
As soon as the hones are cemented down, this tool
must be fixed in the lathe, and turned as exactly true
to the gage as possible. It should be of a circular fig-
ure, and but very little larger than the metal intended
to be figured upon it. If it be made considerably lar-
ger, it will grind the metal into a larger sphere and a
bad figure; and if it be made exactly of the same size,
it will work the metal indeed into a figure truly spheri-
cal, but will be apt to shorten its focus, unless the met-
tal and tool be worked alternately upwards. On these
accounts Mr. Edwards recommends it to be made about
one twentieth part longer in diameter than the speculum,
because he has found that it does not then alter its fo-
cus; and he earnestly dissuades the use of much water
on the hone pavement at the time of using it, otherwise,
he says, that the metal in different parts of it will be of
different degrees of brightness.

The metal being brought to a very fine face and
figure by the bed of stones, is ready to receive a polish,
which is given to it by the elliptical rough grinder
covered with pitch. With respect to the consistencey
of this pitch, Mr Mudge and Mr Edwards give very dif-
ferent directions. Whilst the former says that it should
be neither too hard nor too soft, the latter affirms that
the harder the pitch is, the better figure it will give
to the metal. Pitch may be easily made of a sufficient
hardness by adding a proper quantity of rosin; and
when it is hardened in this way, it is not so brittle as
pitch alone, which is hardened by boiling. Mr Ed-
wards advises to make the mixture just so hard as to
receive, when cold, an impression from a moderate pres-
sure of the nail of one's finger. When the elliptical
tool is to be covered with this mixture, it must be made
pretty warm, and in that state have the mixture poured
upon it when beginning to cool in the crucible. Our
author
the mirror, Mr Edwards assures us, that a very little Speculum experience in these matters will enable any one to give it with certainty, by polishing the speculum in the common manner, only with cross strokes in every direction, upon an elliptical tool of the proper dimensions.

Speculum, a looking-glass or mirror, capable of reflecting the rays of the sun.

Speculum, in Surgery, an instrument for dilating a wound, or the like, in order to examine it attentively. See SURGERY.

SPEECH, in general, the art or act of expressing a person's thoughts by means of articulate sounds, which we call words. See LANGUAGE, GRAMMAR, READING, and ORATORY, Part IV.

SPEED, John, an English historian, was born at Farington, in Cheshire, in the year 1542. He was by profession a tailor, and Freeman of the company of merchant tailors in the city of London. In 1606, he published his Theatre of Great Britain, which was afterwards reprinted in folio, under the title of the Theatre of the Empire of Great Britain. His genealogies of Scripture were first bound up with the Bible in 1611, when the first edition of the present translation was printed. In 1614 appeared his History of Great Britain, which has been translated into Latin; and in 1616 he published his Cloud of Witnesses, in octavo. He lived in marriage 37 years with his wife, by whom he had twelve sons and six daughters; and died in 1639. He was interred in the church of St Giles's, Cripplegate, London, where a monument was erected to his memory.

SPEEDWELL. See VERONICA, BOTANY Index.

SPELL, a charm consisting of some words of occult power, generally attended with some ceremony. In order to explain it, we will produce a few examples. On St Agnes's night, 21st of January, take a row of pins, and pull out every one, one after another, saying a Pater-noster on sticking a pin in your sleeve, and you will dream of him or her you shall marry.

Another method to see a future spouse in a dream. (Grose's.) The party inquiring must lie in a different county from that in which he commonly resides, and on going to bed must knit the left garter about the right-legged stocking, letting the other garter and stocking alone; and as he rehearse the following verses, at every comma, knit a knot:

This knot I knit,
To know the thing I know not yet;
That I may see
The man (woman) that shall my husband (wife) be;
How he goes, and what he wears,
And what he does all days and years.

Accordingly, in a dream, he will appear with the insignia of his trade or profession.

Another, performed by charming the moon, thus: At the first appearance of the new moon, immediately after the new year's day, (though some say any other new moon is as good), go out in the evening, and stand over the spars or a gate or stile, and, looking on the moon, repeat the following lines:

All hail to the moon! all hail to thee!
I prithee, good moon, reveal to me
This night who my husband (wife) must be.
Immediately after you must go to bed, when you will dream of the person destined for your future husband or wife.

SPELLING, in Grammar, that part of orthography which teaches the true manner of resolving words into their syllables.

All words are either simple or compound, as use, devise; done, undone; and the rules for dividing each must be such as are derived from the analogy of language in general, or from the established custom of speaking; which, for the English language, are reduced to the following rules: 1. A consonant between two vowels must be joined with the letter in spelling, as na-ture, ve-ri-ty, ge-ne-rous; except, however, the letter y, which is joined to the first, as in fly, ox-en, &c. and compound words, as in up-on, un-used, &c.

2. A double consonant must be divided, as in letter, man-ner, &c.

3. Those consonants which can begin a word, must not be parted in spelling, as in de-fraud, re-prove, di-stinct; however, this rule is found sometimes to fail; for though gn begins a word, as gnaw, gnat, &c. yet it must be divided in spelling, as in ro-gni-ance, ma-lig-ni-ty, &c.

4. Those consonants which cannot begin a word must be divided, as ld in seldom, lt in mut-ti-ude, mp in temper, rd in ar-dent; but in final syllables there are exceptions, as tl in tit-le, dl in handle, &c.

When two vowels come together, and are both of them distinctly sounded, they must be separated in spelling, as in co-ol, mu-ta-l, &c.

6. The grammatical terminations or endings must be separated in spelling, as ed in wing-ed, ets in de-fi-er-est, ing in hear-ing, once in de-fi-er-once, &c.

7. Compound words must be resolved into their simple or component words, as up-on, in-to, ne-er-the-less, not-with-stand- ing, &c.

SPelman, Sir Henry, an eminent English antiquarian, was descended from an ancient family, and born at Cengnam, near Lynn in Norfolk, about the year 1561. He was knighted by King James I., who had a particular esteem for him on account of his known capacity for business; and he employed him several times in Ireland on public affairs. When he was about 50 years of age, he went to reside in London; where falling into a study to which his own genius had always inclined him, he collected all such books and MSS. as concerned the subject of antiquities, either foreign or domestic. In 1620, he published the first part of his well-known Glossary, which he never carried beyond the letter L; because, as some have suggested, he had said things under "Magna charta," and "Maximunm consilium," that could not then have appeared without giving offence. Upon his death all his papers came into the hands of his son Sir John Spelman, a gentleman who had abilities to have completed his father's design, if death had not prevented him. The second part was afterwards published by Sir William Dugdale; but with all the marks of a scanty unfinished performance. The next work he entered upon was an edition of the English Councils, of which he published the first volume about two years before his death, leaving the second volume, as well as all of this as of his Glossary, to be published by Sir William Dugdale. Sir Henry wrote several other things, all relating to ancient laws and customs, and died in 1641. His Posthumous Works were published in folio, 1698, under the inspection of Mr. Gibson, afterwards bishop of London.

SPELTER, in Metallurgy, the same with Zinc.

SPENCE, Joseph, an eminent writer, was fellow of New College, Oxford, where he took the degree of A.M. in 1727. About that time he became first known as an author, by an Essay on Pope's Odyssey, in which some particular beauties and blemishes of that work are considered; a work of great merit, and which for sound criticism and candid disquisition is almost without a parallel. He was elected professor of poetry by the university in 1728, and held that office ten years, which is as long as the statutes will allow. His History of Stephen Duck was first published in 1731; but it was afterwards much altered, and prefixed to an edition of Duck's poems.

About this time he travelled into Italy as tutor to the earl of Lincoln, afterwards duke of Newcastle. In 1736 he republished Gorboduc, at Mr. Pope's desire, with a preface giving an account of the author, the earl of Dorset. He quitted his fellowship in 1742, upon being presented by the Society of New College to the rectory of Great Harwood in Buckinghamshire.

He never resided in his living; but paid it an annual visit, distributing large sums of money among the poor, and providing for many of their children. The same year he was made professor of modern history at Oxford. In 1747 he published Polyneus; or an inquiry concerning the agreement between the works of the Roman poets and the remains of ancient artists, being an attempt to illustrate them mutually from each other. This work was treated by Gray with a contempt which it did not deserve. He raised objections because the author did not illustrate his subject from Greek writers; that is, because he failed to execute what he never undertook. He was installed prebendary of the seventh stall at Durham the 24th May 1754. He published the same year, "An Account of the Life, Character, and Poems, of Mr Blacklock, student of philosophy at Edinburgh," which was afterwards prefixed to his Poems. The prose pieces which he printed in the Museum he collected and published, together with some others, in a pamphlet called Moralia, by Sir Harry Beaumont. Under the same name he published "Crito, or a Dialogue on Beauty," and "A particular Account of the emperor of China's Gardens near Pekin, in a letter from F. Attiret, a French missionary now employed by that emperor to paint the apartments in those gardens, to his friend at Paris." Both these treatises are printed in Dodsley's fugitive pieces, as is also "A Letter from a Swiss Officer to his friend at Rome," which Mr. Spence first published in the Museum. In 1758 he published "A Parallel, in the Manner of Plutarch, between a most celebrated man of Florence and one scarce ever heard of in England." This was also inserted in the fugitive pieces. The same year he made a journey into Scotland, which he described in an affectionate letter to Mr. Shenstone, published in Hall's Collection of Letters, 1778. In 1764 he was very well described by Mr. James Ridgway in his admirable Tales of the Genii, under the name of Phoebus Ecreupe (his name read backwards), devise of the groves. A letter from Mr. Spence to that ingenious moralist, under the same signature, is preserved in the 3d volume of "Letters
S P E

ners of Eminent Persons." In 1768 he published "Remarks and Dissertations on Virgil, with some other classical observations, by the late Mr Holdsworth." On the 20th of August the same year he was unfortunately drowned in a canal in his garden at Byfleet in Surrey. He was found flat upon his face at the edge of the canal, where the water was so shallow as not even to cover his head. The accident, it was supposed, for he was quite alone, was owing to a fit.

The duke of Newcastle possesses some manuscript volumes of anecdotes collected by Mr Spence, from which Dr Johnson was permitted to insert many extracts in his Lives of the Poets.

S P E N C E R, DR. JOHN, an eminent divine, was born in Kent in 1630, and educated at Cambridge. He was chosen fellow of his college, and took a doctor's degree in 1663. In 1667 he was chosen master of Corpus Christi College, and preferred to the deanery of Ely in 1677. He died on the 20th of May 1695. His works are: 1. The Righteous Ruler; a Sermon on Proverbs xxix. 2. preached June 28. 1660. 2. A Discourse concerning Prodigies, wherein the vanity of presages by them is reprehended, and their true and proper ends asserted and vindicated. To this excellent work was afterwards added, A Discourse concerning vulgar prophecies, wherein the vanity of receiving them as the certain indications of any future event is exposed; and some marks of distinction between true and pretended prophets are laid down. 3. A Latin dissertation concerning Urim and Thummim. 4. His famous treatise De legibus Hebraeorum ritualibus et eorum rationibus. The intention of this book, as he informs us himself, was to vindicate the Deity from the imputation of acting from arbitrary and fantastical motives. It has been highly and justly esteemed both for the elegance of style and the uncommon erudition and sound sense which it displays. It has, however, (that part of it particularly which endeavours to deduce some of the Jewish ceremonies from the practices of their heathen neighbours), alarmed many persons, as if such a doctrine, if it could be proved, would derogate from the Divine wisdom, and undermine revelation. But this is so far from being the case, that Dr Spencer's attempt, whether successful or not, deserves the gratitude of Christians, because it has a tendency to throw light on an important and difficult subject.

S P E N C E R, EDMUND, the poet, was born in London in the year 1553, and descended from an ancient family of the Spencers in Northamptonshire. All we know concerning his education is, that he was admitted a sizar of Pembroke hall in Cambridge, and matriculated in 1569. At this time began his intimacy with Mr Gabriel Harvey, a man of genius and a poet. In 1576, having completed his degrees in arts, he left the university, as is conjectured, for want of subsistence, and retired to the north of England. Here he had the misfortune to become enamoured of his Rosalind, who, after flattering his passion for a time, at length preferred his happier rival. Spenser continued in the country till the year 1578, when at the persuasion of his friend Mr Spenser, he removed to London, where that gentleman introduced him to Mr Sidney (afterwards Sir Philip Sidney). Concerning his first introduction to Sir Philip there is indeed a different story, which was first told by the writer of his life, prefixed to his works in 1670, and transcribed by Hughes, Gibber, and several others; which, nevertheless, is certainly not true. The purport of it is, that Spenser, being unknown to this Mecenas of the age, went to Leicester-house, and sent in the 9th canto of the first book of the Fairy Queen, that, on reading part of it, Sir Philip ordered his steward to give the bearer 50l. on reading a little farther 50l. more; then 200l. bidding him to make haste and pay the money, lest he should give the poet his whole estate. The story tells prettily enough; but it is very certain, that the Fairy Queen was begun long after his acquaintance with Sir Philip. By this universal patron of genius, however, he was presented to Queen Elizabeth, who honoured him with the place of poet-laureat. About this time he finished his Shepherd's Calendar, which was first printed in 1579; and in the following year, being recommended by his patron to the earl of Leicester, he went to Ireland as secretary to the lord Grey of Wilton, then appointed lord lieutenant of that kingdom. Lord Grey was recalled in 1582, and with him Spenser returned to London, where he continued till after the death of Sir Philip Sidney in 1586; a loss which he bewailed to the end of his life. The following year, our poet, having obtained a royal grant of 5000 acres of forfeited lands in the county of Cork in Ireland, set out for that kingdom, took possession of his estate, and fixed his residence in the castle of Kildalman, which had belonged to the earl of Desmond. In this retirement he resumed his great work of the Fairy Queen; and continued in Ireland till, being visited by his old friend Sir Walter Raleigh in 1589, he came over with him to England, but returned to Ireland the year following, where he fell in love with a country girl, and married her. Soon after his marriage, he paid another visit to his native country, where we also find him in 1596. In the following year he returned once more to Kildalman; but on the rebellion of Lord Tyrone, who ravaged the whole county of Cork, he was obliged to fly for safety with his family to England, where, in the year 1599, he died in extreme poverty (A). He was buried in Westminster Abbey, according to his request, near Chaucer. A monument was erected to his memory by Ann countess of Dorset. We know but little of his character as a man; as a poet, considering the age in which he lived, he deserves our utmost veneration. He wrote various pieces besides those above mentioned. His whole works, with his life by Hughes, were published in six volumes 12mo, in 1715 and 1755.

S P E N C R U L A, SPURREY, a genus of plants belonging to the class of decandria; and in the natural system 4 E 2 arranged.

(A) This is Camden's account, and it has been generally believed; but Mr Malone, the last editor of Shakespeare's works, by examining the patent roll, 33 Eliz. p. 3, has discovered, that in February 1690-1 Spenser obtained from Queen Elizabeth an annuity or pension of 50l. during his life; a sum equivalent to 225l. at present.
SPE  [588] SPH

Spermula

arranged under the 22d order, Caryophyllaceae. See Botany Index.

S. spermaceti, the seed whereof an animal is formed. See Physiology.

SPERMACETI, a whitish, unctuous, fatty substance, prepared from oil, but chiefly from the brains of a species of whale called Physeter macrocephalus.

The method of preparing spermaceti is kept a secret; but the process is said to be this: The brains being taken out of the animal, are then, as some say, melted over a gentle fire, poured into moulds, and when cold melted again; and this process is continued till they are purified. Others say, that after being pressed and drained, they are more thoroughly purified by steeping them in a lea of alkaline salt and quicklime. The brains are then washed, and cut into thin flakes or slices with wooden knives. One fish is said to afford some tons of brains. Good spermaceti is glossy and semitransparent, in fine white flakes; soft and unctuous to the touch, yet dry and friable; in taste, somewhat like butter, and of a faint smell like that of tallow. Some adulterate it with wax; but the deceit is discovered, either by the smell of the wax or by the dulness of the colour. Some also sold a preparation of oil taken from the tail of the whale instead of that from the brain; but this kind turns yellow as soon as exposed to the air. Indeed it is apt in general to grow yellowish, and to contrast a rancid fishy smell if not carefully secured from the air. The more perfectly it has been purified at first, the less susceptible it is of these alterations; and after it has been changed, it may be rendered white and sweet again by steeping it afresh in a lea of alkaline salt and quicklime. It melts in a small degree of heat, and congeals again as it cools.

Spermaceti is of use in medicine. Quincy says it is a noble remedy in the asthma, &c. Though chiefly used in bruises, inward hurts, and after delivery. For internal use, it may be dissolved in aqueous liquor into the form of an emulsion, by trituration with almonds, the yoke or white of an egg, and more elegantly by mucilages; or made into a lecho, by mixing two drams of it with a suitable quantity of yolk of egg, then adding half an ounce of fresh drawn oil of almonds, and an ounce of balsamic syrup. Spermaceti is not capable of being dissolved by caustic alkalies, and of forming soaps, like other oily matters: but it is altogether soluble in oils, and unites by liquefaction with wax and resins; and in these forms is applied externally. But it is certain, its greatest property, and that which makes it so much in vogue in many places, is its softening the skin. Whence it comes to be used by the ladies in pastes, washes, &c.

Spermaceti candles are of modern manufacture: they are made smooth, with a fine gloss, free from rings and scars, superior to the finest wax candles in colour and lustre: and, when genuine, leave no spot or stain on the finest silk, cloth, or linen.

A method has been lately proposed by Dr Smith Gibbes of Bristol, to covert animal muscle into a substance much resembling spermaceti. The process is remarkably simple: Nothing more is necessary than to take a dead carcasse and expose it to a stream of running water: it will in a short time be changed to a mass of fatty matter. To remove the offensive smell, a quantity of nitrous acid may then be poured upon it, which uniting with the fetid matter, the fat is separated in a pure state. This acid indeed turns it yellow, but it may be rendered white and pure by the action of the oxygenated muriatic acid. Mr Gibbs brought about the same change in a much shorter time. He took three lean pieces of mutton and poured on them the three mineral acids, and he perceived that at the end of three days the flesh was much altered; that in the mean time the acid was much softened, and on separating the acid from it, he found it to be exactly the same with that which he had before got from the water; that in the muriatic acid was not in that time so much altered; the vitriolic acid had turned the other black.

SPERMACOEUS, BOTTLE-WOOD, a genus of plants belonging to the class of tetrandria; and in the natural system arranged under the 47th order, Stellatae. See Botany Index.

SPERMATIC, in Anatomy, something belonging to the sperm or seed.

SPEUSIPPUS, an Athenian philosopher, the nephew and successor of Plato. Contrary to the practice of Plato, Speusippus required from his pupils a stated gratuity. He placed statues of the Graces in the school which Plato had built. On account of his inward state of health, he was commonly carried to and from the academy in a vehicle. On his way thither he one day met Diogenes, and saluted him; the erudite philosopher refused to return the salutation, and told him, that such a feeble wretch ought to be ashamed to live; to which Speusippus replied, that he lived not in his limbs, but in his mind. At length, being wholly incapacitated, by a paralytic stroke, for the duties of the chair, he resigned it to Xenocrates. He is said to have been of a violent temper, fond of pleasures, and exceedingly avaricious. Speusippus wrote many philosophical works, which are now lost, but which Aristotle thought sufficiently valuable to purchase at the ex pense of three talents. From the few fragments which remain of his philosophy, it appears that he adhered very strictly to the doctrine of his master.

SPEY, a river of Scotland, rising from a lake of the same name in Badenoch, and, after a serpentine course of 76 miles, passes by Rothie castle, and falls into the German sea at Garnock near Elgin. Mr Pennant tells us, that the Spey is a dangerous neighbour to Castle Gordon, overflowing frequently in a dreadful manner, as appears by its ravages far beyond its banks. The bed of the river is wide and full of gravel, and the channel very shifting. In 1746 the duke of Cumberland passed this river at St. Mary church near Castle Gordon, when the channel was so deep as to take an officer, from whom Mr Pennant had the account, and who was six feet four inches high, up to the breast. The banks are here very high and steep; so that had not the rebels been infatuated in such a manner as to neglect opposition, the passage must have been attended with considerable loss. On this river there is a great salmonfishery; about 1700 barrels full are caught in the season, and the shore was formerly rented for about 1200l. per annum: now it is probably doubled.

SPHACELUS, in Surgery and Medicine, an absolute and perfect corruption or death of the parts.

SPHÆRANTHUS, a genus of plants belonging to
the class of syngenesia, and to the order of polygamia segregata; and in the natural system arranged under the 49th order, Compositae. See Botany Index.

SPHAGNUM, Bog-moss, a genus of plants belonging to the class of cryptogamia and order of musci. See Botany Index.

SPHENOIDES, the seventh bone of the cranium or skull. See Anatomy, No. 11.

SPHERE, is a solid contained under one uniform round surface, every point of which is equally distant from a certain point in the middle called its centre; and is formed by the revolution of a semicircle about its diameter. See Geometry.

Projection of the Sphere. See Projection.

Sphere, in Astronomy, that concave orb or expanse which invests our globe, and in which the heavenly bodies appear to be fixed, and at an equal distance from the eye.

The better to determine the places of the heavenly bodies in the sphere, several circles are supposed to be described on the surface thereof, hence called the circles of the sphere: of these some are called great circles, as the equinocial, ecliptic, meridian, &c. and others small circles, as the tropica, parallele, &c. See Geography; and Astronomy, passim.

Armillary Sphere. See Geography.

Sphere of Activity of a Body, is that determinate space or extent to which, and no farther, the effluvia continually emitted from that body reach; and where they operate according to their nature.

SPHERES, in Optics, the same with metallic mirrors, for telescopes or other purposes. See Mirror.

SPHEROID, in Geometry, a solid approaching to the figure of a sphere. It is generated by the entire revolution of a semi-ellipsoid about its axis. When the revolution is made round the largest axis, the spheroid is called prolate; and when round the shortest, oblate. This last is the figure of the earth, and probably of all the planets.

SPHEX, Ichneumon Wasp, or Savage; a genus of insects belonging to the order of hymenoptera. See Entomology Index.

SPHINCTER, in Anatomy, a term applied to a kind of circular muscles, or muscles in form of rings, which serve to close and draw up several orifices of the body, and prevent the excretion of the contents.

SPHINX, in fabulous history, a monster which had the head and breasts of a woman, the body of a dog, the tail of a serpent, the wings of a bird, the paws of a lion, and a human voice. It sprang from the union of Orthos with the Chimera, or of Typhon with Echidna. The Sphinx had been sent into the neighbourhood of Thebes by Juno, who wished to punish the family of Cadmus, which she persecuted with immortal hatred, and it laid this part of Boceia under continual alarms, by proposing enigmas, and devouring the inhabitants, if unable to explain them. In the midst of their consternation the Thebans were told by the oracle, that the sphinx would destroy herself as soon as one of the enigmas she proposed was explained. In this enigma she wished to know what animal walked on four legs in the morning, two at noon, and three in the evening. Upon this Creon king of Thebes promised his crown and his sister Jocasta in marriage to him who could deliver his country from the monster by a successful explanation of the enigma. It was at last happily explained by Oedipus, who observed, that man walked on his hands and feet when young, or in the morning of life; at the noon of life he walked erect; and in the evening of his days he supported his infirmities upon a stick. (Vid. Oedipus.) The sphinx no sooner heard this explanation than she dashed her head against a rock, and immediately expired. Some mythologists were to unridge the fabulous traditions about the sphinx by the assertion that one of the daughters of Cadmus, or Latus, infested the country of Thebes by her continual depredations, because she had been refused a part of her father's possessions. The lion's paw expressed, as they observe, her cruelty, the body of the dog her lasciviousness, her enigma the snares she laid for strangers and travellers, and her wings the dispatch she used in her expeditions.

Among the Egyptians the sphinx was the symbol of religion, by reason of the obscurity of its mysteries: and on the same account the Romans placed a sphinx in the pronoa or porch of their temples. Sphinxes were used by the Egyptians to show the beginning of the water's rising in the Nile: with this view, as it had the head of a woman and body of a lion, it signified that the Nile began to swell in the months of July and August, when the sun passes through the signs of Leo and Virgo. There are several of these still to be seen; one in particular, near the pyramids, much spoken of by the ancients; being of a prodigious size, and cut out of the rock; the head and neck appear only at present, the rest of the body being hid in the sand. This, according to Tixedo, is 26 feet high, and 15 feet from the ear to the chin: but Pliny assures us, the head was no less than 102 feet in circumference, and 62 feet high from the belly, and that the body was 143 feet long, and was thought to be the sepulchre of King Amon.

The learned Mr Bryant observes that the sphinx, seems to have been originally a vast rock of different strata; which, from a shapeless mass, the Egyptians fashioned into an object of beauty and veneration. The Egyptians used this figure in their building; from them the Greeks derived it, and afterwards improved it into an elegant ornament. It is also frequently used in modern architecture.

It is proper to observe, that the sphinx of the Egyptians is said in the Asiatic Researches to have been p. 334. found in India. Colonel Pearse was told by Murari Pandit, a man of learning among the Hindoos, that the sphinx, there called singh, is to appear at the end of the world, and as soon as he is born will prey on an elephant: he is therefore figured seizing an elephant in his claws; and the elephant is made small, to show that the singh, even a moment after his birth, will be very large in proportion to it. But in opposition to this account given by Murari Pandit, the late Sir William Jones, the learned and illustrious president of the Asiatic Society, was assured by several Brahmanas, that the figure taken for a sphinx was a representation of a lion seizing a young elephant. This point therefore requires further investigation.

SPHINX, Hawk-Moth, a genus of insects belonging to the order of lepidoptera. See Entomology Index.

SHOLELIA, Worm-grass, a genus of plants belonging to
longing to the class of pentandria; and in the natural
system arranged under the 47th order, Stellate. See
Botany and Materia Medica Index.

SPICE, any kind of aromatic drug that has hot and
sugant qualities; such as pepper, nutmeg, ginger,
cinnamon, cloves, &c.

SPICE-Islands, in the East Indies. See Banda,
Molucca-Islands, and Ceylon.

SPIDER. See ARANA, Entomology Index.

SPIDERWORT. See PHALANGIUM, Botany

SPIGEL. See ATHAMANTA, Index

SPIKE, or Oil of Spiken, a name given to an essen-
tial oil distilled from lavender, and much used by the
varnish-makers and the painters in enamel.

SPIKENARD. See NARDUS, Botany Index.

SPILANThUS, a genus of plants belonging to the
class of syngecysia. See Botany Index.

SPINA Cervina, an old name for rhannus cathart-
icus. See Rhannus, Botany Index.

SPINA Ventosa, in Surgery, that species of corruption
of the bones which takes its rise in the internal parts,
and by degrees enlarges the bone, and raises it into a
tumor. See Surgery.

SPINACIA, Spinage, a genus of plants belonging to
the class of dicesia; and in the natural system arranged
under the 12th order, Holarc, See Botany

INDEX; and for an account of the method of cultivating
spinage in the garden, see Gardening.

SPINAGE, or Spinach. See Spinacea.

SPINE, in Botany, thorns, rigid prickles: a species
of arma, growing on various parts of certain plants
for their defence: spine termor unct perora. On the
branches we find examples in the pyrus prunus, citrus,
hippophae, gnetina, rhannus, sycamor, &c.; on the
leaves, in the aloe, agave, yucca, ixia, hipppomane,
thephrasta, carlina, &c.; on the calyx, in the carda
nica, centaurea, moluccella, galopsis, &c.; on the
fruit, in the trapa, tribulus, murex, spinacea, agrim-
nonia, datura, &c.

SPINAL MARROW. See Anatomy Index.

SPINALIS, in Anatomy, the name of several muscles,
&c. of the spine.

SPINDE, in Geometry, a solid body generated by
the revolution of some curve line about its base or double
ordinate; in opposition to a conoid, which is generated
by the rotation of the curve about its axis or abscissa,
perpendicular to its ordinate. The spindle is denomi-
nated circular, elliptic, hyperbolic, or parabolical, accord-
ing to the figure of its generating curve.

SPINDE-TREE. See Egonimus, Botany Index.

SPINE, Spina Dorsal. See Anatomy, No. 30.

SPINE. See Pinke.

SPINET, or SPINET, a musical instrument ranked
in the second or third place among harmonious instru-
mements. It consists of a chest or belly made of the
most porous and resinous wood to be found, and a table of
for glued on slips of wood called summers, which bear
the sides. On the table are raised two little promin-
ences or bridges, wherein are placed so many pins as
there are chords or strings to the instrument. It is
played on by two ranges of continued keys, the former
range being the order of the diatonic scale, and that be-
hind the order of the artificial notes or semitones.
The keys are so many flat pieces of wood, which, touched
and pressed down at the end, make the other raise a
jack which strikes and sounds the strings by means of
the end of a crown's quill, wherewith it is armed. The
30 first strings are of brass, the other more delicate ones
of steel or iron-wire; they are all stretched over the
two bridges already mentioned. The figure of the spin-
et is a long square or parallelogram; some call it an
harp couched, and the harp an inverted spinet. See the
article Harp.

This instrument is generally tuned by the ear, which
method of the practical musicians is founded on a sup-
position that the ear is a perfect judge of an octave
and a fifth. The general rule is to begin at a certain note,
as C, taken towards the middle of the instrument, and
turning all the octaves up and down, and also the fifths,
reckoning seven semitones to each fifth, by which means
the whole is tuned. Sometimes to the common or funda-
mental play of the spinet is added another similar one
in unison, and a third in octave to the first, to make the
harmony the fuller; they are either played separately
or together by means of a stop: these are called double
or triple spinets; sometimes a play of violins is added,
by means of a bow, or a few wheels parallel to the keys,
which press the strings and make the sounds last as long
as the musician pleases, and heighten and soften them
more or less, as they are more or less pressed. The
harpischord is a kind of spinet, only with another dispo-
nition of the keys (see the article Harpischord).
The instrument takes its name from the small quill one
which touch the strings, resembling spina or thorns.

SPINIFEX, a genus of plants belonging to the class
of polygamius. See Botany Index.

SPINNING, in Commerce, the act or art of redu-
cing silk, flax, hemp, wool, hair or other matters, into
thread. Spinning is either performed on the wheel,
or with a distaff and spindle, or with other machines
proper for the several kinds of working. Hemp, flax,
nettle-thread, and other like vegetable matters, are to
be wetted in spinning: silks, wool, &c. are spun dry,
and do not need water; yet there is a way of spinning
or reeling silk as it comes off the cases or bales, where
hot and even boiling water is to be used (see Silk).
The vast variety, and the importance of those branches
of our manufactures, which are produced from cotton,
wool, and flax, spun into yarn, together with the cheap-
ness of provisions, and the low price of labour in many
foreign countries, which are our rivals in trade, have
occasioned many attempts at home to render spinning
more easy, cheap, and expeditious; for which see Cotton-
Spinning and Cotton Mills.

To give an intelligible and accurate description of a
cotton mill would be abundant employment for a vo-

te. Our limits admit of nothing like this; but as
we are certain that many of our readers have viewed
a cotton mill with wonder, but not with intelligence,
or with leisure to trace the steps by which the wool from
the gill ultimately assumes the form of a very fine thread.
Bewildered by such a complication of machinery, all in
rapid motion, very few, we imagine, are able to recollect
with distinctness and intelligence the essential part of
the progress by which the form of the cotton is so won-
derfully changed. Such readers will not think a page
or two misemployed, if they are thereby able to under-
stand this particular, to which all the rest of the process
is subservient.

We pass over the operation of carding, by which $1

the
the cloths and inequalities of the cotton wool are removed, and the whole is reduced to a uniform thin fleece, about 25 inches broad. This is gradually detached from the finishing card, and, if allowed to hang down from it, would pile up on the floor as long as the mill continues to work; but it is guided off from the card, very tenderly, in a horizontal direction, by laying its detached end over a roller, which is slowly turned round by the machine. Another roller lies above the fleece, pressing it down by its weight. By this pressure, a gentle hold is taken of the fleece, and therefore the slow motion of the rollers draws it gently from the card at the same rate as it is disengaged from the comb; but between the card and the rollers a set of smooth pins are placed in two rows, leading from the card to the rollers, and gradually approaching each other as we approach the rollers. By these pins the broad fleece is hemmed in on both sides, and gradually contracted to a thick roll; and in this state passes between the rollers, and is compressed in a pretty firm flat riband, about two inches broad, which falls off from the rollers, and piles up in deep tinplate cans set below to receive it.

It is upon this stripe or riband of cotton wool that the operation of spinning begins. The general effect of the spinning process is to draw out this massive roll, and to twist it as it is drawn out. But this is not to be done by the fingers, pulling out as many cotton fibres at once as are necessary for composing a thread of the intended fineness, and continuing this manipulation regularly across the whole end of the riband, and thus, as it were, nibbling the whole of it away. The fingers must be directed for this purpose, by an attentive eye. But in performing this by machinery, the whole riband must be drawn out together, and twisted as it is drawn. This requires great art, and very delicate management. It cannot be done at once; that is, the cotton roll cannot first be stretched or drawn out to the length that is ultimately produced from a tenth of an inch of the roll, and then be twisted. There is not cohesion enough for this purpose; we should only break off a bit of the roll, and could make no farther use of it. The fibres of cotton are very little implicated among each other in the roll, because the operation of carding has laid them almost parallel in the roll; and though compressed a little by its contraction from a fleece of 20 inches to a riband of only two, and afterwards compressed between the discharging rollers of the carding machine, yet they cohere so slightly, that a few fibres may be drawn out without bringing many others along with them. For these reasons, the whole thickness and breadth of two or three inches of the riband is stretched to a very minute quantity, and then a very slight degree of twist is given it, viz. about three turns in the inch; so that it shall now compose an extremely soft and spungy cylinder, which cannot be called a thread or cord, because it has scarcely any firmness, and is merely rounder and much slenderer than before, being stretched to about threes its former length. It is now called slub, or roove.

Although it be still extremely tender, and will not carry a weight of two ounces, it is much more cohesive than before; but a very slight twist is given to it makes all the longitudinal fibres bind each other together, and compress those which lie athwart; therefore it will require more force to pull a fibre from among the rest, but still not nearly enough to break it. In drawing out a single fibre, others are drawn out along with it; and if we take hold of the whole assemblage, in two places, about an inch or two inches asunder, we shall find that we may draw it to near twice its length without any risk of its separating in any intermediate part, or becoming much smaller in one part than another. It seems to yield equally over all.

Such is the state of the slub or roove of the first formation. It is usually called the preparation; and the operation of spinning is considered as not yet begun. This preparation is the most tedious, and requires more attendance and hand-labour than any subsequent part of the process. For the stripes or ribands from which it is made are so light and bulky, that a few yards only can be piled up in the cans set to receive them. A person must therefore attend each thread of slub, to join fresh stripes as they are expended. It is also the most important in the manufacture: for as every inch of the slub meets with precisely the same drawing and the same twisting in the subsequent parts of the process, therefore every inequality and fault in the slub (indeed in the fleece as it quits the finishing card) will continue through the whole manufacture. The spinning of cotton yarn now divides into two branches. The first, performed by what are called jennies, perfectly resembles the ancient spinning with the distaff and spindle; the other, called spinning of twist, is an imitation of the spinning with the fly-wheel. They differ in the same manner as the spinning with the old wool or cotton wheel differs from the spinning with the flax-wheel. Mr. Arkwright's chief invention, the substitution of machinery for the immediate work of the human finger, is seen only in the manufacture of twist. We shall therefore confine our attention to this.

The rest of the process is little more than a repetition of that gone through in making the first slub or roove. It is formed on bobbins. These are set on the back part of the drawing frame; and the end of the slub is brought forwards toward the attending workman. As it comes forward, it is stretched or drawn about four-thirds of its former length, or lengthened one-third; and is then twisted about twice as much as before, and in this state wound up on another bobbin. In some mills two rooves, after having been properly drawn, are brought together through one hole, and twisted into one; but we believe that, in the greater number of mills, this is deferred to the second drawing. It is only after the first drawing that the produce of the operation gets the name of slub; before this it is called preparation, or roove, or by some other name. The slub is still a very feebble, soft, and delicate yarn, and will not carry much more weight than it did before in the form of roove. The perfection of the ultimate thread or yarn depends on this extreme softness; for it is this only which makes it susceptible of an equable stretching; all the fibres yielding and separating alike.

The next operation is the second drawing, which no way differs from the first, except in the different proportions of the lengthening, and the proportion between the lengthening and the subsequent twist. On these points we cannot give any very distinct information. It is different in different parts, and with different species of cotton wool, as may be easily imagined. The immediate mechanism or manipulation must be skilfully accommodated to the nature of that friction which
which the fibres of cotton exert on each other, enabling one of them to pull others along with it. This is greatly aided by the contorted curled form of a cotton fibre, and a considerable degree of elasticity which it possesses. In this respect it greatly resembles woollen fibres, and differs exceedingly from those of flax: and it is for this reason that it is scarcely possible to spin flax in this way: its fibres become tangled, and take any shape by the slightest compression, especially when damp in the slightest degree. But besides this, the surface of a cotton fibre has a harshness or roughness, which greatly augments their mutual friction. This is probably the reason why it is so unfit for tent and other dressings for wounds, and is refused by the surgeon even in the meanest hospitals. But this harshness and its elasticity fit it admirably for the manufacture of yarn. Even the shortness of the fibre is favourable; and the manufacture would hardly be possible if the fibre were twice as long as it generally is. If it be just so long that in the finished thread a fibre will rather break than come out from among the rest, it is plain that no additional length can make the yarn any stronger with the same degree of compression by twining. A longer fibre will indeed give the same firmness of adherence with a smaller compression. This would be an advantage in any other yarn; but in cotton yarn the compression is already as slight as can be allowed; were it less, it would become woody and rough by the smallest usage, and is already too much disposed to tease out. It can hardly be used as sewing thread. Now suppose the fibres much longer; some of them may chance to be stretched along the slub through their whole length. If the slub is pulled in opposite directions, by pinching it at each end of such fibres, it is plain that it will not stretch till this fibre be broken or drawn out; and that while it is in its extended state, it is acting on the other fibres in a very unequal manner, according to their positions, and renders the whole apt to the spinning of flax by similar machinery; and it has hitherto prevented (we believe) the working up of any thing but the short or tow, which is separated from the long fine flax in the operation of hatitching.

A third, and sometimes even a fourth, drawing is given to the slub formed on the bobbins of this second operation. The slub produced is now a slender, but still extremely soft cord, susceptible of considerable extension, without risk of separation, and without the smallest chance of breaking a single fibre in the attempt. In one or more of the preparatory drawings now described, two, and sometimes three slubs, of a former drawing, are united before the twist is given them. The practice is different in different mills. It is plain, that unless great care be taken to preserve the slub extremely soft and compressible during the whole process, the subsequent drawing becomes more precarious, and we run a risk of at last making a bad loose thread instead of a uniform and simple yarn. Such a thread will have very little lateral connection, and will not bear much handling without separating into strands. The perfection of the yarn depends on having the last slub as free of all appearance of strands as possible.

The last operation is the spinning this slub. This hardly differs from the foregoing drawings in any thing but the twist that is given it after the last stretching in its length. This is much greater than any of the preceding, being intended to give the yarn hardness and firmness, so that it will now break rather than stretch any more.

The reader, moderately acquainted with mechanics, cannot but perceive that each of the operations now described, by which the rove is changed into the soft slub, and each of these into one slenderer and somewhat firmer, by alternately teasling out and twining the soft cord, is a substitute for a single pull of the finger and thumb of the spinner, which she accommodates precisely to the peculiar condition of the lack of wool which she touches at the moment. She can follow this through all its irregularities; and perhaps no two succeeding pulls are alike. But when we cannot give this momentary attention to every minute portion, we must be careful to introduce the rove in a state of perfect uniformity; and then every inch being treated in the same manner, the final result will be equable—the yarn will be uniform.

We are now to describe the mechanism by which all this is effected. But we do not mean to describe a cotton mill; we only mean to describe what comes into immediate contact with the thread; and in so doing, to confine ourselves to what is necessary for making the reader perceive its ability to perform the required task. We see many cases where individuals can apply this knowledge to useful purposes. More than this would, we think, be improper, in a national point of view.

Let ABC (fig. 1.) represent the section of a roller, whose pivot D does not turn in the slot hole, but in the bottom of a long narrow notch DE, as in an iron standard. abc is the section of another iron roller, whose pivot d is in the same notch at each end, while the roller itself lies or rests on the roller ABC below it. The surfaces of these rollers are fluted lengthwise like a column: only the flutings are very small and sharp, like deep strokes of engraving very close together. It is plain, that if the roller ABC be made to turn slowly round its axis by machinery, in the direction ABC (as expressed by the dart), the roughness of the flutings will take hold of the similar roughness of the upper roller abc, and carry it round also in the direction of the dart, while its pivots are engaged in the notches DE, which they cannot quit. If therefore we introduce the end F of the cotton string or riband, formed by the carding machine, it will be pulled in by this motion, and will be delivered out on the other side at H, considerably compressed by the weight of the upper roller, which is of iron, and is also pressed down by a lever which rests on its pivots, or other proper places, and is loaded with a weight. There is nothing to hinder this motion of the riband thus compressed between the rollers, and it will therefore be drawn through from the cans. The compressed part at H would hang down, and be piled upon the floor as it is drawn through; but it is not permitted to hang down in this manner, but is brought to another pair of sharp fluted iron rollers K and L. Supposing this pair of rollers to be of the same diameter, and to turn round in the same time, and in the same direction, with the rollers ABC, abc; it is plain that K and L drag in the compressed riband at I, and would deliver it on the other side at M, still more compressed. But the roller K is made (by the wheelwork) to turn round more swiftly than...
the surface of the rollers is, however, very small, seldom exceeding one part in 12 or 15. But the consequence of this difference is, that the sheen of cotton III will be lengthened in the same proportion; for the upper rollers pressing on the under ones with a considerable force, their sharp filings take good hold of the cotton between them; and since K and L take up the cotton faster than ABCD and DE deliver it out, it must either be forcibly pulled through between the first rollers, or it must be stretched a little by the fibre slipping among each other, or it must break. When the extension is so very moderate as we have just now said, the only effect of it is merely to begin to draw the fibres (which at present are lying in every possible direction) into a more favourable position for the subsequent extensions.

The fibres being thus drawn together into a more favourable position, the cotton is introduced between a third pair of rollers O, P, constructed in the same way, but so made by the workwheel that the surface of O moves nearly or fully twice as fast as the surface of K. The roller P being also well loaded, they take a firm hold of the cotton, and the part between K and O is nearly or fully doubled in its length, and now requires a little twisting to make it round and to consolidate it a little.

It is therefore led sloping downwards into a hole or eye in the upper pivot of the first fly, called a "jock." This turns round an upright axis or spindle; the lower end of which has a pulley on it to give it motion by means of a band or belt, which passes round a drum that is turned by the machinery. This jock is of a very ingenious and complicated construction. It is a substitute for the fly of the common spinning wheel. It made precisely in the form of that fly, the thread being so very bulky and spongy, and unable to bear close packing on the bobbin, would swing out by the whirling of the fly, and would never coil up. The bobbin therefore is made to lie horizontally; and this occasions the complication by the difficulty of giving it a motion round a horizontal axis, in order to coil up the twisted rove.

Mr. Anstis has accomplished this in a very ingenious manner; the essential circumstances of which we shall here briefly describe. A is a roller of hard wood, having its surface cut into sharp flutes longitudinally. On the axis, which projects through the side of the general frame, there is a pulley P, connected by a band with another pulley Q, turning with the horizontal axis QR. This axis is made to turn by a contrivance which is different in every different cotton mill. The simplest of all is to place above the pulley C (which is turned by the great band of the machinery, and thus gives motion to the jock), a thin circular disc D, loose upon the axis, so as to turn round on it without obstruction. If this disc exceed the pulley in breadth about \( \frac{1}{40} \) th of an inch, the broad belt which turns the pulley will also turn it; but as its diameter is greater than that of the pulley, it will turn somewhat slower, and will therefore have a relative motion with respect to the axis QR. This can be employed in order to give that axis a very slow motion, such as one turn of it for 20 or 30 of the jock. Thus we have to the ingenuity of the reader. The bobbin b, on which the rove is to be coiled up, lies on this roller, its points passing through upward slits in the sides of the general frame. It lies on A, and is moved round by it, in the same manner as the uppermost of a pair of drawing rollers lies on the under one, and receives motion from it. It is evident that the fluted surface of A, by turning slowly round, and carrying the weight of the bobbin, compresses a little the cotton that is between them; and its fluting, being sharp, takes a slight hold of it, and cause it to turn round also, and thus coil up the rove, pulling it in through the hole E in the upper pivot (which resembles the fore pivot or eye of a spinning wheel) in so gentle a manner as to yield whenever the motion of the bobbin is too great for the speed with which the cotton skin is discharged by the rollers O and P. — N. B. The axis QR below, also gives motion to a guide within the jock, which leads the rove gradually from one end of the bobbin to the other, and back again, so as to coil it with regularity till the bobbin is full. The whole of this internal mechanism of the jock is commonly shut up in a tin cylinder. This is particularly necessary when the whirling motion must be rapid, as in the second and third drawings. If open, the jocks would meet with much resistance from the air, which would load the mill with a great deal of useless work.

The reader is desired now to return to the beginning of the process, and to consider it attentively in its different stages. We apprehend that the description is sufficiently perspicuous to make him perceive the efficacy of the mechanism to execute all that is wanted, and prepare a slab that is uniform, coils, and still very extensible, in short, fit for undergoing the last treatment, by which it is made a fine and firm yarn.

As this part of the process differs from each of the former, merely by the degree of twist that is given to the yarn, and as this is given by means of a fly, not materially different from that of the spinning wheel for flax, we do not think it at all necessary to say anything more about it.

The intelligent reader is surely sensible that the yarn produced in this way must be exceedingly uniform. The uniformity really produced even exceeds all expectation; for even although there be some small inequalities in the cased fleece, yet if these are not matted clots, which the card could not equalise, and only consist of a little more thickness of cotton in some places than in others, when such a piece of the stripe comes to the first roller, it will be rather more stretched by the second, and again by the bobbin, after the first very slight twining. That this may be done with greater certainty, the weights of the first roving rollers are made very small, so that the middle part of the skin can be drawn through, while the outer parts remain fast held.

It is said that a pound of the finest Bourbon cotton has been spun into a yarn extending a few yards beyond 110 miles!

These contrivances have in some parts of Scotland been applied to the spinning of flax.

Spinning Wheel. A very considerable improvement has been made by Mr. Anstis of Fulneck near Leeds of Arts. the common spinning wheel. It is well known that about a much time has been lost by stopping the wheel in order to shift the thread from one staple on the flyer to another; but in Mr. Anstis's wheel the bobbin is made to move backwards and forwards, so as to prevent the necessity of this perpetual interruption, as well as to obviate
to be the word of God, and becomes nothing better than waste paper and iail; just as the two tables, which Moses broke on observing the idolatry of his countrymen, were not the covenant between Jehovah and the Israelites, but merely two pieces of stone! The Scriptures, however, are the work of God, because they teach the true religion of which God is the author; and they have taught it in such a manner, he says, that it cannot be lost or corrupted: whatever became of the books of the Old and New Testaments, or of the languages in which they are written. The whole of religion, as the Scriptures themselves testify, consists in the love of God above all things, and of our neighbours as ourselves: whence it follows, that we must believe that God exists, and watch over all things by his providence; that he is omnipotent, and has decreed the pious to be ultimately happy, and the impious miserable; and that our final salvation depends solely on His grace or favour. These truths, with their necessary consequences, are the word of God: they are clearly taught in the Scriptures, and can never be corrupted; but everything else in these volumes is vain, he says, and of no greater importance to us than facts related in very other ancient and authentic history.

Such are the opinions which were entertained of revelation by a man, whom a critic, writing in a Christian country, and professing to be a zealous Christian himself, has lately pronounced to have been a Coven vessel. For what purpose he was chosen it is not easy to conceive. His religion, as it appears in the Tractatus, is the worst kind of Deism, and his politics are such as our monthly critics are not wont to teach, and such as we trust shall never be seriously taught by any British subject. By the law of nature, he says, every man before the formation of civil government has an unequitable right to whatever appears eligible either to his reason or to his appetite; and may get possession of it by intrigue, by violence, by fraud, or by any other means attended with less trouble to himself (sive vi, sive dol, sive precibus, sive quodcumque demum modo facultatis potentia); and may treat as an enemy every person who shall attempt to obstruct his purpose. But when men agree to devolve this right upon others, and to constitute a political state, which both reason and appetite must persuade them to do, then are they in duty bound to obey every mandate of the government, however absurd it may be (omnia mandata tenui absurdissima), as long as that government can enforce its edicts, and no longer; for according to him, right and power are so inseparably united, that when a government loses its power, it has no longer the smallest claim to obedience. This doctrine, he says, is most obviously just when taught of democratical governmen; but it is in fact equally true of monarchies and aristocracies: "Nam quisquis summam habet potestatem, sive unus sit, sive pauci, sive denique omnes, certum est et summum jus quodvis vellet imperare, competere: et praeclara quisquis potestatem se defendendi, sive sponte, sive vi coercet, in alium transituit, cum suo jure naturali planae cessisse, et consequenter eadem ad omnia absolutum parere decreviessit quod omnia prestare tenetur, quamid rex, sive nobiles, sive populus summam, quam accepserunt, potestatem, quae juris transferendi fundamentum fuit, conservare: nec his plura addere opus est." We heartily agree with him, thus to this precious conclusion it is needless to add a single word.

Taking our leave therefore of his Tractatus Philosophicus, we shall now give our readers a short account of his Opera Posthuma. These consist of 1. Ethica, seu de affectu intellectus; 2. Politica; 3. De remmatione intellectus; 4. Epistola, et utraque responsiones; 5. Compendium Grammaticum Lingue Hebreae.

The Ethica are divided into five parts, which treat in order, de Deo; de nature et origine mentis; de origine et natura affectuum; de servitute humana, seu de affectuum viribus; de potentia intellectus, seu de libertate humana. As the author prefers to tread in the footsteps of the geometers, and to deduce all his conclusions by rigid demonstration from very few self-evident truths, he introduces his work, after the manner of Euclid, with a collection of definitions and axioms. These are couched in terms generally ambiguous, and therefore the reader will do well to consider attentively in what sense, if in any, they can be admitted; for it will not be found easy to grant his premises, and at the same time refuse his conclusions. His definition of substance, for instance, is so expressed as to admit of two senses; in one of which it is just, whilst in the other the term is the parent of the most impious absurdity. We shall give it in his own words: "Per substantiam intelligi id, quod in se est, et per se concipitur: hoc est id, cujus conceptus non indiget conceptus alterius rei, a quo formari debet." If by this he meant, that a substance is that which we can conceive by itself without attending to any thing else, or thinking of its formation, the definition, we believe, will be admitted by every reflecting mind as sufficiently distinguishing the thing defined from an attribute, which, he says, is that which we perceive of a substance, and which we certainly cannot conceive as existing by itself. Thus the writer of this article can shut his eyes and contemplate in idea the small 40 to volume now before him, without attending to any thing else, or thinking of its paradoxical author, or even of the Great Being who created the matter both of him and it; but he cannot for an instant contemplate the yellow colour of its vellum boards without thinking of triple extension, or, in other words, of body. The book therefore is a substance, because conceivable by itself; the colour is an attribute or quality, because it cannot be conceived by itself, but necessarily leads to the conception of something else. But if Spinoza's meaning be, that nothing is a substance but what is conceived as existing from eternity, independent of every thing as a cause, his definition cannot be admitted; for every man conceives that which in himself thinks, and wills, and is conscious, as a substance; at the same time that he has the best evidence possible that he existed not as a conscious, thinking, and acting being, from eternity.

His fourth axiom is thus expressed: "Effectus cognitivus cognitione causam dependet, et tandem involvit;" and his fifth: "Qua nihil commune cum se invicem habent, etiam per se invicem intelligi non possunt, sive conceptus unius alterius conceptum non involvit." The former of these propositions, so far from being self-evident, is not even true; and the latter is capable of two very different from each other. That every effect
Spinoza's phrase used by Spinoza is concise, and it gives an unity and simplicity to his whole system, however strange it may sound in our ears."

From this account of Spinozism, one who had never looked into the works of the author would be led to suppose that his system is the same with that of Berkeley; which, denying the existence of material substance, attributes all our perceptions of what we call the qualities of body to the immediate agency of the Deity on our minds (see Metaphysics, Part II. chap. 3.). But Spinoza's doctrine is very different. According to him, bodies are either attributes or affections of God; and as he says there is but one extended substance, he affirms that substance to be indivisible, and employs a long scholium to prove that those are mistaken who suppose it finite and not essential to the Deity. That we do prop. xvi. not misrepresent his sentiments, the learned reader will be convinced by the two following definitions, with which he introduces that part of his ethics which treats of the nature and origin of mind. 1. "Per corpus intelligo modum, qui Dei essentiam, quatenus, ut res extensa consideratur, certe et determinato modo exprimit." 2. "Ad essentiam alicujus rei id pertinere dico, quo dato res necessario ponitur, et quo subito res necessario solvitur; vel id, sine quo res, et vice versa quod siuo re nec esse nec conscripsi potest." In conformity with these definitions, he attempts to prove that God is an extended as well as a thinking substance; that as a thinking substance he is the same of the idea of a circle, prop. vii., and as an extended substance of the circle itself; and that the minds of men are not substances, but certain modifications of the divine attributes; or, as he sometimes expresses it, "Quod humanum mentis actu constat, est idea rei singularis acta existetis." Hence he says, it follows that the human mind is a part of the intellect of the infinite God; so that when we speak of the human mind perceiving this or that, we can only mean that God, not as he is infinite, but as he appears in the human mind or constitutes its essence, has this or that idea; and when we speak of God's having this or that idea, we must conceive of Him not only as constituting the human mind, but as, together with it, having the idea of something else (A). In another place he tells us, that the human mind is nothing but the idea which God has of the human body as actually existing; that this idea of the body, and the body itself, are one and the same thing; and that thinking and extended substances are in reality but one and the same substance, which is sometimes comprehended under one attribute of the Deity, and sometimes under another.*

By way of apology for this jargon, it has been lately said that "Spinoza takes the word substance in its most simple and perfect sense; which is necessary, as he writes mathematically, and proposes a simple idea as the foundation of his theory. What is the proper signification of a substance? It is not that which stands alone, which has the cause of its existence within itself. I wish that this simple meaning of the word could be universally admitted in philosophy. Strictly speaking, no worldly thing is a substance; since all mutually depend on each other, and finally on God, who, in this exalted sense, is the only substance. The word modification sounds harsh and improper, and therefore it cannot be expected to gain a place in philosophy; but if the school of Leibnitz may term matter the appearance of substances, why may not Spinoza be allowed a bolder term? Worldly substances are kept in union by divine power, as it was by divino power that they had existence. They represent also, if you please, modified appearances of divine power; each according to the station, the time, and the organs, in and with which it appears. The

* Prop. vii.

If this impious jargon be not Atheism, as it has been sometimes called Pantheism, we know not what it is (see Pantheism). According to Spinoza, there is but one substance, which is extended, infinite, and indivisible. That substance indeed he calls God; but he labours to prove that it is corporeal; that there is no difference between mind and matter; that both are attributes

"(A) Hinc sequitur mentem humanam partem esse infiniti intellectus Dei; ac proinde cum dicimus, mentem humanam hoc vel illud percipere, nihil aliud dicius quam quod Deus, non quatenus infinitus est, sed quatenus per naturam humanae mentis explicatur, sive quatenus humanae mentis essentiam constituit, hanc vel illam habet ideam; et cum dicimus Deum hanc vel illam ideam habere, non tantum, quatenus naturam humanae mentis constituit; sed quatenus simul cum mente humana alterius rei etiam habet ideam. Corol. prop. xi. part 2."
tributes of the Deity variously considered; that the hu-
man soul is a part of the intellect of God; that the
same soul is nothing but the idea of the human body;
that this idea of the body, and the body itself, are one
and the same thing; that God could not exist, or be
conceived, were the visible universe annihilated; and
therefore that the visible universe is either the one su-
stance, or at least an essential attribute or modification
of that substance. He sometimes indeed speaks of the
power of this substance; but when he comes to explain
himself he finds that by power he means nothing but
blind necessity; and though he frequently talks of
the wisdom of God, he seems to make use of the word
without meaning. This we think evident from the
long appendix to his 36th proposition; in which he
labours to prove that the notion of final causes is an idle
figure of the imagination, since, according to him,
nothing but the prejudices of education could have led
men to fancy that there is any real distinction between
good and evil, merit and demerit, praise and reproach, or
order and confusion; that eyes were given them that they
might be enabled to see; teeth for the purpose of chew-
ing their food; herbs and animals for the matter of that
food; that the sun was formed to give light, or the ocean
to nourish fishes. If this be true, it is impossible to dis-
cover wisdom in the operations of his one substance;
since, in common apprehension, it is the very charac-
teristic of folly to act without any end in view.

Such are the reveries of that writer, whose works a
German philosopher of some name has lately recom-
pended to the public, as calculated to convey to the
mind more just and sublime conceptions of God than
are to be found in most other systems. The recom-
mandation has had its effect. A literary journalist of our
own, reviewing the volume in which it is given, feels a
peculiar satisfaction from the discovery, that Spinoza,
instead of a formidable enemy to the cause of virtue and
religion, was indeed their warmest friend; and piously
hopes that we shall become more cautious not to suffer
ourselves to be deceived by empty names, which those
who cannot reason (Sir Isaac Newton and Dr Clarke
perhaps) give to those who can (Hobbes, we suppose,
and Spinoza). But though we have the honour to think
on this question, with our illustrious countrymen, we
have no desire to depict Spinoza as a reprobate, which
the critic says has often been done by ignorance and
enthusiasm. We admit that his conduct in active life
was irreproachable; and for his speculative opinions, he
must stand or fall by his own Master. His Ethics ap-
ppear to us indeed a system shockingly impious; and in
the tract intitled Politica, power and right are con-
founded as in the former volume; but in the tracts De
Intellecution Emendatione, are scattered many
precepts of practical wisdom, as well as some judicious
rules for conducting philosophical investigation; and we
only regret, that the reader must wade to them through
pages of fatalism, scepticism, and palpable contradic-
tions. His Compendium Grammaticae Linguæ Hebraelæ,
though left imperfect, appears to have so much merit,
that it is to be wished he had fulfilled his intention of
writing a philosophical grammar of that language, in-
stead of wasting his time on abstruse speculations, which
though they seem not to have been injurious to his own
virtue, are certainly not calculated to promote the vir-
tue of others; or to increase the sum of human hap-
iness.

SPIRÆA, a genus of plants belonging to the class
of Roscææ, and to the order of pentagynia; and in
the natural system arranged under the 26th order, Pe-
maææ. See Botany Index.

SPIRAL, in Geometry, a curve line of the circular
kind, which in its progress recedes from its centre.

SPIRE, in Architecture, was used by the ancients
for the base of a column, and sometimes for the astragal
or tore; but among the moderns it denotes a steeple
which continually diminishes as it ascends, whether coni-
cally or pyramidally.

SPIRIT, in Metaphysics, an incorporeal being or
intelligence; in which sense God is said to be a spirit, as
are angels and the human soul. See Metaphysics,
Part III.

SPIRIT, in Chemistry and Pharmacy, a name applied
to every volatile liquid which is not inept like phlegm
or water; and hence the distinction into acid, alkaline,
and vinous spirits.

SPIRIT OF WINE. See Alcohol, Chemistry Index;
Distillation, and Materia Medica Index.

SPIRITS, or Animal Spirits. See Anatomy,
Part V. No. 136.

SPIRITUAL, in general something belonging to, or
partaking of the nature of spirit. See Spirit.

SPIRITUOUS LIQUORS have in all nations been
considered as a proper subject of heavy taxation for the
support of the state. This has naturally occasioned a
nice examination of their strength. It having been at
last found that this was intimately connected with the
specific gravity, this has been examined with the most
scrupulous attention to every circumstance which could
affect it, so that the duties might be exactly proportion-
ed to the quantity of spirit in any strong liquor, inde-
dependent on every other circumstance of flavour or taste,
or other valued quality. The chemist at last found
that the basis of all strong liquors is the same, produced
by the vinous fermentation of pure saccharine matter
dissolved in water. He also found, that whether this
vegetable salt be taken as it is spontaneously formed in
the juices of plants and fruits, or as it may be formed
or extracted from farinaceous fruits and roots by a cer-
tain part of the process of vegetation, it produces the
same ardent spirit, which has always the same density
in every mixture with water. The minute portions of
aromatic oils, which are in some degree inseparable from
it, and give it a different flavour according to the sub-
stance from which it was obtained, are not found to
have any sensible effect on its density or specific gravity.
This seems very completely established in consequence
of the unwearied attempts of the manufacturers to lessen
the duties payable on their goods by mixtures of other
substances, which would increase their density without
making them less palatable. The vigilance of the re-
venue officers was no less employed to detect every such
contrivance. In short, it is now an acknowledged point,
that the specific gravity is an accurate test of the
strength.

But though this is true in general, we cannot derive
much benefit from it, unless we know the precise rela-
tion between the strength and the density of a spiritu-
ous liquor. Do they increase port passim, or by what
law
SPI

Spiritus law are they connected? It was natural to expect that equal additions of ardent spirits or alcohol to a given quantity of water would produce equal diminutions of density. Areometers were accordingly made on this principle above 200 years ago, as may be seen in the works of Gaspar Schottius, Sturmius, Agricola, and other old authors. But when mathematical physics became more generally known, this was easily discovered to be erroneous; and it was shown (we think first by Mr Boyle) that equal additions to the specific gravity would be produced by successively taking out of any vessel a certain measure of alcohol and replacing it with an equal measure of water. This was the most convenient discovery for all parties, because then the duties payable on a cask of spirits would be in the exact proportion of the diminution of its density. But it was soon found by those who were appointed guardians of the revenue that this conclusion was erroneous, and that a mixture which appeared by this rule to contain 35 gallons of alcohol, did really contain 35%. This they found by actually making such a mixture: 18 gallons of alcohol mixed with 18 of water produced only 35 gallons of spirits. The revenue officers, finding that this condensation was most remarkable in mixtures of equal parts of water and the strongest spirits which could then be procured, determined to levy the duties by this mixture; because, whether the spirituous liquor was stronger or weaker than this, it would appear, by its specific gravity, rather stronger than it really was. This sagacious observation, and the simplicity of the composition, which could at all times be made for comparison, seem to be the reasons for our excise officers selecting this mode of estimating the strength and levying the duties. A mixture of nearly equal measures of water and alcohol is called PROOF SPIRIT, and pays a certain duty per gallon; and the strength of a spirituous liquor is estimated by the gallons, not of alcohol, but of proof spirit, which the cask contains. But because it might be difficult to procure at all times this proof spirit for comparison, such a mixture was made by order of the board of excise: and it was found, that when six gallons of it was mixed with one gallon of water, a wine gallon of the mixture weighed 7 pounds 13 ouncesavoirdupois. The board therefore declared, that the spirituous liquor of which the gallon weighed 7 pounds 13 ounces should be reckoned 1 to 6 or 1 in 7 under proof. This is but an awkward and complex formula; it was in order to suit matters to a mode of examination which had by time obtained the sanction of the board. Mr Clarke, an ingenious artist of that time, had made a hydrometer incomparably more exact than any other, and constructed on mathematical principles fit for computation. This had a set of weights corresponding to the additions of water or proof spirit, and the mixture 1 to 6 or 1 in 7 was the only one which weighed an exact number of ounces per gallon without a fraction.

Thus stands the excise law; and Clarke's hydrometer is still the instrument of authority, although others have been since constructed by Dicas, Quin, and others, which are more ingenious and convenient. The mathematician who examines Dicas's hydrometer, with its sliding scale, by which it is adjusted to the different temperatures, and points out the condensations, will perceive a beautiful and sagacious combination of quantities, which he will find difficult to bring under any analytical formula. Perhaps Quin's may have some preference in respect of convenience; but facilis事件 adde, Mr Dicas was original (A).

As naturalists became more accustomed to exact observations in every topic of inquiry, the condensation which obtains in the mixture of different substances became more familiarly known. This evidently affects the present question; and both the excise and the distillers are interested in its accurate decision. This occasioned an application to the Royal Society; and a most scrupulous examination of the strength of spirituous liquors was made by Sir Charles Blagden and Mr Gilpin, of which they have given a very particular account in the Philosophical Transactions for 1790 and 1792.

We have taken notice of this in the article Specific Gravity, mentioning such circumstances of the results as suited our purposes of physical discussion. At present

(A) Among the various contrivances which have been thought of, among manufacturers and dealers, as well as for the purposes of revenue, for ascertaining the specific gravity, and consequently the real strength and value of high-priced and high-taxed liquors, we are persuaded there is none equal, in point of accuracy, simplicity, and facility of application, to the areometrical beads lately announced to the public by Mrs Lovi of Edinburgh, under the privilege of a patent; and with this persuasion we have no hesitation in recommending them to those to whom the use of a simple and accurate instrument is of great importance in determining the value of high-priced spirituous liquors. Our recommendation rests not solely on our own opinion, but is supported by that of others who are well acquainted with such subjects. We know, too, that the beads have been examined and compared by several intelligent manufacturers and dealers with some of the most accurate hydrometrical instruments, and after a fair trial, a decided preference has been given to the beads. The whole apparatus consists of 100 beads, a sliding rule, a thermometer, a glass jar and brass hook, which are packed in a neat small box; and it is accompanied with directions, which point out, 1. In what manner the real strength of spirits may be ascertained at any given temperature between 40° and 80°. 2. How much per cent. the spirit to be tried is over or under proof according to the practice of spirit-dealers; and, 3. The proportion of water and the strongest spirits or alcohol, according to the views and language of excisemen. The advantages of these beads are, that being made of a substance which is little acted on by chemical agents, they are less liable to be injured by use, than instruments composed of metal; and when a bead happens to be broken, it can be easily replaced. They possess this farther advantage, that with the application of the thermometer, and the calculation of the sliding-rule, the real strength of the spirits may be taken at all temperatures. It has been suggested, that these beads, from their being less liable to change than other instruments, might be usefully employed in checking the errors and variations of other hydrometers. Beads are prepared by Mrs Lovi on the same principle for ascertaining the strength of worts, acids, &c.
SPI

[Spirituos sent we give the general result in the table of specific gravity, as peculiarly belonging to spirituous liquors, affording the most exact account of their density in every state of dilution of alcohol with water. And as the relation between the proportion of ingredients and the density is peculiar to every substance, so that scarcely any inference can be made from one to another, the reader will consider the tables here given as characteristic with respect to alcohol. In all solutions of salts we found that the condensation increases continually with the dilution, whereas it is greatest when equal bulbs of water and alcohol are mixed; yet we do not consider this as an exception; for it is certain, that in the strongest brine the saline ingredient bears but a small proportion to the water—and when we mix two solutions, the condensation is greatest when they are nearly equal in bulk. But we think ourselves entitled to infer, that alcohol is not a dilution of a substance in a quantity of water; but that water, in a certain proportion, not very distant from what we can produce by slow distillation, is an ingredient of alcohol, or is one of its component parts, and not merely a vehicle or menstruum. We therefore imagine that proof spirit contains nearly equal bulbs of water and ardent spirits.

The great difficulty in this examination arose from the very dissimular expansions of water and alcohol by heat. This determined Sir Charles Blagden to estimate the proportions of ingredients by weight, and made it absolutely necessary to give a scale of specific gravity and strength for every temperature. For it must be remarked, that the question (whether in commerce or philosophy) always is, "How many gallons of alcohol and of water, taken just now and mixed together, will produce a hundred gallons of the spirit we are examining?" The proportion of these two will be different according to the temperature of both. As many mixtures therefore must have been made in each proportion as there were temperatures considered; but by taking the ingredients by weight, and examining the density of the compound in one temperature, it is then heated and cooled, and its change of density observed. Calculation then can tell us the change in the proportion of the bulbs or numbers of gallons in the mixture, by means of a previous table showing the expansions of water and of alcohol.

The alcohol selected for this examination had the specific gravity .825. This is not the purest that can be procured; some was produced of .816, of .814, and .819, both obtained from rum, from brandy, and from malt spirit. We are informed that Dr. Black has obtained it of the specific gravity .8 by digesting alcohol with fixed ammoniac (muriatic acid united with lime) made very dry. It dephlegmated alcohol very powerfully without decomposing it, which always happens when we use caustic alkalis. Alcohol of .825 was chosen because expressed by a number of easy management in computation.

The examination commenced by ascertaining the expansions of water and alcohol. The temperature 60° of Fahrenheit's scale was selected for the general temperature of comparison, being easily attainable even in cold weather, and allowing the examiner to operate at ease. The first and last compartments of the tables contain the weights and specific gravities of alcohol and water for every fifth degree of heat from 50° to 100°.

From these we have constructed the two following little tables of expansions. The bulk of 100,000 ounces, pounds, or other weight of water and of alcohol of the temperature 60°, occupies the bulbs expressed in the tables for every other temperature. Water could not be easily or usefully examined when of the temperature 30°, because it is with great difficulty kept fluid in that temperature. It is very remarkable, that when it can be so kept, it expands instead of contracting; while cooling down from 35° or thereabouts, and as it approaches to 30°, it expands rapidly. We observe the same thing in the crystallization of Glauber salt, mental vitriol, and some others, which contain much water in their crystals. We observe, on the other hand, a remarkable contraction in the ecolite just before its beginning to swell into bubbles by a red heat.

</table>

This being premised, the examination was conducted in the following manner. It was determined to mix 100 parts by weight of pure alcohol with five, ten, fifteen, twenty, parts of distilled water, till they were compounded in equal quantities, and then to mix 100 parts of distilled water with, 95, 90, 85, 80, &c. parts of alcohol, till they were mixed in the proportion of 100 to 5. Thus a series of mixtures would be obtained, extending from pure alcohol to pure water. This series would be such, that the examinations would be most frequent in the cases most usual in the commerce of strong liquors. A set of phials, fitted with ground stoppers, were provided, of sizes fit to hold the intended mixtures. Those mixtures were made by suspending the phial to the arm of a very nice balance, in the opposite scale of which (besides the counterpoise of the phial) there was placed the weight 100. Spirit was then poured into the phial till it exactly balanced the weight 100. The weight for the water to be added was then put into the opposite scale, and water was poured into the phial by means of a slender glass funnel, by small quantities at a time, and the phial frequently agitated to promote the mixture. When the additional weight was exactly balanced, the phial was taken off, its stopper put in, and leather tied over it, and it was set by, for at least a month, that the mixture and the whole process of condensation might be completed. The same

method
method was followed in the mixtures where the water was predominant. When the ingredients of these mixtures were judged to have completely incorporated, their specific gravity was examined by weighing with the most scrupulous precision the contents of a vessel which held 2925 troy grains of water, of the temperature 60°. The balance was so exceedingly sensible, that the 30th part of a grain greatly disturbed its position when loaded with the scales and their contents. It was constructed by Mr. Ramsden, and some account of its exquisite sensibility may be seen in the *Journal de Physique*, vol. xxxii. This quantity of materials was therefore thought abundantly sufficient for ascertaining the density of the liquor. It is needless to detail the precautions which were taken for having the contents of the weighing bottle brought to the precise temperature proper for the experiment. They were such as every person, conversant with such things, is accustomed to take. The bottle had a slender neck, and being put on a lathe, a mark was made round it with a diamond. The bottle was filled till the bottom of the hollow surface of the fluid was in the plane of this mark; and to judge of the accuracy attainable in filling the bottle, the operation was several times repeated and the contents weighed, without the difference of 1/125 of a grain in 2925. The only source of error which was to be guarded against was air-bubbles adhering to the inside of the bottle, or moisture condensing (in the experiments with low temperatures) on the outside. Both of these were attended to as much as possible.

This method of determining the specific gravity was preferred to the usual method, observing the weight lost by a lump of glass when suspended in water; for Mr. Gilpin had been enabled, by means of this nice balance, to discover, even in pure water and in alcohol, a want of perfect fluidity. Something like viscosity rendered the motion of a lump of glass through the liquor sensibly sluggish, so that when the balance was brought to a level, there was not a perfect equilibrium of weight: (See what we have said of this matter in *Specific Gravity*). Mr. Gilpin also tried the ingenious instrument proposed for such experiments by Mr. Ramsden, and described by him in a pamphlet on this very subject; and he found the anomalies of experiment much greater than in this method by weighing. Indeed the regular progression of weights to be seen in the annexed tables is an unquestionable proof of the sufficiency of the method; and it has the evident advantage of all other methods in point of simplicity and practicability without any uncommon apparatus. Any person possessed of a good ordinary balance and a set of exact weights may examine all questions of this kind, by weighing pure water and the liquor which he may have occasion to examine in a common 6 or 8 ounce phial. For this reason, it is recommended (in preference to all hydrometers) to the board of excise to provide this simple apparatus in every principal office.

Every experiment was made at least three times; and the mean result (which never differed one grain from the extreme) was taken.

From these experiments the annexed tables were constructed. The first is the simple abstract of the experiments, containing the weights of the contents of the bottle of every mixture. The second contains the specific gravities deduced from them.

We have said that the experiments appear surprisingly accurate. This we said on the authority of the regular progression of the specific gravity in any of the horizontal rows. In the series, for instance, for the temperature 60°, the greatest anomaly is in the mixture of 50 parts of spirit with 100 of water. The specific gravity is 0.804, wanting 3 or 4 of the regular progression. This does not amount to 1 in 1800.

We formerly observed, that the series of mixtures chosen by Sir Charles Blagden, for the advantages attendant on making the experiment, was not suited for solving the questions which commonly occur in the spirit business. He accordingly suggests the propriety of forming tables in a convenient series from the data furnished by these experiments, indicating the proportion of ingredients contained in some constant weight or bulk.

To facilitate the construction of such tables, it is necessary to consider the subject in the most general manner. Therefore let \( a \) represent the constant number 100. Let \( w \) and \( s \) represent the quantities of water and spirit by weight in any mixture; that is, the pounds, ounces, or grains of each. Let \( x \) represent the quantity per cent. of spirits also by weight; that is, the number of pounds of spirits contained in \( 100 \) pounds of the mixture; and let \( y \) be its quantity per cent. in gallons, or the number of gallons contained in \( 100 \) gallons of the unmixed ingredients. Let \( m \) be the bulk of a pound of spirit of any given temperature, the bulk of a pound of water of the same temperature being accounted 1.

Then \( w + s \) is the weight of any mixture, and \( w + ms \) is its bulk.

We have the following proportions: 1. \( w + s = x \times a \times y \) (Equation 1st); and hence \( s \) may be found when \( x \) the per centage in weight is given, for

\[
\frac{w x}{a - y} = s \quad \text{(Equation 2d)}
\]

2. \( w + ms = m a : y \), and \( y = a - ms \) (Equation 3d); and \( s \) may be found when \( y \), the per centage in gallons, is given; for \( s = \frac{m y}{a - y} \) (Equation 4th).

The usual questions which can be solved from these experiments are,

1. To ascertain the quantity of spirits per cent. in bulk from observation of the specific gravity, or to tell how many gallons of spirit are in \( 100 \) gallons of mixture.

Look for the specific gravity in the table, and at the head of the column will be found the \( w \) and \( s \) corresponding. If the precise specific gravity observed is not in the tables, the \( s \) must be found by interpolation. And here it is proper to remark, that taking the simple proportions of specific gravity will not be sufficiently exact, especially near the beginning or the end of the table, because the densities corresponding to the series of mixtures does not change uniformly. We must have recourse to the general rules of interpolation, by means of first and second differences, or be provided with a subsidiary table of differences. A good deal of practice in computations of this kind suggested the following method of making such interpolations with great dispatch and abundant accuracy. On a plate of wood or metal, or stiff card-paper, draw a line \( EF \) (fig. 1.), as a scale of equal parts, representing the leading or equable arithmetical series of any table. (In the present case \( EF \) is the scale on which \( s \) is computed).—Through every point of division draw the perpendiculars \( BA, EC, FD, \) &c. Make one of them \( AB \) more conspicuous than the rest, and distinguish the others also in such sort, that the eye shall readily catch their distance from the principal line \( AB \). Let \( GPL \) be a thin slip of whalebone, uniform breadth and thickness, also divided into equal parts properly distinguishable. Lastly, let there be a point \( P \) fixed near the middle of the principal line \( AB \).

Now suppose that a value of \( s \) is to be interpolated by means of an observed specific gravity not in the table. Look for the nearest to it, and not its distance from the preceding and the following. Let these be \( PH \) and \( PK \) on the flexible scale. Also take notice of the lines \( K 10 \) and \( H 10 \), whose distances from \( AB \) are equal to the constant difference between the successive values of \( s \), or to any easily estimated multiple of it (as in the present case we have taken 10 and 10, instead of \( \xi \) and \( \xi \), the running difference of Sir Charles Blagden's table). Then, leaning the middle point \( P \) of the whalebone on the pin \( P \) in the board, bend it, and place it slantwise till the points \( K \) and \( H \) fall somewhere on the two parallels \( K 10 \) and \( H 10 \). No matter how oblique the position of the whalebone is. It will bend in such a manner that its different points of division (representing different specific gravities) will fall on the parallels which represent the corresponding values of \( s \). We can say that all this may be done in less than half a minute, and less time than is necessary for inspecting a table of proportional parts, and not the tenth part of that necessary for interpolating by second differences. Yet it is exact enough (if of the size of a duodecimo page) for interpolating three decimal places. This is ten times more exact than the present case requires. To return from this digression.

Having thus found \( s \) in the table, we get \( x \) or \( y \) by the equations \( \frac{a s}{w + s} = x \), and \( \frac{a - ms}{w + ms} = y \).

But here a material circumstance occurs. The weight of alcohol, and its per centage \( x \), was rightly determined by the specific gravity, because it was interpolated between two values, which were experimentally connected with this specific gravity. But in making the transition from \( x \) to \( y \), we only give the per centage in gallons before mixture, but not the number of gallons of alcohol contained in an hundred gallons of mixed liquor. For when we have taken \( a - y \) and \( y \) instead of \( w \) and \( s \); they will indeed make a similar compound when mixed, because the proportion of their ingredients is the same. But they will not make \( 100 \) gallons of this compound, because there is a shrinking or condensation by mixture, and the specific gravity by which we interpolated \( s \) is the physical or real specific gravity corresponding to \( w \) and \( s \); while \( \frac{w + s}{m a} \), the specific gravity implied in the value of \( y \), is the mathematical density independent on this condensation. Since therefore \( y \), together with \( a - y \), make less than \( 100 \) gallons of the compound, there must in \( 100 \) gallons of it be more alcohol than is expressed by \( y \).

Let \( G \) be the mathematical specific gravity (\( \frac{w + s}{w + ms} \)), and \( g \) the physical or real observed specific gravity (which we cannot express algebraically); and let \( w \) be the gallons of alcohol really contained in \( 100 \) gallons of the compound. The bulk being inversely as the density or specific gravity, it is evident that the bulk of the compound must be to \( 100 \) gallons as \( g \) to...

Spir...
Spirits of Liqueurs.

Listed at Edinburgh tables somewhat similar, founded on the same experiments. Both of these tables show the quantities by measure corresponding to every unit by weight of Sir Charles Blagden's experiments, and for every degree of temperature. They also show the per centage of alcohol, and the condensation or the quantity lost by mixture. But as they both retain the original series of parts by weight, which is very unusual, the spirit traders will find considerable difficulty in making use of them. Retaining this series also causes all the per centage numbers (which are the only interesting ones to the trader) to be fractional, and no answer can be had without a double interpolation.

We have therefore calculated a table in the form in which it must be most useful and acceptable to those who are engaged in the spirit trade, showing at once the specific gravity which results from any proportion of admixture in hundredths parts of the whole. This answers immediately the chief questions in the terms in which they are usually conceived and proposed. The two first or leading columns show the proportion in gallons, pints, or other cubic measures, of the mixture, the whole quantity being always 100. The second column shows the corresponding specific gravity: so that we can either find the proportion of the ingredients by the observed specific gravity, or find the gravity resulting from any proportion of the ingredients. A third column shows how much the hundred measures of the two ingredients fall short of making an hundred measures of the compound. A simple proportion, which can be done without the pen, will determine what part of this deficiency must be made up by spirit. The use of this table must now be so familiar to the reader's mind, that we need not give further instructions about it.

This is followed by another similar table, giving an immediate answer to the most usual question, 1. How many measures of alcohol are there really contained in 100 measures? This is also accompanied by a column of condensation. It would have been somewhat more elegant, had the specific gravities in this table made the equable series and leading column. But we did not advert to this till we had computed the table, and the labour was too great to be repeated for slight reasons. The tables are only for the temperature 60°. To this the spirituous liquors can always be brought in these climates; and in cases where we cannot, a moment's inspection of Sir Charles Blagden's table will point out very nearly (or exactly, by a short computation) the necessary corrections.

</tbody>
</table>
In the first table, of which the sole intention is to point out the proportion of ingredients, the specific gravities are computed only to four places, which will always give the answer true to the fourth part. In the last, which is more immediately interesting to the merchant in his transactions with the excise office, the computation is carried one place further.

The consideration of the first of these two tables will furnish some useful information to the reader who is interested in the philosophy of chemical mixture, and who endeavours to investigate the nature of those forces which connect the particles of tangible matter. These vary with the distance of the particle; and therefore the law of their action, like that of universal gravitation, is to be discovered by measuring their sensible effects at their various distances. Their change of distance is seen in the change of density or specific gravity.

Did the individual densities of the water and spirit remain unchanged by mixture, the specific gravity would change by equal differences, the series of mixtures on which this table is constructed; for the bulk being always the same, the change of specific gravity must be the difference between the weight of the gallon of water which is added and that of the gallon of spirit which is taken out. The whole difference of the specific gravities of spirits and water being 1.750 parts in 10,000, the augmentation by each successive change of a measure of spirit for a measure of water would be the 100th part of this, or 17.5. But, by taking the successive differences of density as they occur in the table, we see that they are vastly greater in the first additions of water, being then about 10; after which they gradually diminish to the medium quantity 17.5 when water and spirits are mixed in nearly equal bulks. The differences of specific gravity still diminish, and are reduced to 9, when about 75 parts of water are mixed with 25 of spirit. The differences now increase again; and the last, when 99 parts of water are mixed with one part of spirit, the difference from the specific gravity of pure water is above 14.

The mechanical effect, therefore, of the addition of a measure of water to a great quantity of spirit is greater than the similar effect of the addition of a measure of spirits to a great quantity of water. What we call mechanical effect is the local motion, the change of distance of the particles, that the corpuscular forces may again be in equilibrum. Observe, too, that this change is greater than in the proportion of the distance of the particles;
particles; for the density of water is to that of spirits nearly as 6 to 5, and the changes of specific gravity are nearly as 6 to 3.

We also see that the changing cause, which produces the absolute condensation of each ingredient, ceases to operate when 75 parts of water have been mixed with 25 of alcohol: for the variation of specific gravity, from diminishing comes now to increase; and therefore, in this particular state of composition, is equable. Things are now in the same state as if we were mixing two fluids which did not act on each other, but were mutually disseminated, and whose specific gravities are nearly as 9 to 10; for the variation of specific gravity may be considered as the 100th part of the whole difference, in the same manner as 17.7 would have been had water and alcohol sustained no contraction.

The imagination is greatly assisted in the contemplation of geometrical quantity by exhibiting it in its own form. Specific gravity, being an expression of density (a notion purely geometrical), admits of this illustration.

Therefore let AB (fig. 2.) represent the bulk of any mixture of water and alcohol. The specific gravity of water may be represented by a line of such a length, that AB shall be the difference between the gravities of alcohol and water. Suppose it extended upwards, towards a, till B a is to A a as 10,000 to 8.350. It will suit our purpose better to represent it by a parallelogram a BF, of any breadth BF. In this case the difference of the specific gravities of alcohol and water will be expressed by the parallelogram ABFE. If there were no change produced in the density of one or both ingredients, the specific gravity of the compound would increase as this parallelogram does, and AGHE would be the augmentation corresponding to the mixture of the quantity AG of alcohol with the quantity GB of water, and so of other mixtures. But, to express the augmentation of density as it really obtains, we must do it by some curvilinear area DABCHD, which varies at the rate determined by Sir Charles Blagden's experiments. This area must be precisely equal to the rectangle ABFE. It must therefore fall without it in some places, and be deficient in others. Let DNHK be the curve which corresponds with these experiments. It is evident to the mathematical reader, that the ordinates LM, GH, IK, &c. of this curve are in the ultimate ratio of the differences of the observed specific gravities. If A = a, &c. are each = 5, the little spaces A a = D, a b = 5, &c. will be precisely equal to the differences of the specific gravities 0.8250; 0.8387; 0.8516; &c. corresponding to the different mixtures of water and alcohol.

The curve cuts the side of the parallelogram in K, where the ordinate GK expresses the mean variation of density 0.0017.5. IK is the smallest variation. The condensation may be expressed by drawing a curve d m G f k parallel to D M G K F, making D d = AE. The condensation is now represented by the spaces comprehended between this last curve and the abscissa AG, reckoning those negative which lie on the other side of it. This shows, not only that the condensation is greatest in the mixture AG x GB, but also that in mixing such a compound with another Al x IB, there is a rarefaction. Another curve A N O P B may be drawn, of which the ordinates LN, GP, IO, &c. are proportional to the areas A L m d, A G m d, A L K G m d ( = A C m d - G L k), &c. This curve shows the whole condensation.

This manner of representing the specific gravities of mixtures will suggest many curious inferences to such as will consider them in the manner of Boscovich, with a view to ascertain the nature of the forces of cohesion and chemical affinities: And this manner of viewing the subject becomes every day more promising, in consequence of our improvements in chemical knowledge; for we now see, that mechanism, or motive forces, are the causes of chemical action. We see in almost every case, that chemical affinities are comparable with mechanical pressures; because the conversion of a liquid into a vapour or gas is prevented by atmospheric pressure, and produced by the great chemical agent heat. The action of heat, therefore, or of the cause of heat, is a mechanical action, and the forces are common mechanical forces, with which we are familiarly acquainted.

"It may be also remarked in the column of contractions, that in the beginning the contractions augment nearly in the proportion of the quantity of spirits (but more slowly); whereas, in the end, the contractions are nearly in the duplicate proportion of the quantity of water. This circumstance deserves the consideration of the philosopher. We have represented it to the eye by the curve a g h d."

Attempts are made to elude some part of the duties, by adding some ingredient to the spirits. But it would be doing no service to the trader to put fraud more in his power. There are some salts which make a very great augmentation of density, but they render the liquor unpalatable. Sugar is frequently used with this view; 16 grains of refined sugar dissolved in 1000 grains of proof spirits gave it no suspicious taste, and increased its specific gravity from 0.920 to 0.925, which is a very great change, equivalent to the addition of 9 grains of water to a mixture of 100 grains of alcohol and 80 of water. For an account of the process of manufacturing spirits, see B E N T E L LER, P. 100.

SPIRING, a species of fish. See SALMO, Ichthyology, p. 99.

SPIRITHEAD, a road between Portsmouth and the isle of Wight, where the royal navy of Great Britain frequently rendezvous.

SPIT, in Physiology. See SALIV.

SPITZBERGEN. See GREENLAND, N° 10.

SPLAUNCHNUM, a genus of plants belonging to the class of cryptogramia, and order of musci. See BOTANY Index.

SPLEEN. See ANATOMY Index.

Spleen-Wort. See ASPLENIUM, BOTANY Index.

SPLENETIC, a person afflicted with an obstruction of the spleen.

SPLINT, or SPLINT, among farriers, a callous insensitive excrescence, breeding on the shank-bone of horses. See FARRIERS.

SPLICING, in the sea-language, is the untwisting the ends of two cables or ropes, and working the several strands into one another by a fidd, so that they become as strong as if they were but one rope.

SPOILS, whatever is taken from the enemy in time of war. Among the ancient Greeks, the spoils were divided among the whole army; only the general's share...
was largest; but among the Romans, the spoils belonged to the republic.

SPOLETTO, a duchy of Italy, bounded on the north by the marquisate of Ancona and duchy of Urbino, on the east by Foligno and Assisi, on the south by Sabina and the patrimony of St Peter, and on the west by Orvieto and Perugino. It is about 35 miles in length and 40 in breadth. It was anciently a part of Umbria, and now belongs to the pope. — The name of the capital city is also Spoleto. It was formerly a large place, but in 1703 was ruined by an earthquake; from whence it has never recovered itself.

SPOLIALITY, in ecclesiastical law, is an injury done by one clerk or incumbent to another, in taking the fruits of his benefice without any right thereto, but under a pretended title. It is remedied by a decree to account for the profits so taken. This injury, when the jus patronatus, or right of advowson, doth not come in debate, is cognizable in the spiritual court: as if a patron first presents A to a benefice, who is instituted and inducted thereto; and then, upon pretense of a vacancy, the same patron presents B to the same living, and he also obtains institution and induction. Now if A disposes the fact of the vacancy, then that clerk who is kept out of the profits of the living, whichever it be, may sue the other in the spiritual court for the spoliating, or taking the profits of his benefice. And it shall there be tried, whether the living were or were not vacant; upon which the validity of the second clerk's pretensions must depend. But if the right of patronage comes at all into dispute, as if one patron presented A, and another patron presented B, there the ecclesiastical court has no cognizance, provided the tithes sued for amount to a fourth part of the value of the living, but may be prohibited at the instance of the patron by the king's writ of indicavit. So also if a clerk, without any colour of title, ejects another from his patronage, this injury must be redressed in the temporal courts: for it depends upon no question determinable by the spiritual law (as plurality of benefices or no plurality, vacancy or no vacancy), but is merely a civil injury.

SPONDEE, in ancient poetry, a foot consisting of two long syllables, as onyx.

SPONDIA, or JAMAICA PLUM, a genus of plants belonging to the class of decandria. See Botany Index.

SPONGIA, SPONGE; a genus of animals belonging to the class of vermes, and order of zoeapha. It is fixed, flexible, and very torpid, growing in a variety of forms, composed either of reticulated fibres, or masses of small spines interwoven together, and clothed with a living gelatinous flesh, full of small mouths or holes on its surface, by which it sucks in and throws out the water. Fifty species have already been discovered, of which 10 belong to the British coasts. See Helminthology Index.

So early as the days of Aristotle sponges were supposed to possess animal life; the persons employed in collecting them having observed them shrink when torn from the rocks, thus exhibiting symptoms of sensation. The same opinion prevailed in the time of Pliny: But no attention was paid to this subject till Count Marsigli examined them, and declared them vegetables. Dr Peysonell, in a paper which he sent to the Royal Society in the year 1752, and in a second in 1757, affirmed they were not vegetables, but the production of animals; and has accordingly described the animals, and the process which they performed in making the sponges. Mr Ellys, in the year 1762, was at great pains to discover the animals. For this purpose he dissected the spongia urens, and was surprised to find a great number of small worms of the genus of nereis or sea scolopendra, which had pierced their way through the soft substance of the sponge in quest of a safe retreat. That this was really the case, he was fully assured of, by inspecting a number of specimens of the same sort of sponge, just fresh from the sea. He put them into a glass filled with seawater; and then, instead of seeing any of the little animals which Dr Peysonell described, he observed the papillae or small holes with which the papillæ are surrounded contract and dilate themselves. He examined another variety of the same species of sponge, and plainly perceived the small tubes inspire and expire the water. He therefore concluded that the sponge is an animal, and that the ends or openings of the branched tubes are the mouths by which it receives its nourishment, and discharges its excrements.

SPONSORS, among Christians, are those persons who, in the office of baptism, answer or are sureties for the persons baptized.

SPONTANEOUS, a term applied to such motions of the body and operations of the mind as we perform of ourselves without any constraint.

SPON-BILL. See Platalea, Ornithology Index.

SPONING, in the sea-language, is said of a ship, which being under sail in a storm at sea, is unable to bear it, and consequently forced to go right before the wind.

SPORADES, among ancient astronomers, a name given to such stars as were not included in any constellation.

SPORADIC DISEASES, among physicians, are such as seize particular persons at any time or season, and in any place; in which sense they are distinguished from epidemical and endemical diseases.

SPOTS, in Astronomy, certain places of the sun's or moon's disk, observed to be either more bright or dark than the rest; and accordingly called fuscule et macule. See Astronomy Index.

SPOTSWOOD, John, archbishop of St Andrew's in Scotland, was descended from the lairds of Spotswood in the Merse, and was born in the year 1565. He was educated in the university of Glasgow, and succeeded his father in the patronage of Calder when but 18 years of age. In 1601 he attended Lodowick duke of Lennox as his chaplain, in an embassy to the court of France for confirming the ancient amity between the two nations, and returned in the ambassador's retinue through England. When he entered into the archiepiscopacy of Glasgow, he found there was not 100. sterling of yearly revenue left; yet such was his care for his successors, that he greatly improved it, and much to the satisfaction of his diocese. After having filled this see 35 years, he was raised to that of St Andrew's in 1615, and made primate and metropolitan of all Scotland. He presided in several assemblies for restoring the ancient discipline, and bringing the church of Scotland to some degree of uniformity with that of England. He continued in high esteem with King James I, nor was he less valued by His Majesty's son, prince Charles, who died in 1630, and was given into the care of King James II. He died in the year 1641.
King Charles I., who was crowned by him in 1633, in the abbey-church of Holyroodhouse. In 1635, upon the death of the earl of Kinmou, chancellor of Scotland, our prime minister was advanced to that post; but had scarcely held it four years, when the confusions beginning in Scotland, he was obliged to retire into England; and being broken with age, grief, and sickness, died at London in 1639, and was interred in Westminster-abbey. He wrote An History of the Church of Scotland from the year 203 to the reign of King James VI. in folio.

SPROUT, or WATER-SPROUT. See WATER-SPROUT.
SPROUT-FISH. See SOLEN, CONCHOLOGY INDEX.

SPRAT, DR. THOMAS, bishop of Rochester, was born in 1636. He had his education at Oxford, and after the Restoration entered into holy orders. He became fellow of the Royal Society, chaplain to George duke of Buckingham, and chaplain in ordinary to King Charles II. In 1657 he published the History of the Royal Society, and a Life of Mr Cowley; who, by his last will, left to his care his printed works and MSS. which were accordingly published by him. In 1668 he was installed prebendar of Westminster; in 1680, was appointed canon of Windsor; in 1683, dean of Westminster; and in 1684, consecrated to the bishopric of Rochester. He was clerk of the closet to King James II.; in 1685, was made dean of the chapel royal; and the year following, was appointed one of the commissioners for ecclesiastical affairs. In 1692 his lordship, with several other persons, was charged with treason by two men, who drew up an association, in which they whose names were subscribed declared their resolution to restore King James; to seize the princess of Orange, dead or alive; and to be ready with 30,000 men to meet King James when he should land. To this they put the names of Sancroft, Sprat, Marlborough, Salisbury, and others. The bishop was arrested, and kept as a messenger's, under a strict guard, for eleven days. His house was searched, and his papers seized, among which nothing was found of treasonable appearance, except one memorandum, in the following words: Thorow-paced doctrine. Being asked at his examination the meaning of the words, he said that, about 20 years before, curiosity had led him to hear Daniel Burgess preach; and that being struck with his account of a certain kind of doctrine, which he said entered at one ear, and pacing through the head went out at the other, he had inserted the memorandum in his table-book, that he might not lose the substance of so strange a sermon. His innocence being proved, he was set at liberty, when he published an account of his examination and deliverance; which made such an impression upon him, that he commemorated it through life by an yearly day of thanksgiving. He lived to the 79th year of his age, and died May 10, 1713. His works, besides a few poems of little value, are, “The History of the Royal Society;” “The Life of Cowley;” “The Answer to Sorbiere;” “The History of the Rye-house Plot;” “The Relation of his own Examination;” and a volume of “Sermons.” Dr Johnson says, “I have heard it observed with great justice, that every book is the offspring of a different kind, and that each has its distinct and characteristic excellence.”

SPRAT. See CLUPEA, Ichthyology Index.

SPRAY, the sprinkling of the sea, which is driven from the top of a wave in stormy weather. It differs from spoon-drift, as being only blown occasionally from the broken surface of a high wave; whereas the latter continues to fly horizontally along the sea, without intermission, during the excess of a tempest or hurricane.

SPRING, in Natural History, a fountain or source of water rising out of the ground.

Many have been the conjectures of philosophers concerning the origin of fountains, and great pains have been taken both by the members of the Royal Society and those of the Academy of Sciences at Paris, in order to ascertain the true cause of it. It was Aristotle's opinion, and held by most of the ancient philosophers after him, that the air contained in the caverns of the earth, being condensed by cold near its surface, was thereby changed into water; and that it made its way through, where it could find a passage. But we have no experience of any such transmutation of air into water.

Those who imagine that fountains owe their origin to waters brought from the sea by subterraneous ducts, give a tolerable account how they lose their saltness by percolation as they pass through the earth: but they find great difficulty in explaining how water rises above the level of the sea to near the tops of mountains, where springs generally abound; it being contrary to the laws of hydrostatics, that a fluid should rise in a tube above the level of its source. However, they have found two ways whereby they endeavour to extricate themselves from this difficulty. The one is that of Des Cartes, who imagines, that after the water is become fresh by percolation, it is raised out of the caverns of the earth in vapour towards its surface; where meeting with rocks near the tops of mountains in the form of arches or vaults, it sticks to them, and runs down their sides, (like water in an alembic), till it meets with proper receptacles, from which it supplies the fountains. Now this is a mere hypothesis, without foundation or probability: for, in the first place, we know of no internal heat of the earth to cause such evaporation; or if that were allowed, yet it is quite incredible that there should be any caverns so smooth and void of protuberances as to answer the ends of an alembic, in collecting and condensing the vapours together in every place where fountains arise. There are others (as Varenius, &c.) who suppose that the water may rise through the pores of the earth, as through capillary tubes, by attraction. But hereby they show, that they are quite unacquainted with what relates to the motion of a fluid through such tubes: for when a capillary tube opens into a cavity at its upper end, or grows larger and larger, so as to cease to be capillary at that end, the water will not ascend through that tube into the cavity, or beyond where the tube is capillary; because that part of the periphery of the cavity, which is partly above the surface of the water, and partly below it, is not of the capillary kind. Nay, if the cavity is continually supplied with water, it will be attracted into the capillary tube, and run down it as through a funnel, if the lower end is immersed in the same fluid, as metals do in a container of that kind. It has been a generally received opinion, and much espoused by Mariotte (a diligent observer of nature), that the rise of springs is owing to the rains and melted snow. According to him, the rain-water which falls upon the hills and mountains, penetrating the surface,
all objections, makes allowances, probably greater than what were absolutely necessary.

The Mediterranean receives the following considerable rivers, viz. the Iberus, the Rhone, the Tiber, the Po, the Danube, the Niester, the Borysthenes, the Tanais, and the Nile. Each of these it supposes to bring down ten times as much water as the Thames, whereby he allows for smaller rivers which fall into the same sea.

The Thames, then, he finds by measurement to discharge about 30,000,000 tons of water a day. If therefore the above-said nine rivers yield ten times as much water as the Thames doth, it will follow that all of them together yield but 1827 millions of tons in a day, which is but little more than one-third of what is proved to be raised in vapour out of the Mediterranean in the same time. We have therefore from hence a source abundantly sufficient for the supply of fountains.

Now having found that the vapour exhaled from the sea is a sufficient supply for the fountains, he proceeds in the next place to consider the manner in which they are raised; and how they are condensed into water again, and conveyed to the source of springs.

In order to this he considers, that if an atom of water was expanded into a shell or bubble, so as to be ten times as big in diameter as when it was water, that atom would become specifically lighter than air; and therefore would rise so long as the warmth which first separated it from the surface of the water should continue to distend it to the same degree; and consequently, that vapours may be raised from the surface of the sea in that manner, till they arrive at a certain height in the atmosphere, at which they find air of equal specific gravity with themselves. Here they will float till, being condensed by cold, they become specifically heavier than the air, and fall down in dew; or being driven by the winds against the sides of mountains (many of which far surpass the usual height to which the vapours would of themselves ascend), are compelled by the stream of the air to mount up with it to the tops of them; where being condensed into water, they presently precipitate, and glistening down by the crannies of the stones, part of them enters into the caverns of the hills; which being once filled, all the surplus water in the hills runs over by the lowest place, and breaking out by the sides of the hills forms single springs. Many of these running down by the valleys between the ridges of the hills, and coming to unite, form little rivulets or brooks; many of these again meeting in one common valley, and gaining the plain ground, being grown less rapid, become a river; and many of these being united in one common channel, make such streams as the Rhine and the Danube; which latter, he observes, one would hardly think to be a collection of water condensed out of vapour, unless we consider how vast a tract of ground that river drains, and that it is the sum of all those springs which break out on the south side of the Carpathian mountains, and on the north side of the immense ridge of the Alps, which is one continued chain of mountains from Switzerland to the Black sea.

Thus one part of the vapours which are blown on the land is returned by the rivers into the sea from whence it came. Another part falls into the sea before it reaches the land; and this is the reason why the rivers do not return so much water into the Mediterranean.

4 H 2
mean as is raised in vapour. A third part falls on the low lands, where it affords nourishment to plants; yet it does not rest there, but is again exhaled in vapour by the action of the sun, and is either carried by the winds to the sea to fall in rain or dew there, or else to the mountains to become the sources of springs.

However, it is not to be supposed that all fountains are owing to one and the same cause; but that some proceed from rain and melted snow, which, subsiding through the surface of the earth, makes its way into certain cavities, and thence issues out in the form of springs; because the waters of several are found to increase and diminish in proportion to the rain which falls: that others again, especially such as are salt, and spring near the sea-shore, owe their origin to sea-water percolated through the earth; and some to both these causes: though without doubt most of them, and especially such as spring near the tops of high mountains, receive their waters from vapours, as before explained.

This reasoning of Dr Halley's is confirmed by more recent observations and discoveries. It is now found, that though water is a tolerable conductor of the electric fluid, dry earth is an electric per se, consequently the dry land must always be in an electrified state compared with the ocean, unless in such particular cases as are mentioned under the article EARTHQUAKE, No. 82. It is also well known, that such bodies as are in an electrified state, whether plus or minus, will attract vapour, or other light substances that come near them. Hence the vapours that are raised from the ocean must necessarily have a tendency to approach the land in great quantity, even without the assistance of the wind, though this last must undoubtedly contribute greatly towards the same purpose, as Dr Halley justly observes. In like manner, the higher grounds are always in a more electrified state than the lower ones: and hence the vapours having once left the ocean and approached the shore, are attracted by the high mountains; of which Mr Pennant gives an instance in Snowdon. Hence we may see the reason why springs are so common in the neighbourhood of mountains, they being so advantageously formed in every respect for collecting and condensing the vapour into water.

The heat of springs is generally the same with the mean temperature of the atmosphere. The mean temperature of the south of England is 48°; in Scotland, near Edinburgh, it is 45°; in the north of Ireland it is 48°, and on the south coast about 51°. At Upsal, in Sweden, it is 43°, and in Paris 53°. According to accurate experiments made by eminent philosophers, the heat of the springs in these different countries corresponds with the medium temperature. We have not heard that similar experiments have been made in other countries, or we should have been careful to collect them. We do not, however, doubt but they have been made in most countries of Europe; yet we suspect little attention has been paid to this subject within the tropical regions. See CLIMATE, SUPPLEMENT.

Though this coincidence of the heat of springs with the mean temperature of the climate where they flow, seems to be a general fact, yet it admits of many exceptions. In many parts of the world there are springs which not only exceed the mean temperature, but even the strongest meridian heat ever known in the torrid regions. The following table will give a distinct notion of the degrees of heat which different springs have been found to possess, according to the experiments of philosophers. It is necessary to remark that experiments made upon the same springs, made by different persons, vary a little from one another, which may be owing to many accidents easily accounted for. Where this is the case, we shall mention both the lowest and highest degree of heat which has been ascribed to the same spring, according to Fahrenheit's thermometer.

In cold countries where congelation takes place, the heat of the earth is considerably above the freezing point, and continues so through the whole year. From experiments that have been made in mines and deep pits, it appears that this heat is uniform and stationary at a certain depth. But as the heat of these springs far exceeds the common heat of the internal parts of the earth, it must be occasioned by causes peculiar to certain places; but what these causes are it is no easy matter to determine. We are certain, indeed, that hot springs receive their heat from some subterranean cause; but it is a matter of difficulty to investigate how this heat is produced and preserved. Theories, however, have been formed on this subject. The subterranean heat has been ascribed to the electrical fluid, and to a great body of fire in the centre of the earth. But we suspect that the nature of the electrical fluid and its effects are not sufficiently understood. As to the supposition that the heat of springs is owing to a central fire, it is too hypothetical to require any refutation. From what then does this heat originate, and whence is the fuel which has produced it for so many ages? To enable us to answer these questions with precision, more information is necessary than we have hitherto obtained respecting the structure of the internal parts of the earth. It is particularly requisite that we should be made acquainted with the fossils which are most common in those places where hot springs abound. We should then perhaps discover that hot springs always pass through bodies of a combustible nature. It is well known to chemists, that when water is mixed with the vitriolic acid, a degree of heat is produced superior to that of boiling water. It is also an established fact, that when water meets with pyrites, that is, a mixture of sulphur and iron, a violent inflammation takes place. If, therefore, we could prove that these materials exist in the strata from which hot springs are derived, we should be enabled to give a satisfactory account of this curious phenomenon. As some apology for this supposition, we may add, that most of the hot springs mentioned above have been found by analysis to be impregnated with sulphur, and some of them with iron.
SPRINT, a small boom or pole which crosses the sail of a boat diagonally, from the mast to the upper hindmost corner of the sail, which it is used to extend and elevate; the lower end of the sprit rests in a sort of wreath or collar called the smother, which encircles the mast in that place.

SPRINTSAIL. See Sail and Ship.

SPRITSAIL-TOPMAST. See Sail and Ship.

SPRUCE-TREE. See Pinus, Botany Index.

SPRUCE: Beer, a cheap and wholesome liquor, which is thus made: Take of water 16 gallons, and boil the half of it. Put the water thus boiled, while in full heat, to the reserved cold part, which should be previously put into a barrel or other vessel; then add 16 pounds of treacle or molasses, with a few table spoonfuls of the essence of spruce, stirring the whole well together; add half a pint of yeast, and keep it in a temperate situation, with the bung hole open, for two days, till the fermentation be abated. Then close it up or bottle it off, and it will be fit for being drunk in a few days afterwards. In North America, and perhaps in other countries, where the black and white spruce fire abound, instead of adding the essence of the spruce at the same time with the molasses, they make a decoction of the leaves and small branches of these trees, and find the liquor equally good. It is a powerful antiscorbutic, and may prove very useful in long sea voyages.

SPUNGE, or Sponge. See Spongia.

SPUNGING, in Gunnery, the cleaning of the inside of a gun with a sponge, in order to prevent any sparks of fire from remaining in it, which would endanger the life of him that should load it again.

SPUN-YARN, among sailors, is a kind of line made from rope yarn, and used for seizing or fastening things together.

SPUNK. See Boletus, Botany Index.

SPUR, a piece of metal consisting of two branches encompassing a horsemans's heel, and a rowel in form of a star, advancing out behind to prick the horse.

SPUR-WINGED Water-Hen. See Parra, Ornithology Index.

SPURGE. See Euphorbia, Spurious-Laurel. See Daphne, Botany Index.

SPURREY. See Spercula.

SPY, a person hired to watch the actions, motions, &c. of another; particularly what passes in a camp. When a spy is discovered, he is hanged immediately.

SQUADRON, in military affairs, denotes a body of horse whose number of men is not fixed, but it is usually from 100 to 200.

Squadron of Ships, either implies a detachment of ships employed on any particular expedition, or the third part of a naval armament.

SQUADS, in a military sense, are certain divisions of a company into so many squads, generally into three or four. The use of forming companies into as many squads of inspection as it has serjeants and corporals, is proved by those regiments who have practised that method; as by it the irregularity of the soldiers is considerably restrained, their dress improved, and the discipline of the regiment in general most remarkably forwarded. Every officer should have a roll of his company by squads.

SQUALL, a sudden and violent blast of wind usually occasioned by the interruption and reverberation of the wind from high mountains. These are very frequent in the Mediterranean, particularly that part of it which is known by the name of the Lecant, as produced by the repulsion and new direction which the wind meets with in its passage between the various islands of the Archipelago.

SQUALUS, the Shark; a genus of fishes arranged by Linneus under the class of amphibia, and the order of nantes, but by Gmelin referred to the class of pisces, and order of chondropterygi. See Ichthyology Index.

SQUAMARIA. See Lanthra, Botany Index.

SQUAMOUS, in Anatomy, a name given to the spurious or false sutures of the skull, because composed of squamae or scales like those of fishes.

SQUARE, in Geometry, a quadrilateral figure both equilateral and equiangular. See Geometry.

Square Root. See Algebra and Arithmetic, No 33 and 34.

Hollow Square, in the military art, a body of foot drawn...
drawn up with an empty space in the middle, for the colours, drums, and baggage, faced and covered by the pikes every way to keep off the horse.

SQUARE, among mechanics, an instrument consisting of two rules or branches, fastened perpendicularly at one end of their extremities, so as to form a right angle. It is of great use in the description and measurement of right angles, and laying down perpendiculars.

T. SQUARE, or TEE SQUARE, an instrument used in drawing, so called from its resemblance to the capital letter T.

SQUARE-RIGGED, an epithet applied to a ship whose yards are very long. It is also used in contradiction to all vessels whose sails are extended by stays or lateen-yards, or by booms and gaffs; the usual situation of which is nearly in the plane of the keel, and hence,

SQUARE-SAIL, is a sail extended to a yard which hangs parallel to the horizon, as distinguished from the other sails which are extended by booms and stays placed obliquely. This sail is only used in fair winds, or to scud under a tempest. In the former case, it is furnished with a large additional part called the bonnet, which is then attached to its bottom, and removed when it is necessary to scud. See SCUDDING.

SQUARING or QUADRATURE of the Circle, signifies the finding a square exactly equal to the area of a given circle. This problem however has not been, and probably cannot be, strictly resolved by the commonly admitted principles of geometry; mathematicians having hitherto been unable to do more than to find a square that shall differ from the area of any proposed circle by as small a quantity as they please. The quadrature of the circle is a problem of the same degree of difficulty, and indeed may be regarded as identical with another geometrical problem, namely, the Rectification of the circle, or the finding a straight line equal to its circumference; for the area of a circle is equal to that of a rectangle contained by the radius and a straight line equal to half the circumference (GEOMETRY, Sect. VI. Prop. 3.); therefore, if a straight line exactly equal to the circumference could be found, a rectilinear space precisely equal to the area might also be found, and the contrary. But although no perfectly accurate resolution of the problem has been obtained under either form, we can always find approximate values of the area and circumference; and therefore it is now customary to apply the terms quadrature and rectification of the circle also to these.

The problem of the quadrature of the circle appears to have engaged the attention of geometers at a very early period; for we are told that Anaxagoras, who lived about 500 years before Christ, attempted its solution while confined in prison on account of his philosophical opinions. We are ignorant of the result of his researches; but although we cannot suppose they were attended with any success, we may reasonably conclude that we are indebted to them for the discovery of some of the properties of the figure, which are now known as elementary propositions in geometry.

Hippocrates of Chios was likewise engaged in trying to resolve the same problem, and it was no doubt in the course of his inquiries into this subject that he discovered the quadrature of the curvilinear space, which is now known by the name of the Lune of Hippocrates. The nature of this discovery may be briefly explained as follows. Let ABCD be a circle (Plate D. fig. 1.), H its centre, AC its diameter, ADC a triangle inscribed in the semicircle, having its sides AD, DC equal to one another. On D as a centre, with DA or DC as a radius, let the quadrantial arch AEC be described, then shall the curvilinear space bounded by the semicircle ABC and the quadrantial arch AEC (which is the Lune of Hippocrates) be equal to the rectilinear triangle ADC. For because circles are to one another as the squares of the radii (GEOMETRY, Sect. VI. Prop. 11.), the circle having DA for its radius will be to the circle having HA for its radius as the square of DA to the square of HA, that is, as 2 to 1; hence the former of these circles will be double the latter, and consequently one-fourth of the former will be equal to one half of the latter; that is, the quadrant AEC will be equal to the semicircle ABC; from these equals take away the common space bounded by the diameter AC and the arch AEC, and there will remain the triangle ADC equal to the lunular space AECBA.

Although Hippocrates' discovery has led to no important conclusion either relating to the quadrature of the circle or that of any other curve, yet at the time it was made it might be regarded as of some consequence, chiefly because it shewed the possibility of exhibiting a rectilinear figure equal to a space bounded by curve lines, a thing which we have reason to suppose was then done for the first time, and might have been fairly doubted, considering the insuperable difficulty that was found to attend the quadrature of the circle or its rectification.

Aristotle speaks of two persons, viz. Bryson and Antipholon, who about his time, or a little earlier, were occupied with the quadrature of the circle. The former appears, according to the testimony of Alexander Aprodicus, to have erred most egregiously; he having concluded that the circumference was exactly 3 1/2 times the diameter. And the latter seems to have proceeded pretty much in the same manner as Archimedes afterwards did in squaring the parabola, that is, by first inscribing a square in the circle, then an isosceles triangle in each of the segments of the curve, having for its base a side of the square; and next again a series of triangles in the segments, having for their bases the sides of the former series, and so on: this mode of procedure, however, could not be attended with any success, as it is well known that the spaces thus formed do not, as in the case of the parabola admit of being absolutely summed.

It may naturally be supposed that Archimedes exerted his utmost efforts to resolve this problem; and probably it was only after long meditation on the subject that he lost all hopes of success, and contented himself with that approximation to the ratio of the diameter to the circumference which is contained in his treatise De Circuli Dimensione, which has been preserved from the period in which he wrote, about 250 years before Christ, to the present times. He found his approximation to the ratio, by supposing a regular polygon of 96 sides to be described about the circle, and another of the same number of sides to be inscribed in it, and by showing that the perimeter of the circumscribing polygon was less than 3 1/4 or 3 1/2 times the diameter, but that the perimeter of the inscribed figure was greater than 3 1/4 times the
SQUARING or Quadrature of the Circle.

STARCH. Manufacture of.
the diameter; now the circumference of the circle being less than the perimeter of the one polygon but greater than that of the other, it follows that the circumference must be less than \( \frac{3}{7} \) times the diameter, but greater than \( \frac{343}{107} \) times; so that, taking the first of these limits as being expressed by the smallest numbers, the circumference will be to the diameter as \( \frac{343}{107} \) to 1, or as 22 to 7 nearly.

Although the approximate ratio investigated by Archimedes be the oldest known to have been found in the western world, yet one more accurate seems to have been known at a much earlier period in India. This we learn from the Institutes of Akbar (Ayoen Akberry) where it is said that the Hindoos suppose the diameter of a circle to be to its circumference as 1250 to 3927. Now this ratio, which is the same as that of \( \frac{1}{2} \) to 3.1416, when found in the simplest and most elementary manner must have required the inscription of a polygon of 768 sides in the circle, and must have been attended with nine extractions of the square root, each carried as far as ten places of figures.

We learn from Simplicius that Nicomedes and Apollonius both attempted to square the circle, the former by means of a curve which he called the Quadratrix; the invention of which, however, is ascribed to Dinostratus, and the latter also by the help of a curve denominated the sister to the tortoise line or spiral, and which was probably no other than the quadratrix of Dinostratus; the nature of which, and the manner of its application to the subject in question, we shall briefly explain.

Let \( AFB \) be a quadrant of a circle (fig. 2.) and \( C \) its center, and conceive the radius \( CF \) to revolve uniformly about \( C \) from the position \( CA \) until at last it coincide with \( CB \); while at the same time a line \( DG \) is carried with an uniform motion from \( A \) towards \( CB \), the former line continuing always parallel to the latter, until at last they coincide; both motions being supposed to begin and end at the same instant. Then the point \( E \) in which the revolving radius \( CF \) and the moveable line \( DG \) intersect one another will generate a certain curve line \( AEH \), which is the Quadratrix of Dinostratus.

Draw \( EK, FL \) both perpendicular to \( CB \); then because the radius \( AC \) and the quadrantal arch \( AFB \) are uniformly generated in the same time by the points \( D \) and \( F \), the contemporaneous spaces described will have to one another the same ratio as the whole spaces; that is, \( AD/AF = AC/AB \); hence we have \( AC/AB = DC/EC \), or \( EC/EB \). Now as the moveable point \( F \) approaches to \( B \), the ratio of the straight line \( EK \) to the straight line \( FI \), which again is equal to the ratio of \( CE \) to \( CF \); therefore the ratio of the radius \( AC \) to the quadrantal arch \( AFB \) is the limit of the ratio of \( CE \) to \( CF \), and consequently equal to the ratio of \( CH \) to \( CB \), \( H \) being the point in which the quadratrix meets \( CB \). Hence therefore \( CE/CH = CA/CH \), and \( CH \); quadrantal arch \( AFB \); if by any means we could determine the point \( H \), we might then find a straight line equal to the quadrantal arch, (by finding a third proportional to \( CH \) and \( CB \)) and consequently a straight line equal to the circumference. The point \( H \), however, cannot be determined by a geometrical construction, and therefore all the ingenuity evinced by the person who first thought of this method of rectifying the circle (which certainly is considerable) has been unavailing.

The Arabs, who succeeded the Greeks in the cultivation of the sciences, would not doubt have their pretended squares of the circle. We however know nothing more than that some one of them believed he had discovered that the diameter being unity, the circumference was the square root of 10; a very gross mistake; for the square root of 10 exceeds 3.162; but Archimedes had demonstrated that the circumference was less than 3.143.

It appears that, even during the dark ages, some attempts were made at the resolution of this famous problem, which however have always remained in manuscripts buried in the dust of old libraries. But upon the revival of learning the problem was again agitated by different writers, and particularly by the celebrated Cardinal De Cusa, who distinguished himself by his unfortunate attempt to resolve it. His mode of investigation, which had no solid foundation in geometry, led him to conclude, that if a line equal to the sum of the radius of a circle and the side of its inscribed square were made the diameter of another circle, and an equilateral triangle were inscribed in this last, the perimeter of this triangle would be equal to the circumference of the other circle. This pretended quadrature of the cardinal’s was refuted by Regiomontanus; and indeed the task was not difficult; for, according to his construction, the diameter being 1, the circumference was greater than \( \frac{343}{107} \); a conclusion which must be absurd, proving that Archimedes had demonstrated that it must be less than that number.

It would be trespassing too much upon the patience of our readers, were we to mention all the absurd and erroneous attempts which have been made during the last three centuries to square the circle. In a supplement to Montucla’s excellent work, Histoire des Mathématiques, we find upwards of forty pretenders to the honour of this discovery enumerated. These were almost all very ignorant of geometry; and many of them were wild visionaries, pretending to discover inexplicable relations between the plain truths of mathematics and the most mysterious doctrines of religion. If those who have sought the quadrature of the circle had been previously initiated in the doctrines of geometry, although they missed attaining the object they had in view, yet they could not have failed to have extended the boundaries of the science by the discovery of many new propositions. From such persons, however, as have generally pursued this inquiry, no improvement whatever of the science was to be expected; although, indeed, in some instances, it has derived advantage from the labours of such as have undertaken to expose the absurdity of their conclusions; as in the case of Metius, who in refuting the quadrature of one Simon à Quereus, found a much nearer approximation to the ratio of the diameter to the circumference than had been previously known, at least in Europe, viz. that of 113.5 to 355, which reduced to decimals is the same as the ratio of \( \pi \) to \( 3.1415926 \), differing from the truth only in the seventh place of decimals.

Among the most remarkable of those who have recorded their own folly by publishing erroneous resolutions of the problem, we may reckon the celebrated Joseph Scaliger. Full of self-conceit, he believed that, en-
Squaring, entering upon the study of geometry, he could not fail to surmount by the force of his genius those obstacles which had completely stopt the progress of all preceding inquirers. He gave the result of his meditations to the world in 1592, under the title *Nova Cycloemetrica*; but he was refuted by Clavius, by Vieta, and others, who shewed that the magnitude he had assign-
ed to the circumference was a little less than the per-
imeter of the inscribed polygon of 192 sides, which proved beyond a doubt that he was wrong. Scaliger, how-

ever, was not to be convinced of the absurdity of his conclusion; and indeed, in almost every instance, pre-
tenders to this discovery have not been more remarkable for their folly in committing absurd blunders, than for their obstinacy in maintaining that they were in the right, and all who held a contrary opinion in an error.

The famous Hobbes came also upon the field about the year 1650, with pretensions not only to the qua-
drature of the circle, but also to the trisection of an angle, the rectification of the parabola, &c.; but his pretended solutions were refuted by Dr Wallis. And this circumstance afforded him occasion to write not only against geometers, but even against the science of geometry itself.

We find it recorded by *Monteucia*, as a sort of phe-

nomenon, that one Richard White, an English Jesuit, having happened upon what he conceived to be a qua-
drature of the circle, which he published under the title *Chrysogesi seu Quadratura Circuli*, suffered himself at last to be convinced by some of his friends that he was wrong both in his quadrature of the circle, and in his rectification of the spiral. But a solution of the same problem found out by one Mathunel of Lyons, did not produce in the end so much advantage to its author. This man in 1728 announced to the learned world that he had discovered both the quadrature of the circle and a perpetual motion; and he was so certain of the truth of these discoveries, that he consigned 1000 ecus (about 123l.) to be paid to any one who should demonstrate that he was deceived in either. The task was not difficult. Nicole of the Academy of Sciences demon-

strated that he was wrong, and he himself allowed it; but he hesitated to pay the money, which Nicole had re-
linquished in favour of the *Hotel Dieu* of Lyons. The affair went before a court of justice, which adjudged the money to be paid, as Nicole had destined it, to the poor. At a later period, viz. in 1753, the Chevalier de Causans, a French officer, and a man who was never expected to be a mathematician, suddenly found a qua-
drature of the circle in procuring a circular piece of turf to be cut; and rising from one truth to another, he explained by his quadrature the doctrine of original sin, and the Trinity. He engaged himself by a public writing to deposit with a notary the sum of 300,000 francs, to be wagered against such as should oppose him, and he actually lodged 10,000, which were to devolve to him who should demonstrate his error. This was easily done, as it resulted from his discovery that a circle was equal to its circumscribing square, that is, a part to the whole! Some persons came forward to answer his challenge, and in particular a young lady sued him at one of the courts of law; but the French king judged that the Chevalier's fortune ought not to suffer on ac-
count of his whim; for, setting aside this piece of folly, in every other respect he was a worthy man. The pro-

cedure was therefore stopt, and the wager declared void.

We shall not enter farther into the history of these vain and absurd attempts to resolve this important pro-

blem, but proceed to state what has actually been done by men of sound minds and real mathematical acquire-
ments towards its solution. And in the first place it may be observed that the problem admits of being pro-

posed under two different forms: for it may be required to find either the area of the whole circle, or, which is the same thing, the length of the whole circumference; or else to find the area of any proposed sector or seg-

ment, or, which is equivalent, the length of the arch of the sector or segment. The former is termed the *definite* and the latter the *indefinite* quadrature of the circle. The latter evidently is more general than the former, and includes it as a particular case. Now if we could find by any means a finite algebraic equation that should express the relation between any proposed arch of a circle, and some known straight line or lines, the magnitude of one or more of which depended on that arch, then we would have an absolute rectification of the arch, and consequently a rectification or qua-
drature also of the whole circle. We here speak of an analytical solution of the problem; the ancients, how-

ever, who were almost entirely ignorant of this branch of mathematical science, must have endeavoured to treat it entirely upon geometrical principles. It is now well known, however, that all geometrical problems may be subjected to analysis; and that it is only by such a mode of proceeding they have in many cases been resolved.

With respect to the definite quadrature of the circle, it is commonly understood that no unexceptionable de-

monstration of its impossibility has hitherto been published. It is true that James Gregory, in his *sua circuiti et Hyperbole quadratura*, has given what he considered as such a demonstration; but it has been objected to, particularly by Huygens, one of the best geometers of his time. We are, however, certain that the ratio of the diameter to the circumference, as also, that the ratio of the square of the diameter to the square of a straight line equal to the circumference, cannot be expressed by ra-

tional numbers, for this has been strictly demonstrated by Lambert in the Berlin Memoirs for 1761. A demo-

stration is also given in Legendre's *Géométrie*. As to the indefinite quadrature, if Newton's demonstration of the 28th lemma of the first book of his *Principia* be cor-

tect, the thing ought to be absolutely impossible. For the object of that proposition is to prove that in no oval figure whatever, that returns into itself, can the area cut off by straight lines at pleasure be universally found by an equation of a finite dimension, and composed of a finite number of terms. If this be true, then it will be impossible to express any sector of a circle taken at pleasure in finite terms. It is however to be remarked, that the accuracy of the reasoning by which Newton has attempted to establish the truth of the general proposition has been questioned by no less a geomter as D'Alembert; and indeed we know one oval curve, which returns into itself, and which, according to New-

ton's proposition, ought therefore not to admit of an in-

definite quadrature; yet this is by no means the case, for it does really admit of such a quadrature. The curve we mean is the *lemniscata*, the equation of which is $(x^a+y^a)=a(x^a-y^a)$, where $x$ and $y$ denote its co-

ordinates,
much elegance after the manner of the ancients, that
it would be wrong to number him with those absurd
pretenders which we have already noticed. Gregory's
mistake was the cause of a sharp controversy carried on
between his disciples on the one side, and by Huygens,
Merianus, and Lestaud, on the other; and it was this
that gave Huygens occasion to consider particularly the
quadrature of the circle, and to investigate various
new and curious theorems relating to it, which are
contained in his Theorematum de Quadraturae Hyperbolae,
Elipsis, et Circuli, 1655; and in his work De Circuli Magnitu
Indentura. 1659. In particular he showed, that if
c denote the chord of an arc, and e its sine, then the
arc itself will be greater than 
\( c + \frac{4e}{2c+4e} \cos (c-e) \), but less
than 
\( c + \frac{4e}{2c+4e} \cos (c-e) \).

James Gregory, in his Vera Circuli et Hyperbola Quadratura, gave several curious theorems upon the relation of the circle to its inscribed and circumscribed polygons, and their ratios to one another; and by means of these
he found with infinitely less trouble than by the ordinary
methods, and even by those of Snellius, the measure
of the circle as far as 20 places of figures. He
gave also, after the example of Huygens, constructions for finding straight lines nearly equal to arches of a
circle, and of which the degree of accuracy was greater.
For example, he found that if A be put for the chord
of an arch of a circle, and B for twice the chord of half the arch, and C be taken such that 
\( A + B : B = 2 : C \), then the arch itself is nearly equal to
\( 8C+8B-A \), but a little less, the error in the case of
a complete semicircle being less than its \( \frac{1}{12} \) part;
and when the arch does not exceed 120\(^\circ\), it is less than
its \( \frac{1}{10} \) part; and finally, for a quadrant the error is
not greater than its \( \frac{1}{40} \) part. And farther, that
if D be such that 
\( A : B : D = 12C+4B-D \), then the arc
is nearly equal to 
\( \frac{15}{12} \), but a little greater, the
error in the semicircle being less than its \( \frac{1}{8} \) part, and
in a quadrant less than its \( \frac{1}{32} \) part.
The discoveries of De Wallis, delivered in his Arithmetica
Infinitorum published in 1655, led him to a singular
expression for the ratio of the circle to the square of its diameter. He found that the former was to the latter as 1 to the product
\( 3 \times 3 \times 5 \times 5 \times 7 \times 7 \times 9 \times 9 \times 11 \times 11 \times \ldots \)
\( 2 \times 4 \times 4 \times 6 \times 6 \times 8 \times 8 \times 10 \times 10 \times 12 \)
the fractions \( \frac{1}{4}, \frac{1}{4}, \frac{1}{8}, \ldots \) being supposed infinite in number. The products being supposed continued to infinity, we have the ratio exactly; but if we stop at any
finite number of terms, as must necessarily be the case in
its application, the result will be alternately too great
and too small, according as we take an odd or an even
number of terms of the numerator and denominator.

Thus
Squaring. Thus the fraction \( \frac{1}{3} \) is too great; on the other hand,
\[
\frac{5 \times 3}{2 \times 4} = \frac{5}{8} \quad \text{is too small, and} \quad \frac{5 \times 3 \times 5}{2 \times 4 \times 4} = \frac{45}{64} \quad \text{too great,}
\]
and so on. But to approach as near as possible in each case, Wallis directs to multiply the product by the square
root of a fraction formed by adding to unity the reciprocal of the last factor in either its numerator or denominator;
then the result, although much nearer, will be too great if the number whose reciprocal is taken be the last in the numerator, but too small if it be the number in the denominator. Thus the following series of expressions will give approximate values of the infinite
product \[
\frac{3 \times 3 \times 5 \times 7 \times \cdots}{2 \times 4 \times 6 \times 8 \times \cdots}
\]
which are alternately too great and too small.

\[
\begin{align*}
3 & \cdot 3 \cdot 5 \cdot 7 \cdot 2 \cdot 4 \cdot 6 \cdot 8 \cdot & (1 + \frac{1}{2}) \cdot (1 + \frac{1}{5}) \cdot (1 + \frac{1}{7}) \cdot + & \cdots; \\
3 & \cdot 3 \cdot 5 \cdot 7 \cdot 2 \cdot 4 \cdot 6 \cdot 8 \cdot & (1 + \frac{1}{4}) \cdot (1 + \frac{1}{5}) \cdot (1 + \frac{1}{7}) \cdot + & \cdots; \\
3 & \cdot 3 \cdot 5 \cdot 7 \cdot 2 \cdot 4 \cdot 6 \cdot 8 \cdot & (1 + \frac{1}{4}) \cdot (1 + \frac{1}{6}) \cdot (1 + \frac{1}{7}) \cdot + & \cdots; & \&c.
\end{align*}
\]
these values, alternately too great and too small, fall between the known limits.

An expression of another kind for the ratio of the circle to the square of the diameter was found by Lord
Bruncker. He showed that the circle being unity, the square of the diameter is expressed by the continued fraction
\[
1 + \frac{1}{2 + \frac{2}{9 + \frac{2}{2 + \frac{25}{2 + \frac{49}{2 + \cdots}}}}} = \frac{1}{\sqrt{2}}
\]
which is supposed to go on to infinity, the numerators 1, 2, 3, 9, 25, 49, &c. being the squares of the odd numbers 1, 3, 5, 7, &c. By taking two, three, four, &c. terms of this fraction, we shall have a series of approximate values which are alternately greater and less than its accurate value.

Such were the chief discoveries relating to the quadrature of the circle made before the time of Newton: many others, however, were quickly added by that truly great man, as well as by his contemporaries. In particular, Newton himself showed that if \( s \) denote the sine, and \( v \) the versed sine of an arch, then the radius being unity, the arch is equal to either of the following series,

\[
\begin{align*}
& \frac{s + 1}{2} + \frac{1.3}{2} + \frac{1.3.5}{2} + \frac{1.3.5.7}{2} + \cdots; \\
& \sqrt{2\over 1 + 1.3} \cdot \left( 1 + 1.3 + 1.3.5 + 1.3.5.7 + 1.3.5.7.9 + \cdots \right), & \&c.
\end{align*}
\]
And James Gregory found that \( t \) being put for the tangent, the arch is expressed by the very simple series
\[
t - \frac{t^3}{3} + \frac{t^5}{5} - \frac{t^7}{7} + \frac{t^9}{9} - \cdots, & \&c.
\]
We have investigated the first of these series at § 140, and the third at § 137, of the article Fluxions: the
second is easily obtained from the first by considering that since the sine of an arch is half the chord of twice
the arch, that is, half of a mean proportional between the diameter and versed sine of twice the arch; we have
therefore only to multiply the first series by \( 2 \), and to substitute \( 1/\sqrt{2}v \) instead of \( s \), and we get the second series.

By taking \( t = 1 \), then, because in this case the arch contains \( 30^\circ \), we have half the circumference to the
radius \( r \), or the whole circumference to the diameter \( t \), expressed by the infinite series
\[
3(1 + \frac{1}{2.f^2} + \frac{1.3}{2.4.f^2} + \frac{1.3.5}{2.4.6.f^2} + \frac{1.3.5.7}{2.4.6.8.f^2} + \cdots, & \&c.).
\]

And by supposing that in the third series \( t = 1 \), in which the arc is one-eighth of the circumference, we have the same things expressed by the series
\[
4(1 - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} + \frac{1}{9} - \cdots + \frac{1}{11} + , & \&c.).
\]
which was given by Leibnitz as a quadrature of the circle in the Leipsic Acts in the year 1682; but was discovered by him 1673. Gregory, however, had found the series under its general form several years before. By the first of these two numerical series we can readily compute the circumference of the circle to a tolerable degree of accuracy; but the second is altogether inapplicable in its present form on account of the slowness of its convergency; for Newton has observed that to exhibit its value exact to twenty places of figures, there would be occasion for no less than five thousand millions of its terms, to compute which would take up above a thousand years.

The slowness of the convergency has arisen from our supposing \( t = 1 \). If we had supposed \( t \) greater than 1, then the series would not have converged at all, but on the contrary diverged. But by giving to \( t \) a value less than 1, then the rate of convergency will be increased, and that so much the more, as \( t \) is smaller.

If we suppose the arc of the tangent to be \( 30^\circ \), then \( t \) will be \( \frac{1}{2}\sqrt{3} = \frac{1}{2}\sqrt{3} \), and therefore half the circumference to radius unity, or the circumference to the diameter unity, which in this case is
\[
6t (1 - \frac{t^3}{3} + \frac{t^5}{5} - \frac{t^7}{7} + \frac{t^9}{9} + \cdots, & \&c.)\]
\[
\frac{1}{\sqrt{12}} (1 - \frac{1}{3} + \frac{1}{3.5} - \frac{1}{3.5.7} + \frac{1}{3.5.7.9} + \cdots, & \&c.).
\]

By means of this series, in an hour's time the circumference may be found to be nearly 3.141592653589793238462643383279502884197169399375105820974944592307816462862089988628034825342117064.

After him, De Lagny continued it as far as
Squaring. 128 figures. But he has also been outdone for in Radcliffe's library at Oxford, there is a manuscript in which it is carried as far as 150 figures:

Although this last series, which was first proposed by Dr Halley, gives the ratio of the diameter to the circumference with wonderful facility when compared with the opus method employed by Van Ceulen, yet others have been since found which accomplish it with still greater ease. In Halley's series we have to compute the irrational quantity \( \sqrt{12} \), because of the irrational value which it was necessary to give to \( t \) in order to render it sufficiently small, and at the same time an exact part of the whole circumference; but Mr Machin contrived, by a very ingenious artifice, to reduce the computation of an arch of \( 45^\circ \), and consequently the length of the whole circumference, to two series which contain only rational quantities, and which at the same time converge with great rapidity. The nature of this artifice, and the manner in which it occurred to its author, is explained by Dr Hutton in his very excellent treatise on Mensuration, as follows: "Since the chief advantage (in the application of Gregory's series to the rectification of the circle) consists in taking small arches, whose tangents shall be numbers easy to manage, Mr Machin very properly considered, that since the tangent of \( 45^\circ \) is \( 1 \), and that the tangent of any arch being given, the tangent of the double of that arch can easily be had; if you assume some small simple number as the tangent of an arch, and then the tangent of the double arch be continually taken, until a tangent be found nearly equal to \( 1 \), which is the tangent of \( 45^\circ \), by taking the tangent answering to the small difference of \( 45^\circ \) and this multiple, there would be found two very small tangents, viz. the tangent first assumed, and the tangent of the difference between \( 45^\circ \) and the multiple arch, and since that the lengths of the arches corresponding to these two tangents being calculated, and the arch belonging to the tangent first assumed being so often doubled as the multiple directly, the result, increased or diminished by the other arch, according as the multiple should be below or above it, would be the arch of \( 45^\circ \).

"Having thus thought of his method, by a few trials he was lucky enough to find a number (and perhaps the only one) proper for his purpose; viz. knowing that the tangent of \( 45^\circ \) is \( \frac{\sqrt{2}}{2} \), he assumed \( \frac{\sqrt{2}}{2} \) as the tangent of an arch. Then, since if \( t \) be the tangent of an arch, the tangent of the double arch will be \( \frac{2t}{1-t^2} \), the radius being \( 1 \); the tangent of the double arch to that of which \( \frac{\sqrt{2}}{2} \) is the tangent will be \( \frac{\sqrt{2}}{2} \), and the tangent of the double of this arch will be \( \frac{2}{\sqrt{2}} \), which being very nearly equal to \( 1 \), shows, that the arch which is equal to four times the first arch is very near \( 45^\circ \). Then, since the tangent of the difference between an arch of \( 45^\circ \) and an arch greater than \( 45^\circ \), whose tangent is \( T \), is \( T+1 \), we shall have the tangent of the difference between \( 45^\circ \) and the arch whose tangent is \( \frac{1}{2} \), equal to \( \frac{1}{2} \). Now, by calculating from the general series the arch whose tangents are \( \frac{1}{2} \) and \( \sqrt{2} \), (which may be quickly done by reason of the smallness and simplicity of the numbers), and taking the latter arch from four times the former, the remainder will be the arch of squaring."

If we substitute \( \frac{1}{2} \) instead of \( t \) in the general series, we shall have the arch whose tangent is \( \frac{1}{2} \) expressed by the series \( \frac{1}{5} + \frac{1}{5} + \frac{1}{5} + \frac{1}{7} + \ldots \), &c.; and, in like manner, by substituting \( \frac{\sqrt{2}}{2} \) for \( t \), we get the arch whose tangent is \( \frac{\sqrt{2}}{2} \) expressed by the series \( \frac{1}{2} + \frac{1}{3} + \frac{1}{5} + \frac{1}{7} + \ldots \), &c. Now, since four times the arch to \( \frac{1}{2} \) diminished by the arch to \( \frac{\sqrt{2}}{2} \) is equal to the arch to \( \frac{\sqrt{2}}{2} \), that is, to the arch of \( 45^\circ \), or \( \frac{\sqrt{2}}{2} \) of the semicircumference; therefore, half the circumference of a circle to \( \frac{\sqrt{2}}{2} \), or \( \sqrt{2} \ldots \), is equal to \( \frac{1}{2} \), or the whole circumference, the diameter being \( 1 \), is equal to \( \frac{1}{2} \), &c.

\[
16 \left( \frac{1}{5} + \frac{1}{5} + \frac{1}{5} + \frac{1}{7} + \ldots \right) \left( \frac{1}{5} + \frac{1}{5} + \frac{1}{5} + \frac{1}{7} + \ldots \right)
\]

and this is Machin's series for the rectification of the circle.

The happy idea which Machin had conceived of reducing the rectification of the arch whose tangent is unity to that of two arches whose tangents are small rational fractions, having each unity for a numerator, appears also to have occurred to Euler; and the same thought has, since his time, been pursued by other mathematicians, who have contrived to resolve an arch of \( 45^\circ \) into three or more such arches. We shall show how this may be done, beginning with the investigation of the following problem.

"Problem. Supposing \( n, x, \) and \( y \), to denote three whole numbers, such that the arch whose tangent is \( \frac{1}{n} \) is equal to the sum of two arches whose tangents are \( \frac{1}{x} \) and \( \frac{1}{y} \), radius being unity, it is required to determine all possible values of the numbers \( x \) and \( y \) in terms of the number \( n \).

"Solution. It is manifest from the formula for the tangent of the sum of two arches (Algebra, § 368) that

\[
\frac{1}{n} = \frac{x+y}{m} \quad \text{hence we have} \quad \frac{x+y}{m} = \frac{1}{n},
\]

\[
x = y - 1, \quad \text{and} \quad (x - n) = n + 1; \quad \text{and, lastly,} \quad y = \frac{n + 1}{n} = n + \frac{1}{n}.
\]

Now, as by hypothesis, \( y \) is a whole number, it is manifest that \( \frac{n + 1}{n} \) must be a whole number; therefore, \( x - n \) must be a divisor of \( n + 1 \).

Let \( p \) be any divisor of \( n + 1 \), and \( q \) the quotient, that is, let \( p = n + 1 \), then \( x = p + q \), and \( x = n + p \):

Since

\[
\frac{n + 1}{p} = q,
\]

therefore \( y = n + q \); thus the values of \( x \) and \( y \) are determined in terms of \( n \) as required; and by giving to \( p \) and \( q \) all possible values, we shall have
THEOREM. Let \( n \) denote any whole number, and let \( n^2 + 1 \) be resolved into any two factors \( p \) and \( q \), one of which may be unity), that is, let \( pq = n^2 + 1 \); the arch whose tangent is \( \frac{1}{n} \) is equal to the sum of the arches \( \frac{1}{n+p} \) and \( \frac{1}{n+q} \) respectively.

For the sake of brevity, let \( \frac{1}{n} \) be put to denote the arch, having for its tangent \( \frac{1}{n} \); then, according to this notation, our theorem will be expressed thus, \( \frac{1}{n} = \frac{1}{n+p} + \frac{1}{n+q} \).

Let us now suppose \( n = 1 \), then \( n^2 + 1 = 2^2 - 1 \times 2 \), therefore, the only values which we can give in this case to \( p \) and \( q \) are \( p = 1, q = 2 \), and these being substituted, we have

\[ A = A_1 + A_2. \]

From which it appears, that the arch whose tangent is unity (that is, \( \frac{1}{n} \) of the circumference), is the sum of the arches whose tangents are \( \frac{1}{n+1} \) and \( \frac{1}{n+2} \). This is Euler's theorem, and by means of it, putting \( \frac{1}{n} \) and \( \frac{1}{n+1} \) for \( t \) in the general series \( t = \frac{1}{2} n^2 + \frac{1}{3} n^3 + \frac{1}{4} n^4 + \cdots \), c. we get half the circumference to radius \( r \) equal to

\[ 4 \left\{ \frac{1}{2} + \frac{1}{3} - \frac{1}{5} + \frac{1}{7} - \frac{1}{9} + \cdots, \right. \]

\[ + \frac{1}{3} + \frac{1}{5} - \frac{1}{7} + \frac{1}{9} + \cdots, \]

Let us now suppose \( n = 2 \), then \( n^2 + 1 = 5 = 1 \times 5 \); hence the only values which \( p \) and \( q \) can have are \( 1 \) and \( 5 \), and in this case our general formula gives \( A_1 = A_2 + A_3 \).

If now from the two equations

\[ A_1 = A_4 + A_5; \quad A_2 = A_3 + A_4, \]

we eliminate successively \( A_4 \) and \( A_5 \), we shall obtain the two following:

\[ A_1 = 2 A_4 + A_5; \quad A_1 = 2 A_5 - A_4. \]

From the first of these it appears that \( \frac{1}{n} \) of the circumference is equal to the sum of twice the arch to tan. \( \frac{1}{n} \), and once the arch to tan. \( \frac{1}{n^2} \); and from the second, that the same quantity is equal to the excess of twice the arch to tan. \( \frac{1}{n} \) above the arch to tan. \( \frac{1}{n^2} \); and from each of these, an expression for the whole circumference may be obtained analogous to that which we have found above from Euler's formula, but which will converge faster, and therefore is better.

The resolution of an arch of \( A_4 \) into three other arches, may be effected by means of our general formula, as follows: Put \( n = 3 \), then \( n^2 + 1 = 10 = 2 \times 5 \), hence we have \( p = 1 \), and \( q = 10 \), and also \( p = 2 \) and \( q = 5 \); therefore, substituting, we get two different values of \( A_4 \), viz.

\[ A_4 = A_3 + A_9; \quad A_4 = A_5 + A_5. \]

From these, and the equation \( A_1 = 2 A_3 + A_4 \), we get, by exminating \( A_3 \), the two following expressions for \( A_1 \), an arch of \( A_4 \):

\[ A_1 = 2 A_3 + A_4 + A_5; \quad A_1 = 2 A_3 + A_4 + 2 A_5. \]

These give such an expression for the circumference composed of three series. The labour, however, of computing by either of them, particularly the latter, will probably be less than by any of the formulas composed of two series, on account of the greater degree of quickness with which the series will converge. All the preceding formulas have been investigated in different ways by different mathematicians. That, however, which we are about to investigate, we believe, is new.

Let \( n \) in the general formula be taken equal to \( 5 \); then \( n^2 + 1 = 26 = 1 \times 26 = 2 \times 13 \), therefore \( p = 1, q = 26 \), also \( p = 2, q = 13 \), hence we find \( A_2 = A_3 + A_5 \), and also \( A_2 = A_3 + A_7 \). From this last equation, and the equation \( A_1 = 2 A_3 + A_4 + 2 A_5 \), let \( A_4 \) be eliminated, and the result is

\[ A_1 = 3 A_3 + 2 A_4 + 2 A_5. \]

This appears to be the most convenient expression of any we have yet found, because the fractions are smaller, while at the same time two of the denominators consist of only one figure, and the third, which consists of two, admits of being resolved into factors. By the same mode of reasoning we have found this expression

\[ A_1 = 2 A_3 + 3 A_4 + 2 A_5 + 3 A_7 \]

which consists of four terms; but for the sake of brevity we omit its investigation.

We shall now apply the formula \( A_1 = 3 A_3 + 2 A_4 + 2 A_5 \) to the actual calculation of the arch of \( A_4 \), the radius of the circle being unity.

I. Calculation of the length of the arch whose tangent is \( \frac{1}{n} \).

In this case, because \( t = \frac{1}{3} \), we have

\[ A_1 = \frac{1}{7} - \frac{1}{3} + \frac{1}{7} + \frac{1}{9} - \frac{1}{7} + \frac{1}{9} - \frac{1}{7} + \cdots, \]

\[ = \frac{1}{7} \times 1.428571428571 \times 1 \times 3.71 \times 5.71 \times 7.71 \times 9.71 \times \cdots, \]

\[ = 0.009718172983 \]

\[ = 0.000118998037 \times 1 \times 3.71 \times 5.71 \times 7.71 \times 9.71 \times \cdots, \]

\[ = 0.0000000040 \]

\[ = 0.000000000008 \times 1 \times 11.71 \times 13.71 \times 15.71 \times \cdots, \]

\[ = 0.009719808108 \]

\[ + 0.009709645150 \text{ amount of positive terms.} \]

\[ = 0.0009719098108 \text{ amount of negative terms.} \]

II. Calculation of the length of the arch whose tangent is \( \frac{1}{n} \).

Here \( t = \frac{1}{3} \), therefore,

\[ A_1 = \frac{1}{8} - \frac{1}{3.81} + \frac{1}{5.85} - \frac{1}{7.81} + \cdots, \]

\[ \frac{1}{8} \]
SQU [ 621 ]

SQU

Squaring.

\[ \begin{array}{c}
\frac{1}{8} = 0.1250000000 \\
\frac{1}{5.8} = 0.00006103516 \\
\frac{1}{9.8} = 0.00000008378 \\
\frac{1}{3.8} = 0.00000000106 \\
\frac{1}{0.8} = 0.00000000001 \\
\end{array} \]

+ 0.1250061043435

- 0.00006109769

\[ A_8 = 1.24354994546 \]

III. Calculation of the arch whose tangent is \( \frac{1}{y} \).

Here \( t = \frac{1}{y} \), therefore,

\[ A_{18} = \frac{1}{18} \left( \frac{1}{3.18} + \frac{1}{5.18} - \frac{1}{7.18} \right) + \cdots, \]

\[ \frac{1}{18} = 0.05555555556 \\
\frac{1}{3.18} = 0.00000571559214 \\
\frac{1}{7.18} = 0.00000002333 \\
\frac{1}{9.18} = 0.00000000006 \\
\frac{1}{5.56} = 0.00000000008 \\
\frac{1}{A_{18}} = 0.055498502548 \]

\[ \frac{1}{2} \] of the circumference or \( A = 78.53938163397 \)

Thus by a very easy calculation we have obtained one-fourth of the circumference true to 12 decimal places, and indeed by this method we may find an approximate value of the ratio of the diameter to the circumference to 200 places of figures, with perhaps as much ease as Vieta or Romanus found it to 10 or 15 figures.

We have already observed that Van Ceulen desired that his quadrature, which extended only to 35 decimals, might be inscribed on his tomb; from which we may reasonably infer that the time and labour he had bestowed in the calculation must have been very great; but by an artifice of the kind we have been explaining, Euler in 18 hours verified Laguyn's quadrature of 128 figures.

In concluding this article we shall briefly notice some series for the indefinite rectification of the circle, which have just appeared in the sixth volume of the Edinburgh Philosophical Transactions. They are given by Mr W. Wallace of the Royal Military College, in a paper entitled, New Series for the Quadrature of the Conic Sections, and the Computation of Logarithms. These series do not give the arch directly, but only its reciprocal, or the powers of that reciprocal; it is however evident, that any one of these being known, the arch itself becomes immediately known. The first series is as follows. Let \( a \) denote any arch of a circle, and let its tangent, the tangents of its half, &c. be briefly denoted by \( \tan \frac{1}{a}, \tan \frac{1}{2}a, \tan \frac{1}{3}a, &c. \). Then shall

\[ \frac{1}{a} = \frac{1}{\tan a} + \frac{1}{\tan \frac{1}{2}a} + \frac{1}{\tan \frac{1}{3}a} + \cdots + T + T' + S. \]

Here the arches \( \frac{1}{a}, \frac{1}{2}a, \frac{1}{4}a, \frac{1}{8}a, &c. \) constitute a geometrical progression, having the number of its terms infinite, and their common ratio \( \frac{1}{2} \). The letters \( T \) and \( T' \) are put for any two adjoining terms (after the first) of the series, and \( S \) is put for the sum of all the terms following these; and this sum is always contained between two limits, one of which is \( \frac{1}{2} \) of the latter of the two terms \( T \) and \( T' \), and the other is a third proportional to their difference; and the last of the two being always less than the first of these limits, but greater than the second. As a specimen of the way of applying this series, we shall give the calculation of the length of an arch of \( 90^\circ \) to six decimal places. In this case \( \frac{1}{\tan a} = \cotan \frac{1}{2a} = \cotan \frac{1}{3a} = 1 \), the remaining quantities \( \tan \frac{1}{4a}, \tan \frac{1}{8a}, \tan \frac{1}{16a}, &c. \) are to be computed from \( \tan \frac{1}{8a} \) by this formula, \( \tan \frac{1}{4a} = \sqrt{\left( \frac{1}{\tan^2 \frac{1}{2a}} + 1 \right)} - \frac{1}{\tan \frac{1}{2a}}. \)

Accordingly we find

\[ \begin{array}{c}
\tan \frac{1}{8a} = 1 \\
\tan \frac{1}{4a} = 1.4142136 \\
\tan \frac{1}{2a} = 1.989123 \\
\end{array} \]

\[ \begin{array}{c}
\frac{1}{2} \tan \frac{1}{8a} = 0.9984914 \\
\frac{1}{4} \tan \frac{1}{4a} = 0.404268 \\
\frac{1}{8} \tan \frac{1}{2a} = 0.0265486 \\
\end{array} \]

\[ \begin{array}{c}
\frac{1}{2} \tan \frac{1}{2a} = 0.500000 \\
\frac{1}{4} \tan \frac{1}{4a} = 0.123534 \\
\frac{1}{8} \tan \frac{1}{8a} = 0.0248630 \\
\end{array} \]

\[ \begin{array}{c}
\tan \frac{1}{2a} = 1.061557 \\
\tan \frac{1}{4a} = 0.601332 \\
\tan \frac{1}{8a} = 0.033836 \\
\end{array} \]

\[ S = \sum_{i=0}^{\infty} \tan \left( \frac{1}{2a} \right) = 1.570796 \]

Hence \( S = 1 \).

Arch of \( 90^\circ = a = 1.570796 \).

The second series given in this paper is expressed as follows. Let \( \cos \frac{1}{a}, \cos \frac{1}{2a}, &c. \) denote the cosine of the arch, the cosine of its half, &c. Then

\[ \begin{align*}
\frac{1}{a^2} &= \frac{1}{4} \left( \frac{1}{\cos \frac{1}{a}} + \frac{1}{\cos \frac{1}{2a}} + \frac{1}{\cos \frac{1}{3a}} + \cdots \right) \\
&= \frac{1}{4} \left( \frac{1}{\cos \frac{1}{a}} + \frac{1}{\cos \frac{1}{2a}} + \frac{1}{\cos \frac{1}{3a}} + \cdots \right) + T + T' + S.
\end{align*} \]

Here, as before, the letters \( T, T' \) denote any two adjacent terms of the series in the parenthesis, and \( S \) is put for the sum of all the following terms, which in this case is always less than \( \frac{1}{2} T' \), but greater than a third proportional to \( T - T' \) and \( T' \). This second series converges.
SQUADRING. Stabbing, verges quicker than the first, and is besides better adapted to calculation, because the cosines of the series of arches $\frac{\alpha}{2}$, $\frac{\alpha}{2}$, &c. are now easily deduced from the cosine of $\alpha$ and one another than the tangents. The formula in this case being

$$\cos \frac{\alpha}{2} = \sqrt{\frac{1 + \cos \alpha}{2}}.$$ 

There are various other series for the rectification of any arch of a circle given in the same paper, some of which converge faster than either of the two we have here specified, and all have the property of being applicable to every possible case, and of having very simple limits, between which the sums of all their terms following any proposed term are always contained. It may also be observed that the principles from which they are deduced are of the most simple and elementary kind, insomuch that the author has stated it as his opinion, that their investigation might even be admitted into and form a part of the elements of geometry.

SQUATINA. See Squalus, Ichthyology Index.

SQUIRREL. See Medicine, No. 383.

SQUILLING. See Medicine, No. 383.

SQUILLING, in Law. The offence of mortally stabbing another, though done upon a sudden provocation, is punished as murder; the benefit of clergy being taken away from it by statute. (See Murder.) For by 253. 8. when one thrusts or stabs another, not then having a weapon drawn, or who hath not then first striken the party stabbing, so that he dies thereof within six months after, the offender shall not have the benefit of clergy, though he did it not of malice aforethought. This statute was made on account of the frequent quarrels and stabbings with short daggers between the Scotch and the English at the accession of James I.; and being therefore of a temporary nature, ought to have expired with the mischief which it meant to remedy. For, in point of solid and substantial justice, it cannot be said that the mode of killing, whether by stabbing, strangling, or shooting, can either extenuate or enhance the guilt; unless where, as in the case of poisoning, it carries with it internal evidence of cool and deliberate malice. But the benignity of the law hath construed the statute so favourably in behalf of the subject, and so strictly when against him, that the offence of stabbing now stands almost upon the same footing as it did at the common law. Thus, (not to repeat the cases mentioned under Manslaughter, of stabbing an adulteress, &c. which are barely manslaughter, as at common law), in the construction of this statute it hath been doubted, whether, if the decessor had struck at all before the mortal blow given, this does not take it out of the statute, though in the preceding quarrel the stabber had given the first blow; and it seems to be the better opinion, that this is not within the statute. Also it hath been resolved, that the killing a man, by throwing a hammer or other weapon, is not within the statute; and whether a shot with a pistol be so or not is doubted. But if the party slain had a cudgel in his hand, or had thrown a pot or a bottle, or discharged a pistol at the party stabbing, this is a sufficient reason for having a weapon drawn on his side within the words of the statute.

STACHYS, HEDGE-NETTLE, or ALL-HEAL, a genus of plants belonging to the class of diodymania, and order of gymnopoulos; and in the natural system arranged under the 43d order, Verticillatae. See Botany Index.

STADIUM, an ancient Greek long measure, containing 125 geometrical paces, or 625 Roman feet, corresponding to our furlong. The word is said to be formed from the Greek word ἀστεῖον, "a station," or ἀστήρ, "to stand," because it is reported that Hercules having run a stadium at one breath, stood still at the end of it. The Greeks usually measured distances by stadia, which they called σταδία. Stadium also signified the course on which their races were run.

STADTHOLDER, formerly the principal magistrate or governor of the Seven United Provinces. Although this office is now abolished and that of king substituted, our readers will probably not be ill pleased with a short account of the several powers and claims connected with it. To render that account the more intelligible, we shall trace the office of a stadtholder from its origin.

The Seven Provinces of the Low Countries were long governed by princes invested with the sovereignty, though limited in their powers, and under various titles; as Counts of Holland, Dukes of Guelder, Bishop of Utrecht, &c. When these countries fell to the princes of the house of Burgundy, and afterwards to those of Austria, who had many other dominions, the absence of the sovereign was supplied by a stadtholder or governor, vested with very ample powers. These stadtholders or lieutenants had the administration of the government, and presided in the courts of justice, whose jurisdiction was not at that time confined merely to the trial of causes, but extended to affairs of state. The stadtholders swore allegiance to the princes at their inauguration, jointly with the states of the provinces they governed. They likewise took an oath to the states, by which they promised to maintain their fundamental laws and privileges.

It was upon this footing that William the First, prince of Orange, was made governor and lieutenant-general of Holland, Zeeland, and Utrecht, by Philip the Second, upon his leaving the Low Countries to go into Spain. The troubles beginning soon after, this prince found means to bring about an union, in 1576, between Holland and Zeeland; the states of which two provinces put into his hands, as far as was in their power, the sovereign authority (for so long time as they should remain in war and under arms), upon the same footing as Holland had intrusted him with it the year before. In 1581 the same authority was again renewed to him by Holland, as it was soon after by Zeeland likewise; and in 1584, being already elected count of Holland, upon certain conditions he would have been formally invested with the sovereignty, had not a wretch hired and employed by the court of Spain, put an end to his life by a horrid assassination.

In the preamble of the instruments by which the states in 1581 conferred the sovereign authority upon Prince William the First, we find these remarkable words, which are there set down as fundamental rules: "That all republics and communities ought to pr-
serve, maintain, and fortify themselves by unanimity; which being impossible to be kept up always among so many members, often differing in inclinations and sentiments, it is consequently necessary that the government should be placed in the hands of one single chief magistrate." Many good politicians, and the greatest part of the inhabitants of these provinces, since the establishment of the republic, looked upon the stadtholderian government as an essential part of her constitution; nor has she been without a stadtholder but twice, that is to say, from the end of 1650 to 1672, and again from March 1702 till April 1747. The provinces of Friesland and Groningen, with Ommelanden, had always a stadtholder without interruption: their instructions may be seen in Aitzema; but formerly the powers of the stadtholder of these provinces were confined within narrower bounds, and till William the Fourth there was no stadtholder of the seven provinces together.

The stadtholder could not declare war or make peace, but he had, in quality of captain-general of the union, the command in chief of all the forces of the state (A); and military persons were obliged to obey him in everything that concerned the service. He was not limited by instructions; but he had the important power of giving out orders for the march of troops, and the disposition of all matters relative to them. He not only directed their marches, but provided for the garrisons, and changed them at pleasure. All military edicts and regulations came from him alone; he constituted and authorised the high council of war of the United Provinces, and, as captain-general of every province, disposed of all military offices, as far as the rank of colonel inclusively. The higher posts, such as those of veldmarshals, generals, lieutenant-generals, major-generals, were given by the states-general, who chose the persons recommended by his highness. He made the governors, commandants, &c. of towns and strong places of the republic, and of the barrier. The persons nominated presented their instruments of appointment to their high mightinesses, who provided them with commissions. The states-general had likewise great regard to the recommendation of the prince stadtholder in the disposition of those civil employments which were in their gift.

The power of the stadtholder as high-admiral, extended to every thing that concerned the naval force of the republic, and to all the other affairs that were here within the jurisdiction of the admiralty. He presided at these boards either in person or by his representatives; and as chief of them all in general, and of every one in particular, he had power to make their orders and instructions be observed by themselves and others. He bestowed the posts of lieutenant-admiral, vice-admiral, and rear-admiral, who commanded under him; and he made likewise post-captains.

The stadtholder granted likewise letters of grace, pardons, and abolition, as well for the crimes called Communita Delicta, as for military offences. In Holland and Zeeland these letters were made out for crimes of the first sort, in the name of the states, with the advice of his highness. In military offences he consulted the high council of war; and upon the communita delicta he took the advice of the courts of justice, of the counsellors, committees of the provinces, of the council of state, and the tribunal of justice in the respective towns, according to the nature of the case.

In the provinces of Holland and Zeeland, the stadtholder elected the magistrates of the towns annually, out of a double number that were returned to him by the towns themselves.

When any of these offices became vacant, which, at the time there was no governor, were in the disposal of the states of Holland, or as formerly in that of the chamber of accounts, the stadtholder had his choice of two, or, in some cases, of three candidates, named by their noble and great mightinesses. He chose likewise the counsellors, inspectors of the dykes of Rynland, Delfland, and Scheeland, out of three persons presented to him by the boards of the counsellors inspectors; which boards were of very ancient establishment in Holland.

His highness presided in the courts of Holland, and in the courts of justice of the other provinces; and his name was placed at the head of the proclamations and acts, called in Dutch Mandamenten, or Provisien von Justiteit. In Overssel and in the province of Utrecht the possessors of liefs held of the prince stadtholder. He was supreme curator of the universities of Guelder, Friesland, and Groningen; grand forester and grand venture in Guelder, in Holland, and other places. In the province of Utrecht, his highness, by virtue of the regulation of 1674, disposed of the provostships and other benefices which remained to the chapters, as also of the canonical prebends that fell in the months which were formerly the papal months.

By the first article of the council of state of the United Provinces, the stadtholder was the first member of it, and had a right of voting there, with an appointment of 25,000 guilders a year. He assisted also, as often as he thought it for the service of the state, at the deliberations of the states-general, to make propositions to them, and sometimes also at the conferences which the deputies of their high mightinesses held in their different committees, in consequence of their standing orders. He likewise assisted at the assemblies of the states of each particular province, and at that of the counsellors committees. In Guelder, Holland, and Utrecht, his highness had a share of the sovereignty, as chief or president of the body of nobles; and in Zeeland, where he possessed the marquisate of Veer and Flushing, as first noble, and representing the whole nobility. In his absence he had

(A) In times of war, however, the states had always named deputies for the army, to accompany the stadholders in the field, and to serve them as counsellors in all their enterprises, particularly in the most important affairs, such as giving battle, or undertaking a siege, &c. This was always practised till the accession of King William the Third to the crown of Great Britain, and after his death was continued with regard to the general in chief of the army of the republic. In 1747 and 1748 there were likewise deputies with the army, but with more limited power.
lumbkill: its greatest length is about an English mile, and its breadth about half an one. On the east side of the island is a small bay where boats generally land; a little to the southward of which the first appearance of pillars is to be observed; they are small; and instead of being placed upright, lie down on their side, each forming a segment of a circle. From thence you pass a small cave, above which the pillars, now grown a little larger, are inclining in all directions: in one place in particular, a small mass of them very much resembles the ribs of a ship. From hence having passed the cave, which, if it is not low-water, you must do in a boat, you come to the first ranges of pillars, which are still not above half as large as those a little beyond. Over against this place is a small island, called in Erse Boo-sha-la, separated from the main by a channel not many fathoms wide. The whole island is composed of pillars without any stratrum above them; they are still small, but by much the neatest formed of any about the place.

"The first division of the island, for at high water it is divided into two, makes a kind of a cone, the pillars converging together towards the centre: on the other they are in general laid down flat: and in the front next to the main, you see how beautifully they are packed together, their ends coming out square with the bank which they form. All these have their transverse sections exact, and their surfaces smooth; which is by no means the case with the large ones, which are cracked in all directions. I must question, however, if any part of this whole island of Boo-sha-la is two feet in diameter.

"The main island opposite to Boo-sha-la, and farther towards the north-west, is supported by ranges of pillars pretty erect, and, though not tall (as they are not uncovered to the base), of large diameters; and at their feet is an irregular pavement, made by the upper sides of such as have been broken off, which extends as far under water as the eye can reach. Here the forms of the pillars are apparent; these are of three, four, five, six, and seven sides; but the numbers of five and six are by much the most prevalent. The largest I measured was of seven; it was four feet five inches in diameter.

"The surfaces of these large pillars, in general, are rough and uneven, full of cracks in all directions; the transverse figures in the upright ones never fail to run in their true directions. The surfaces upon which we walked were often flat, having neither concavity nor convexity; the larger number, however, was concave, though some were very evi dently convex. In some places, the interstices within the perpendicular figures were filed up with a yellow spar: in one place, a vein passed in among the mass of pillars, carrying here and there small threads of spar. Though they were broken and cracked through in all directions, yet their perpendicular figures might easily be traced: from whence it is easy to infer, that whatever the accident might have been that caused the dislocation, it happened after the formation of the pillars.

"From hence proceeding along shore, you arrive at Fingal's cave. Its dimensions I have given in the form of a table:

| Length of the cave from the rock without | 371 6 |
| From the pitch of the arch | 250 0 |
| Breadth | 2 |
"The cave runs into the rock in the direction of north-east by east by the compass.

"Proceeding farther to the north-west, you meet with the highest ranges of pillars; the magnificent appearance of which is past all description. Here they are bare to their very basis, and the stratum below them is also visible: in a short time it rises many feet above the water, and gives an opportunity of examining its quality. Its surface is rough, and has often large lumps of stone sticking in it as if half immersed: itself, when broken, is composed of a thousand heterogeneous parts, which together have very much the appearance of a lava; and the more so, as many of the lumps appear to be of the same stone of which the pillars are formed. This whole stratum lies in an inclined position, dipping gradually towards the south-east. As hereabouts is the situation of the highest pillars, I shall mention my measurements of them, and the different strata in this place, presuming, that the measurements were made with a line held in the hand of a person who stood at the top of the cliff, and reaching to the bottom; to the lower end of which was tied a white mark, which was observed by one who stood below for the purpose: when this mark was set off from the water, the person below noted it down, and made signal to him above, who made then a mark in his rope: whenever this mark passed a notable place, the same signal was made, and the name of the place noted down as before: the line being all hauled up, and the distances between the marks measured and noted down, gave, when compared with the book kept below, the distances, as for instance in the cave:

"No 1. in the book below, was called from the water to the foot of the first pillar in the book above; No 1. gave 36 feet eight inches, the highest of that ascent, which was composed of broken pillars.

"No 1. Pillar at the west corner of Fingal's cave.

Facts. In.

1 From the water to the foot of the pillar, 12 10
2 Height of the pillar, 37 3
3 Stratum above the pillar, 66 9

"No 2. Fingal's cave.

1 From the water to the foot of the pillar, 36 8
2 Height of the pillar, 39 6
3 From the top of the pillar to the top of the arch, 31 4
4 Thickness of the stratum above, 34 4
By adding together the three first measurements, we get the height of the arch from the water, 117 6

"No 3. Corner pillar to the westward of Fingal's cave.

**STA-Bestle. See **Lucanus, **Entomology Index.**

**STAGE.** in the modern drama, the place of action and representation, included between the pit and the Stagemans.

**STAGGERS.** See *Farriery Index.*

**STAILH, George Ernest,** an eminent German chemist, was born at Onolod in Franconia in 1662, and chosen professor of medicine at Hull, when a university was founded in that city in 1693. The excellency of his lectures whilst he filled that chair, the importance of his various publications, and his extensive practice, soon raised his reputation to a very great height. He received an invitation to Berlin in 1716, which having accepted, he was made councillor of state and physician to the king. He died in 1734, in the 75th year of his age. Stahl is without doubt one of the greatest men of which the annals of medicine can boast; his name marks the commencement of a new and more illustrous era in chemistry. He was the author of the doctrine of phlogiston, which, though now completely overturned by the discoveries of Lavoisier and others, was not without its use; as it served to combine the scattered fragments of former chemists into a system, and as it gave rise to more accurate experiments and a more scientific view of the subject, to which many of the subsequent discoveries were owing. This theory maintained its ground for more than half a century, and was received and supported by some of the most eminent men which Europe has produced; a sufficient proof of the ingenuity and the abilities of its author. He was the author also of *A Theory of Medicine,* founded upon the notions which he entertained of the absolute dominium of mind over body; in consequence of which, he affirmed, that every muscular action is a voluntary act of the mind, whether attended with consciousness or not. This theory he and his followers carried a great deal too far, but the advice which least which he gives to attend to the state of the mind of the patient are worthy of the attention of physicians.

His principal works are, 1. *Experimenta et Observationes Chemicae et Physicae,* Berlin, 1731, 8vo. 2. *Dissertationes Medicus,* Hall, 2 vols 4to. This is a collection of these. 3. *Theoria Medica vera,* 1737, 4to. 4. *Opusculum Chymico-physico-medicum,* 1740, 4to. 5. A Treatise on Sulphur, both Inflammable and Fixed, written in German. 6. *Negotium Oitomm,* Hall, 1720, 4to. It is in this treatise chiefly that he establishes his system concerning the action of the soul upon the body. 7. *Fundamenta Chymie Dogmatica et Experimentalis,* Nuremberg, 1747, 3 vols 4to. 8. A Treatise on Salts, written in German. 9. *Commentarium in Metalurgiam Beccheri,* 1723.

**STAINING OR COLOURING OF BONE, HORN, MARBLE, PAPER, WOOD, &c.** See these articles.

**STAIRCASE, in Architecture,** an ascent enclosed between walls, or a balustrade consisting of stairs or steps, with landing places and rails, serving to make a communication between the several stories of a house. See Architecture, *N*° 89, &c.

**STALACTITES, in Mineralogy,** crystalline spars formed into oblong, conical, round, or irregular bodies, composed of various cruts, and usually found hanging in form of sticles from the roofs of groitores, &c.

**STALAGMITIES, a genus of the monocia order, belonging**
Stalagmitis, belonging to the polygaminia class of plants; and in the natural method ranking under the 38th order, Tricosoec.

See Botany and Materia Medica Index.

STALE, among sportsmen, a living fowl put in a place to allure and bring others where they may be taken. For want of these, a bird shot, his entrails taken out, and dried in an oven in his feathers, with a stick thrust through to keep it in a convenient posture, may serve as well as a live one.

STALE is also a name for the urine of cattle.

ANIMAL STALK. This remarkable animal was found by Mr. Ives at Cuddalore: and he mentions several kinds of it; some appearing like dry straws tied together, others like grass; some have bodies much larger than others, with the addition of two scaly imperfect wings; their neck is no bigger than a pin, but twice as long as their bodies; their heads are like those of an hare, and their eyes vertical and very brisk. They live upon flies, and catch these insects very dexterously with the two fore-feet, which they keep doubled up in three parts close to their head, and dart out very quick on the approach of their prey; and when they have caught it, they eat it very voraciously, holding it in the same manner as a squirrel does its food. On the outer joints of the fore-feet are several very sharp hooks for the easier catching and holding of their prey; while, with the other feet, which are four in number, they take hold of trees or any other thing, the better to surprise whatever they lie in wait for. They drink like a horse, putting their mouths into the water. Their excrements, which are very white, are almost as large as the body of the animal, and as the natives say, dangerous to the eyes.

STALLION, or STONE-HORSE, in the manage, a horse designed for the covering of mares, in order to propagate the species. See EQUUS, MAMMALIA Index.

STAMFORD, an ancient town of Lincolnshire in England; seated on the river Welland, on the edge of Northamptonshire. It contains nine parish-churches, several good streets, and fine buildings. It had formerly a college, the students of which removed to Brazen Nose college in Oxford. The population in 1811 was 5,852. It has no considerable manufactures, but deals chiefly in malt. W. Long. 1. 27. N. Lat. 52° 42'

STAMINA, in Botany, are those upright filaments which, on opening a flower, we find within the corolla surrounding the pistillum. According to Linneus, they are the male organs of generation, whose office it is to prepare the pollen. Each of them consists of two distinct parts, viz. the FILAMENTUM and the ANTHEMA.

STAMINA, in the animal body, are defined to be those simple original parts which existed first in the embryo or even in the seed; and by whose distinction, augmentation, and accretion by additional juices, the animal body at its utmost bulk is supposed to be formed.

STAMP-DUTIES, a branch of the perpetual revenue.

See Revenue.

In Great Britain there is a tax imposed upon all parchment and paper, wherein any legal proceedings or private instruments of almost any nature whatsoever are written; and also upon licenses for retailing wines, of all denominations; upon all almanacs, newspapers, advertisements, cards, dice, &c. These imports are very various; being higher or lower, not so much according to the value of the property transferred, as according to the nature of the deed. The highest do not exceed six pounds upon every sheet of paper or skin of parchment; and these high duties fall chiefly upon grants from the crown, and upon certain law proceedings, without any regard to the value of the subject. There are in Great Britain no duties on the registration of deeds or writings, except the fees of the officers who keep the register; and these are seldom more than a Nation's reasonable recompense for their labour. The crown derives no revenue from them.

The stamp-duities constitute a tax which, though in some instances it may be heavily felt, by greatly increasing the expense of all mercantile as well as legal proceedings, yet (if moderately imposed) is of service to the public in general, by authenticating instruments and rendering it much more difficult than formerly to forge deeds of any standing; since, as the officers of this branch of the revenue vary their stamps frequently, by marks perceptible to none but themselves, a man that would forge a deed of King William's time, must know and be able to counterfeit the stamp of that date also.

In France and some other countries the duty is laid on the contract itself, not on the instrument in which it is contained; as, with us too in England (besides the stamps on the indentures), a tax is laid, by statute 8 Ann. c. 9, on every apprentice-fee; of 6d. in the pound if it be 5s. or under, and 1s. in the pound if a greater sum: but this tends to draw the subject into a thousand nice dispositions and disputes concerning the nature of his contract, and whether taxable or not; in which the farmers of the revenue are sure to have the advantage.

Our general method answers the purposes of the state as well, and consults the ease of the subject much better. The first institution of the stamp-duities was by statute 5 and 6 W. and M. c. 21, and they have since, in many instances, been increased to five times their original amount.

STANCHION, or STANCHIONS, a sort of small pillars of wood or iron used for various purposes in a ship; as to support the decks, the quarter-rails, the nettings, the awnings, &c. The first of those are two ranges of small columns fixed under the beams, throughout the ship's length between decks; one range being on the starboard and the other on the larboard side of the hatchways. They are chiefly intended to support the weight of the artillery.

STAND, in commerce, a weight from two hundred and a half to three hundred of pitch.

STANDARD, in War, a sort of banner or flag borne as a signal for the joining together of the several troops belonging to the same body.

STANDARD, in commerce, the original of a weight, measure, or coin, committed to the keeping of a magistrate, or deposited in some public place, to regulate, adjust, and try the weights used by particular persons in traffic. See MONEY.

STANHOPE, Philip Dormer, Earl of Chesterfield, was born in 1695, and educated in Trinity-hall, Cambridge; which place he left in 1714, when, by his own account, he was an absolute pedant. In this character he went abroad, where a familiarity with good company soon convinced him he was totally mistaken in almost all his notions: and an attentive study of the air, manner, and address of people of fashion, soon polished a man whose predominant desire was to please; and who, as it afterwards appeared, valued exterior accomplishments.
ments beyond any other human acquirement. While
Lord Stanhope, he got an early seat in parliament; and in
1722, succeeded to his father's estate and titles. In
1728, and in 1745, he was appointed ambassador ex-
traordinary and plenipotentiary to Holland: which
high character he supported with the greatest dignity;
serving his own country, and gaining the esteem of the
states-general. Upon his return from Holland, he was
sent lord-lieutenant of Ireland; and during his adminis-
tration there, gave general satisfaction to all parties.
He left Dublin in 1746, and in October succeeded the
earl of Harrington as secretary of state, in which post
he officiated until February 6th 1748. Being seized
with a deafness in 1752 that incapacitated him for the
pleasures of society, he from that time led a private
and retired life, amusing himself with books and his
pen; in particular, he engaged largely as a volunteer
in a periodical miscellaneous paper called The World,
in which his contributions have a distinguished degree
of excellence. He died in 1773, leaving a character
for wit and abilities that had few equals. He disingu-
ished himself by his eloquence in parliament on many
important occasions; of which we have a characteristi-
c instance, of his own relating. He was an active pro-
moter of the bill for altering the style; on which oc-
casion, as he himself writes in one of his letters to his
son, he made so eloquent a speech in the house, that
everyone was pleased, and said he had made the whole
very clear to them; "when (says he), God knows, I
had not even attempted it. I could just as soon have
talked Celtic or Sclavonian to them, as astronomy;
and they would have understood me full as well." Lord
Macclesfield, one of the greatest mathematicians in Eu-
rope, and who had a principal hand in framing the bill,
spoke afterwards, with all the clearness that a thorough
knowledge of the subject could dictate; but not having
a flow of words equal to Lord Chesterfield, the latter
gained the applause from the former, to the equal credit
of the speaker and the auditors. The high character
Lord Chesterfield supported during life, received no
small injury soon after his death, from a fuller display
of it by his own hand. He left no issue by his lady,
but had a natural son, Philip Stanhope, Esq. whose
education was for many years a close object of his attention,
and who was afterward envoy extraordinary at the court
of Dresden, but died before him. When Lord Chester-
field died, Mr Stanhope's widow published a course of
letters, written by the father to the son, filled with in-
structions suitable to the different gradations of the
young man's life to whom they were addressed. These
letters contain many fine observations on mankind, and
rules of conduct: but it is observable that he lays a great-
er stress on exterior accomplishments and address, than
on intellectual qualifications and sincerity; and allows
greater latitude to fashionable pleasures than good morals
will justify, especially in paternal instructions. Hence

Dr John— it is that a celebrated writer * , and of manners some-
what different from those of the polite earl of Chester-
field, is said to have observed of these letters, that "they
inculcate only the morals of a whore, with the manners of
a dancing-master."

STANHOPE, Dr George, an eminent divine, was born
at Hertshorn in Derbyshire, in the year 1660. His
father was rector of that place, vicar of St Margaret's
church in Leicester, and chaplain to the earls of Chest-
erfield and Clare. His grandfather, Dr George Stan-
hope, was chaplain to James I. and Charles I.; had the
chancellorship of York, where he was also a canon-resi-
dentary, held a prebend, and was rector of Weidrake
in that county. He was for his loyalty driven from his
home with eleven children; and died in 1644. Our
author was sent to school, first at Uppingham in Rut-
land, then at Leicester; afterwards removed to Eaton;
and thence chosen to King's college in Cambridge, in
the place of W. Cleaver. He took the degree of B. A.
in 1681; M. A. 1685; was elected one of the syndics
for the university of Cambridge, in the business of Al-
bain Francis, 1687; minister of Quoi near Cambridge,
and vice-proctor, 1688; was that year preferred to the
rectory of Tring in Hertfordshire, which after some
time he quitted. He was in 1689 presented to the vic-

care of Lewisham in Kent by Lord Dartmouth, to
whom he had been chaplain, and tutor to his son. He
was also appointed chaplain to King William and Queen
Mary, and continued to enjoy that honour under Queen
Anne. He commenced D. D. July 5th 1697, per-
forming all the offices required to that degree publicly
and with great applause. He was made vicar of Dep-
ford in 1703; succeeded Dr Hooper as dean of Can-
terbury the same year; and was thrice chosen prolocutor
of the lower house of convolution. His uncommon di-
ligence and industry, assisted by his excellent parts, en-
riched him with a large stock of polite, solid, and useful
learning. His discourses from the pulpit were equally
pleasing and profitable; a beautiful intermixture of the
clearest reasoning with the purest diction, attended with
all the graces of a just elocution. The good Christian,
the solid divine, and the fine gentleman, in him were
happily united. His conversation was polite and deli-
cate, grave without preciseness, facetious without levity.
His piety was real and rational, his charity great and
universal, fruitful in acts of mercy, and in all good
works. He died March 18th 1728, aged 68 years;
and was buried in the chancel of the church at Lewis-
ham. The dean was twice married: first to Olivia
Cotton, by whom he had one son and four daughters.
His second lady, who was sister to Sir Charles Wager,
survived him, dying October 1st 1738, aged about 54.
One of the dean's daughters was married to a son of
Bishop Burnet. Bishop Moore of Ely died the day be-
fore Queen Anne; who, it has been said, designed our
dean for that see when it should become vacant. Dr
Felton says, "The late dean of Canterbury is excellent
in the whole. His thoughts and reasoning are bright
and solid. His style is just, both for the purity of the
language and for the strength and beauty of expression;
but the periods are formed in so peculiar an order of
the words, that it was an observation, nobody could
censure them with the same grace and advantage as him-
self." His writings, which are an inestimable treasure
of piety and devotion, are, A Paraphrase and Comment
upon the Epistles and Gospels, 4 vols, 1705, 8vo. Ser-
mons at Boyle's Lectures, 1706, 4to. Fifteen Sermons,
1700, 8vo. Twelve Sermons on Several Occasions,
1727, 8vo. Thomas à Kempis, 1696, 8vo. Epictetus's
Morals, with Simplicius's Comment, and the Life of
Epictetus, 1700, 8vo. Parson's Christian Directory,
1716, 8vo. Rochester's Maxims, 1706, 8vo. A
Funeral Sermon on Mr Richard Sare bookseller, 1724;
two editions 4to. Twenty Sermons, published singly
between.
between the years 1692 and 1724. Private Prayers for every Day in the Week, and for the several Parts of each Day; translated from the Greek Devotions of Bishop Andrews, with Additions, 1730. In his translations, it is well known, Dr Stanhope did not confine himself to a strict and literal version: he took the liberty of paraphrasing, explaining, and improving upon his author; as will evidently appear (not to mention any other work) by the slightest perusal of St Augustine's Meditations, and the Devotions of Bishop Andrews.

STANISLAUS LECZINSKI, king of Poland, was born at Leopold the 20th of October 1677. His father was a Polish nobleman, distinguished by his rank and the important offices which he held, but still more by his firmness and courage. Stanislaus was sent ambassador in 1704 by the assembly of Warsaw to Charles XII of Sweden, who had conquered Poland. He was at that time 27 years old, was general of Great Poland, and had been ambassador extraordinary to the Grand Signor in 1699. Charles was so delighted with the frankness and sincerity of his deportment, and with the firmness and sweetness which appeared in his countenance, that he offered him the crown of Poland, and ordered him to be crowned at Warsaw in 1705. He accompanied Charles XII. into Saxony, where a treaty was concluded with King Augustus in 1705, by which that prince resigned the crown, and acknowledged Stanislaus king of Poland. The new monarch remained in Saxony with Charles till 1727, when they returned into Poland and attacked the Russians, who were obliged to evacuate that kingdom in 1708. But Charles being defeated by Peter the Great in 1709, Augustus returned into Poland, and being assisted by a Russian army, obliged Stanislaus to retire first into Sweden, and afterwards into Turkey. Soon after he took up his residence at Weissenburg, a town in Alacce. Augustus dispatched Sum's envoy to France to complain of this; but the duke of Orleans, who was then regent, returned this answer: "Tell your king that France has always been the asylum of unhappy princes." Stanislaus lived in obscurity till 1725, when Louis XV. espoused the princess Mary his daughter. Upon the death of King Augustus in 1733, he returned to Poland in hopes of remounting the throne of that kingdom. A large party declared for him; but his competitor the young elector of Saxony, being supported by the emperor Charles VI. and the empress of Russia, was chosen king, though the majority was against him. Dantzig, to which Stanislaus had retired, was quickly taken, and the unfortunate prince made his escape in disguise with great difficulty, after hearing that a price was set upon his head by the Russians. When peace was concluded in 1736 between the emperor and France, it was agreed that Stanislaus should abdicate the throne, but that he should be acknowledged king of Poland and grand duke of Lithuania, and continue to bear these titles during life; that all his effects and those of the queen his spouse should be restored; that an amnesty should be declared in Poland for all that was past, and that every person should be restored to his possession, rights, and privileges: that the elector of Saxony should be acknowledged king of Poland by all the powers who acceded to the treaty: that Stanislaus should be put in peaceable possession of the duchies of Lorraine and Bar; but that immediately after his death these duchies should be united for ever to the crown of France. Stanislaus succeeded a race of princes in Lorraine, who were beloved and regretted: and his subjects found their ancient sovereigns revived in him. He tasted then the pleasure which he had so long desired, the pleasure of making men happy. He assisted his new subjects; he embellished Nancy and Lunéville; he made useful establishments; he founded colleges and built hospitals. He was engaged in these noble employments, when an accident occurred his death. His night-gown caught fire, and burned him so severely before it could be extinguished, that he was declared dead on the 23d of February 1766. His death occasioned a public mourning: the tears of his subjects indeed are the best eulogium upon this prince. In his youth he had accustomed himself to fatigue, and had thereby strengthened his mind as well as his constitution. He lay always upon a kind of mattress, and seldom required any service from his domestics. He was temperate, liberal, adored by his vassals, and perhaps the only nobleman in Poland who had any friends. He was in Lorraine what he had been in his own country, gentle, affable, compassionate, treating his subjects like equals, participating their sorrows and alleviating their misfortunes. He resembled completely the picture of a philosopher which he himself has drawn. "The true philosopher (said he) ought to be free from prejudices, and to know the value of reason: he ought neither to think the higher ranks of life of more value than they are, nor to treat the lower orders of mankind with greater contempt than they deserve: he ought to enjoy pleasures without being a slave to them, riches without being attached to them, honours without pride or vanity: he ought to support disgrace without either fearing or courting them: he ought to reckon what he possesses sufficient for him, and to regard what he has not as useless: he ought to be equal in every fortune, always tranquil, always gay: he ought to love order, and to observe it in all his actions: he ought to be severe to himself, but indulgent to others: he ought to be frank and ingenuous without rudeness, polite without false-hood, complaisant without baseness: he ought to have the courage to disregard every kind of glory, and to reckon as nothing even philosophy itself." Such was Stanislaus in every situation. His temper was affectionate. He told his treasurer one day to put a certain officer on his list, to whom he was very much attached: "In what quality (said the treasurer) shall I mark him down?" "As my friend" (replied the monarch). A young painter conceiving hopes of making his fortune if his talents were made known to Stanislaus, presented him with a picture, which the courtiers criticised severely. The prince praised the performance, and paid the painter very generously: then turning to his courtiers, he said, "Do ye not see, gentlemen, that this poor man must provide for his family by his abilities? if you discourage him by your censures, he is undone. We ought always to assist men; we never gain anything by hurting them." His revenues were small; but were we to judge of him by what he did, we should probably reckon him the richest potentate in Europe. A single instance will be sufficient to show the well-judged economy with which his benevolent plans were conducted. He gave 18000 crowns to the magistrates of Bar to be employed in purchasing grain, when at a low price, to be sold out again to the poor at a moderate rate when the
the price should rise above a certain sum. By this arrangement (say the authors of the Dictionnaire Historique) the money increases continually, and its good effects may in a short time be extended over the whole province.

He was a protector of the arts and sciences: he wrote several works of philosophy, politics, and morality, which were collected and published in France in 1765, in 4 vols. 8vo, under the title "Oeuvres de Philosophe Bienfaisant," "the works of the Benevolent Philosopher."

STANITZAS, villages or small districts of the banks of the Don, inhabited by Cosacans.

STANLEY, Thomas, a learned English writer in the 17th century, was the son of Sir Thomas Stanley of Cumberlow-Green in Herefordshire, knight. He was born at Cumberlow about 1644, and educated in his father's house, whence he removed to the university of Cambridge. He afterwards travelled; and, upon his return to England, prosecuted his studies in the Middle Temple. He married, when young, Dorothy, the eldest daughter of Sir James Engan of Flower, in Northamptonshire. He wrote, 1. A volume of Poems. 2. History of Philosophy, and Lives of the Philosophers. 3. A Translation of Eschylus, with a Commentary; and several other works. He died in 1678.

STANNARIES, the mines and works where tin is dug and purified; as in Cornwall, Devonshire, &c.

STANNARY COURTS, in Devonshire and Cornwall, for the administration of justice among the tinners therein. They are held before the lord-warden and his substitutes, in virtue of a privilege granted to the workers in the tin-mines there, to sue and be sued only in their own courts, that they may not be drawn from their business, which is highly profitable to the public, by attending their law-suits in other courts. The privileges of the tinners are confirmed by a charter, 33 Edw. I. and fully expounded by a private statute, 50 Edw. III. which has since been explained by a public act, 16 Car. I. c. 15. What relates to our present purpose is only this: That all tinners and labourers in and about the stannaries shall, during the time of their working therein bona fide, be privileged from suits of other courts, and be only pleaded in the stannary court in all matters, excepting pleas of land, life, and member. No writ of error lies from hence to any court in Westminster Hall; as was agreed by all the judges, in 4 Jac. I. But an appeal lies from the steward of the court to the under warden; and from him to the lord warden; and thence to the privy-council of the prince of Wales, as duke of Cornwall, when he hath had livery or investiture of the same. And from thence the appeal lies to the king himself, in the last resort.

STANNUM, TIN. See Tin, Chemistry and Mineralogy Index.

STANZA, in Poetry, a number of lines regularly adjusted to each other; so much of a poem as contains every variation of measure or relation of rhyme used in that poem.

STAPELIA, a genus of plants belonging to the class pentandria and order dicynia, and in the natural orders arranged under the Suculenta. See Botany Index. This singular tribe of plants is peculiar to the sandy deserts of Africa and Arabia. They are extremely succulent. From this peculiarity of structure, the power of retaining water to support and nourish them, they are enabled to live during the prevalent droughts of those arid regions. On this account the stapelia has been compared to the camel; and we are told that by a very apt similitude, it has been denominated "the camel of the vegetable kingdom." We must confess ourselves quite at a loss to see the propriety or aptitude of this comparison. In many parts of the animal and vegetable economy there is doubtless a very obvious and striking analogy: but this analogy has been often carried too far; much farther than fair experiment and accurate observation will in any degree support. It is perhaps owing to this inaccuracy in observing the peculiarity of structure and diversity of functions, that a resemblance is supposed to exist, as in the present case, where in reality there is none. The camel is provided with a bag or fifth stomach, in addition to the four with which ruminant animals are furnished. This fifth stomach is destined as a reservoir to contain water; and it is sufficiently capacious to receive a quantity of that necessary fluid, equal to the wants of the animal, for many days: and this water, as long as it remains in the fifth stomach, is said to be perfectly pure and unchanged. The Stapelia, and other succulent plants, have no such reservoir. The water is equally, or nearly so, diffused through the whole plant. Every vessel and every cell is fully distended. But besides, this water, whether it be received by the roots, or absorbed from the atmosphere, has probably undergone a complete change, and become, after it has been a short time within the plant, a fluid possessed of very different qualities.

The peculiar economy in the stapelia, and other succulent plants, seems to exist in the absorbent and exhalant systems. The power of absorption is as much increased as the power of the exhalant or perpiration vessels is diminished. In these plants, a small quantity of nourishment is required. There is no solid part to be formed, no large fruit to be produced. They generally have very small leaves, often are entirely naked; so that taking the whole plant, a small surface only is exposed to the action of light and heat, and consequently a much smaller proportion of water is decomposed than in plants which are much branched and furnished with leaves.

Two species of stapelia only were known at the beginning of the century. The unfortunate Forskal, the companion of Niebuhr, who was sent out by the king of Denmark to explore the interior of Arabia, and who fell a sacrifice to the pestilential diseases of those inhospitable regions, discovered two new species. Thunberg, in his Prodomus, has mentioned five more. Forty new species have been discovered by Mr. Mason of Kew Gardens, who was sent out by his present Majesty for the purpose of collecting plants round the Cape of Good Hope. Descriptions of these, with elegant and highly finished coloured engravings, have lately been published. They are chiefly natives of the extensive deserts called Karra, on the western side of the Cape.

STAPHILEA, BLADDER-NUT, a genus of plants belonging to the class pentandria and order of triynia; and in the natural system arranged under the 23d order, Trihiliate. See Botany Index.

STAPHYLINUS, a genus of insects belonging to the order of coleoptera. See Entomology Index.
STAPLE, primarily signifies a public place or market, whither merchants, 
&c. are obliged to bring their goods to be bought by the people; as the Greve, or 
the places along the Seine, for sale of wines and corn, at Paris, whither the merchants of other parts are obli-
ged to bring those commodities.

Formerly, the merchants of England were obliged to carry their wool, cloth, lead, and other like staple
commodities of this realm, in order to expose them by wholesale; and these staples were appointed to be con-
stantly kept at York, Lincoln, Newcastle-upon-Tyne, 
Norwich, Westminster, Canterbury, Chichester, Win-
chester, Exeter, and Bristol; in each whereof a public 
mar.t was appointed to be kept, and each of them had a 
court of the mayor of the staple, for deciding differ-
ces, held according to the law-merchant, in a sum-
mary way.

STAR, in Astronomy, a general name for all the 
heavenly bodies, which, like so many brilliant studs, 
are dispersed throughout the whole heavens. The stars 
are distinguished, from the phenomena of their motion, 
&c. into fixed, and erratic or wandering stars: these last 
are again distinguished into the greater luminaries, viz. 
the sun and moon; the planets, or wandering stars, pro-
perly so called, and the comets; which have been all 
fully considered and explained under the article Astro-
nomy. As to the fixed stars, they are so called, be-
cause they seem to be fixed, or perfectly at rest, and 
consequently appear always at the same distance from 
each other.

Falling Stars, in Meteorology, fiery meteors which 
dart through the sky in form of a star. See METEOR.

Twinkling of the Stars. See OPTICS.

STAR, is also a badge of honour, worn by the knights 
of the Garter, Bath, and Thistle. See GARTER.

STAR of Bethlehem. See ORNITHOGALUM, BOTANY

Index.

STAR, in Fortification, denotes a small fort, having 
five or more points, or salient and re-entering angles, 
flanking one another, and their faces 90 or 100 feet 
long.

Court of STAR-CHAMBER, (camera stellata), a fa-
mous, or rather infamous, English tribunal, said to have 
been so called either from a Saxon word signifying to 
steer or govern; or from its punishing the crimen stellari-
num, or censure; or because the room wherein it sat, 
the old council-chamber of the palace of Westminster, 
(Lamb. 143.) which is now converted into the lottery-
office, and forms the eastern side of New-Palace yard, 
was full of windows; or, (to which Sir Edward Coke, 
4 Inst. 66. accedes), because kingly the roof thereof was 
at the first garnished with gilded stars. As all these are 
merely conjectures, (for no stars are now in the roof, 
nor are any said to have remained there so late as the 
reign of Queen Elizabeth), it may be allowable to pro-
spose another conjectural etymology, as plausible perhaps 
as any of them. It is well known, that, before the ban-
ishment of the Jews under Edward I. their contracts 
and obligations were denominated in our ancient records 
sterra or starrs, from a corruption of the Hebrew word, 
shatar, a covenant. (Tovey's Angl. Judaic. 32. Selden, 
tit. of hon. ii. 34. Uxor. Ebraic. i. 14.). These stars, 
by an ordinance of Richard I. preserved by Hoveden, 
were commanded to be enrolled and deposited in chests 
under three keys in certain places; one, and the most 
considerable, of which was in the king's exchequer
at Westminster; and no star was allowed to be valid, un-
less it were found in some of the said repositories. (Men-
non. in Sece P. 6. Edw. I. prefixed to Maynard's
§ 4, 5. 6.). The room at the exchequer, where the 
chests containing these stars were kept, was probably 
called the star-chamber; and, when the Jews were ex-
pelled the kingdom, was applied to the use of the king's 
council, sitting in their judicial capacity. To confirm 
this, the first time the star-chamber is mentioned in any 
record, it is said to have been situated near the receipt 
of the exchequer at Westminster: (the king's council, 
his chancellor, treasurer, justices, and other sages, were 
sembled en la chambre des estelles pres la recepct at 
Westminster. Claus. 41 Edw. III. m. 13.). For in pro-
cess of time, when the meaning of the Jewish starrs was 
forgetten, the word star-chamber was naturally rendered 
in law French, la chambre des estelles, and in law La-
tin camera stellata; which continued to be the style in 
Latin till the dissolution of that court.

This was a court of very ancient original; but now-
modelled by statutes 3 Hen. VII. c. 1. and 21 Hen-
ry VIII. c. 20. consisting of divers lords spiritual and 
temporal, being privy-counsellors, together with two 
judges of the courts of common law, without the inter-
vention of any jury. Their jurisdiction extended legally 
over riots, perjury, misbehaviour of sheriffs, and other 
notorious misdemeanors, contrary to the laws of the 
land. Yct this was afterwards (as Lord Clarendon in-
forms us) stretched " to the asserting of all proclama-
tions and orders of state; to the vindicating of illegal 
commissions and grants of monopolies; holding for 
honourable that which pleased, and for just that which 
profited; and becoming both a court of law to determine 
civil rights, and a court of revenue to enrich the trea-
sury: the council-table by proclamations enjoining to 
the people that which was not enjoined by the laws, and 
prohibiting that which was not prohibited; and the star-
chamber, which consisted of the same persons in different 
rooms, censoring the breach and disobedience to those 
proclamations by very great fines, imprisonments, and 
corporal severities: so that any disrespect to any acts of 
state, or to the persons of state-men, was in no time 
more penal, and the foundations of right never more in 
danger to be destroyed." For which reasons, it was fi-
ally abolished by statute 16 Car. I. c. 10. to the gen-
eral joy of the whole nation. See KING's Bench. There 
is in the British Museum (Harr. MSS. vol. I. No. 126.) 
a very full, methodical, and accurate account of the 
constitution and course of this court, compiled by Wil-
liam Hudson of Gray's Inn, an eminent practitioner 
therein. A short account of the same, with copies of 
all its process, may also be found in 18 Rym. Fed. 192. 
&c.

STAR-BOARD, the right side of the ship when the eye 
of the spectator is directed forward.

STAR-FISH. See ASTERIAS, HELMINTHOLGY

Index.

STAR-shot, a gelatinous substance frequently found in 
fields, and supposed by the vulgar to have been 
produced from the meteor called a falling-star: but, 
in reality, is the half-digested food of herons, sea- 
nefs,
and the like birds; for these birds have been found when newly shot, to disgorge a substance of the same kind.

**Star-Stone**, in Natural History, a name given to certain extraneous fossil stones, in form of short, and commonly somewhat crooked columns, composed of several joints, each resembling the figure of a radiated star, with a greater or smaller number of rays in the different species: they are usually found of about an inch in length, and of the thickness of a goose-quill. Some of them have five angles or rays, and others only four; and in some the angles are equidistant, while in others they are irregularly so: in some also they are short and blunt, while in others they are long, narrow, and pointed; and some have their angles very short and obtuse. The several joints in the same specimen are usually all of the same thickness; this, however, is not always the case: but in some they are larger at one end, and in others at the middle, than in any other part of the body; and some species have one of the rays bifid, so as to emulate the appearance of a six-rayed kind.

**Star-Thistle**. See CENTAUREA, Botany Index. **Star-Wort**. See ASTER.

**STARCH**, a fecula or sediment, found at the bottom of vessels wherein wheat has been steeped in water, of which fecula, after separating the bran from it, by passing it through sieves, they form a kind of loaves, which being dried in the sun or an oven, is afterwards cut into little pieces, and so sold. The best starch is white, soft, and friable, and easily broken into powder. Such as require fine starch, do not content themselves, like the starchmen, with refuse wheat, but use the finest grain. The process is as follows: The grain, being well cleaned, is put to ferment in vessels full of water, which they expose to the sun while in its greatest heat; changing the water twice a-day, for the space of eight or twelve days, according to the season. When the grain bursts easily under the finger, they judge it sufficiently fermented. The fermentation perfected, and the grain thus softened, it is put, handful by handful, into a canvas-bag, to separate the flour from the husks; which is done by rubbing and beating it on a plank laid across the mouth of an empty vessel that is to receive the flour.

As the vessels are filled with this liquid flour, there is seen swimming at top a reddish water, which is to be carefully scummed off from time to time, and clean water is to be put in its place, which, after stirring the whole together, is also to be strained through a cloth or sieve, and what is left behind put into the vessel with new water, and exposed to the sun for some time. As the sediment thickens at the bottom, they drain off the water four or five times, by inclining the vessel, but without passing it through the sieve. What remains at bottom is the starch, which is cut in pieces to get out, and left to dry in the sun. When dry, it is laid up for use.

The following mill, was invented by M. Baume for grinding potatoes, with a view to extract starch from them.

He had a grater made of plate iron, in a cylindrical form (fig. 1.), about seven inches in diameter, and about eight inches high; the burs made by stumping the holes are on the inside. This grater is supported upon three feet AAA, made of flat iron bars, seven feet high, strongly rivetted to the grater; the bottom of each foot is bent horizontally, and has a hole in it which receives a screw, as at A, fig. 4. A little below the upper end of the three feet is fixed a cross piece B (fig. 1. and 4.), divided into three branches, and rivetted to the feet. This cross piece not only serves to keep the feet at a proper distance from each other, and to prevent their bending; but the centre of it having a hole cut in it, serves to support an axis or spindle of iron, to be presently described.

The upper end of this cylindrical grater has a diverging border of iron C (fig. 1. 4. and 7.), about ten inches in diameter at the top, and five inches in height.

Within this cylindrical grater is placed a second grater (fig. 2. and 3.), in the form of a cone, the point of which is cut off. The latter is made of thick plate iron, and the burs of the holes are on the outside; it is fixed, with the broad end at the bottom, as in fig. 4. At the upper end of the cone is rivetted a small triangle, or cross piece of iron, consisting of the three branches D (fig. 2.), in the middle of which is made a square hole, to receive an axis or spindle; to give more resistance to this part of the cone, it is strengthened by means of a cap of iron E, which is fixed to the grater by means of rivets, and has also a square hole made in it, to let the axis pass through.

Fig. 3. represents the same cone seen in front; the base F has also a cross piece of three branches, rivetted to a hoop of iron, which is fixed to the inner surface of the cone; the centre of this cross piece has also a square hole for the passage of the axis.

Fig. 5. is a spindle or axis itself; it is a square bar of iron about 16 inches long, and more than half an inch thick; round at the bottom, and also towards the top, where it fits into the cross piece I, fig. 7. and B. fig. 1. and 4.; in these pieces it turns round, and by them it is kept in its place. It must be square at its upper extremity, that it may have a handle, about nine inches long, fixed to it, by means of which the conical grater is turned round. At G, (fig. 5.), a small hole is made through the axis, to receive a pin H, by means of which the conical grater is kept at its proper height within the cylindrical one.

Fig. 6. is a bird's-eye view, in which the mill is represented placed in an oval tub, like a bathing-tub. I is the fore-mentioned triangular iron cross, fixed with screws to the side of the tub; the centre of it has a round hole, for the axis of the mill to move in when it is used.

Fig. 7. represents the mill in the oval tub; it is placed at one end of it, that the other end may be left free for any operation to be performed in it which may be necessary. A part of the tub is cut off, that the inside of it, and the manner of fixing the mill, may be seen. That the bottom of the tub may not be worn by the screws which pass through the feet of the mill, a deal board, about an inch thick, and properly shaped, is placed under the mill.

When we wish to make use of this mill, it is to be fixed by the feet, in the manner already described; it is also fixed at the top, by means of the cross piece I, fig. 6. and 7. The tub is then to have water poured into it as high as K, and the top of the mill is to be filled with potatoes, properly washed and cut; the handle L is to be turned round, and the potatoes, after being ground between
if any clotted lumps should have been formed they may be divided. It is to be kept in glass-vessels stopped with paper only.

A patent was granted in 1796 to Lord William Murray for his discovery of a method by which starch may be extracted from horse-chestnuts. It is as follows:

Take the horse-chestnuts out of the outward green prickly husks; and either by hand, with a knife, or other tool, or else with a mill adapted for that purpose, very carefully pare off the brown rind, being particular not to leave the smallest speck, and to entirely eradicate the sprout or growth. Next take the nuts, and rasp, grate, or grind them fine into water, either by hand, or by a mill adapted for that purpose. Wash the pulp, which is thereby formed in this water, as clean as possible, through a coarse horse-hair sieve; this again wash through a finer sieve, and then again through a still finer, constantly adding clean water, to prevent any starch from adhering to the pulp. The last process is, to put it with a large quantity of water (about four gallons to a pound of starch) through a fine gauze, muslin, or lawn, so as entirely to clear it of all bran or other impurities. As soon as it settles, pour off the water; then mix it up with clean water, repeating this operation till it no longer imparts any green, yellow, or other colour to the water. Then drain it off till nearly dry, and set it to bake, either in the usual mode of baking starch, or else spread out before a brisk fire; being very attentive to stir it frequently to prevent its horning, that is to say, turning to a paste or jelly, which, on being dried, turns hard like horn. The whole process should be conducted as quickly as possible.

Mention is here made of a mill which may be employed to grind the horse-chestnuts; but it is not described; perhaps the one described above for grinding potatoes might answer the purpose.

STARK, DR WILLIAM, known to the public by a volume containing Clinical and Anatomical Observations, with some curious Experiments on Diet, was born at Manchester in the month of July 1742; but the family from which he sprang was Scotch, and respectable for its antiquity. His grandfather John Stark of Killermont was a covenanter; and having appeared in arms against his sovereign at the battle of Bothwell bridge in the year 1679, became obnoxious to the government, and, to conceal himself, withdrew into Ireland. There is reason to believe that he had not imbibed either the extravagant zeal or the savage manners of the political and religious party to which he adhered; for after residing a few years in the country which he had chosen for the scene of his banishment, he married Elizabeth daughter of Thomas Stewart, Esq. of Ballydore in the north of Ireland; who, being descended of the noble family of Galloway, would not probably have matched his daughter to such an exile as a ruthless fanatic of the last century. By this lady Mr Stark had several children; and his second son Thomas, who settled at Manchester as a wholesale linen-draper, and married Margaret Stirling, daughter of William Stirling, Esq. of Northwoodside, in the neighbourhood of Glasgow, was the father of the subject of this article. Another of his sons, the reverend John Stark, was minister of Lecropt in Perthshire; and it was under the care of this gentleman that our author received the rudiments of his education, which, when we consider the character of the master,
and reflect on the relation between him and his pupil, we may presume was calculated to store the mind of Dr Stark with those virtuous principles which influenced his conduct through life.

From Leckopt young Stark was sent to the university of Glasgow, where under the tuition of the doctors Smith and Black, with other eminent masters, he learned the rudiments of science, and acquired that mathematical accuracy, that logical precision, and that contempt of hypotheses, with which he prosecuted all his future studies. Having chosen physic for his profession, he removed from the university of Glasgow to that of Edinburgh, where he was soon distinguished, and honoured with the friendship of the late Dr Cullen; a man who was not more eminently conspicuous for the superiority of his own genius, than quick-sighted in perceiving, and liberal in encouraging, genius in his pupils. Having finished his studies at Edinburgh, though he took there no degree, Mr Stark, in the year 1765, went to London, and devoted himself entirely to the study of physic and the elements of surgery; and looking upon anatomy as one of the principal pillars of both these arts, he endeavoured to complete with Dr Hunter what he had begun with Dr Monro; and under these two eminent professors he appears to have acquired a high degree of anatomical knowledge. He likewise entered himself about this time a pupil at St George’s hospital; for being disgusted, as he often confided, with the inaccuracy or want of candour observable in the generality of practical writers, he determined to obtain an acquaintance with diseases at a better school and from an abler master; and to have from his own experience a standard, by which he might judge of the experience of others. With what industry he prosecuted this plan, and with what success his labours were crowned, may be seen in a series of Clinical and Anatomical Observations, which were made by him during his attendance at the hospital, and were published after his death by his friend Dr Carmichael Smyth. These observations give the public no cause to complain of want of candour in their author; for whatever delicacy he may have observed, when relating the cases of patients treated by other physicians, he has related those treated by himself with the utmost impartiality. Whilst attending the hospital, he likewise employed himself in making experiments on the blood, and other animal fluids; and also in a course of experiments in chemical pharmacy; but though accounts of these experiments were left behind him, we believe they have not yet been given to the public.

In the year 1767 Mr Stark went abroad, and obtained the degree of M. D. in the university of Leyden, publishing an inaugural dissertation on the dysentery. On his return to London, he recommenced his studies at the hospital; and when Dr Black was called to the chemical chair in Edinburgh, which he has long filled with so much honour to himself and credit to the university, Dr Stark was solicited by several members of the university of Glasgow to stand a candidate for their professorship of the theory and practice of physic, rendered vacant by Dr Black’s removal to Edinburgh. This however Dr Stark declined, being influenced by the advice of his English friends, who wished to detain him in London, and having likewise some prospects of an appointment in the hospital.

In the mean time he had commenced (1769) a series of experiments on diet, which he was encouraged to undertake by Sir John Pringle and Dr Franklin, whose friendship he enjoyed, and from whom he received many hints respecting both the plan and its execution. These experiments, or rather the imprudent zeal with which he prosecuted them, proved, in the opinion of his friends, fatal to himself; for he began them on the 12th of July 1769 in perfect health and vigour, and from that day, though his health varied, it was seldom if ever good, till the 23d of February 1770, when he died, after suffering much uneasiness. His friend and biographer Dr Smyth thinks, that other causes, particularly chagrin and disappointment, had no small share in hastening his death; and as the Doctor was intimately acquainted with his character and disposition, his opinion is probably well-founded, though the pernicious effects of the experiments are visible in Dr Stark’s own journal. When he entered upon them, the weight of his body was 12 stone 3 lb. avoirdupois, which in a very few days was reduced to 11 stone 10 lb. 8 oz.: and though some kinds of food increased it, by much the greater part of what he used had a contrary effect, and it continued on the whole to decrease till the day of his death. This indeed can excite no wonder. Though the professed object of his experiments was to prove that a pleasant and varied diet is equally conducive to health with a more strict and simple one, most of the dishes which he ate during these experiments were neither pleasant nor simple, but compounds, such as every stomach must nauseate. He began with bread and water; from which he proceeded to bread, water, and sugar; then to bread, water, and oil of olives; then to bread and water with milk; afterwards he tried bread and water with roasted goose; bread and water with boiled beef; stewed lean of beef with the gravy and water without bread; stewed lean of beef with the gravy, oil of fat or sweet and water; flour, oil of sweet, water and salt; flour, water, and salt; and a number of others infinitely more disagreeable to the stomach than even these, such as bread, fat of bacon, ham, infusion of tea with sugar; and bread or flour with honey and the infusion of rosemary. But though we consider Dr Stark’s experiments as whimsical, it cannot be denied that they indicate eccentricity of genius in the person who made them; and such of our readers as think genius hereditary, may perhaps be of opinion, that he derived a ray from the celebrated Napier the inventor of the logarithms, who was his ancestor by both parents. At any rate, these experiments, of which a full account is given in the same volume with his clinical and anatomical observations, display an uncommon degree of fortitude, perseverance, self-denial, and zeal for the promoting of useful knowledge in their author; and with respect to his moral character, we believe it is in great justice that Dr Smyth compares him to Cato, by applying to him what was said of that virtuous Roman by Sallust—"Non divitiis cum divite, neque factione cum factiose; sed cum strenuo virtute, cum modesto pudore, cum innocentia abstinentia certatbat; esse, quam videri, bonus malebat."

STARLING. See STURNUS, ORNITHOLOGY In-Cultivatisum.

STARLINGS, or STERLINGS, the name given to the strong pieces of timber which were driven into the bed of the river to protect the piles, on the top of which were laid the flat beams upon which were built the
the bases of the stone piers that support the arches of
London bridge. In general, starlings are large piles
placed on the outside of the foundation of the piers of
bridges, to break the force of the water, and to protect
the stone work from injury by floating ice. They are
otherwise called jetes, and their place is often supplied
by large stones thrown at random round the piers of
bridges, as may be seen at Stirling bridge when the riv-
er is low; and as was done by Mr Smeaton’s direction
round the piers of the centre arch of London bridge,
when it was thought in danger of being undermined by
the current.

STATE OF A CONTROVERSY. See ORATORY, Part
1. No. 14.

STATES, or ESTATES, a term applied to several or-
ders or classes of people assembled to consult of matters
for the public good.

Thus States-General, in the old government of Hol-
lund, is the name of an assembly consisting of the deput-
tees of the seven United Provinces. These were usual-
ly 30 in number, some provinces sending two, others
more; and whatever resolution the states-general took
was confirmed by every province, and by every city and
public in that province, before it had the force of a
law. The deputies of each province, of what number
soever they were, had only one voice, and were esteem-
ed as but one person, the votes being given by provin-
ces. Each province presided in the assembly in its turn,
according to the order settled among them. Guelders
land presided first, then Holland, &c.

States of Holland were the deputies of eighteen cities,
and one representative of the nobility, constituting the
states of the province of Holland: the other provinces
had likewise their states, representing their sovereignty;
deputies from which made what was called the states-
general. In an assembly of the states of a particular
province, one dissenting voice prevented their coming
to any resolution.

STATICE, Thrift, a genus of plants belonging to
the class of pentandria, and order of pentagynia; and
in the natural system ranging under the 48th order, Aggre-
gate. See BOTANY Index.

STATICS, a term which the modern improvements in
knowledge have made it necessary to introduce into
physico-mathematical science. It was found convenient
to distribute the doctrines of universal mechanics into
two classes, which required both a different mode of con-
sideration and different principles of reasoning.

Till the time of Archimedes little science of this
kind was possessed by the ancients, from whom we
have received the first rudiments. His investigation of
the centre of gravity, and his theory of the lever, are
the foundations of our knowledge of common mechana-
ic; and his theory of the equilibrium of floating bodies
contains the greatest part of our hydrostatic knowledge.
But it was as yet limited to the simplest cases;
and there were some in which Archimedes was igno-
rant, or was mistaken. The marquis Guido Ubald, in
1558, published his theory of mechanics, in which the
doctrines of Archimedes were well explained and consid-
erably augmented. Stevinus, the celebrated Dutch
engineer, published about 20 years after an excellent
system of mechanics, containing the chief principles
which now form the science of equilibrium among solid
bodies. In particular, he gave the theory of inclined
planes, which was unknown to the ancients, though it
is of the very first importance in almost every machine.
He even states in the most express terms the principle
afterwards mad of the foundation of the whole of mecha-

nics, and published as a valuable discovery by Varig-
non, viz., that three forces, whose directions and inten-
sities are as the sides of a triangle, balance each other.
His theory of the pressure of fluids, or hydrostatics, is
no less estimable, including every thing that is now re-
duced as a leading principle in the science. When we
consider the ignorance, even of the most learned of
that age, in mechanical or physico-mathematical knowl-
edge, we must consider these performances as the works
of a great genius; and we regret that they are so little
known, being lost in a crowd of good writings on those
subjects which appeared soon after.

Hitherto the attention had been turned entirely to
equilibrium, and the circumstances necessary for produ-
cing it. Mechanicians indeed saw, that the energy of a
machine might be somehow measured by the force
which could be opposed or overcome by its interven-
tion: but they did not remark, that the force which
prevented its motion, but did no more than prevent it,
was an exact measure of its energy, because it was in
immediate equilibrium with the pressure exerted by that
part of the machine with which it was connected. If
this opposed force was less, or the force acting at the
other extremity of the machine was greater, the me-
chanicians knew that the machine would move, and
that work would be performed; but what would be
the rate of its motion or its performance, they hardly
pretended to conjecture. They had not studied the ac-
tion of moving forces, nor conceived what was done
when motion was communicated.

The great Galileo opened a new field of speculation
in his work on Local Motion. He there considers a
change of motion as the indication and exact and ade-
quate measure of a moving force; and be considers every
kind of pressure as competent to the production of such
changes. He contented himself with the application of
this principle to the motion of bodies by the action of
gravity, and gave the theory of projectiles, which re-
mains to this day without change, and only improved
by considering the changes which are produced in it by
the resistance of the air.

Sir Isaac Newton took up this subject nearly as Ga-
ileo had left it. For, if we except the theory of the
centrifugal forces arising from rotation, and the theory
of pendulums, published by Huygens, hardly anything
had been added to the science of motion. Newton con-
sidered the subject in its utmost extent; and in his ma-
thematical principles of natural philosophy he considers
every conceivable variation of moving force, and deter-
mine the motion resulting from its actions. His first
application of these doctrines was to explain the celestial
motions; and the magnificence of this subject caused it
to occupy for a while the whole attention of the mathe-
ematicians. But the same work contained proposi-
tions equally conducitve to the improvement of common
mechanics, and to the complete understanding of the me-
chanical actions of bodies. Philosophers began to make
these applications also. They saw that every kind of work
which is to be performed by a machine may be consid-
ered abstractedly as a retarding force; that the impulse
of water or wind, which are employed as moving powers,

4 L 2

act
Statics. act by means of pressures which they exert on the impelled point of the machine; and that the machine itself may be considered as an assemblage of bodies moveable in certain limited circumstances, with determined directions and proportions of velocity. From all these considerations resulted a general abstract condition of a body acted on by known powers. And they found, that after all conditions of equilibrium were satisfied, there remains a surplus of moving force. They could now state the motion which will ensue, the new resistance which this will excite, the additional power which this will absorb; and they at last determined a new kind of equilibrium, not thought of by the ancient mechanicians, between the resistance to the machine performing work and the moving power, which exactly balance each other, and is indicated, not by the rest, but by the uniform motion of the machine. In like manner, the mathematician was enabled to calculate that precise motion of water which would completely absorb, or, in the new language, balance the superiority of pressure by which water is forced through a sluice, a pipe, or canal, with a constant velocity.

Thus the general doctrines of motion came to be considered in two points of view, according as they balanced each other in a state of rest or of uniform motion. These two ways of considering the same subject required both different principles and a different manner of reasoning. The first has been named statics, as expressing that rest which is the test of this kind of equilibrium. The second has been called dynamics or universal mechanics, because the different kinds of motion are characteristic of the powers or forces which produce them. A knowledge of both is indispensably necessary for acquiring any useful practical knowledge of machines; and it was ignorance of the doctrines of accelerated and retarded motions which made the progress of practical mechanical knowledge so very slow and imperfect. The mechanics, even of the moderns, before Galileo, went no further than to state the proportion of the power and resistance which would be balanced by the intervention of a given machine, or the proportion of the parts of a machine by which two known forces may balance each other. This view of the matter introduced a principle, which even Galileo considered as a mechanical axiom, viz. that what is gained in force by means of a machine is exactly compensated by the additional time which it obliges us to employ. This is false in every instance, and not only prevents improvement in the construction of machines, but leads us into erroneous maxims of construction. The true principles of dynamics teach us, that there is a certain proportion of the machine, dependent on the kind and proportion of the power and resistance, which enables the machine to perform the greatest possible work.

It is highly proper therefore to keep separate these two ways of considering machines, that both may be improved to the utmost, and then to blend them together in every practical discussion.

Statics therefore is preparatory to the proper study of mechanics; but it does not hence derive all its importance. It is the sole foundation of many useful parts of knowledge. This will be best seen by a brief enumeration.

1. It comprehends all the doctrines of the excitement and propagation of pressure through the parts of solid bodies, by which the energies of machines are produced. A pressure is excited on the impelled point of a machine, such as the float-boards or buckets of a mill-wheel. This excites a pressure at the pivots of its axle, which act on the points of support. This must be understood, both as to direction and intensity, that it may be effectually resisted. A pressure is also excited at the acting tooth of the cog-wheel on the same axle, by which it urges round another wheel, exciting similar pressures on its pivots and on the acting tooth perhaps of a third wheel. Thus a pressure is ultimately excited in the working point of the machine, perhaps a wiper, which lifts a heavy stamper, to let it fall again on some matter to be pounded. Now statics teaches us the intensities and direction of all these pressures, and therefore how much remains at the working point of the machine unbalanced by resistance.

2. It comprehends every circumstance which influences the stability of heavy bodies; the investigation and properties of the centre of gravity; the theory of the construction of arches, vaults, and domes; the attitudes of animals.

3. The strength of materials, and the principles of construction, so as to make the proper adjustment of strength and strain in every part of a machine, edifice, or structure of any kind. Statics therefore furnishes us with what may be called a theory of carpentry, and gives us proper instructions for framing floors, roofs, centres, &c.

4. Statics comprehends the whole doctrine of the pressure of fluids, whether liquid or aeriform, whether arising from their weight or from any external action. Hence therefore we derive our knowledge of the stability of ships, or their power of maintaining themselves in a position nearly upright, in opposition to the action of the wind on the sails. We learn on what circumstances of figure and storage this quality depends, and what will augment or diminish it.

Very complete examples will be given in the remaining part of this work of the advantages of this separate consideration of the condition of a machine at rest and in working motion; and in what yet remains to be delivered of the hydraulic doctrines in our account of Water-Works in general, will be perceived the propriety of stating apart the equilibrium which is indicated by the uniform motion of the fluid. The observations too which we have to make on the strength of the materials employed in our edifices or mechanical structures, will be examples of the investigation of those powers, pressures, or strains, which are excited in all their parts.

STATIONARY, in Astronomy, the state of a planet when, to an observer on the earth, it appears for some time to stand still, or remain immovable in the same place in the heavens. For as the planets, to such an observer, have sometimes a progressive motion, and sometimes a retrograde one, there must be some point between the two where they must appear stationary.

STATISTICS, a word lately introduced to express a view or survey of any kingdom, county, or parish. A statistical view of Germany was published in 1790 by Mr B. Clarke: giving an account of the imperial and territorial constitutions, forms of government, legislation, administration of justice, and of the ecclesiastical state;
instances of good and bad seasons; quantity and value of each species of crop; total value of the whole produce of the district; total quantity of grain and other articles consumed in the parish; wages and price of labour; services, whether exacted or abolished; commerce; manufactures; manufacture of help, its amount, and the number of people employed in it; fisheries; towns and villages; police; inns and alehouses; roads and bridges; harbours, ferries, and their state; number of ships and vessels; number of seamen; state of the church; stipend, manse, glebe, and patron; number of poor; parochial funds, and the management of them; state of the schools, and number of scholars; ancient state of population; causes of its increase or decrease; number of families; exact amount of the number of souls now living; division of the inhabitants; 1. by the place of their birth; 2. by their ages; 3. by their religious persuasions; 4. by their occupations and situation in life; 5. by their residence, whether in town, village, or in the country: number of houses; number of uninhabited houses; number of dove-cots, and to what extent they are destructive to the crops; number of horses, their nature and value; number of cattle, their nature and value; number of sheep, their nature and value; number of swine, their nature and value; minerals in general; mineral springs; coal and fuel; eminent men; antiquities; parochial records; miscellaneous observations; character of the people; their manners, customs, stature, &c.; advantages and disadvantages; means by which their situation could be mitigated.

If similar surveys (says the public-spirited editor of this work) were instituted in the other kingdoms of Europe, it might be the means of establishing, on sure foundations, the principles of that most important of all sciences, viz. political or statistical philosophy; that is, the science, which, in preference to every other, ought to be held in reverence. No science can furnish, to any mind capable of receiving useful information, so much real entertainment; none can yield such important hints for the improvement of agriculture, for the extension of commercial industry, for regulating the conduct of individuals, or for extending the prosperity of the state; none can tend so much to promote the general happiness of the species.

STATIUS, Publius Papinius, a celebrated Latin poet of the first century, was born at Naples, and was the son of Statius, a native of Epirus, who went to Rome to teach poetry and eloquence, and had Domitian for his scholar. Statius the poet also obtained the favour and friendship of that prince; and dedicated to him his Thebaids and Achilleis; the first in twelve books, and the last in two. He died at Naples about the year 100. Besides the above poems, there are also still extant his Sylvae, in five books; the style of which is purer, more agreeable, and more natural, than that of his Thebaids and Achilleis.

STATUARY, a branch of sculpture, employed in the making of statues. See SCULPTURE and the next article.

Statuary is one of those arts wherein the ancients surpassed the moderns; and indeed it was much more popular, and more cultivated, among the former than the latter. It is disputed between statuary and painting, which of the two is the most difficult and the most artful.
Statuary is also used for the artificer who makes statues. Phidias was the greatest statuary among the ancients, and Michael Angelo among the moderns.

**Statuary,** is defined to be a piece of sculpture in full relief, representing a human figure. Daviler more scientifically defines statue a representation, in high relief and insulate, of some person distinguished by his birth, merit, or great actions, placed as an ornament in a fine building, or exposed in a public place, to preserve the memory of his worth. In Greece one of the highest honours to which a citizen could aspire was to obtain a statue.

Statues are formed with the chisel, of several matters, as stone, marble, plaster, &c. They are also cast of various kinds of metal, particularly gold, silver, brass, and lead. For the method of casting statues, see the article **FOUNDEY OF Statues.**

Statues are usually distinguished into four general kinds. The first are those less than the life; of which kind we have several statues of great men, of kings, and of gods themselves. The second are those equal to the life; in which manner it was that the ancients, as the public expense, used to make statues of persons eminent for virtue, learning, or the services they had done. The third are those that exceed the life; among which those that surpassed the life once and a half were for kings and emperors: and those double the life, for heroes. The fourth kind were those that exceeded the life twice, thrice, and even more, and were called **Colossuses.** See Colossus.

Every statue resembling the person whom it is intended to represent, is called *status iconico.* Statues acquire various other denominations. 1. Thus, allegorical statue is that which, under a human figure, or other symbol, represents something of another kind; as a part of the earth, a season, age, element, temperament, hour, &c. 2. Curule statues, are those which are represented in chariots drawn by bige or quadriga, that is, by two or four horses; of which kind there were several in the circuses, hippodromes, &c. or in cars, as we see some, with triumphal arches on antique medals. 3. Equestrian statue, that which represents some illustrious person on horseback, as that famous one of Marcus Aurelius at Rome: that of King Charles I. at Charing-cross; King George II. in Leicester Square, &c. 4. Greek statue, denotes a figure that is naked and antique; it being in this manner the Greeks represented their deities, athletes of the Olympic games, and heroes; the statues of heroes were particularly called *Achilles statues,* by reason of the great number of figures of Achilles in most of the cities of Greece. 5. Hydraulic statue, is any figure placed as an ornament of a fountain or grotto, or that does the office of a jet d'eau, a cock, spout, or the like, by any of its parts, or by any attribute it holds: the like is to be understood of any animal serving for the same use. 6. Pedestrian statue, a statue standing on foot; as that of King Charles II. in the Royal Exchange, and of King James II. in the Privy-Gardens. 7. Roman statue, is an appellation given to such as are clothed, and which receive various names from their various dresses. Those of emperors, with long gowns over their armour, were called *status palliato:* those of captains and cavaliers, with coats of arms, *thoraces*; those of soldiers with cuirasses, *loriato:* those of senators and augurs, *trabeato:* those of magistrates with long robes, *toga.*; those of the people with a plain tunic, *tunicato:* and, lastly, those of women with long trains, *stola.*

In repairing a statue cast in a mould, they touch it up with a chisel, graver, or other instrument, to finish the places which have not come well off: they also clear off the barb, and what is redundant in the joints and projections.

**Statue.** See Dwarf and Giant.

**Statute,** in its general sense, signifies a law, ordinance, decree, &c. See Law, &c.

**Statute,** in our laws and customs, more immediately signifies an act of parliament made by the three estates of the realm; and such statutes are either general, of which the courts at Westminster must take notice without pleading them; or they are special and private, which last must be pleaded.

**STAVESACRE,** a species of Delphinium, which see, Botany Index.

**Stay,** a large strong rope employed to support the mast on the fore part, by extending from its upper end towards the fore part of the ship, as the shrouds are extended to the right and left, and behind it. See **Mast,** Rigging, and Shroud.

The stay of the fore-mast, which is called the *forestay,* reaches from the mast-head towards the bowsprit end: the main stay extends over the forecastle to the ship's stem; and the mizen-stay is stretched down to that part of the main-mast which lies immediately above the quarter-deck: the fore-top-mast-stay comes also to the end of the bowsprit, a little beyond the fore-stay: the main-top-mast stay is attached to the head or hounds of the fore-mast; and the mizen-top-mast stay comes also to the hounds of the main-mast: the fore-top-gallant stay comes to the outer end of the jib-boom; and the main-top-gallant stay is extended to the head of the fore-top-mast.

**Stay-Sail,** a sort of triangular sail extended upon a stay. See Sail.

**Steam,** is the name given in our language to the visible moist vapour which arises from all bodies which contain juices easily expelled from them by heat not sufficient for their combustion. Thus we say, the steam of boiling water, of malt, of a tan-bed, &c. It is distinguished from smoke by its not having been produced by combustion, by not containing any soot, and by its being condensable by cold into water, oil, inflammable spirits, or liquids composed of these.

We see it rise in great abundance from bodies when they are heated, forming a white cloud, which diffuses itself and disappears at no very great distance from the white body from which it was produced. In this case the cloud, surrounding air is found loaded with the water or other juices which seem to have produced it, and the steam seems to be completely soluble in air, as salt is in water, composing whilst thus united a transparent elastic fluid.

But in order to its appearance in the form of a mist when dispersed white cloud, the mixture with or dissemination seminated in air seems absolutely necessary. If a tea-kettle boil in air violently, so that the steam is formed at the spout, in great abundance, it may be observed, that the visible cloud is not formed at the very mouth of the spout, but at a small distance before it, and that the vapour is perfectly transparent at its first emission. This is rendered still more evident byfitting to the spout of the tea-kettle
before it be all melted, remaining all the while of the temperature 32°, and therefore continually absorbing heat from the surrounding air. By comparing the time in which the ice had its temperature changed from 28° to 32° with the subsequent time of its complete liquefaction, he found that it absorbed about 130 or 140 times as much heat as would raise its temperature one degree; and he found that one pound of ice, when mixed with one pound of water 140 degrees warmer, was just melted, but without rising in its temperature above 32°. Hence he justly concluded, that water differed from ice of the same temperature by containing, as a constituent ingredient, a great quantity of fire, or of the cause of heat, united with it in such a way as not to quit it for another colder body, and therefore so as not to go into the liquor of the thermometer and expand it. Considered therefore as the possible cause of heat, it was latent, which Dr Black expressed by the abbreviated term latent heat. If any more heat was added to the water it was not latent, but would readily quit it for the thermometer, and, by expanding the thermometer, would show what is the degree of this redundant heat, while fluidity alone is the indication of the combined and latent heat.

Dr Black, in like manner, concluded, that in order to convert water into an elastic vapour, it was necessary, not only to increase its uncombined heat till its temperature is 212°, in which state it is just ready to become elastic; but also to pour into it a great quantity of fire, or the cause of heat, which combines with every particle of it, so as make it repel, or to recede from its adjoining particles, and thus to make it a particle of an elastic fluid. He supposed that this additional heat might be combined with it so as not to quit it for the thermometer; and therefore so as to be in a latent state, having elastic fluidity for its sole indication.

This opinion was very consistent with the phenomenon of boiling off a quantity of water. The application of heat to it causes it gradually to rise in its temperature till it reaches the temperature 212°. Then it begins to send off elastic vapour, and is slowly expended in this way, continuing all the while of the same heat which temperature. The steam also is of no higher temperature, it absorbs, as appears by holding a thermometer in it. We must conclude that this steam contains all the heat which is expended in its formation. Accordingly the scalding power of steam is well known; but it is extremely difficult to obtain precise measures of the quantity of heat absorbed by water during its conversion into steam. Dr Black endeavoured to ascertain this point, by comparing the time of raising its temperature a certain number of degrees with the time of boiling it off by the same external heat; and he found that the heat latent in steam, which balanced the pressure of the atmosphere, was not less than 500 degrees. He also directed Dr Irvine of Glasgow to the form of an experiment for measuring the heat actually extracted from such steam during its condensation in the refrigeratory of a still, which was found to be not less than 774 degrees. Dr Black was afterwards informed by Mr Watt, that a course of experiments, which he had made in each of these ways with great precision, determined the latent heat of steam under the ordinary pressure of the atmosphere to be about 548 or 550 degrees. Mr Watt also found that water would distil with great ease.

4. It is again converted into water by cold.

5. Its appearance explained.

6. And the cause of its conversion, by Dr Black's discovery of latent heat.
Steam. When the temperature is 70°, and that in this case the latent heat of the steam is not less than 1200 or 1300 degrees; and a train of experiments, which he had made by distilling in different temperatures, made him conclude that the sum of the sensible and latent heats is a constant quantity. This is a curious and not an improbable circumstance; but we have no information of the particulars of these experiments. The conclusion evidently presupposes a knowledge of that particular temperature in which the water has no heat; but this is a point which is still sub judice.

This conversion of liquids (for it is not confined to water, but obtains also in ardent spirits, oils, mercury, &c.) is the cause of their boiling. The heat is applied to the bottom and sides of the vessel, and gradually accumulates in the fluid, in a sensible state, uncombined, and ready to quit it and to enter into any body that is colder, and to diffuse itself between them. Thus it enters into the fluid of a thermometer, expands it, and gives us the indication of the degree in which it has been accumulated in the water; for the thermometer swells as long as it continues to absorb sensible heat from the water: and when the sensible heat in both is in equilibrio, in a proportion depending on the nature of the two fluids, the thermometer rises no more, because it absorbs no more heat or fire from the water; for the particles of water which are in immediate contact with the bottom, are now (by this gradual expansion of liquidity) at such distance from each other, that their laws of attraction for each other and for heat are totally changed. Each particle either no longer attracts, or perhaps it repels its adjoining particle, and now accumulates round itself a great number of the particles of heat, and forms a particle of elastic fluid, so related to the adjoining new formed particles, as to repel them to a distance at least a hundred times greater than their distances in the state of water. Thus a mass of elastic vapour of sensible magnitude is formed. Being at least ten thousand times lighter than an equal bulk of water, it must rise up through it, as a cork would do, in form of a transparent ball or bubble, and getting to the top, it dissipates, filling the upper part of the vessel with vapour or steam. Thus, by toasting the liquid into bubbles, which are produced all over the bottom and sides of the vessel, it produces the phenomenon of ebullition or boiling. Observe, that during its passage up through the water, it is not changed nor condensed; for the surrounding water is already so hot that the sensible or uncombined heat in it, is in equilibrio with that in the vapour, and therefore it is not disposed to absorb any of the heat which is combined as an ingredient of this vapour, and gives it its elasticity. For this reason, it happens that water will not boil till its whole mass be heated up to 212°; for if the upper part be colder, it rolls the rising bubble of that heat which is necessary for its elasticity, so that it immediately collapses again, and the surface of the water remains still. This may be perceived by holding water in a Florence flask over a lamp or chafier. It will be observed, some time before the real ebullition, that some bubbles are formed at the bottom, and get up a very little way, and then disappear. The distances which they reach before collapsing increase as the water continues to warm farther up the mass, till at last it breaks out into boiling. If the handle of a tea-kettle be grasped with the hand, a tremor will be felt for some little time before boiling, arising from the little successes which are produced by the collapsing of the bubbles of vapour. This is much more violent, and is really a remarkable phenomenon, if we suddenly plunge a lump of red hot iron into a vessel of cold water, taking care that no red part be near the surface. If the hand be now applied to the side of the vessel, a most violent tremor is felt, and sometimes strong thumps; these arise from the collapsing of very large bubbles. If the upper part of the iron be too hot, it warms the surrounding water so much that the bubbles from below come up through it uncondensed, and produce ebullition without this succession. The great resemblance of this tremor to the feeling which we have during the shock of an earthquake has led many to suppose that these last are produced in the same way, and their hypothesis, notwithstanding the objections which we have elsewhere stated to it, is by no means unfeasible.

It is owing to a similar cause that violent thumps are sometimes felt on the bottom of a tea-kettle, especially one which has been long in use. Such are frequently observed in the boiling of a tea-kettle sometimes felt on the bottom with a stony concretion. This sometimes is detached in little scales. When one of these is adhering by one end to the bottom, the water gets between them in a thin film. Hence it may be heated considerably above the boiling temperature, and it suddenly rises up in a large bubble, which collapses immediately. A smooth shifting lying on the bottom will produce this appearance very violently, or a thimble with the mouth down.

In order to make water boil, the fire must be applied to the bottom or sides of the vessel. If the heat be applied at the top of the water, it will waste away without boiling; for the very superficial particles at the top are first supplied with the heat necessary for rendering them elastic, and they fly off without agitating the rest (A).

Since this disengagement of vapour is the effect of its

(A) We explained the opaque and cloudy appearance of steam, by saying that the vapour is condensed by coming into contact with the cooler air. There is something in the form of this cloud which is very inexplicable. The particles of it are sometimes very distinguishable by the eye; but they have not the smart star-like brilliancy of very small drops of water, but give the fainter reflection of a very thin film or vesicle like a soap bubble. If we attend also to their motion, we see them descending very slowly in comparison with the descent of a solid drop; and this vesicular constitution is established beyond a doubt by looking at a candle through a cloud of steam. It is seen surrounded by a faint halo with prismatic colours, precisely such as we can demonstrate by optical laws to belong to a collection of vesicles, but totally different from the halo which would be produced by a collection of solid drops. It is very difficult to conceive how these vesicles can be formed of watery particles, each of which was surrounded...
its elasticity, and since this elasticity is a determined force when the temperature is given, it follows, that fluids cannot boil till the elasticity of the vapour overcomes the pressure of the incipient fluid and of the atmosphere. Therefore, when this pressure is removed or diminished, the fluids must sooner overcome what remains, and boil at a lower temperature. Accordingly it is observed that water will boil in an exhausted receiver when of the heat of the human body. If two glass bulbs A and B (fig. 1.) be connected by a slender tube, and one of them A be filled with water (a small opening or pipe b being left at top of the other), and this be made to boil, the vapour produced from it will drive all the air out of the other, and will at last come out itself, producing steam at the mouth of the pipe. When the ball B is observed to be occupied by transparent vapour, we may conclude that the air is completely expelled. Now shut the pipe by sticking it into a piece of tallow or bees-wax; the vapour in B will soon condense, and there will be a vacuum. The flame of a lamp and blow-pipe being directed to the little-pipe, will cause it immediately to close and seal hermetically. We now have a pretty instrument or toy called a Pulse Glass. Grasp the ball A in the hollow of the hand; the heat of the hand will immediately expand the bubble of vapour which may be in it, and this vapour will drive the water into B, and then will boil up through it for a long while, keeping it in a state of violent ebullition, as long as there remains a drop or film of water in A. But care must be taken that B is all the while kept cold, that it may condense the vapour as fast as it rises through the water. Touching B with the hand, or breathing warm on it, will immediately stop the ebullition in it. When the water in A has thus been dissipated, grasp B in the hand; the water will be driven into A, and the ebullition will take place there as it did in B. Putting one of the balls into the mouth will make the ebullition more violent in the other, and the one in the mouth will feel very cold. This is a pretty illustration of the rapid absorption of the heat by the particles of water which are thus converted into elastic vapour. We have seen this little toy suspended by the middle of the tube like a balance, and thus placed in the inside of a window, having two holes a and b cut in the pane, in such a situation that when A is full of water and preponderates, B is opposite to the hole b. Whenever the room became sufficiently warm, the vapour was formed in A, and immediately drove the water into B, which was kept cool by the air coming into the room through the hole b. By this means B was made to preponderate in its turn, and A was then opposite to the hole a, and the process was then repeated in the opposite direction; and this amusement continued as long as the room was warm enough.

We know that liquors differ exceedingly in the temperature necessary for their ebullition. This forms the great chemical distinction between volatile and fixed bodies. But the difference of temperature in which they boil, or are converted into permanently elastic vapour, under the pressure of the atmosphere, is not a certain measure of their differences of volatility. The natural boiling point of a body is that in which it will be converted into elastic vapour under no pressure, or in vacuo. The boiling point in the open air depends on the law of the elasticity of the vapour in relation to its heat. A fluid A may be less volatile, that is, may require more heat to make it boil in vacuo, than a fluid B: But if the elasticity of the vapour of A be more increased by an increase of temperature than that of the vapour of B, A may boil at a lower temperature, or at a lower temperature, in the open air, than B does; for the increased elasticity of the vapour of A may sooner overcome the pressure of the atmosphere. Few experiments have been made on the relation between the temperature and the elasticity of different vapours. So long ago as the year 1765, we had occasion to examine the boiling points of all such liquors as we could manage in an air-pump; that is, such as did not produce vapours which destroyed the valves and the leathers of the pistons: and we thought that the experiments gave us reason to conclude, that the elasticity of all the vapours was affected by heat nearly in the same degree. For we found that the difference between their boiling points in the air and in vacuo was nearly the same in all, namely, about 120 degrees Fahrenheit's thermometer: it is exceedingly in air and difficult to make experiments of this kind: The vapours are so condensable, and change their elasticity so about 110?, prodigiously by a trifling change of temperature, that it is almost impossible to examine this point with precision. It is, however, as we shall see by and by, a subject of considerable practical importance in the mechanical arts; and an accurate knowledge of the relation would be of great use also to the distiller; and it would be no less important to discover the relation of their elasticity and density, by examining their compressibility, in the same manner as we have ascertained the relation in the case of what we call aerial fluids, that is, such as we have never observed in the form of liquids or solids, except in consequence of their union with each other or with other bodies. In the article PNEUMATICS we took notice of it as something like a natural law, that all these airs, or gases as they are now called, had their elasticity very nearly, if not exactly proportional to their density. This appears from the experiments of Acland, of Fontana, and others, on vital air, inflammable air, fixed air, and some others. It gives us some presumption to suppose that it holds in all elastic vapours whatever, and that it is connected with their elasticity; and it renders it somewhat probable that they are all elastic, only because the cause of heat (the matter of fire if you will) is elastic, and that their law of elasticity, in respect of density, is the same with that of fire. But it must
be observed, that although we thus assign the elasticity of fire as the immediate cause of the elasticity of vapour in the same way, and on the same grounds, that we ascribe the fluidity of brine to the fluidity of the water which holds the solid salt in solution, it does not follow that this is owing, as is commonly supposed, to a repulsion or tendency to recede from each other exerted by the particles of fire. We are as much entitled to infer a repulsion of unlimited extent between the particles of water; for we see that by its means a single particle of sea salt becomes disseminated through the whole of a very large vessel. If water had not been a visible and palpable substance, and the salt only had been visible and palpable, we might have formed a similar notion of chemical solution. But we, on the contrary, have considered the quaquaversal motion or expansion of the salt as a dissemination among the particles of water; and we have ascribed it to the strong attraction of the atoms of salt for the atoms of water, and the attraction of these last for each other, thinking that each atom of salt accumulates round itself a multitude of watery atoms, and by so doing must recede from the other saline atoms. Nay, we further see, that by forces which we naturally consider as attractions, an expansion may be produced of the whole mass, which will act against external mechanical forces. It is thus that wood swells with almost insuperable force by imbuing moisture; it is thus that a sponge immersed in water becomes really an elastic compressible body; resembling a blown bladder; and there are appearances which warrant us to apply this mode of conception to elastic fluids.—When air is suddenly compressed, a thermometer included in it shows a rise of temperature; that is, an appearance of heat now redundant which was formerly combined. The heat seems to be squeezed out as the water from the sponge.

Accordingly this opinion, that the elasticity of steam and other vapours is owing merely to the attraction for fire, and the consequent dissemination of their particles through the whole mass of fire, has been entertained by many naturalists, and it has been ascribed entirely to attraction. We by no means pretend to decide; but we think the analogy by far too slight to found any confident opinion on it. The aim is to solve phenomena by attraction only, as if it were of more easy conception than repulsion. We consider merely as facts, they are quite on a par. The appearances of nature in which we observe actual recesses of the parts of body from each other, are as distinct, and as frequent and familiar, as the appearances of actual reappraise. And if we attempt to go farther in our contemplation, and to conceive the way and the forces by which either the approximation or recesses of the atoms are produced, we must acknowledge that we have no conception of the matter; and we can only say, that there is a cause of these motions, and we call it a force, as in every case of the production of motion. We call it attraction or repulsion just as we happen to contemplate an access or a recess. But the analogy here is not only slight, but imperfect, and fails most in those cases which are most simple, and where we should expect it to be most complete. We can squeeze water out of a sponge, it is true, or out of a piece of green wood; but when the white of an egg, the tremella, or some gums, swell to a hundred times their dry dimensions by imbuing water, we cannot squeeze out a particle. If fluidity (for the reasoning must equally apply to this as to vaporousness) be owing to an accumulation of the extended matter of fire, which gradually expanded the solid by its very minute additions; and if the accumulation round a particle of ice, which is necessary for making it a particle of water, be so great in comparison of what gives it the expansion of one degree, as experiment obliges us to conclude—it seems an inevitable consequence that all fluids should be many times rarer than the solids from which they are produced. But we know that the difference is trifling in all cases, and in some (water, for instance, and iron) the solid is rarer than the fluid.

Many other arguments, (each of them perhaps of little proverbs weight when taken alone, but which are systemati-

ically connected) concur in rendering it much more probable that the matter of fire, in causing elasticity, pulsion be acts immediately by its own elasticity, which we cannot conceive in any other way than as a mutual tendency in its particles to recede from each other; and we doubt not that, if it could be obtained alone, we should find it an elastic fluid like air. We even think there are cases in which it is observed in this state. The elastic force of gunpowder is very much beyond elasticity of all the vapours which are produced in its deflagration, each of them being expanded as much as we can reasonably suppose by the great heat to which they are exposed. The writer of this article exploded some gunpowder mixed with a considerable portion of finely powdered quartz, and another parcel mixed with fine filings of copper. The elasticity was measured by the penetration of the ball which was discharged, and was great in the degree now mentioned. The experiment was so conducted, that much of the quartz and copper was collected; none of the quartz had been melted, and some of the copper was not melted. The heat, therefore, could not be so as to explain the elasticity by expansion of the vapours; and it became not improbable that fire was acting here as a detached chemical fluid by its own elasticity. But to return to our subject.

There is one circumstance in which we think our own experiments show a remarkable difference (at least a great difference in degree) between the condensible and incondensible vapours. It is well known, that when air is very suddenly expanded, cold is produced, and heat when it is and suddenly condensed. When making experiments with gas, we lose the hopes of discovering the connection between the elasticity and density of the vapours by boiling water, and also of boiling spirits of turpentine, we found the change of density accompanied by a change of temperature vastly greater than in the case of incorrigible gases. When the vapour of boiling water was suddenly allowed to expand into five times its bulk, we observed the depression of a large and sensible air thermometer to be at least four or five times greater than in a similar expansion of common air of the same temperature. The chemical reader will readily see reasons for expecting, on the contrary, a smaller alteration of temperature, both on account of the much greater rarity of the fluid, and on account of a partial condensation of its water and the consequent disengagement of combined heat.

This difference in the quantity of fire which is combined in vapours and gases is so considerable, as to authorize us to suppose that there is some difference in the chemical constitution of vapours and gases, and that the connection...
connection between the specific bases of the vapour and
the fire which it contains is not the same in air, for in-
stance, as in the vapour of boiling water; and this dif-
fERENCE may be the reason why the one is easily conden-
sible by cold, while the other has never been exhibited
in a liquid or solid form, except by means of its chemi-
cal union with other substances. In this particular
instance we know that there is an essential difference—
that in vital or atmospheric air there is not only a pro-
digous quantity of fire which is not in the vapour of
water, but that it also contains light, or the cause of
light, in a combined state. This is fully evinced by
the great discovery of Mr Cavendish of the composition
of water. Here we are taught that water (and conse-
quently its vapour) consists of air from which the light
and greatest part of the fire have been separated. And
the subsequent discoveries of the celebrated Lavoisier show,
that almost all the condensible gases with which we are
acquainted consist either of air which have already
lost much of their fire (and perhaps light too), or of
matters in which we have no evidence of fire or light
being combined in this manner.

This consideration may go far in explaining this dif-
fERENCE in the condensibility of these different species
of aerial fluids, the gases and the vapours; and it is
with this qualification only that we are disposed to al-
low that all bodies are condensible into liquids or solids
by abstracting the heat. In order that vital air may
become liquid or solid, we hold that it is not sufficient
that a body be presented to it which shall simply ab-
stract its heat. This would only abstract its uncom-
bined fire. But another and much larger portion re-
 mains chemically combined by means of light. A che-
 mical affinity must be brought into action which may
abstract, not the fire from the oxygen (to speak the
language of Mr Lavoisier), but the oxygen from the
fire and light. And our production is not the detached
basis of air, but detached heat and light, and the forma-
tion of an oxide of some kind.

To prosecute the chemical consideration of STEAMS
farther than these general observations, which are ap-
plicable to all, would be almost to write a treatise of
experiments, and would be a repetition of many things
which have been treated of in sufficient detail in other
articles of this work. We shall therefore conclude this
article with some other observations, which are also
general, with respect to the different kinds of coercible
vapours, but which have a particular relation to the fol-
lowing article.

Steam or vapour is an elastic fluid, whose elasticity
balances the pressure of the atmosphere; and it has been
produced from a solid or liquid body raised to a suffi-
cient temperature for giving it this elasticity; that is,
for causing the fluid to boil. This temperature must vary
with the pressure of the air. Accordingly it is found,
that when the air is light (indicated by the barometer
being low), the fluid will boil sooner. When the bar-
ometer stands at 30 inches, water boils at the tempe-
rature 212°. If it stands low as 28 inches, water
will boil at 208°. In the plains of Quito, or at Go-
dar in Abyssinia, where the barometer stands at about
21 inches, water will boil at 197°. Highly rectified
alcohol will boil at 160°, and vitriolic ether will boil at
88° or 89°. This is a temperature by no means un-
common in these places; nay, the air is frequently
warmer. Vitriolic ether, therefore, is a liquid which
can hardly be known in those countries. It is hardly
possible to preserve it in that form. If a phial have
not its stopper firmly tied down, it will be blown out,
and the liquid will boil and be dissipated in steam. On
the top of Chimborazo, the human blood must be dis-
pensed to give out air-bubbles.

We said some time ago, that we had concluded, from
some experiments made in the receiver of an air-pump,
that fluids boil its convex at a temperature nearly 120
degrees lower than that necessary for their boiling in
the open air. But we now see that this must have been
but a gross approximation; for in these experiments
the fluids were boiling under the pressure of the vapour
which they produced, and which could not be abstract-
ated by working the pump. It appears from the experi-
ments of Lord Charles Cavendish, mentioned in the ar-
icle Pneumatics, that water of the temperature 72°
only a gross approxima-
tion.

Upon reading these experiments, and some very curi-
ous ones of Mr Nairne, in the Phil. Trans. vol. lxi.
experiments to
determine the relation
between the vapour and its elasticit-
ty, in the following manner:

ABCD (fig. 2.) is the section of a small digester made
of copper. Its lid, which is fastened to the body
and pierced with three holes, each of which,
had a small pipe soldered into it. The first hole was
turned with a brass safety-valve V, nicely fitted to it
by grinding. The area of this valve was exactly 4th
of an inch. There rested on the stake at top of this
valve the arm of a steelyard carrying a sliding weight.
This arm had a scale of equal parts, so adjusted to the
weight that the number on the scale corresponded to the
inches of mercury, whose pressure on the under surface
of the valve is equal to that of the steelyard on its top;
so that when the weight was at the division 10, the pres-
sure of the steelyard on the valve was just equal to that
of a column of mercury 10 inches high, and 4th of an
inch base. The middle hole contained a thermometer
T firmly fixed into it, so that no vapour could escape
by its sides. The ball of this thermometer was but a little
way below the lid. The third hole received occasion-
ally the end of a glass pipe SEF, whose descending leg
was about 36 inches long. When this syphon was not
used, the hole was properly shut with a plug.

The vessel was half filled with distilled water which
had been purged of air by boiling. The lid was then
fixed on, having the third hole S plugged up. A lamp
being placed under the vessel, the water boiled, and the
steam issued copiously by the safety-valve. The ther-

11

mometer stood at 213., and a barometer in the room at
99 inches. The weight was then put on the fifth di-
vision. The thermometer immediately began to rise;
when it was at 220, the steam issued by the sides

of

STE
Steam of the valve. The weight was removed to the 10th division; but before the thermometer could be distinctly observed, the steam was issuing at the valve. The lamp was removed farther from the bottom of the vessel, that the progress of heating might be more moderate; and when the steam ceased to issue from the valve, the thermometer was at 227. The weight was now shifted to 15; and by gradually approaching the lamp, the steam again issued, and the thermometer was at 132. This mode of trial was continued all the way to the 75th division of the scale. The experiments were then repeated in the contrary order; that is, the weight being suspended at the 75th division, and the steam issuing strongly at the valve, the lamp was withdrawn, and the moment the steam ceased to come out, the thermometer was observed. The same was done at the 70th, 65th, division, &c. These experiments were several times repeated both ways; and the means of all the results for each division are expressed in the following table, where column 1st expresses the elasticity of the steam, being the sum of 29.9, and the division of the steelyard; column 2d expresses the temperature of the steam corresponding to this elasticity.

A very different process was necessary for ascertaining the elasticity of the steam in lower temperatures, and consequently under smaller pressures than that of the atmosphere. The glass syphon SGF was now fixed into its hole in the lid of the digester. The water was made to boil smartly for some time, and the steam issued copiously both at the valve and at the syphon. The lower end of the syphon was now immersed into a broad saucer of mercury, and the lamp instantly removed, and every thing was allowed to grow cold. By this the steam was gradually condensed, and the mercury rose in the syphon, without sensibly sinking in the saucer. The valve and all the joints were smeared with a thick clamy cement, composed of oil, tallow, and rosin, which effectually prevented all ingress of air. The weather was clear and frosty, and the barometer standing at 29.84, and the thermometer in the vessel at 42°. The mercury in the syphon stood at 29.7, or somewhat higher, thus showing a very complete condensation. The whole vessel was surrounded with pounded ice, of the temperature 32°. This made no sensible change in the height of the mercury. A mark was now made at the surface of the mercury. One observer was stationed at the thermometer, with instructions to call out as the thermometer reached the divisions 42, 47, 52, 57, and so on by every five degrees till it should attain the boiling heat. Another observer noted the corresponding descents of the mercury by a scale of inches, which had its beginning placed at 29.84 from the surface of the mercury in the saucer.

The pounded ice was now removed, and the lamp placed at a considerable distance below the vessel, so as to warm its contents very slowly. These observations being very easily made, were several times repeated, and their mean results are set down in the following table:

Four or five numbers at the top of the column of elasticities are not so accurate as the others, because the mercury passed pretty quickly through these points. But the progress was extremely regular through the remaining points; so that the elasticities corresponding to temperatures above 70° may be considered as very accurately ascertained.

Not being altogether satisfied with the method employed for measuring the elasticity in temperatures above that of boiling water, a better form of experiment was adopted. (Indeed it was the want of other apparatus which made it necessary to employ the former.) A glass tube was procured of the form represented in fig. 3, having a little cistern L, from the top and bottom of which proceeded the syphons K. and MN. The cistern contained mercury, and the tube MN was of a slender bore, and was about six feet two inches long. The end K was firmly fixed in the third hole of the lid, and the long leg of the syphon was furnished with a scale of inches, and firmly fastened to an upright post.

The lamp was now applied at such a distance from the vessel as to warm it slowly, and make the water boil, the steam escaping for some time through the safety-valve. A heavy weight was then suspended on the steelyard; such as it was known that the vessel would support, and at the same time, such as would not allow the steam to force the mercury out of the long tube. The thermometer began immediately to rise, as also the mercury
mercury in the tube MN. Their correspondent stations are marked in the following table:

This form of the experiment is much more susceptible of accuracy than the other, and the measures of elasticity are more to be depended on. In repeating the experiment, they were found much more constant; whereas, in the former method, differences occurred of two inches and upwards.

We may now connect the two sets of experiments into one table, by adding to the numbers in this last table the constant height 29.0, which was the height of the mercury in the barometer during the last set of observations.

We say that the result was unexpected; for as the natural boiling point seemed by former experiments to be accepted relatively in all fluids about 120° or more below their boiling points, it is reasonable to expect that the temperature at which their tares of glass ceased to emit sensibly elastic steam would have some equal relation to their temperatures when emitting steam of elastic vapors of water any determinate elasticity. Now as the vapour of alcohol has its temperature about 36° lower than the temperature of water, equally elastic, it was to be expected that the temperature at which it ceased to be sensibly affected would be several degrees lower than 32°. It is evident, however, that this is not the case. But this is a point that deserves more attention, because it is closely connected with the chemical relation between the element (if such there be) of fire, and the bodies into whose composition it seems to enter as a constituent part. What is the temperature 32°, to make it peculiarly connected with elasticity? It is a temperature assumed by us for our own convenience, on account of the similarity of water in our experiments. Either, we know, boils in a temperature far below this, as appears from Dr. Cullen's experiments narrated in the Essays Physical and Literary of Edinburgh. On the faith of former experiments, we may be pretty certain that it will boil in vacuo at the temperature—14°, because in the air it boils at +106°. Therefore we may be certain, that the steam or vapour of ether, when of the temperature 32°, will be very sensibly elastic. Indeed Mr. Lavoisier says, that if it be exposed in an exhausted receiver in winter, its vapour will support mercury at the height of 10 inches. A series of experiments on this vapour similar to the above would be very instructive. We even wish that those on alcohol were more carefully repeated. If we draw a curve line, of which the abcissa is the line of temperatures, and the ordinates are the corresponding heights of the mercury in these experiments on water and alcohol,
we shall observe, that although they both sensibly coincide at 32°, and have the abscissa for their common tangent, a very small error of observation may be the cause of this, and the curve which expresses the elasticity of spirituous vapour may really intersect the other, and go backwards considerably beyond 32°.

This range of experiments gives rise to some curious and important reflections. We now see that no particular temperature is necessary for water assuming the form of permanently elastic vapour; and that it is highly probable that it assumes this form even at the temperature 32°; only its elasticity is too small to afford us any sensible measure. It is well known that even ice evaporates (see experiments to this purpose by Mr Wilson in the Philosophical Transactions, when a piece of polished metal covered with hoar-frost became perfectly clear by exposing it to a dry frosty wind).

Even mercury evaporates, or is converted into elastic vapour, when all external pressure is removed. The dim film which may frequently be observed in the upper part of a barometer which stands near a stream of air, is found to be small globules of mercury sticking to the inside of the tube. They may be seen by the help of a magnifying glass, and are the best test of a well made barometer. They will be entirely removed by causing the mercury to rise along the tube. It will lick them all up. They consist of mercury which had evaporated in the void space, and was afterwards condensed by the cold glass. But the elasticity is too small to occasion a sensible depression of the column, even when considerably warmed by a candle.

Many philosophers accordingly imagine, that spontaneous evaporation in low temperatures is produced in this way. But we cannot be of this opinion, and must still think that this kind of evaporation is produced by the dissolving power of the air. When moist air is suddenly rarified, there is always a precipitation of water. This is most distinctly seen when we work an air-pump briskly. A mist is produced, which we see plainly fall to the bottom of the receiver. But by this new doctrine the very contrary should happen, because the tendency of water to appear in the elastic form is promoted by removing the external pressure; and we really imagine that more of it now actually becomes simple elastic watery vapour. But the mist or precipitation shows incontestably, that there had been a previous solution. Solution is performed by forces which act in the way of attraction; or, to express it more safely, solutions are accompanied by the mutual approaches of the particles of the menstruum and solved; all such tendencies are observed to increase by a diminution of distance. Hence it must follow, that air of double density will dissolve more than twice as much water. Therefore when we suddenly rarify saturated air (even though its heat should not diminish) some water must be let go. What may be its quantity we know not; but it may be more than what would now become elastic by this diminution of surrounding pressure; and it is not unlikely but this may have some effect in producing the vesicles which we found it so difficult to explain. These may be filled with pure watery vapour, and be floating in a fluid composed of water dissolved in air. An experiment of Fontana's seems to put this matter out of doubt. A distilling apparatus AB (fig. 4.)

was so contrived, that the heat was applied above the surface of the water in the alembic A. This was done by inclining it in another vessel CC, filled with hot water. In the receiver E there was a sort of barometer D, with an open column, in order to see what pressure there was on the surface of the fluid. While the receiver and alembic contained air, the heat applied at A produced no sensible distillation during several hours: But on opening a cock E in the receiver at its bottom, and making the water in the alembic to boil, steam was produced which soon expelled all the air, and followed it through the cock. The cock was now shut, and the whole allowed to grow cold by removing the fire, and applying cold water to the alembic. The barometer fell to a level nearly. Then warm water was allowed to get into the outer vessel CC. The barometer rose a little, and the distillation went on briskly without the smallest ebullition in the alembic. The conclusion is obvious: while there was air in the receiver and communicating pipe, the distillation proceeded entirely by the dissolving power of this air. Above the water in the alembic it was quickly saturated; and this saturation proceeded slowly along the still air in the communicating pipe, and at last might take place through the whole of the receiver. The sides of the receiver being kept cold, should condense part of the water dissolved in the air in contact with them, and this should trickle down the sides and be collected. But any person who has observed how long a crystal of blue vitriol will lie at the bottom of a glass of still water before the tinge will reach the surface, will see that it must be next to impossible for distillation to go on in these circumstances; and accordingly none was observed. But when the upper part of the apparatus was filled with pure watery vapour, it was supplied from the alembic as fast as it was condensed in the receiver, just as in the pulse glass.

Another inference which may be drawn from these experiments is, that Nature seems to affect a certain law in the dilatation of aeriform fluids by heat. They seem to be dilatable nearly in proportion of their present dilatation. For if we suppose that the vapours resemble air, in having their elasticity in any given temperature proportional to their density, we must suppose that if steam of the elasticity 60, that is, supporting 60 inches of mercury, were subjected to a pressure of 30 inches, it would expand into twice its present bulk. The augmentation of elasticity therefore is the measure of the bulk into which it would expand in order to acquire its former elasticity. Taking the increase of elasticity therefore as a measure of the bulk into which it would expand under one constant pressure, we see that equal increments of temperature produce nearly equal multiplications of bulk. Thus if a certain diminution of temperature diminishes its bulk 2/3rds, another equal diminution of temperature will diminish this new bulk 4th very nearly. Thus, in our experiments, the temperatures 110°, 140°, 170°, 200°, 230°, are in arithmetical progression, having equal differences; and we see that the corresponding elasticities 2.25, 5.15, 11.05, 22.62, 44.7, are very nearly in the continued proportion of 1 to 2. The elasticity corresponding to the temperature 260 deviates considerably from this law, which would give 88 or 89 instead of 80; and the deviation
deviation increases in the higher temperatures. But still we see that there is a considerable approximation to this law; and it will frequently assist us to recollect, that whatever be the present temperature, an increase of 30 degrees doubles the elasticity and the bulk of watery vapour.

That 40 will increase the elasticity from 1 to 1 1/3
8 - - - 1 to 1 1/3
10 - - - 1 to 1 1/3
12 1/4 - - - 1 to 1 1/3
18 - - - 1 to 1 1/3
22 - - - 1 to 1 1/3
24 - - - 1 to 1 1/3
26 - - - 1 to 1 1/3

This is sufficiently exact for most practical purposes. Thus an engineer finds that the injection cools the cylinder of a steam-engine to 192°. It therefore leaves a steam whose elasticity is three-fifths of its full elasticity, = 18 inches 9. But it is better at all times to have recourse to the table. Observe, too, that in the lower temperatures, i.e. below 110°, this increment of temperature does more than double the elasticity.

This law obtains more remarkably in incorrigible vapours; such as vital air, atmospheric air, fixed air, &c. of which have also their elasticity proportional to their bulk inversely; and perhaps the deviation from the law in steam is connected with their chemical difference of constitution. If the bulk were all augmented in the same proportion by equal augmentations of temperature, the elasticity would be accurately represented by the ordinates of a logarithmic curve, of which the temperatures are the corresponding abscissae; and we might contrive such a scale for our thermometer, that the temperatures would be the common logarithms of the elasticities, or of the bulbs having equal elasticity; or, with our present scale, we may find such a multiplier m for the number x of degrees of our thermometer (above that temperature where the elasticity is equal to unity), that this multiple shall be the common logarithm of the elasticity y; so that m x = log y.

But our experiments are not sufficiently accurate for determining the temperature where the elasticity is measured by 1 inch; but in these temperatures the elasticities vary by exceedingly small quantities. But if we take 110.4 for the unit of elasticity, and number our temperature from 170°, and make m =0.0100315, we shall find the product m x to be very nearly the logarithm of the elasticity. The deviations, however, from this law, are too great to make this equation of any use. But it is very practicable to frame an equation which shall correspond with the experiments to any degree of accuracy; and it has been done for air in a translation of General Roy's Measurement of the Base at Hounslow Heath into French by Mr. Prony. It is as follows: Let x be the degrees of Reaumur's thermometer; let y be the expansion of 10,000 parts of air; let e be = 10, m = 2,719,972, n = 0.01768; then y = e = 627.5. Now e being = 10, it is plain that e = the number, of which m + n x is the common logarithm. This formula is very exact as far as the temperature 60°; but beyond this it needs a correction: because air, like the vapour of water, does not expand in the exact proportion of its bulk.

We observe this law considerably approximated to in the augmentation of the bulk or elasticity of elastic vapours; that is, it is a fact that a given increment of approximation of temperature makes very nearly the same proportional to an augmentation of bulk and elasticity. This gives us some notion of the manner in which the supposed expanding power produces the effect. When vapour of the bulk or elasticity 4 is expanded into a bulk 5 by an addition of 10 degrees of sensible heat, a certain quantity of fire goes into it, and is accumulated round each particle, in such a manner that the temperature of each, which formerly was m, is now m + 10. Let it now receive another equal augmentation of temperature. This is now m + 20, and the bulk is 5 x 5 or 62, and the arithmetical increase of the bulk is 12. The absolute quantity of fire which has entered it is greater than the former, both on account of the greater augmentation of space and the greater temperature. Consequently if this vapour be compressed into the bulk 5, there must be heat or fire in it which is not necessary for the temperature m + 20, far less for the temperature m + 10. It must therefore emerge, and be disposed to enter a thermometer which has already the temperature m + 20: that is, the vapour must grow hotter by compression; not by squeezing out the heat, like water out of a sponge, but because the law of attraction for heat is deranged. It would be a very valuable acquisition to our knowledge to learn with precision the quantity of sensible heat produced in this way; but no satisfactory experiments have yet been made. M. Lavosier, with his chemical friends and colleagues, were busily employed in this inquiry; but the wickedness of their countrymen deprived the world of this and many other important additions which we might have expected from this celebrated and unfortunate philosopher. He had made, in conjunction with M. de la Place, a numerous train of accurate and expensive experiments for measuring the quantity of latent or combined heat in elastic vapours. This is evidently a very important point to the distiller and practical chemist. This heat must all come from the fuel; and it is greatly worth while to know whether any saving may be made of this article. Thus we know that distillation will go on either under the pressure of the air, or in an alembic and receiver from which the air has been expelled by steam; and we know that this last may be conducted in a very low temperature, even not exceeding that of the human body. But it is uncertain whether this may not employ even a greater quantity of fuel, as well as occasion a great expense of time. We are disposed to think, that when there is no air in the apparatus, and when the condensation can be speedily performed, the proportion of fuel expended to the fluid which comes over will diminish continually as the heat, and consequently the density of the steam, is augmented; because in this case the quantity of combined heat must be less. In the mean time, we earnestly recommend the trial of this mode of distillation in vessels cleared of air. It is undoubtedly of great advantage to be able to work with smaller fires; and it would secure us against all accidents of blowing off the
the head of the still, often attended with terrible consequences (b).

We must not conclude this article without taking notice of some natural phenomena which seem to owe their origin to the action of elastic steam.

We have already taken notice of the resemblance of the tremor and successions observed in the shocks of many earthquakes to those which may be felt in a vessel where water is made to boil internally, while the breaking out of the ebullition is stifled by the cold of the upper parts; and we have likewise stated the objections which are usually made to this theory of earthquakes. We may perhaps resume the subject under the article Volcano; but in the mean time we do not hesitate to say, that the wonderful appearances of the Geyser spring in Iceland (see Huer; and Iceland, No 3—5) are undoubtedly produced by the expansion of steam in ignited caverns. Of these appearances we suppose the whole train to be produced as follows.

A cavern may be supposed of a shape analogous to CBDEF (fig. 5.), having a perpendicular funnel AB issuing from a depressed part of the roof. The part F may be continually trickling into the part CD. It will fill it up to B, and even up to E, and then trickle slowly along into F. As soon as any gets into contact with an ignited part, it expands into elastic steam, and is partly condensed by the cold sides of the cavern, which it gradually warms, till it condenses no more. This production of steam hinders not in the smallest degree the trickling of more water into F, and the continual production of more steam. This now presses on the surface of the water in CD, and causes it to rise gradually in the funnel BA; but slowly, because its cold surface is condensing an immense quantity of steam. We may easily suppose that the water trickles faster into F than it is expanded in the production of steam; so that it reaches farther into the ignited part, and may even fall in a steam into some deeper pit highly ignited. It will now produce steam in vast abundance, and of prodigious elasticity; and at once push up the water through the funnel in a solid jet, and to a great height. This must continue till the surface of the water sinks to BD. If the lower end of the funnel have any inequalities or notches, as is most likely, the steam will get admission along with the water, which in this particular place is boiling hot, being superficial, and will get to the mouth of the funnel, while water is still pressed in below. At last the steam gets in at B on all sides; and as it is converging to B, along the surface of the water, with prodigious velocity it sweeps along with it much water, and blows it up through the funnel with great force. When this is over, the remaining steam blows out unmixed with water, growing weaker as it is expended, till the bottom of the funnel is again stopped by the water increasing in the cavern CBD. All the phenomena above ground are perfectly conformable to the necessary consequences of this very probable construction of the cavern. The feeling of being lifted up, immediately before the jet, in all probability owing to a real heaving up of the whole roof of the cavern by the first expansion of the great body of steam. We had an accurate description of the phenomena from persons well qualified to judge of these matters who visited these celebrated springs in 1789.

STEAM-ENGINE,

Steam-Engine.

Is the name of a machine which derives its moving power from the elasticity and condensibility of the steam of boiling water. It is the most valuable present which the arts of life have ever received from the philosopher. The mariner's compass, the telescope, gunpowder, and other most useful servants to human weakness and ingenuity, were the productions of chance, and we do not exactly know to whom we are indebted for them; but the steam-engine was, in the very beginning, the result of reflection, and the production of a very ingenious mind; and every improvement it has received, and every alteration in its construction and principles, were also the results of philosophical study.

The steam-engine was beyond all doubt invented by the Marquis of Worcester during the reign of Charles II. This nobleman published in 1663 a small book entitled A Century of Inventions; giving some obscure and enigmatical account of a hundred discoveries or contrivances of his own, which he extols as of great importance to the public. He appears to have been a person of much knowledge and great ingenuity: but his description or accounts of these inventions seem not so much

(b) We earnestly recommend this subject to the consideration of the philosopher. The laws which regulate the formation of elastic vapour, or the general phenomena which it exhibits, give us that link which connects chemistry with mechanical philosophy. Here we see chemical affinities and mechanical forces set in immediate opposition to each other, and the one made the indication, characteristic, and measure of the other. We have not the least doubt that they make but one science, the Science of Universal Mechanics; nor do we despair of seeing the phenomena of solution, precipitation, crystallization, fermentation, ray animal and vegetable secretion and assimilation, successfully investigated, as cases of local motion, and explained by the agency of central forces. Something of this kind, and that not inconsiderable, was done when Dr Cullen first showed how the double affinities might be illustrated by the assistance of numbers. Dr Black gave to this hint (for it was little more) that elegant precision which characterizes all his views.
STEAM-ENGINE.

much intended to instruct the public, as to raise wonder; and his encomiums on their utility and importance are to a great degree extravagant, resembling more the puff of an advertising tradesman than the patriotic communications of a gentleman. The marquis of Worcester was indeed a projector, and very important and mysterious withal in his applications for public encouragement. His account, however, of the steam-engine, although by no means fall to give us any distinct notions of its structure and operation, is exact as far as it goes, agreeing precisely with what we now know of the subject. It is No. 68 of his inventions. His words are as follow: “This admirable method which I propose of raising water by the force of fire has no bounds if the vessels be strong enough: for I have taken a cannon, and having filled it three-fourths full of water, and shut up its muzzle and touch-hole, and exposed it to the fire for 24 hours, it burst with a great explosion. Having afterwards discovered a method of fortifying vessels internally, and combined them in such a way that they filled and acted alternately, I made the water spout in an uninterrupted stream 40 feet high; and one vessel of rarefied water raised 40 of cold water. The person who conducted the operation had nothing to do but turn two cocks; so that one vessel of water being consumed, another begins to force, and then to fill itself with cold water, and so on in succession.”

Best first reduced to practice by Captain Savary.

It does not appear that the noble inventor could ever interest the public by these accounts. His character as a projector, and the many failures which persons of this turn of mind daily experience, probably prejudiced people against him, and prevented all attention to his project. It was not till towards the end of the century, when experimental philosophy was prosecuted all over Europe with uncommon ardour, that these notions again engaged attention. Captain Savary, a person also of great ingenuity and ardent mind, saw the reality and practicability of the marquis of Worcester’s project. He knew the great expansive power of steam, and had discovered the inconceivable rapidity with which it is reconverted into water by cold; and he soon contrived a machine for raising water, in which both of these properties were employed. He says, that it was entirely his own invention. Dr. Desaguliers insists that he only copied the marquis’s invention, and charges him with gross plagiarism, and with having bought up and burned the copies of the marquis’s book, in order to secure the honour of the discovery to himself. This is a very grievous charge, and should have been substantiated by very distinct evidence. Desaguliers produces none such; and he was much too late to know what happened at that time. The argument which he gives is a very foolish one; and gave him no title to consider Savary’s experiment as a falsehood; for it might have happened precisely as Savary relates, and not as it happened to Desaguliers. The fact is, that Savary obtained his patent of invention after a hearing of objections, among which the discovery of the marquis of Worcester was not mentioned: and it is certain that the account given in the Century of Inventions could instruct no person who was not sufficiently acquainted with the properties of steam.

Papin has no claim to the invention as the French pretend.

Captain Savary obtained his patent after having actually erected several machines, of which he gave a description in a book entitled THE MINER’S FRIEND, published in 1695, and in another work published in 1699. Much about this time Dr. Papin, a Frenchman and fellow of the Royal Society, invented a method of dissolving bones and other animal solids in water, by confining them in close vessels, which he called DIGESTERS, so as to acquire a great degree of heat. For it must be observed in this place, that it had been discovered long before (in 1634) by Dr. Hook, the most inquisitive experimental philosopher of that inquisitive age, that water could not be made to acquire above a certain temperature in the open air; and that as soon as it begins to boil, its temperature remains fixed, and an increase of heat only produces a more violent ebullition, and a more rapid waste. But Papin’s experiments made the elastic power of steam very familiar to him: and when he left England and settled as professor of mathematics at Marburg, he made many awkward attempts to employ this force in mechanics, and even for raising water. It appears that he had made experiments with this view in 1698, by order of Charles, landgrave of Hesse. For this reason the French affect to consider him as the inventor of the steam-engine. He indeed published some account of his invention in 1705; but he acknowledges that Captain Savary had also, without any communication with him, invented the same thing. Whoever will take the trouble of looking at the description which he has given of these inventions, which are to be seen in the Acta Eruditorum Lipsiae, and in Leopold’s Theatrum Machinarum, will see that they are most awkward, absurd, and impracticable. His conceptions of natural operations were always vague and imperfect, and he was never a philosopher nor mechanician.

We are thus anxious about the claim of those gentlemen, because a most respectable French author, Mr. Bossut, says in his Hydrodynamique, that the first notion of the steam-engine was certainly owing to Dr. Papin, who had not only invented the digester, but had in 1695 published a little performance describing a machine for raising water, in which the pistons are moved by the vapour of boiling water alternately dilated and condensed. Now the fact is, that Papin’s first publication was in 1707, and his piston is nothing more than a flasque on the surface of the water, to prevent the waste of steam by condensation; and the return of the piston is not produced, as in the steam-engine, by the condensation of the steam, but by admitting the air and a column of water to pass it back into its place. The whole contrivance is so awkward, and so unlike any distinct notions of the subject, that it cannot do credit to any person. We may add, that much about the same time Mr. Amontons contrived a very ingenious but intricate machine, which he called MR. Amon.

Mr. Amontons contrived an ingenious but intricate machine, which he called a fire-wheel. It consisted of a number of buckets placed in the circumference of a wheel, and communicating with each other by very intricate circuitous passages. One part of this circumference was exposed to the heat of a furnace, and another to a stream of cold water. The communications were so disposed, that the steam produced in the buckets on one side of the wheel drove the water into buckets on the other side, so that one side of the wheel was always much heavier than the other; and it must therefore turn round, and may execute some work. The death of the inventor, and the intricacy of the machine, caused it to be neglected. Another member of the Parisian academy of science
Steam-Engine.

(Mr Deslandes) also presented to the academy a project of a steam-wheel, where the impulsive force of the vapour was employed; but it met with no encouragement. The English engineers had by this time so much improved Savary's first invention that it supplanted all others. We have therefore no hesitation in giving the honour of the first and complete invention to the marquis of Worcester; and we are not disposed to refuse Captain Savary's claim to originality as to the construction of the machine, and even think it probable that his own experiments made him see the whole independent of the marquis's account.

Captain Savary's engine, as improved and simplified by himself is as follows.

A (fig. 6) represents a strong copper boiler properly built up in a furnace. There proceeds from its top a large steam-pipe B, which enters into the top of another strong vessel R called the receiver. This pipe has a cock at C called the steam-cock. In the bottom of the receiver is a pipe F, which communicates with the rising pipe KGH. The lower end H of this pipe is immersed in the water of the pit or well, and its upper part K opens into the cistern into which the water is to be delivered. Immediately below the pipe of communication F there is a valve G, opening when pressed from below, and shutting when pressed downwards. A similar valve is placed at L, immediately above the pipe of communication. Lastly, there is a pipe ED which branches off from the rising pipe, and enters into the top of the receiver. This pipe has a cock D called the injection-cock. The mouth of the pipe ED has a nozzle pierced with small holes, pointing from a centre in every direction. The keys of the two cocks C and D are united, and the handle A is called the regulator.

Let the regulator be so placed that the steam-cock C is open and the injection-cock D is shut; put water into the boiler A, and make it boil strongly. The steam coming from it will enter the receiver, and gradually warm it, much steam being condensed in producing this effect. When it has been warmed so as to condense no more, the steam proceeds into the rising pipe; the valve G remains shut by its weight; the steam lifts the valve I, and gets into the rising pipe, and gradually warms it. When the workman feels this to be the case, or hears the rattling of the valve I, he immediately turns the steam-cock so as to shut it; the injection-cock still remaining shut (at least we may suppose this for the present). The apparatus must now cool, and the steam in the receiver collapses into water. There is nothing now to balance the pressure of the atmosphere; the valve I remains shut by its weight; but the air incumbent on the water in the pit presses up this water through the suction-pipe HG, and causes it to lift the valve G, and flow into the receiver R, and fill it to the top, if not more than 20 or 25 feet above the surface of the pit-water.

The steam cock is now opened. The steam which, during the cooling of the receiver, has been accumulating in the boiler, and acquiring a great elasticity by the action of the fire, now rushes in with great violence, and, pressing on the surface of the water in the receiver, causes it to shut the valve G and open the valve I by its weight alone, and it now flows into the rising pipe, and would stand on a level if the elasticity of the steam were no more than what would balance the atmospheric pressure. But it is much more than this, and therefore it proceeds out of the receiver into the rising pipe, and will even cause it to come out at K, if the elasticity of the steam is sufficiently great. In order to ensure this, the boiler has another pipe in its top, covered with a safety-valve V, which is kept down by a weight W suspended on a steel yard LM. This weight is so adjusted that its pressure on the safety-valve is somewhat greater than the pressure of a column of water in K as high as the point of discharge K. The fire is so regulated that the steam is always issuing a little by the loaded valve V. The workman keeps the steam-valve open till he hears the valve I rattle. This tells him that the water is all forced out of the receiver, and that the steam is now following it. He immediately turns the regulator which turns the steam-cock, and now, for the first time, opens the injection-cock. The cold water trickles at first through the holes of the nozzle f, and falling down through the steam, begins to condense it; and then its elasticity being less than the pressure of the valve in the pipe KED, the cold water spouts in all directions through the cistern, and, quick as thought, produces a complete condensation.

The valve G now opens again by the pressure of the atmosphere on the water of the pit, and the receiver is soon filled with cold water. The injection-cock is now shut, and the steam-cock opened, and the whole operation is now repeated; and so on continually.

This is the simple account of the process, and will serve to give the reader an introductory notion of the operation; but a more minute attention must be paid to many particulars before we can see the properties and defects of this ingenious machine.

The water is driven along the rising pipe by the elasticity of the steam. This must in the boiler, and in every part of the machine, exert a pressure on every square inch of the vessels equal to that of the upright column of water. Suppose the water to be raised 100 feet, about 25 of this may be done in the suction-pipe; that is, the upper part of the receiver may be about 25 feet above the surface of the pit-water. The remaining 75 must be done by forcing, and every square inch of the boiler will be squeezed out by a pressure of more than 30 pounds. This very moderate height therefore requires very strong vessels; and the marquis of Worcester was well aware of the danger of their bursting. A copper boiler of six feet diameter must be nine-tenths of an inch thick to be just in equilibrio with this pressure; and soldered boiler will not be able to withstand it, especially in the high temperature to which the water must be heated in order to produce steam of sufficient elasticity. By consulting the table of the elasticity of steam deduced from our experiments mentioned in the preceding article, we see that this temperature must be at least 280° of Fahrenheit's thermometer. In this heat soft solder is just ready to melt, and has no tenacity; even spelter solder is considerably weakened by it. Accordingly, in a machine erected by Dr Desaguliers, the workman having loaded the safety-valve a little more than usual to make the engine work more briskly, the boiler burst with a dreadful explosion, and blew up the furnace and adjoining parts of the building as if it had been gunpowder. Mr Savary succeeded pretty well in raising moderate quantities of water to small heights, but could make nothing of deep mines. Many attempts were made, on the marquis's
STEAM ENGINE.

quis's principle, to strengthen the vessels from within by radiated bars and by hoops, but in vain. Very small boilers or evaporators were then tried, kept red hot, or nearly so, and supplied with a slender stream of water trickling into them; but this afforded no opportunity of making a collection of steam during the refrigeration of the receiver, so as to have a magazine of steam in readiness for the next forcing operation; and the working of such machines was always an employment of great danger and anxiety.

The only situation in which this machine could be employed with perfect safety, and with some effect, was where the whole lift did not exceed 30 or 35 feet. In this case the greatest part of it was performed by the suction-pipe, and a very manageable pressure was sufficient for the rest. Several machines of this kind were erected in England about the beginning of this century. A very large one was erected at a salt-work in the south of France. Here the water was to be raised no more than 18 feet. The receiver was capacious, and it was occasionally supplied with steam from a small salt-pan constructed on purpose with a cover. The entry of the steam into the receiver merely allowed the water to run out of it by a large valve, which was opened by hand, and the condensation was produced by the help of a small forcing pump also worked by hand. In particular a situation as this (and many such may occur in the endless variety of human wants), this is a very powerful engine; and having few moving and rubbing parts, it must be of great durability. This circumstance has occasioned much attention to be given to this first form of the engine, even long after it was supplanted by those of a much better construction. A very ingenious attempt was made very lately to adapt this construction to the uses of the miners. The whole depth of the pit was divided into stages of 15 feet, in the same manner as is frequently done in pump-machines. In each of these was a suction-pipe 14 feet long, having above it a small receiver like R, about a foot high, and its capacity somewhat greater than that of the pipe. This receiver had a valve at the head of the suction-pipe, and another opening outwards into the little cistern, into which the next suction-pipe above dipped to take in water. Each of these receivers sent up a pipe from its top, which all met in the cover of a large vessel above ground, which was of double the capacity of all the receivers and pipes. This vessel was close on all sides. Another vessel of equal capacity was placed immediately above it, with a pipe from its bottom passing through the cover of the lower vessel and reaching near to its bottom. This upper vessel communicates with the boiler, and constitutes the receiver of the steam-engine. The operation is as follows: The lower vessel is full of water. Steam is admitted into the upper vessel, which expels the air by a valve, and fills the vessel. It is then condensed by cold water. The pressure of the atmosphere would cause it to enter by all the suction-pipes of the different lifts, and press on the surface of the water in the lower receiver, and force it into the upper one. But because each suction-pipe dips in a cistern of water, the air press this water before it raises it into each of the little receivers which it fills, and allows the spring of the air (which was formerly in them, but which now passes up into the lower receiver) to force the water out of the lower receiver into the upper one. When this has been completed, the steam is again admitted into the upper receiver. This allows the water to run back into the lower receiver, and the air returns into the small receivers in the pit, and allows the water to run out of each into its proper cistern. By this means the water of each pipe has been raised 15 feet. The operation may thus be repeated continually.

The contrivance is ingenious, and similar to those which are to be met with in the hydraulics of Schottus, Sturm, and other German writers. But the operation must be exceedingly slow; and we imagine that the expense of steam must be great, because it must fill a very large and very cold vessel, which must waste a great portion of it by condensation. We see by some late publications of the very ingenious Mr. Blackey, that he is still attempting to maintain the reputation of this machine by some contrivances of this kind; but we imagine that they will be ineffectual, except in some very particular situations.

For the great defect of the machine, even when we can secure it against all risk of bursting, is the prodigious waste of steam, and consequently of fuel. Daily experience shows, that a few scattered drops of cold water are sufficient for producing an almost instantaneous condensation of a great quantity of steam. Therefore when the steam is admitted into the receiver of Savary's engine, and comes into contact with the cold top and cold water, it is condensed with great rapidity; and the water does not begin to subside till its surface has become so hot that it condenses no more steam. It may now begin to yield to the pressure of the incumbent steam; but as soon as it descends a little, more of the cold surface of the receiver comes into contact with the steam, and condenses more of it, and the water can descend no farther till this addition of cold surface is heated up to the state of evaporation. This rapid condensation goes on all the while the water is descending. By some experiments frequently repeated by the writer of this article, it appears that no less than \( \frac{1}{4} \) of the whole steam is uselessly condensed in this manner, and not more than \( \frac{1}{4} \) is employed in allowing the water to descend by its own weight; and he has reason to think that the portion thus wasted would be considerably greater, if the steam be employed to force the water out of the receiver to any considerable height.

Observe, too, that all this waste must be repeated in every succeeding stroke; for the whole receiver must be cooled again in order to fill itself with water.

Many attempts have been made to diminish this waste; but all to little purpose, because the very filling of the receiver with cold water occasions its sides to condense a prodigious quantity of steam in the succeeding stroke. Mr. Blackey has attempted to lessen this waste by using two receivers. In the first was oil; and into this only the steam was admitted. This oil passed into and fro between the two receivers, and never touched the water except in a small surface. But this barely produced a sensible diminution of the waste; for it must now be observed, that there is a necessity for the first cylinder's being cooled to a considerable degree below the boiling point; otherwise, though it will condense much steam, and allow the water to rise into the receiver, there will be a great diminution of the height of suction, unless the vessel be much cooled. This appears plainly by 4 N 2
By inspecting the table of elasticity. Thus, if the vessel be cooled no lower than 180°, we should lose one half of the pressure of the atmosphere; if cooled to 123, we should still lose 27%.

The rapidity with which the steam is condensed is really astonishing. Experiments have been made on steam-vessels of six feet in diameter and seven feet high; and it has been found, that about four ounces of water, as warm as the human blood, will produce a complete condensation in less than a second; that is, will produce all the condensation that it is capable of producing, leaving an elasticity about one-fifth of the elasticity of the air. In another experiment with the same steam-vessel, no cold water was allowed to get into it, but it was made to communicate by a long pipe, four inches in diameter with another vessel immersed in cold water. The condensation was so rapid that the time could not be measured; it certainly did not exceed half a second.

Now this condensation was performed by a very trifling surface of contact. Perhaps we may explain it a little in this way: When a mass of steam, in immediate contact with the cold water, is condensed, it leaves a void, into which the adjoining steam instantly expands; and by this very expansion its capacity for heat is increased, or it grows cold, that is, abstracts the heat from the steam situated immediately beyond it. And in this expansion and refrigeration it is itself partly condensed or converted into water, and leaves a void, into which the surrounding steam immediately expands, and produces the same effect on the steam beyond it. And thus it may happen that the abstraction of a small quantity of heat from an inconsiderable mass of steam may produce a condensation which may be very extensive. Did we know the change made in the capacity of steam for heat by a given change of bulk, we should be able to tell exactly what would be the effect of this local actual condensation. But experiment has not yet given us any precise notions on this subject. We think that this rapid abstraction of heat is a proof that the capacity of steam for heat is prodigiously increased by expansion.
STEAM-ENGINE.

The water in the boiler being supposed to be in a state of strong ebullition, and the steam issuing through the safety-valve, let us consider the machine in a state of rest, having both the steam-cock and injection-cock shut. The resting position or attitude of the machine in the sketch, the pump-rod, pump, and the head of the pump are in the horizontal plane.

Now open the steam-cock by turning the handle of the regulator. The steam from the boiler will immediately rush into the cylinder, which will be condensed by the cold surface of the cylinder and piston, and the water produced from it will trickle down the sides, and run off by the eduction-pipe. This condensation and waste of steam will continue till the whole cylinder and piston be made as hot as boiling water.

When this happens, the steam will begin to open the snuffing-valve, and issue through the pipe, slowly at first and very gradually, being mixed with much air. The blast at first will grow stronger by degrees, and more transparent, having already carried off the greatest part of the common air which filled the cylinder. We supposed that the air was boiling briskly, so that the steam was issuing by the safety-valve which is in the top of the boiler, and through every crevice. The opening of the steam-cock puts an end to this at once, and it has sometimes happened that the cold cylinder abstracts the steam from the boiler with such astonishing rapidity, that the pressure of the atmosphere has burst up the bottom of the boiler. We may here mention an accident of which we were witnesses, which also shows the immense rapidity of the condensation. The boiler was in a frail shed at the side of the engine-house; a shower of snow from the top of the house fell down and broke through the roof of the shed, and was scattered over the head of the boiler, which was of air-blowing or oval shape.

In an instant the sides of it were squeezed together by the pressure of the atmosphere.

When the manager of the engine perceives that not only the blast at the snuffing-valve is strong and steady, but that the boiler is now fully supplied with steam of a proper strength, appearing by the renewal of the discharge at the safety-valve, he shuts the steam-cock, and opens the injection-cock by turning its handle. The pressure of the column of water in the injection-pipe immediately forces some water through the spout R. This coming in contact with the pure vapour which now fills the cylinder, condenses it, and thus makes a partial void, into which the more distant steam immediately expands, and by expanding collapses (as has been already observed). What remains in the cylinder no longer balances the atmospheric pressure on the surface of the water in the injection-cistern, and therefore the water spouts rapidly through the hole R by the joint action of the column ZS, and the unbalanced pressure of the atmosphere; at the same time the snuffing-valve, and the eduction-valve, are shut by the unbalanced pressure of the atmosphere. The velocity of the injection water must therefore rapidly increase, and the jet will dash (if single) against the bottom of the piston, and be scattered through the whole capacity of the cylinder. In a very short space of time, therefore, the condensation of the steam becomes universal, and the elasticity of what remains is almost nothing. The whole

...
Steam-Engine.

The pressure of the atmosphere is exerted in the upper surface of the piston, while there is hardly any on its under side. Therefore, if the load on the outer end of the working beam is inferior to this pressure, it must yield to it. The piston \( P \) must descend, and the pump piston \( L \) must ascend, bringing along with it the water of the mine, and the motion must continue till the great piston reaches the bottom of the cylinder: for it is not like the motion which would take place in a cylinder of air rarefied to the same degree. In this last case, the impelling force would be continually diminished, because the capacity of the cylinder is diminished by the descent of the piston, and the air in it is continually becoming more dense and elastic. The piston would stop at a certain height, where the elasticity of the included air, together with the load at \( E \), would balance the atmospheric pressure on the piston. But when the contents of the cylinder are pure vapour, and the continued stream of injected cold water keeps down its temperature to the same pitch as at the beginning, the elasticity of the remaining steam can never increase by the descent of the piston, nor exceed what corresponds to this temperature. The impelling or accelerating force therefore remains the same, and the descent of the piston will be uniformly accelerated, if there is not an increase of resistance arising from the nature of the work performed by the other end of the beam. This circumstance will come under consideration afterwards, and we need not attend to it at present. It is enough for our present purpose to see, that if the cylinder has been completely purged of common air before the steam-cock was shut, and if none has entered since, the piston will descend to the very bottom of the cylinder. And this may be frequently observed in a good steam-engine, where every part is air-tight. It sometimes happens, by the pit-pump drawing air, or some part of the communication between the two strams giving way, that the piston comes down with such violence as to knock out the bottom of the cylinder with the blow.

The only observation which remains to be made on the motion of the piston in descending is, that it does not begin at the instant the injection is made. The piston was kept at the top by the preponderancy of the outer end of the working beam, and it must remain there till the difference between the elasticity of the steam below it and the pressure of the atmosphere exceeds this preponderancy. There must therefore be a small space of time between the beginning of the condensation and the beginning of the motion. This is very small, not exceeding the third or the fourth part of a second; but it may be very distinctly observed by an attentive spectator. He will see, that the instant the injection cock is opened, the cylinder will sensibly rise upwards a little by the pressure of the air on its bottom. Its whole weight is not nearly equal to this pressure; and instead of its being necessary to support it by a strong floor, we must keep it down by strong joints loaded by heavy walls. It is usual to frame these joints into the posts which carry the axis of the working beam, and are therefore loaded with the whole strain of the machine. This rising of the cylinder shows the instantaneous commencement of the condensation; and it is not till after this has been distinctly observed that the piston is seen to start, and begin to descend.

When the manager sees the piston as low as he thinks proper, he shuts the injection-cock, and opens the steam-cock. The steam has been accumulating above the water in the boiler during the whole time of the piston's descent, and is now rushing violently through the poppet-valve. The moment, therefore, that the steam-cock is opened, it rushes violently into the cylinder, having an elasticity greater than that of the air. It therefore immediately blows open the snuffing valve, and at low temperatures (at least) the water which had come in by the former injection, and what arose from the condensed steam, to descend by its own weight through the eduction pipe \( d e g h \) to open the valve \( A \), and to run out into the hot well. And we must easily see that this water is boiling hot; for while lying in the bottom of the cylinder, it will condense steam till it acquires this temperature, and therefore cannot run down till it condenses no more. There is still a waste of steam at its first admission, in order to heat the inside of the cylinder and the injected water to the boiling temperature: but the space being small, and the whole being already very warm, this is very soon done; and when things are properly constructed, little more steam is wanted than what will warm the cylinder; for the eduction pipe receives the injection water even during the descent of the piston, and it is therefore removed pretty much out of the way of the steam.

This first puff of the entering steam is of great service; it drives out of the cylinder the vapour which it first finds there. This is seldom pure water vapour: all water contains a quantity of air in a state of chemical union. The union is but feeble, and a boiling heat is sufficient for disengaging the greatest part of it by increasing its elasticity. It may also be disengaged by simply removing the external pressure of the atmosphere. This is clearly seen when we expose a glass of water in an exhausted receiver. Therefore the small space below the piston contains watery vapour mixed with all the air which had been disengaged from the water in the boiler by ebullition, and all that was separated from the injection water by the diminution of external pressures. All this is blown out of the cylinder by the first puff of steam. We may observe in this place, that waters differ exceedingly in the quantity of air which they hold in a state of solution. All spring water contains much of it: and water newly brought up from deep mines contains a great deal more, because the solution was aided in these situations by great pressures. Such waters of great sparkle when poured into a glass. It is therefore of consequence to the good performance of a steam-engine to use water containing little air, both in the boiler and in the injection-cistern. The water of running brooks is preferable to all others, and the freser it is from any saline impregnation it generally contains less air. Such engines as are so unfortunately situated that they are obliged to employ the very water which they have brought up from great depths, are found generally inferior in their performance to others. The air collected below the piston greatly diminishes the accelerating force, and the expulsion of such a quantity requires a long continued blast of the best steam at the beginning of every stroke. It is advisable to keep such water in a large shallow pond for a long while before using it.

Let us now consider the state of the piston. It is evident that it will start or begin to rise the moment the
the steam-cock is opened; for at that instant the excess of atmospheric pressure, by which it was kept down in opposition to the preponderancy of the outer end of the beam, is diminished. The piston is therefore dragged upwards, and it will rise even although the steam which is admitted be not so elastic as common air. Suppose the mercury in the barometer to stand at 30 inches, and that the preponderancy at the outer end of the beam is 1 in 50 of the pressure of the air on the piston, the piston will not rise if the elasticity of the steam is not equal to 30 — 1/50, that is, to 26.7 inches nearly; but if it is just this quantity, the piston will rise as fast as this steam can be supplied through the steam-pipe, and the velocity of its ascent depends entirely on the velocity of this supply. This observation is of great importance; and it does not seem to have occurred to the mathematicians, who have paid most attention to the mechanism of the motion of this engine. In the mean time, we may clearly see that the entry of the steam depends chiefly on the counter weight at E: for suppose there was none, steam no stronger than air would not enter the cylinder at all; and if the steam be stronger, it will enter only by the excess of its strength. Writers on the steam-engine (and even some of great reputation) familiarly speak of the steam giving the piston a push: But this is scarcely possible. During the rise of the piston the shifting valve is never observed to blow; and we have not heard any well-attested accounts of the piston-chains ever being slackened by the upward pressure of the steam, even at the very beginning of the stroke. During the rising of the piston the steam is (according to the common conception and manner of speaking) sucked in, in the same way that air is sucked into a common syringe or pump when we draw up the piston; for in the steam-engine the piston is really drawn up by the counter weight. But it is still more sucked in, and requires a more copious supply, for another reason. As the piston descended only in consequence of the inside of the cylinder’s being sufficiently cooled to condense the steam, this cooled surface must again be presented to the steam during the rise of the piston, and must condense steam a second time. The piston cannot rise another inch till the part of the cylinder which the piston has already quit has been warmed up to the boiling point, and steam must be expended in this warming. The inner surface of the cylinder is not only of the heat of boiling water while the piston rises, but is also perfectly dry; for the film of water left on it by the ascending piston must be completely evaporated, otherwise it will be condensing steam. That the quantity thus wasted is considerable, appears by the experiments of Mr Beighton. He found that five pints of water were boiled off in a minute, and produced 16 strokes of an engine whose cylinder contained 113 gallons of 282 inches each; and hence concluded that steam was 2886 times rarer than water. But in no experiment made with scrupulous care on the expansion of boiling water does it appear that the density of steam exceeds the density of water. Desaguliers says that it is above 14,000 times rarer than water. We have frequently attempted to measure the weight of steam which filled a very light vessel, which held 12,000 grains of water, and found it always less than one grain; so that we have no doubt of its being much more than 10,000 times rarer than water. This being the case, we may safely suppose that the number of gallons of steam, instead of being 16 times 113, were nearly five times as much; and that only 1/4 lb was employed in allowing the piston to rise, and the remaining 3/4ths were employed to warm the cylinder. But no distinct experiment shows so great an expansion of water when converted into steam at 212°. Mr Watt never found it under the pressure of the air more than 1800 times rarer than water.

The moving force during the ascent of the piston must be considered as resulting chiefly, if not solely, from the preponderating weight of the pit piston-rods. The office of this is to return the steam-piston to the pit piston-top of the cylinder, where it may again be pressed down by the air, and make another working stroke by raising the pump-rods. But the counter-weight at E has another service to perform in this use of the engine; namely, to return the pump pistons into their places at the bottom of their respective working barrels, in order that they also may make a working stroke. This requires force independent of the friction and inertia of the moving parts; for each piston must be pushed down through the water in the barrel, which must rise through the piston with a velocity whose proportion to the velocity of the piston is the same with that of the bulk of the piston to the bulk of the perforation through which the water rises through the piston. It is enough at present to mention this in general terms: we shall consider it more particularly afterwards, when we come to calculate the performance of the engine, and to derive from our acquired knowledge maxims of construction and improvement.

From this general consideration of the ascent of the piston, we may see that the motion differs greatly from that of the descent. It can hardly be supposed to accelerate greatly even if the steam in the cylinder were in a moment annihiated. For the resistance to the descent of the piston is the same with the weight of the column of water, which would cause it to flow through the box of the pump piston with the velocity with which it really rises through it, and must therefore increase as the square of that velocity increases; that is, as the square of the velocity of the piston increases. Independent of friction, therefore, the velocity of descent through the water must soon become a maximum, and the motion become uniform. We shall see by and by, that in such a pump as is generally used this will happen in less than the 12th part of a second. The friction of the pump will diminish this velocity a little, and retard the time of its attaining uniformity. But, on the other hand, the supply of steam which is necessary for this motion, being susceptible of no acceleration from its previous motion, and depending entirely on the briskness of the ebullition, an almost instantaneous stop is put to acceleration.

Accordingly, any person who observes with attention the working of a steam-engine, will see that the rise of the piston and descent of the pump-rods is extremely uniform, whereas the working stroke is very sensibly accelerated. Before quitting this part of the subject, and the weight of the stroke should afterwards escape our recollection, we may mention to our observer, that the counter-weight is different during the two motions of the pump-rods. While the machine is in the making a working stroke, it is lifting not only the counter-weight but also the whole of the steam which is necessary for the previous motion; but during the return stroke the counter-weight is not employed. The steam must be thrown off, as it were, to enable the piston to return. The mixture of steam and water is used during the working stroke, for the purpose of warming the cylinder and piston, and thus rendering the return stroke easier. It is for this reason that the return stroke is so much easier than the working stroke.
STEAM-ENGINE.

Steam-engine.

656

Column of water in the pump, but the absolute weight of the pistons and piston-rods also: but while the pumps and rods are descending, there is a diminution of the counter-weight by the whole weight lost by the immersion of the rod in water. The wooden rods which are generally used, soaked in water, and joined by iron straps, are heavier, but a little heavier, than water, and they are generally about one-third of the bulk of the water in the pumps.

These two motions complete the period of the operation; and the whole may be repeated by shutting the steam-cock and opening the injection-cock whenever the piston has attained the proper height. We have been very minute in our attention to the different circumstances, that the reader may have a distinct notion of the state of the moving forces in every period of the operation. It is by no means sufficient that we know in general that the injection of cold water makes a void which allows the air to press down the piston, and that the readmission of the steam allows the piston to rise again. This humping and slowing way of viewing it has long prevented even the philosopher from seeing the defects of the construction, and the methods of removing them.

We now see the great difference between Savary's and Newcomen's engine in respect of principle. Savary's was really an engine which raised water by the force of steam; but Newcomen's raises water entirely by the pressure of the atmosphere, and steam is employed merely as the most expeditious method of producing a void, into which the atmospheric pressure may impel the first mover of his machine. The elasticity of the steam is not the first mover.

We see also the great superiority of Newcomen's.

We have no need of steam of great and dangerous elasticity; and we operate by means of very moderate heats, and consequently with much smaller quantities of fuel; and there is no bounds to the power of this machine. How deep soever a mine may be, a cylinder may be employed of such dimensions that the pressure of the air on its piston may exceed in any degree the weight of the column of water to be raised. And lastly, this form of the machine renders it applicable to almost every mechanical purpose; because a skilful mechanic can readily find a method of converting the reciprocating motion of the working beam into a motion of any kind which may suit his purpose. Savary's engine could hardly admit of such an immediate application, and seems almost restricted to raising water.

Inventions improve by degrees. This engine was first offered to the public in 1705. But many difficulties occurred in the execution, which were removed one by one; and it was not till 1712 that the engine seemed to give confidence in its efficacy. The most exact and unremitting attention of the manager was required to the precise moment of opening and shutting the cocks, and neglect might frequently be ruinous, by beating out the bottom of the cylinder, or allowing the piston to be wholly drawn out of it. Stops were contrived to prevent both of these accidents; then strings were used to connect the handles of the cocks with the beam, so that they should be turned whenever it was in certain positions. These were gradually changed and improved into detents and catches of different shapes; at last, in 1717, Mr Beighton's very ingenious and well-informed artist, simplified the whole of these subordinate movements, and brought the machine into the form in which it has continued, without the smallest material change, to the present day. We shall now describe one of these improved engines, copying almost exactly the drawings and description given by Bossut in his Hydrodynamique; these being by far the most accurate and perspicuous of any that have been published.

Fig. 8. No 1. is a perspective view of the boiler cylinder, and all the parts necessary for turning the cocks of the engine. Fig. 8. No 2. is a vertical section of the same; and the same pieces of both are marked with the same letters of reference.

The rod X of the piston P is suspended from the arch of the working-beam, as was represented in the preceding sketch (fig. 7). An upright bar of timber FG is also seen hanging by a chain. This is suspended from a concentric arch of the beam, as may be seen also in the sketch at Qp. The bar is called the plug-beam; and it must rise and fall with the piston, but with a slower motion. The use of this plug-beam is to give motion to the different pieces which turn the cocks.

The steam-pipe K is of one piece with the bottom of the cylinder, and rises within it an inch or two, to prevent any of the cold injection water from falling into the boiler. The lower extremity Z of the steam-pipe penetrates the head of the boiler, projecting a little ways. A flat plate of brass, in shape resembling a racket or battledore, called the regulator, applies itself exactly to the whole circumference of the steam-pipe, and completely excludes the steam from the cylinder. Being movable around a vertical axis, which is represented by the dotted lines at the side of the steam-pipe in the profile, it may be turned aside by the handle t. The profile shows in the section of this plate a protuberance in the middle. This rests on a strong flat spring, which is fixed below it, and supports the mouth of the steam-pipe. This spring presses it strongly towards the arch of the working beam, causing it to apply very close; and this knob slides along the spring, while the regulator turns to the right or left.

We have said that the injection-water is furnished from a cistern placed above the cylinder. When the cistern cannot be supplied by pipes from some more elevated source, its water is raised by the machine itself. A small lifting pump i k (fig. 7), called the jack-head or jackette, is worked by a rod q, suspended from a concentric arch at r, near the outer end of the working beam. This forces a small portion of the pit water along the rising pipe l M into the injection cistern.

In fig. 8 No 1. and 2, the letters QM 3 represent the pipe which brings down the water from the injection cistern. This pipe has a cock at R to open or shut the passage of this water. It spouts through the jet 3', and dash against the bottom of the piston, it is dispersed into drops, and scattered through the whole capacity of the cylinder, so as to produce a rapid condensation of the steam.

An upright post A may be observed in the perspective view of the cylinder, &c. This supports one end B of a horizontal iron-axis BC. The end C is supported by a similar post, of which the place only is marked by the dotted lines A, that the pieces connected...
Steam-Engine.

Steam-Engine.

ted with this axis may not be hid by it. A kind of
stirrup a b c d hangs from this axis, supported by the
hooks a and d. This stirrup is crossed near the bottom
by a round bolt or bar e, which passes through the eyes
or rings that are at the ends of the horizontal fork f g h,
whose long tail h is double, receiving between its
branches the handle i of the regulator. It is plain from
this construction, that when the stirrup is made to vi-
brate round the horizontal axis BC, on which it hangs
freely by its hooks, the bolt e must pull or push the
long fork f g h backwards and forwards horizontally,
and by so doing will move the regulator round its axis
by means of the handle i. Both the tail of the fork and
the handle of the regulator are pierced with several
holes, and a pin is put through them which unites them
by a joint. The motion of the handle may be increased
or diminished by choosing for the joint a hole near to
the axis or remote from it; and the exact position at
which the regulator is to stop on both sides is deter-
mined by pins stuck in the horizontal bar on which the
end of the handle appears to rest.

This alternate motion of the regulator to the right
and left is produced as follows: There is fixed to the
axis BC a piece of iron o k l, called the Y, on account
of its resemblance to that letter of the alphabet inver-
ted. The stalk o carries a heavy lump p of lead or iron;
and a long leather strap q p r is fastened to p by the
middle, and the two ends are fastened to the beam above
it, in such a manner that the lump may be alternately
catched and held up to the right and left of the per-
pendicular. By adjusting the length of the two parts
of the strap, the Y may be stopped in any desired
position. The two claws k and l spread out from each
other, and from the line of the stalk, and they are of
such length as to reach the horizontal bolt e, which
crosses the stirrup below, but not to reach the bottom
of the fork f g h. Now suppose the stirrup hanging
perpendicularly, and the stalk of the Y also held perpen-
dicularly; carry it a little outward from the cylinder,
and then let it go. It will tumble farther out by its
weight, without affecting the stirrup till the claw l
strikes on the horizontal bolt e, and then it pushes the
stirrup and the fork towards the cylinder, and opens
the regulator. It sets it in motion with a smart jerk,
which is an effectual way of overcoming the cohesion
and friction of the regulator with the mouth of the
steam-pipe. This push is adjusted to a proper length
by the strap q p, which stops the Y when it has gone
far enough. If we now take hold of the stalk of the Y,
and move it up to the perpendicular, the width be-
tween its claws is such as to permit this motion, and
something more, without affecting the stirrup. But
when pushed still nearer to the cylinder, it tumbles to-
towards it by its own weight, and then the claw k strikes
the bolt e, and drives the stirrup and fork in the op-
posite direction, till the lump p is caught by the strap r p,
now stretched to its full length, while q p hangs slack.
Thus by the motion of the Y the regulator is opened
and shut. Let us now see how the motion of the Y
is produced by the machine itself. To the horizontal
axis BC are attached two spanners or handles m and n.
The spanner m passes through a long slit in the plug-
beam, and is at liberty to move upwards or down-
wards by its motion round the axis BC. A pin w
which goes through the plug-beam catches hold of m.
when the beam rises along with the piston; and the pin
is so placed, that when the beam is within an inch or two
of its highest rise, the pin has lifted m and thrown the
stalk of the Y past the perpendicular. It therefore
tumbles over with great force, and gives a smart blow
to the fork, and immediately shuts the regulator. By
this motion the spanner m is removed out of the neigh-
bourhood of the plug-beam. But the spanner n, mov-
ing along with it in the same direction, now comes in-
to the way of the pins of the plug-beam. Therefore,
when the piston descends again by the condensation
of the steam in the cylinder, a pin marked & is in the side of
the plug-beam catches hold of the tail of the span-
ner n, and by pressing it down raises the lump on the
stalk of the Y till it passes the perpendicular, and it
then falls down, outwards from the cylinder, and the
claw l again drives the fork in the direction h i, and
opens the steam valve. This opening and shutting of
the steam valve is executed in the precise moment that
is proper, by placing the pins w and & at a proper
height of the plug-beam. For this reason, it is pierced
through with a great number of holes, that the places
of these pins may be varied at pleasure. This, and a
proper curvature of the spanners m and n, make the ad-
justment as nice as we please.

The injection cock R is managed in a similar man-
er. On its key may be observed a forked arm s t, like a
crab's claw: at a little distance above it is the
gudgeon or axis u of a piece y u z, called the hammer
or the F, from its resemblance to that letter. It has
a lump of metal y at one end, and a spear u s projects
from its middle, and passes between the claws s and t
of the arm of the injection cock. The hammer y is
held up by a notch in the under side of a wooden lever
DE, movable round the centre D, and supported at
a proper height by a spring r E, made fast to the joint
above it.

Suppose the injection-cock shut, and the hammer in
the position represented in the figure. A pin w of
the plug-frame rises along with the piston, and catch-
ing hold of the detent DE, raises it, and disengages
the hammer y from its notch. This immediately falls
down, and strikes a board L put in the way to stop it.
The spear u s takes hold of the claw t, and forces it
aside towards s, and opens the injection-cock. The
piston immediately descends, and along with it the
plug-frame. During its descent the pin w meets with
the tail u z of the hammer, which is now raised consi-
derably above the level, and brings it down along with
it, raising the lump y, and gradually shutting the injec-
tion-cock, because the spear takes hold of the claw s
of its arm. When the beam has come to its lowest situa-
tion, the hammer is again engaged in the notch of the
detent DE, and supported by it till the piston again
reaches the top of the cylinder.

In this manner the motions of the injection-cock are
also adjusted to the precise moment that is proper for
them. The different pins are so placed in the plug-
frame, that the steam-cock may be completely shut be-
fore the injection cock is opened. The inherent mo-
tion of the machine will give a small addition to the
ascent of the piston without expanding steam all the
while; and by leaving the steam rather less elastic than
before, the subsequent descent of the piston is promoted.
There was a considerable propriety in the gradual shut-
STEAM-ENGINE.

Steam-Engine.

Steaming of the injection-cock. For after the first dash of the cold water against the bottom of the piston, the condensation is nearly complete, and very little more water is needed; but a continual accession of some is absolutely necessary for completing the condensation, as the capacity of the cylinder diminishes, and the water warms which is already injected.

In this manner the motion of the machine will be repeated as long as there is a supply of steam from the boiler, and of water from the injection cistern, and a discharge procured for what has been injected. We proceed to consider how far these conditions also are provided by the machine itself.

The injection cistern is supplied with water by the jackhead pump, as we have already observed. From this source all the parts of the machine receive their respective supplies. In the first place, a small branch 13, 13, is taken off from the injection-pipe immediately below the cistern, and conducted to the top of the cylinder, where it is furnished with a cock. The spout is so adjusted, that no more runs from it than what will keep a constant supply of a foot of water above the piston to keep it tight. Every time the piston comes to the top of the cylinder, it brings this water along with it, and the surplus of its evaporation and leakage runs off by a waste pipe 14, 14. This water necessarily becomes almost boiling hot, and it was thought proper to employ its surplus for supplying the waste of the boiler. This was accordingly practised for some time. But Mr Beighton improved this economical thought, by supplying the boiler from thejection-pipe, 2, 2, the water of which must be still hotter than that above the piston. This contrivance required attention to many circumstances, which the reader will understand by considering the perspective and profile. The eduction-pipe comes out of the bottom of the cylinder at 1 with a perpendicular part, which bends sidewise below, and is shut at the extremity 1. A deep cup 5 communicates with it, holding a metal valve nicely fitted to it by grinding, like the key of a cock. To secure its being always air-tight, a slender stream of water trickles into it from a branch 6 of the waste-pipe from the top of the cylinder. The eduction-pipe branches off at 2, and goes down to the hot well, where it turns up, and is covered with a valve. In the perspective view may be observed an upright pipe 4, 4, which goes through the head of the boiler, and reaches to within a few inches of its bottom. This pipe is called the feeder, and rises about three or four feet above the boiler. It is open at both ends, and has a branch 3, 3, communicating with the bottom of the cup 5, immediately above the metal valve, and also a few inches below the level of the entry 2 of the eduction-pipe. This communicating branch has a cock by which its passage may be diminished at pleasure. Now suppose the steam in the boiler to be very strong, it will cause the boiling water to rise in the feeding-pipe above 3, and coming along this branch, to rise also in the cup 5, and run over. But the height of this cup above the surface of the water in the boiler is such, that the steam is never strong enough to produce this effect. Therefore, on the contrary, any water that may be in the cup 5 will run off by the branch 3, 3, and go down into the boiler by the feeding-pipe.

These things being understood, let us suppose a quantity of injected water lying at the bottom of the cylinder. It will run into the eduction-pipe, fill the crooked branch 1, 1, and open the valve in the bottom of the cup (its weight being supported by a wire hanging from a slender spring), and it will fill the cup to the level of the entry 2 of the eduction-pipe, and will then flow along 3, 3, and supply the boiler by the feeder 4, 4. What more water runs in at 1 will now go along the eduction-pipe 2, 2, to the hot well. By properly adjusting the cock on the branch 3, 3, the boiler may be supplied as fast as the waste in steam requires. This is a most ingenious contrivance, and does great honour to Mr Beighton. It is not, however, of much importance. The small quantity which the boiler requires may be immediately taken even from a cold cistern, without sensibly diminishing the production of steam: for the quantity of heat necessary for raising the sensible heat of cold water to the boiling temperature is small, when compared with the quantity of heat which must then be combined with it in order to convert the water into steam. For the heat expended in boiling off a cubic foot of water is about six times as much as would bring it to a boiling heat from the temperature of 55°. No difference can be observed in the performance of such engines, and of those which have their boilers supplied from a brook. It has, however, the advantage of being purged of air; and when an engine must derive all its supplies from pit water, the water from the eduction-pipe is vastly preferable to that from the tops of the cylinder.

We may here observe, that many writers (among them the Abbé Bossut), in their descriptions of the steam-engine, have drawn the branch of communication 3, 3, from the feeding-pipe to a part of the crooked pipe 1, 1, lying below the valve in the cup 5. But this is quite erroneous; for, in this case, when the injection is made into the cylinder, and a vacuum produced, the water from the boiler would immediately rush up through the pipes 4, 3, and spout up into the cylinder: so would the external air coming in at the top of the feeder.

This contrivance has also enabled us to form some judgment of the internal state of the engine during its performance. Mr Beighton paid a minute attention to the situation of the water in the feeders and eduction-pipe of the internal state of a pipe of an engine, which seems to have been one of the best which has yet been erected. It was lifting a column of water whose weight was four-sevenths of the pressure of the air on its piston, and made 16 strokes, or 30 feet each, in a minute. This is acknowledged by all to be a very great performance of an engine of this form. He concluded that the elasticity of the steam in the cylinder was never more than one-tenth greater or less than the elasticity of the air. The water in the feeder never rose more than three feet and a half above the surface of the boiling water, even though it was now lighter by 97th than cold water. The eduction-pipe was only four feet and a half long (vertically), and yet it always discharged the injection water completely, and allowed some to pass into the feeder. This could not be if the steam was much more than one-tenth weaker than air. By grasping this pipe in his hand during the rise of the piston, he could guess very well whereby the surface of the hot water in it rested during the motion, and he never found it supported so high as four feet. Therefore the steam in the cylinder had at least eight-ninths of...
STEAM-ENGINE.

Mr. Boult, in his examination of an engine which is erected at Montreuil, in France, by an English engineer, and has always been considered as the pattern in that country, finds it necessary to suppose a much greater variation in the strength of the steam, and says, that it must have been one-fifth stronger and one-fifth weaker than common air. But this engine has not been nearly so perfect. Its lift was not more than one-half the pressure of the atmosphere, and it made but nine strokes in a minute.—At W is a valve covering the mouth of a small pipe, and surrounded with a cup containing water to keep it air-tight. This allows the air to escape which had been extricated from the water of last injection. It is driven out by the first strong puff of steam which is admitted into the cylinder, and makes a noise in its exit. The valve is therefore called the sniffing-valve.

To finish our description, we observe, that besides the safety valve 9 (called the PUPPET CLACK), which is loaded with about 5 pounds on the square inch (though the engine will work very well with a load of 1 or 2 pounds), there is another DISCHARGER 10,10, having a clack at its extremity supported by a cord. Its use is to discharge the steam without doors, when the machine gives over working. There is also a pipe SI near the bottom of the boiler, by which it may be emptied when it needs repairs or cleansing.

There are two small pipes 11,11, and 12,12, with cocks, called GAGE PIPES. The first descends to within two inches of the surface of the water in the boiler, and the second goes about 2 inches below that surface. If both cocks emit steam, the water is too low, and requires a recruit. If neither give steam, it is too high, and there is not sufficient room above it for a collection of steam. Lastly, there is a filling pipe Q, by which the boiler may be filled when the machine is to be set to work.

The engine has continued in this form for many years.

The engine has changed in this form for many years. The only remarkable change introduced has been the manner of placing the boiler. It is no longer placed below the cylinder, but at one side, and the steam is introduced by a pipe from the top of the boiler into a flat box immediately below the cylinder. The use of this box is merely to lodge the regulator, and give room for its motions. This has been a very considerable improvement. It has greatly reduced the height of the building. This was formerly a tower. The walls which supported the beam could hardly be built with sufficient strength for withstanding the violent shocks which were repeated without ceasing; and the buildings seldom lasted more than a very few years. But the boiler is now set up in an adjoining shed, and the gudgeons of the main beam rest on the top of upright posts, which are framed into the joists which support the cylinder. Thus the whole moving parts of the machine are contained in one compact frame of carpentry, and have little or no connection with the slant walls of the building, which is merely a case to hold the machine, and protect it from the weather.

It is now time to inquire what is to be expected from this machine, and to ascertain the most advantageous proportion between the moving power and the load that is to be laid on the machine.

It may be considered as a great pulley, and is indeed sometimes so constructed, the arches at the ends of the working beam being completed to a circle. It must be unequally loaded that it may move. It is loaded, during the working stroke, by the pressure of the atmosphere on the piston side, and by the column of water to be raised and the pump-gear on the pump side.—During the returning stroke it is loaded, on the piston side, by a small part of the atmospheric pressure, and on the pump side by the pump-gear acting as a counter weight. The load during the working stroke must therefore consist of the column of water to be raised and this counter weight. The performance of the machine is to be measured only by the quantity of water raised in a given time to a given height. It varies, therefore, in the joint proportion of the weight of the column of water in the pumps, and the number of strokes made by the machine in a minute. Each stroke consists of two parts, which we have called the working and the returning stroke. It does not, therefore, depend simply on the velocity of the working stroke and the quantity of water raised by it. If this were all that is to be attended to, we know that the weight of the column of water should be nearly 5th of the pressure of the atmosphere, this being the proportion which gives the maximum in the common pulley. But the time of the returning stroke is a necessary part of the whole time elapsed, and therefore the velocity of the returning stroke equally merits attention. This is regulated by the counter weight. The number of strokes per minute does not give an immediate proof of the goodness of the engine. A small load of water and a great counter weight will ensure this, because these conditions will produce a brisk motion in both directions.—The proper adjustment of the pressure of the atmosphere on the piston, the column of water to be raised, and the counter weight, is a problem of very great difficulty; and mathematicians have not turned much of their attention to the subject, although it is certainly the most interesting question that practical mechanics affords them.

Mr. Bosult has solved it very shortly and simply, upon Mr. Boult's this supposition, that the working and the returning stroke should be made in equal times. This, indeed, is generally aimed at in the erection of these machines, and they are not reckoned to be well arranged if it be otherwise. We doubt of the propriety of the maxim. Supposing, however, this condition for the present, we may compute the loadings of the two ends of the beam as follows. Let a be the length of the inner arm of the working beam, or that by which the great piston is supported. Let b be the outer arm carrying the pump rods, and let W be a weight equivalent to all the load which is laid on the machine. Let c be the area of the piston ; let H be the height of a column of water having c as its base, and being equal in weight to the pressure exerted by the steam on the under side of the piston; and let H be the pressure of the atmosphere on the same area, or the height of a column of water of equal weight. It is evident that both strokes will be performed in equal times, if \( \frac{a}{c} = \frac{b}{H} = \frac{W}{c} - \frac{H c a}{2} \) and \( \frac{a}{c} = \frac{b}{H} - \frac{W}{c} \).

The first of these quantities is the energy of the machine during the working stroke, and the second expresses the similar energy during the returning stroke. This equation gives us \( W = \frac{2a}{b} \frac{c}{c} \frac{H c a}{2} \). If

\[ \frac{4}{0} \frac{2}{w} \]
we suppose the arms of the lever equal and \( H = \frac{h}{2} \); that is, the whole weight of the outer end of the beam should be half the pressure of the air on the great piston. This is nearly the usual practice; and the engineers express it by saying, that the engine is loaded with seven or eight pounds on the square inch. This has been found to be nearly the most advantageous load. This way of expressing the matter would do well enough, if the maxim were not founded on erroneous notions, which hinder us from seeing the state of the machine, and the circumstances on which its improvement depends. The piston bears a pressure of 15 pounds, it is said, on the square inch, if the vacuum below it be perfect; but as this is far from being the case, we must not load it above the power of its vacuum, which very little exceeds eight pounds. But this is very far from the truth. When the cylinder is tight, the vacuum is not more than \( \frac{1}{6} \)th deficient, when the cylinder is cooled by the injection to the degree that is every day practicable, and the piston really bears during its descent a pressure very near to 14 pounds on the inch. The load must be diminished, not on account of the imperfect vacuum, but to give the machine a reasonable motion. We must consider not only the moving force, but also the quantity of matter to be put in motion. This is so great in the steam-engine, that even if it were balanced, that is, if there were suspended on the piston arm a weight equal to the whole column of water and the counter weight, the full pressure of the atmosphere on the steam piston would not make it move twice as fast as it does.

This equation by Mr. Basset is moreover essentially faulty in another respect. The \( W \) in the first member is not the same with the \( W \) in the second. In the first it is the column of water to be raised, together with the counter weight. In the second it is the counter weight only. Nor is the quantity \( H \) the same in both cases, as is most evident. The proper equation for ensuring the equal duration of the two strokes may be had in the following manner. Let it be determined by experiment what portion of the atmospheric pressure is exerted on the great piston during its descent. This depends on the remaining elasticity of the steam. Suppose it \( \frac{1}{3} \)th, this we may express by \( a \cdot b \). Then let \( W \) be the weight of the column of water to be raised, and \( c \) the counter weight. Then, if the arms of the beam are equal, we have the energy during the working stroke \( = a \cdot b - W - c \), and during the returning stroke it is \( = c - b \). Therefore \( c - b = a \cdot b - W - c \); and \( c = \frac{a \cdot b - W}{2} \); which, on the above supposition of the values of \( a \) and \( b \), gives us \( c = \frac{h \cdot W}{2} \). We shall make some use of this equation afterwards; but it affords us no information concerning the most advantageous proportion of \( h \) and \( W \), which is the material point.

Another way of considering the matter. We must consider this matter in another way: And that we may not involve ourselves in unnecessary difficulties, let us make the case as simple as possible, and suppose the arms of the working-beam to be of equal length.

We shall first consider the adjustment of things at the outer end of the beam.

Since the sole use of the steam is to give room for the action of the atmospheric pressure by its rapid condensation, it is admitted into the cylinder only to allow things at the one end of the piston to rise again, but without giving it any impulse. The pump-rods must therefore be returned to the bottom of the working barrels, by means of a previously considered ponderality at the outer end of the beam. It may be the weight of the pump-rods themselves, or may be considered as making part of this weight. A weight at the end of the beam will not operate on the rods which are suspended there by chains, and it must therefore be attached to the rods themselves, but above their respective pump-barrels, so that it may not lose part of its efficacy by immersion in the water. We may consider the whole under the notion of the pump-gear, and call it \( p \). Its office is to depress the pump-rods with sufficient velocity, by overcoming the resistances arising from the following causes.

1. From the inertia of the beams and all the parts of the apparatus which are in motion during the descent of the pump-rods.
2. From the loss of weight sustained by the immersion of the pump-rods in water.
3. From the friction of all the pistons and the weight of the plug-frame.
4. From the resistance to the piston's motion, arising from the velocity which must be generated in the water in passing through the descending pistons.

The sum of all these resistances is equal to the pressure of some weight (as yet unknown), which we may call \( m \).

When the pump-rods are brought up again, they bring along with them a column of water, whose weight we may call \( \omega \).

It is evident that the load which must be overcome by the pressure of the atmosphere on the steam piston consists of \( \omega \) and \( p \). Let this load be called \( L \), and the pressure of the air be called \( P \).

If \( p = L \), no water will be raised; if \( p = \omega \), the rods will not descend; therefore there is some intermediate value of \( p \) which will produce the greatest effect.

In order to discover this, let \( g \) be the fall of a heavy body in a second.

The descending mass is \( p \): but it does not descend with its full weight; because it is overcoming a set of resistances which are equivalent to a weight \( m \), and the moving force is \( p - m \). In order to discover the space through which the rods will descend in a second, when urged by the force \( p - m \) (supposed constant notwithstanding the increase of velocity, and consequently of \( m \)), we must institute this proportion \( p : p - m = g : \frac{p - m}{P} \).

The fourth term of this analogy is the space required.

Let \( t \) be the whole time of the descent in seconds.

Then \( t^2 = \frac{g(p - m)}{p} \cdot \frac{P}{P} \). This last term is
STEAM ENGINE.

is the whole descent or length of the stroke accomplished in the time.

The weight of the column of water, which has now got above the piston, is \( w = L - p \). This must be

\[ \frac{r}{g} \left( \frac{p - m}{m} \right) \]

Therefore the performance of the engine

\[ \frac{P}{L - p} \]

That this may be the greatest possible, we must consider \( p \) as the variable quantity, and make the fluxion of the fraction

\[ \frac{m - p \times \frac{L - p}{L}}{P} = 0. \]

This will be found to give us \( p = \sqrt{L m} \); that is, the counter weight or preponderancy of the outer end of the beam is \( \sqrt{L m} \).

This gives us a method of determining \( m \) experimentally. We can discover by actual measurement the quantity \( L \) in any engine, it being equal to the unbalanced weights on the beam and the weight of the water in the pumps. Then \( m = \frac{P}{L} \).

Also we have the weight of the column of water

\[ = L - p, = L - \sqrt{L m}. \]

When therefore we have determined the load which is to be on the outer end of the beam during the working stroke, it must be distributed into two parts, which have the proportion of \( \sqrt{L m} \) to \( L - \sqrt{L m} \). The first is the counter weight, and the second is the weight of the column of water.

If \( m \) is a fraction of \( L \), such as an aliquot part of it; that is, if

\[ \frac{L}{L} = \frac{L}{L} = \frac{L}{L} = \frac{L}{L} = \frac{L}{L} \]

\[ \frac{L}{L} = \frac{L}{L} = \frac{L}{L} = \frac{L}{L} = \frac{L}{L} \]

\[ \frac{L}{L} = \frac{L}{L} = \frac{L}{L} = \frac{L}{L} = \frac{L}{L} \]

\[ \frac{L}{L} = \frac{L}{L} = \frac{L}{L} = \frac{L}{L} = \frac{L}{L} \]

\[ \frac{L}{L} = \frac{L}{L} = \frac{L}{L} = \frac{L}{L} = \frac{L}{L} \]

\[ \frac{L}{L} = \frac{L}{L} = \frac{L}{L} = \frac{L}{L} = \frac{L}{L} \]

The circumstance which is commonly obstructed on us by local considerations is the quantity of water, and the depth from which it is to be raised; that is, \( w \); and it will be convenient to determine the whole thing in conformity to this.

We saw that \( w = L - \sqrt{L m} \). This gives us

\[ L = \sqrt{u m + \frac{m}{m} + \frac{m}{m} + w}, \]

and the counter weight

\[ p = \sqrt{u m + \frac{m}{m} + \frac{m}{m} + \frac{m}{m}} \]

Having thus ascertained that distribution of the load on the outer end of the beam which produces the greatest effect, we now come to consider what proportion of moving force we must apply, so that it may be employed to the best advantage, or so that any expense of power may produce the greatest performance. It will be so much the greater as the work done is greater, and the power employed is less, and will therefore be properly measured by the quotient of the work done divided by the power employed.

The work immediately done is the lifting up the weight \( L \). In order to accomplish this, we must employ a pressure \( P \), which is greater than \( L \). Let it be \( L + y \); also let \( x \) be the length of the stroke.

If the mass \( L \) were urged along the space \( s \) by the force \( L + y \), it would acquire a certain velocity, which we may express by \( \sqrt{s} \); but it is impelled only by the force \( y \); the rest of \( P \) being employed in balancing \( L \).

The velocities which different forces generate by impelling a body along the same space are as the square roots of the forces. Therefore

\[ \sqrt{L + y} : \sqrt{y} = \sqrt{s} : \sqrt{L + y}. \]

The fourth term of this analogy expresses the velocity of the piston at the end of the stroke. The quantity of motion produced will be had by multiplying this velocity by the mass \( L \). This gives

\[ \frac{L \times \sqrt{L + y}}{\sqrt{L + y}} \]

and this divided by the power expended, or by \( L + y \), gives us the measure of the performance; namely,

\[ \frac{L \times \sqrt{L + y}}{L + y} \]

This may be a maximum, consider \( y \) as the variable quantity, and make the fluxion of this formula

\[ = \frac{L}{a}. \]

This will give us \( y = \frac{L}{a} \).

Now \( P = L + y = \frac{L}{a} = \frac{L}{a} \). Therefore the whole load on the outer end of the beam, consisting of the water and the counter weight, must be two-thirds of the pressure of the atmosphere on the steam piston.

We have here supposed that the expenditure is the atmospheric pressure; and so it is if we consider it mechanically. But the expenditure of which we are sensible, and which we are anxious to employ to the best advantage, is fuel. Supposing this to be employed with the same judgment in all cases, we are almost entitled, by what we now know of the production of steam, to say that the steam produced is proportional to the fuel expended. But the steam requisite for merely filling the cylinder is proportional to the area of the piston, and therefore to the atmospheric pressure. The result of our investigation therefore is still just; but the steam wasted by condensation on the sides of the cylinder does not follow this ratio, and this is more than what is necessary for merely filling it. This deranges our calculations, and is in favour of large cylinders; but this advantage must be in a great measure compensated by a similar variation in the production of the steam; for in similar boilers of greater dimensions the fuel is less advantageously employed, because the surface to which the fuel is applied does not increase in the ratio of the capacity, just as the surface of the cylinder which wastes the steam. The rule may therefore be confined in a pretty exact.

It is a satisfactory thing to observe these results agree very well with the most successful practice. By many suits agree changes and trials engineers have established maxims of the construction, which are probably not very far from the best. It is a pretty general maxim, that the load of water should be one-third of the atmospheric pressure. They call this loading the engine with \( 7 \frac{1}{2} \) pounds on the inch, and they say that so small a load is necessary on account of the imperfect vacuum. But we have now seen that it is necessary for giving a reasonable velocity of motion. Since, in this practice, \( w \) is made \( \frac{1}{2} \) or \( \frac{1}{3} \)ths of \( P \), and \( L \) should be \( \frac{1}{4} \)ths of \( P \), and \( L \) is \( \frac{1}{2}w + p \); it follows, that the counter weight should be \( \frac{1}{8} \)th.
STEAM-ENGINE.

It must be remarked, that in the preceding investigation we introduced a quantity M to express the resistances to the motion of the engine. This was done in order to avoid a very troublesome investigation. The resistances are of such a nature as to vary with the velocity, and most of them as the square of the velocity. This is the case with the resistance arising from the motion of the water through the pistons of the pumps, and that arising from the friction in the long lift during the working stroke. Had we taken the direct method, which is similar to the determination of the motion through a medium which resists in the duplicate ratio of the velocity, we must have used a very intricate exponential calculus, which few of our readers would have the patience to look at.

But the greatest part of the quantity M supposes a motion already known, and its determination depends on this motion. We must now show how its different component parts may be computed.

1. What arises from the inertia of the moving parts is by far the most considerable portion of it. To obtain it, we must find a quantity of matter which, when placed at the end of the beam, will have the same momentum of inertia with that of the whole moving parts in their natural places. Therefore (in the returning stroke) add together the weight of the great piston with its rod and chains; the pit-pump-rod, chains, and any weight that is attached to them; the arch-heads and iron-work at the ends of the beam, and $\frac{4}{7}$th of the weight of the beam itself; also the plug-beam with its arch-head and chains, multiplied by the square of its distance from the axis, and divided by the square of half the length of the beam; also the jack-head pump-rod, chain, and arch-head, multiplied by the square of its distance from the axis, and divided by the square of half the length of the beam. These articles added into one sum may be called M, and may be supposed to move with the velocity of the end of the beam. Suppose this beam to have made a six-foot stroke in two seconds, with an uniformly accelerated motion. In one second it would have moved $\frac{1}{2}$ feet, and would have acquired the velocity of three feet per second. But in one second gravity would have produced a velocity of 32 feet in the same mass. Therefore the accelerating force, which has produced the velocity of three feet, is nearly $\frac{11}{11}$th of the weight. Therefore $\frac{11}{11}$ is the first constituent of M in the above investigation. If the observed velocity is greater or less than three feet per second, this value must be increased or diminished in the same proportion.

The second cause of resistance, viz. the immersion of the pump rods in water, is easily computed, being the weight of the water which they displace.

The third cause, the friction of the pistons, &c. is almost insignificant, and must be discovered by experiment.

The fourth cause depends on the structure of the pumps. These pumps, when made of a proper strength, can hardly have the perforation of the piston more than a fourth part of the area of the working-barrel; and the velocity with which the water passes through it is increased at least $\frac{1}{4}$th by the contraction (see PUMP). The velocity of the water is therefore five times greater than that of the piston. A piston 12 inches diameter, and moving one foot per second, meets with a resistance equal to 20 pounds; and this increases as the square of the diameter and as the square of the velocity. If the whole depth of the pit be divided into several lifts, this resistance must be multiplied by the number of lifts, because it obtains in each pump.

Thus we make up the value of M; and we must acknowledge that the method is still indirect, because it supposes the velocity to be known.

We may obtain it more easily in another way, but still with this circumstance of being indirect. We found that $p$ was equal to $\sqrt{Lm}$, and consequently $m = \frac{p^2}{L}$.

Now in any engine L and p can always be had; and unless p deviates greatly from the proportion which we determined to be the best, the value of m thus obtained will not be very erroneous.

It was farther presumed in this investigation, that the observations concerning the motion both up and down were uniformly accelerated; but this cannot be the case when the resistances increase with the velocity. This circumstance makes very little change in the working-stroke, and therefore the theorem which terminates the best relation of P to L may be confided in. The resistances which vary with the velocity in this case are a mere trifle when compared with the moving power y. These resistances are, 1st, The straining of the water at the entry and at the standing valve of each pump: This is about 37 pounds for a pump 12 inches diameter, and the velocity one foot per second, increasing in the duplicate ratio of the diameter and velocity. And, 2d, The friction of the water along the whole lift: This for a pump of the same size and with the same velocity, lifting 20 fathoms, is only about $\frac{1}{2}$ pounds, and varies in the simple proportion of the diameter and the depth, and in the duplicate proportion of the velocity. The resistance arising from inertia is greater than in the returning stroke; because the M in this case must contain the momentum of the water both of the pit-pumps and the jack-head-pump: but this part of the resistance does not affect the uniform acceleration. We may therefore confide in the propriety of the formula $y = \frac{L}{2}$. And we may obtain the velocity of this stroke at the end of a second with great accuracy as follows. Let $2g$ be the velocity communicated by gravity in a second, and the velocity at the end of the first second of the steam piston's descent will be somewhat less than $\frac{y}{M} 2g$; where $M$ expresses the inertia of all the parts which are in motion during the descent of the steam piston, and therefore includes L. Compute the two resistances just mentioned for this velocity. Call this r. Then $\frac{y}{M} 2g$ will give another velocity infinitely near the truth.

But the case is very different in the returning stroke, and the proper ratio of p to L is not ascertained with the same certainty: for the moving force p is not so great in proportion to the resistance m; and therefore the acceleration of the motion is considerably affected by it, and the motion itself is considerably retarded, and in a very moderate time it becomes sensibly uniform: for it is precisely similar to the motion of a heavy body falling...
falling through the air, and may be determined in the manner laid down in the article Resistance of Fluids, viz. by an exponential calculus. We shall content ourselves here with saying, that the resistances in the present case are so great that the motion would be to all sense uniform before the pistons have descended one-third of their stroke, even although there were no other circumstance to affect it.

But this motion is affected by a circumstance quite unconnected with any thing yet considered, depending on conditions not mechanical, and so uncertain, that we are not yet able to ascertain them with any precision; yet they are of the utmost importance to the good performance and improvement of the engine, and therefore deserve a particular consideration.

The counter weight has not only to push down the pump rods, but also to drag up the great piston. This it cannot do unless the steam be admitted into the cylinder. If the steam be not stronger than common air, it cannot enter the cylinder except in consequence of the piston's being dragged up. If common air were admitted into the cylinder, some force would be required to drag up the piston, in the same manner as it is required to draw up the piston of a common syringe; for the air would rush through the small entry of the cylinder in the same manner as through the small nozzle of the syringe. Some part of the atmospheric pressure is employed in driving in the air with sufficient velocity to fill the syringe, and it is only with the remainder that the admitted air presses on the under surface of the syringe. Therefore some part of the atmospheric pressure on its upper surface is not balanced. This is felt by the hand which draws it up. The same thing must happen in the steam-engine, and some part of the counter weight is expended in drawing up the steam piston. We could tell how much is thus expended if we knew the density of the steam; for this would tell us the velocity with which its elasticity would cause it to fill the cylinder. If we suppose it 1.3 times rarer than air, which it certainly is, and the piston rises to the top of the cylinder in two seconds, we can demonstrate that it will enter with a velocity not less than 5.00 feet per second, whereas 500 feet is enough to make it maintain a density \( \frac{2}{3} \)th of that of steam in equilibrio with the air. Hence it follows, that its elasticity will not be less than \( \frac{2}{3} \)th of the elasticity of the air, and therefore not more than \( \frac{2}{3} \)th of counter weight will be expended in drawing up the steam piston.

But all this is on the supposition that there is an unbounded supply of steam of undiminished elasticity. This is by no means the case. Immediately before opening the steam-cock, the steam was issuing through the safety-valve and all the crevices in the top of the boiler, and (in good engines) was about \( \frac{2}{3} \)th stronger or more elastic than air. This having been gathering during something more than the descent of the piston, viz. in about three seconds. The piston rises to the top in about two seconds; therefore about twice and a half as much steam as fills the dome of the boiler is now shared between the boiler and cylinder. The dome is commonly about six times more capacious than the cylinder. If therefore no steam is condensed in the cylinder, the density of the steam, when the piston has reached the top, must be about \( \frac{2}{3} \)th of its former density, and still more elastic than air. But as much steam is condensed by the cold cylinder, its elasticity must be less than this. We cannot tell how much less, both because we do not know how much is thus condensed, and because by this diminution of its pressure on the surface of the boiling water, it must be more copiously produced in the boiler; but an attentive observation of the engine will give us some information. The moment the steam-cock is opened we have a strong puff of steam through the snifting valve. At this time, therefore, it is still more elastic than air; but after this, the snifting valve remains shut during the whole rise of the piston, and no steam any longer issues through the safety-valve or crevices; nay, the whole dome of the boiler may be observed to sink.

These facts give abundant proof that the elasticity of the steam during the ascent of the piston is greatly diminished, and therefore much of the counter weight is expended in dragging up the steam piston in opposition to the unbalanced part of the atmospheric pressure. The motion of the returning stroke is therefore so much delayed by this foreign and unappreciated circumstance, that it would have been quite useless to engage in the intricate exponential investigation, and we must sit down contented with a less perfect adjustment of the counter weight and weight of water. Any person who attends to the motion of a steam-engine will perceive that the descent of the pump-rod is so far from being accelerated, that it is nearly uniform, and frequently it is sensibly retarded towards the end. We learn by the way, that it is of the utmost importance not only to have a quick production of steam, but also a very capacious dome, or empty space above the water in the boiler. In engines where this space was but four or five times the capacity of the cylinder, we have always observed a very sensible check given to the descent of the pump-rod after having made half their stroke. This obliges us to employ a greater counter weight, which diminishes the column of water, or retards the working stroke; it also obliges us to employ a stronger steam, at the risk of bursting the boiler, and increases the expense of fuel.

It would be the most desirable thing to get an exact knowledge of the elasticity of the steam in the cylinder; and this is by no means difficult. Take a long glass tube exactly calibrated, and close at the farther end. Put in the cylinder a small drop of some coloured fluid into it so as to stand in the middle nearly. Let it be placed in a long box filled with water to keep it of a constant temperature. Let the open end communicate with the cylinder, with a cock between. The moment the steam-cock is opened, open the cock of this instrument. The drop will be pushed towards the close end of the tube, while the steam in the cylinder is more elastic than the air, and it will be drawn the other way while it is less elastic, and, by a scale properly adapted to it, the elasticity of the steam corresponding to every position of the piston may be discovered. The same thing may be done more accurately by a barometer properly constructed, so as to prevent the oscillations of the mercury.

It is equally necessary to know the state of the cylinder during the descent of the steam piston. We have been supposed \( P \) to be the full pressure of the atmosphere on the sphere of the piston, supposing the vacuum state of the cylinder below it to be complete. But the inspection of our table of elasticity shows that this can never be the case, because the cylinder is always of a temperature far above the piston. 30°. We have made many attempts to discover its temperature.
STEAM-ENGINE.

We have employed a thermometer in close contact with the side of the cylinder, which soon acquired a steady temperature; this was never less than 145°. We have kept a thermometer in the water which lies on the piston; this never sunk below 135°. It is probable that the cylinder within this may have been somewhat lower, but for this opinion we cannot give any very satisfactory reason. Suppose it cooled down to 120°; this will leave an elasticity which would support three inches of mercury. We cannot think, therefore, that the unbalanced pressure of the atmosphere exceeds that of 27 inches of mercury, which is about 1341/2 pounds on a square inch, or 105 on a circular inch. And this is the value which we should employ in the equation \[ \frac{P}{L} = \frac{1}{y}. \] This question may be decided in the same way as the other, by a barometer connected with the inside of the cylinder.

And thus we shall learn the state of the moving forces in every moment of the performance, and the machine will then be as open to our examination as any water or horse mill; and till this be done, or something equivalent, we can only guess at what the machine is actually performing, and we cannot tell in what particulars we can lend it a helping hand. We are informed that Messrs. Watt and Boulton have made this addition to some of their engines; and we are persuaded that, from the information which they have derived from it, they have been enabled to make the curious improvements from which they have acquired so much reputation and profit.

There is a circumstance of which we have as yet taken no notice, viz., the quantity of water cold injected. Here we confess ourselves unable to give any precise instructions. It is clear at first sight that no more than is absolutely necessary should be injected. It must generally be supplied by the engine, and this expends part of its power. An excess is much more hurtful by cooling the cylinder and piston too much, and therefore wasting steam during the next rise of the piston. But the determination of the proper quantity requires a knowledge, which we have not yet acquired, of the quantity of heat contained in the steam in a latent form. As much water must be injected as will absorb all this without rising near to the boiling temperature. But it is of much more importance to know how far we may cool the cylinder with advantage; that is, when will the loss of steam, during the next rise of the piston, compensate for the diminution of its elasticity during its present descent? Our table of elasticities shows us, that by cooling the cylinder to 120°, we still leave an elasticity equal to one-tenth of the whole power of the engine; if we cool it only to 140°, we leave an elasticity of one-fifth; if we cool it to a blood-heat, we leave an elasticity of one-twentieth. It is extremely difficult to choose among these varieties. Experience, however, informs us, that the best engines are those which use the smallest quantities of injection water.

We know an exceedingly good engine having a cylinder of 30 inches and a six feet stroke, which works with something less than one-fifth of a cubic foot of water at each injection; and we imagine that the quantity should be nearly in the proportion of the capacity of the cylinder. Desaguliers observed, that a very good engine, with a cylinder of 32 inches, worked with 300 inches of water at each injection, which does not much exceed one-sixth of a cubic foot. Mr. Watt's observations, by means of the barometer, must have given him much valuable information in this particular, and we hope that he will not always withhold them from the public.

We have gone thus far in the examination, in order this examination to ascertain the motion of the engine when unladen and balanced in any known manner, and in order to discover that proportion between the moving and the returning stroke which will produce the greatest direct the quantity of work. The result has been very unsatisfactory to the principal circle of circumstances, because the computation of the returning stroke is acknowledged to be beyond our abilities. But it has given us the opportunity of directing the reader's attention to the leading circumstances in this inquiry. By knowing the internal state of the cylinder in machines of very different goodness, we learn the connection between the state of the steam and the performance of the machine; and it is very possible that the result of a full examination may be, that in situations where fuel is expensive, it may be proper to employ a weak steam which will expend less fuel, although less work is performed by it. We shall see this confirmed in the clearest manner in some particular applications of the engines invented by Watt and Boulton.

In the mean time, we see that the equation which we gave from the celebrated Abbé Bosout, is in every respect erroneous even for the purpose which he had in view. We also see that the equation which we substituted in its place, and which was intended for determining that proportion between the counter-weight and the moving force, and the load which would render the working stroke and returning stroke of equal duration, is also erroneous, because these two motions are extremely different in kind, the one being nearly uniform, and the other nearly uniformly accelerated. This being supposed true, it should follow that the counter-weight should be reduced to one-half; and we have found this to be very nearly true in some good engines which we have examined.

We shall add but one observation more on this head. An erroneous maxim, to the practical engineers have almost made it a maxim, one maxim, that the two motions are of equal duration. But the only reason which we have heard for the maxim, is, two motions are of equal duration; that it is awkward to see an engine go otherwise. But we doubt exceedingly the truth of this maxim; and, without being able to give any accurate determination, we think that the engine will do more work if the working stroke be made slower than the returning stroke. Suppose the engine so constructed that they are made in equal times; an addition to the counter-weight will accelerate the returning stroke and retard the working stroke. But as the counter-weight is but small in proportion to the unbalanced portion of the atmospheric pressure, which is the moving force of the machine, it is evident that this addition to the counter-weight must bear a much greater proportion to the counter-weight than it does to the moving force, and must therefore accelerate the returning stroke much more than it retards the working stroke, and the time of both strokes taken together must be diminished by this addition and the performance of the machine improved; and this will be the case as long as the machine is not extravagantly loaded. The best machine which we have seen, in respect of performance, raises a column of water whose weight is very nearly two-thirds of the pressure of the atmosphere.
ST EAM-ENGINE.

atmosphere on the piston, making 11 strokes of six feet each per minute, and the working stroke was almost twice as slow as the other. This engine had worked pumps of 12 inches, which were changed for pumps of 14 inches, all other things remaining the same. In its former state it made from 12 and a half to 13 and a half strokes per minute, the working stroke being considerably slower than the returning stroke. The load was increased, by the change of the pumps, nearly in the proportion of three to four. This had retarded the working stroke; but the performance was evidently increased in the proportion of 3 x 13 to 4 x 11, or of 39 to 44. About 300 pounds were added to the counter-weight, which increased the number of strokes to more than 12 per minute. No sensible change could be observed in the time of the working stroke. The performance was therefore increased in the proportion of 39 to 48. We have therefore no hesitation in saying, that the nearly equality of the two strokes is a sacrifice to fancy. The engineer who observes the working stroke to be slow, feels that his engine may be thought as being and unequal to its work; a similar notion has long misled him in the construction of water-mills, especially of overshot mills; and even now he is submitting with hesitation and fear to the daily correction of experience.

It is needless to engage more deeply in scientific calculations in a subject where so many of the data are so very imperfectly understood.

47

The load of work should not be less than 10 pounds for every square inch of the piston.

We venture to recommend as a maxim of construction (assuming always a large boiler and plentiful supply of pure steam unmixed with air), that the load of work be not less than 10 pounds for every square inch of the piston, and the counter-weight so proportioned that the time of the returning stroke may not exceed two-thirds of that of the working stroke. A serious objection may be made to this maxim, and it deserves mature consideration. Such a load requires the utmost care of the machine, that no admission be given to the common air; and it precludes the possibility of its working, in case the growth of water, or deepening the pit, should make a greater load absolutely necessary. These considerations must be left to the prudence of the engineer. The maxim now recommended relates only to the best actual performance of the engine.

48

Rules for computing the performance of the steam engine.

Before quitting this machine, it will not be amiss to give some easy rules, sanctioned by successful practice, for computing its performance. These will enable any artist, who can go through simple calculations, to suit the size of his engine to the task it is to perform.

The circumstance on which the whole computation must be founded is the quantity of water which must be drawn in a minute, and the depth of the mine; and the performance which may be expected from a good engine is at least 12 strokes of six feet each, working against a column of water whose weight is equal to half of the atmospheric pressure on the steam-piston, or rather to 7.64 pounds on every square inch of its surface.

It is most convenient to estimate the quantity of water in cubic feet, or its weight in pounds, recollecting that a cubic foot of water weighs 62.5 pounds. The depth of the pit is usually reckoned in fathoms of six feet, and the diameter of the cylinder and pump is usually reckoned in inches.

Let Q be the quantity of water to be drawn per minute in cubical feet, and f the depth of the mine in fathoms; let e be the diameter of the cylinder, and p that of the pump; and let us suppose the arms of the beam to be of equal length.

1st. To find the diameter of the pump, the area of the piston in square feet is \( p^2 \times \frac{0.7854}{144} \). The length of the column drawn in one minute is \( 12 \) times \( 6 \) or \( 72 \) feet, and therefore its solid contents is \( p^2 \times \frac{72 \times 0.7854}{144} \) cubical feet, or \( p^2 \times 0.3927 \) cubical feet. This must be equal to Q; therefore \( p^2 \) must be \( \frac{Q}{0.3927} \) or nearly \( Q \times \frac{1}{2} \). Hence this practical rule: Multiply the cubic feet of water which must be drawn in a minute by \( \frac{1}{2} \), and extract the square root of the product: this will be the diameter of the pump in inches.

Thus suppose that 58 cubic feet must be drawn every minute; 58 multiplied by \( \frac{1}{2} \) gives 145, of which the square root is 12, which is the required diameter of the pump.

2. To find the proper diameter of the cylinder.

The piston is to be loaded with 7.64 pounds on every square inch. This is equivalent to six pounds on a circular inch very nearly. The weight of a cylinder of water an inch in diameter and a fathom in height is \( 2\pi \) pounds, or nearly two pounds. Hence it follows that \( 6 \pi \) must be made equal to \( 2pf \), and that \( e \) is equal to \( \frac{2pf}{6} \), or to \( \frac{pf}{3} \).

Hence the following rule: Multiply the square of the diameter of the pump piston (found as above) by the fathoms of lift, and divide the product by \( 3 \); the square root of the quotient is the diameter of the cylinder.

Suppose the pit to which the foregoing pump is to be applied is 24 fathoms deep; then \( 24 \times 144 \times \frac{1}{3} \) gives 1152, of which the square root is 34 inches very nearly.

This engine, constructed with care, will certainly do the work.

Whatever is the load of water proposed for the engine, let \( e \) be the pounds on every circular inch of the steam piston, and make \( c^2 = p^2 \times \frac{2f}{m} \), and the square root will be the diameter of the steam piston in inches.

To free the practical engineer as much as possible from all trouble of calculation, we subjoin the following Table of the Dimensions and Power of the Steam Engine, drawn up by Mr. Beighton in 1717, and fully verified by practice since that time. The measure is in English ale gallons of 282 cubic inches.
The first part of the table gives the size of the pump suited to the growth of water. The second gives the size of the cylinder suited to the load of water. If the depth is greater than any in this table, take its fourth part, and double the diameter of the cylinder. Thus if 150 horseheads are to be drawn in an hour from the depth of 100 fathoms, the last column of part first gives for 149.4 a pump of seven inches bore. In a case with this, under the depth of 50 yards, which is one-fourth of 100 fathoms, we find 205, the double of which is 41 inches for the diameter of the cylinder.

It is almost impossible to give a general rule for strokes of different lengths, &c., but any one who possesses the ability to erect an engine, should surely know as much arithmetic as will accommodate the rule now given to any length of stroke.

We venture to say, that no ordinary engineer can tell à priori the number per minute which an engine will give. We took 12 strokes of six feet each for a standard, which a careful engineer may easily accomplish, and which an employer has a right to expect, the engine being loaded with water to half the depth of the atmosphere: if the load be less, there is some fault—an improper counter weight, or too little boiler, or leaks, &c. &c.

Such is the state in which Newcomen's steam-engine had continued in use for 60 years, neglected by the philosopher, although it is the most curious object which human ingenuity has yet offered to his contemplation, and abandoned to the efforts of the unlettered artist. Its use has been entirely confined to the raising of water. Mr Keane Fitzgerald indeed published in the Philosophical Transactions a method of converting its reciprocating motion into a continued rotary motion by employing the great beam to work a crank or a train of wheel-work. As the real action of the machine is confined to its working stroke, to accomplish this, it became necessary to connect with the crank or wheel-work a very large and heavy fly, which should accumulate in itself the whole pressure of the machine during its time of action, and therefore continue in motion, and urge forward the working machinery, while the steam-engine was going through its inactive returning stroke. This will be the case, provided that the resistance exerted by the working machine during the whole period of the working and returning stroke of the steam-engine, together with the friction of both, does not exceed the whole pressure exerted by the steam-engine during its working stroke; and provided that the momentum of the fly, arising from its great weight and velocity, be very great, so that the resistance of the work during one returning stroke of the steam-engine do not make any very sensible diminution of the velocity of the fly. This is evidently possible and easy. The fly may be made of any magnitude; and being exactly balanced round its axis, it will soon acquire any velocity consistent with the motion of the steam-engine. During the working stroke of the engine it is uniformly accelerated, and by its acquired momentum it produces in the beam the movement of the returning stroke; but in doing this, its momentum is shared with the inert matter of the steam-engine, and consequently its velocity diminished, but not entirely taken away. The next working stroke, therefore, by pressing on it afresh, increases its remaining velocity by a quantity nearly equal to the whole that it acquired during the first stroke. We say nearly, but not quite equal, because the time of the second working stroke must be shorter than that of the first, on account of the velocity already in the machine. In this manner the fly will be more and more accelerated every succeeding stroke, because the pressure of the engine during the working stroke does more than restore to the fly the momentum which it lost in producing the returning movement of the steam-engine. Now suppose the working part of the machine to be added. The acceleration of the fly during each working stroke of the steam-engine will be less than it was before, because the impelling pressure is now partly employed in driving the working machine, and because the fly will lose more of its momentum during the returning stroke of the steam-engine, part of it being expended in driving the working machine. It is evident, therefore, that a time will come...
STEAM-ENGINE.

This circumstance limits the use of steam-engines exceedingly. To draw water from coal-pits, where they can be stocked with unsaleable small coal, they are of universal employment: also for valuable mines, for supplying a great and wealthy city with water, and a use of few other purposes where a great expense can be borne, steam-engines are very proper engines; but in a thousand cases where their unlimited powers might be vastly useable, the enormous expense of fuel completely excludes them. We cannot doubt but that the attention of engineers was much directed to every thing that could promise a diminution of this expense. Every one had his particular nostrum for the construction of his furnace, and some were undoubtedly more successful than others. But science was not sufficiently advanced: It was not till Dr Black had made his beautiful discovery of latent heat, that we could know the intimate relation between the heat expended in boiling off a quantity of water and the quantity of steam that is produced.

Much about the time of this discovery, viz. 1763, Mr James Watt, established in Glasgow in the commercial line, was amusing himself with repairing a working model of the steam-engine which belonged to the philosophical apparatus of the university. Mr Watt was a person of a truly philosophical mind, eminently conversant in all branches of natural knowledge, and the pupil and intimate friend of Dr Black. In the course of the above-mentioned amusement many curious facts in the production and condensation of steam occurred to him; and among others, that remarkable fact which is always appealed to by Dr Black as the proof of the immense quantity of heat which is contained in a very minute quantity of water in the form of elastic heat, steam. When a quantity of water is heated several degrees above the boiling point in a close digester, if a hole be opened, the steam rushes out with prodigious violence, and the heat of the remaining water is reduced, in the course of three or four seconds, to the boiling temperature. The water of the steam which has issued amounts only to a very few drops; and yet these have carried off with them the whole excess of heat from the water in the digester.

Since then a certain quantity of steam contains so in his as great a quantity of heat, it must expend a great quantity of fuel; and no construction of furnace can prevent this. Mr. Watt therefore set his invention to work to discover methods of husbanding this heat. The cylinder of his little model was heated almost in an instant, so that it could not be touched by the hand. It could not be otherwise, because it condensed the vapour by abstracting its heat. But all the heat thus communicated to the cylin-dar, and wasted by it on surrounding bodies, contributed nothing to the performance of the engine.

(8) We do not recollect at present the date of this proposal of Mr Fitzgerald; but in 1781 the Abbé Arnal, canon of Alains in Languedoc, entertained a thought of the same kind, and proposed it for working lighters in the inland navigations; a scheme which has been successfully practised (we are told) in America. His brother, a major of engineers in the Austrian service, has carried the thing much farther, and applied it to manufactures; and the Aulic Chamber of Mines at Vienna has patronized the project: (See Journal Encyclopédique, 1781). But these schemes are long posterior to Mr Fitzgerald's patent, and are even later than the erection of several machines driven by steam-engines which have been erected by Messo Watt and Boulton. We think it our duty to state these particulars, because it is very usual for our neighbours on the continent to assume the credit of British inventions.
STEAM-ENGINE.

Engine, and must be taken away at every injection, and again communicated and wasted. Mr. Watt quickly understood the whole process which was going on within the cylinder, and which we have considered so minutely, and saw that a very considerable portion of the steam must be wasted in warming the cylinder. His first attempts were made to ascertain how much was thus wasted, and he found that it was not less than three or four times as much as would fill the cylinder and work the engine. He attempted to diminish this waste by using wooden cylinders. But though this produced a sensible diminution of the waste, other reasons forced him to give them up. He then cased his metal cylinders in a wooden case with light wood ashes between. By this, and using no more injection than was absolutely necessary for the condensation, he reduced the waste almost one half. But by using so small a quantity of cold water, the inside of the cylinder was hardly brought below the boiling temperature; and there consequently remained in it a steam of very small elasticity, which robbed the engine of a proportion of the atmospheric pressure. He saw that this was unavoidable as long as the condensation was performed in the cylinder. The thought struck him to attempt the condensation at another place. His first experiment was made in the simplest manner. A globular vessel communicated by means of a long pipe of one inch diameter with the bottom of his little cylinder of four inches diameter and 30 inches long. This pipe had a stop-cock, and the globe was immersed in a vessel of cold water. When the piston was at the top, and the cylinder filled with strong steam, he turned the cock. It was scarcely turned, nay he did not think it completely turned, when the sides of his cylinder (only strong tin-plate) were crushed together like an empty bladder. This surprised and delighted him. A new cylinder was immediately made of brass sufficiently thick, and nicely bored. When the experiment was repeated with this cylinder, the condensation was so rapid, that he could not say that he saw any pressure in it. But the most valuable discovery was, that the vacuum in the cylinder was, as he hoped, almost perfect. Mr. Watt found, that when he used water in the boiler purged of air by long boiling, nothing that was very sensibly inferior to the pressure of the atmosphere on the piston could hinder it from coming quite down to the bottom of the cylinder. This alone was gaining a great deal, for in most engines the remaining elasticity of the steam was not less than one-eighth of the atmospheric pressure, and therefore took away one-eighth of the power of the engine.

Having gained this capital point, Mr. Watt found many difficulties to struggle with before he could get the machine to continue its motion. The water produced from the condensed steam, and the air which was extricated from it, or which penetrated through unavoidable leaks, behaved to accumulate in the condensing vessel, and could not be avoided in any way similar to that adopted in Newcomen's engine. He took another method: He applied pumps to extract both, which were worked by the great beam. The contrivance is easy to any good mechanic; only we must observe, that the piston of the water-pump must be under the surface of the water in the condenser, that the water may enter the pump by its own weight, because there is no atmospheric pressure there to force it in. We must also observe, that a considerable force is necessarily expended here, because, as there is but one stroke for rarefying the air, and this rarefaction must be nearly complete, the air-pump must be of large dimensions, and its piston must act against the whole pressure of the atmosphere. Mr. Watt, however, found that this force could be easily spared from his machine, already so much improved in respect of power.

Thus has the steam-engine received a very considerable improvement. The cylinder may be allowed to remain very hot; nay, boiling hot, and yet the condensation be completely performed. The only elastic steam that now remains is the small quantity in the pipe of communication. Even this small quantity Mr. Watt at last got rid of, by admitting a small jet of cold water up this pipe to meet the steam in its passage to the condenser. This both cooled this part of the apparatus in a situation where it was not necessary to warm it again, and it quickened the condensation. He found at last that the small pipe of communication was of itself sufficiently large for the condensation, and that no separate vessel, under the name of condenser, was necessary. This circumstance shows the prodigious rapidity of the condensation. We may add, that unless this had been the case, his improvement would have been vastly diminished; for a large condenser would have required a much larger air-pump, which would have expended much of the power of the engine. By these means the vacuum below the piston is greatly improved: for it will appear clear to any person who understands the subject, that as long as any part of the condenser is kept of a low temperature, it will abstract and condense the vapour from the warmer parts, till the whole acquires the elasticity corresponding to the coldest part. By the same means much of the waste is prevented, because the cylinder is never cooled much below the boiling temperature. Many engines have been erected by Mr. Watt in this form, and their performances gave universal satisfaction.

We have contented ourselves with giving a very slight description without a figure of this improved engine, because we imagine it to be of very easy comprehension, and because it is only a preparation for still greater improvements, which, when understood, will at the same time leave no part of this more simple form unexplained.

During the progress of these improvements Mr. Watt made many experiments on the quantity and density of makes the steam of boiling water. These fully convinced him, that although he had greatly diminished the waste of the steam, a great deal yet remained, and that the steam expended during the rise of the piston was at least three times more than what would fill the cylinder. The cause of this was very apparent. In the subsequent descent of the piston, covered with water much below the boiling temperature, the whole cylinder was necessarily cooled and exposed to the air. Mr. Watt's fertile genius immediately suggested to him the expedient of employing the elasticity of the steam from the boiler to impel the piston down the cylinder, in place of the pressure of the atmosphere; and thus he restored the engine to its first principles, making it an engine really moved by steam. As this is a new epoch in its history, we shall be more particular in the description; at the same
same time still restricting ourselves to the essential circumstances, and avoiding every peculiarity which is to be found in the prodigious varieties which Mr Watt has introduced into the machines which he has erected, every individual of which has been adapted to local circumstances, or diversified by the progress of Mr Watt's improvements.

Let A (fig. 9.) represent the boiler. This has received great improvements from his complete acquaintance with the procedure of nature in the production of steam. In some of his engines the fuel has been placed in the midst of the water, surrounded by an iron or copper vessel, while the exterior boiler was made of wood, which transmits, and therefore wastes the heat very slowly. In others, the flame not only plays round the whole outside, as in common boilers, but also runs along several flues which are conducted through the midst of the water. By such contrivances the fire is applied to the water in a most extensive surface, and for a long time so as to impart to it the greatest part of its heat. So skillfully was it applied in the Albion mills, that although it was perhaps the largest engine in the kingdom, its unconsumed smoke was inferior to that of a very small brew-house. In this second engine of Mr Watt, the top of the cylinder is shut up by a strong metal plate $g$, in the middle of which is a collar or box of leathers $k$, formed in the usual manner of a jack-head pump, through which the piston rod PD, nicely turned and polished, can move up and down, without allowing any air to pass by its sides. From the dome of the boiler proceeds a large pipe BCIOQ, which, after reaching the cylinder with its horizontal part BC, descends parallel to its side, sending off two branches, viz. IM to the top of the cylinder, and ON to its bottom. At I is a puppet valve opening from below upwards. At L, immediately below this branch, there is a similar valve, also opening from below upwards. The pipe descends to Q, near the bottom of a large cistern $c d e f$, filled with cold water constantly renewed. The pipe is then continued horizontally along the bottom of this cistern (but not in contact), and terminates at R in a large pump ST. The piston S has slack valves opening upwards, and its rod S x, passing through a collar of leathers at T, is suspended by a chain to a small arch head on the outer arm of the beam. There is a valve R in the bottom of this pump, as usual, which opens when pressed in the direction QR, and shuts against a contrary pressure. This pump delivers its contents into another pump XY, by means of the small pipe t X, which proceeds from its top. This second pump has a valve at X, and a clack in its piston Z as usual, and the piston rod Z z is suspended from another arch head on the outer arm of the beam. The two valves I and L are opened and shut by means of spanners and handles, which are put in motion by a plug frame, in the same manner as in Newcomen's engine.

Lastly, there may be observed a crooked pipe $a b o$, which enters the upright pipe laterally a little above Q. This has a small jet hole at o; and the other end $d$, which is considerably under the surface of the water of the condensing cistern, is covered with a puppet valve v, whose long stalk u rises above the water, and may be raised or lowered by hand or by the plug beam. The valves R and X, and the clacks in the pistons S and Z, are opened or shut by the pressure to which they are immediately exposed.

This figure is not an exact copy of any of Mr Watt's engines, but has its parts so disposed that all may come distinctly into view, and exactly perform their various functions. It is drawn in its quiescent position, the outer end of the beam preponderating by the counter weight, and the piston P at the top of the cylinder, and the pistons S and Z in their lowest situations.

In this situation let us suppose that a vacuum is (by any means) produced in all the space below the piston, the valve I being shut. It is evident that the valve R will also be shut, as also the valve v. Now let the valve I be opened. The steam from the boiler, as elastic as common air, will rush into the space above the piston, and will exert on it a pressure as great as that of the atmosphere. It will therefore press it down, raise the outer end of the beam, and cause it to perform the same work as an ordinary engine.

When the piston P has reached the bottom of the cylinder, the plug frame shuts the valve I, and opens L. By so doing the communication is open between the top and bottom of the cylinder, and nothing hinders the steam which is above the piston from going along the passage MLON. The piston is now equally affected on both sides by the steam, even though a part of it is continually condensed by a cylinder, and in the pipe IOQ. Nothing therefore hinders the piston from being dragged up by the counter weight, which acts with its whole force, undiminished by any remaining unbalanced elasticity of steam. Here therefore this form of the engine has an advantage (and by no means a small one) over the common engines, in which a great part of the counter weight is expended in overcoming unbalanced atmospheric pressure.

Whenever the piston P arrives at the top of the cylinder, the valve L is shut by the plug frame, and the valves I and v are opened. All the space below the piston is at this time occupied by the steam which came from the upper part of the cylinder. This being a little wasted by condensation, is not quite a balance for the pressure of the atmosphere. Therefore, during the ascent of the piston, the valve R was shut, and it remains so. When therefore, the valve v is opened, the cold water of the cistern must spout up through the hole o, and condense the steam. To this must be added the coldness of the whole pipe OQS. As fast as it is condensed, its place is supplied by steam from the lower part of the cylinder. We have already remarked, that this successive condensation is accomplished with astonishing rapidity. In the mean time steam from the boiler presses on the upper surface of the piston. It must therefore descend as before, and the engine must perform a second working stroke.

But in the mean time the injection water lies in the bottom of the pipe OQR, heated to a considerable degree by the condensation of the steam; also a quantity of air has been disengaged from it and from the water in the boiler. How is this to be discharged?—This is the office of the pumps ST and XY. The capacity of ST is very great in proportion to the space in which the air and water are lodged. When, therefore, the piston S has got to the top of its course, there must be a vacuum in the barrel of this pump, and the water and air must open the valve R and come into it. When the piston
piston $S$ comes down again in the next returning stroke, this water and air gets through the valve of the piston; and in the next working stroke they are discharged by the piston into the pump $XY$, and raised by its piston. The air escapes at $Y$, and as much of the water as is necessary is delivered into the boiler by a small pipe $Yg$ to supply its waste. It is a matter of indifference whether the pistons $S$ and $Z$ rise with the outer or inner end of the beam, but it is rather better that they rise with the inner end. They are otherwise drawn here, in order to detach them from the rest and show them more distinctly.

Such is Mr. Watt's second engine. Let us examine its principles, that we may see the causes of its avowed and great superiority over the common engines.

We have already seen one ground of superiority, the full operation of the counter weight. We are authorised by careful examination to say, that in the common engines at least one-half of the counter weight is expended in counteracting an unbalanced pressure of the air on the piston during its ascent. In most engines, which are not the worst, this extends to 1/4th of the whole pressure. This is evident from the examination of the engine at Montreux by Bosuet. This makes a very great counter weight necessary, which exhausts a proportional part of the moving force.

But the great advantage of Mr. Watt's form is the almost total annihilation of the waste of steam by condensation in the cylinder. The cylinder is always boiling hot, and therefore perfectly dry. This must be evident to any person who understands the subject. By the time that Mr. Watt had completed his improvements, his experiments on the production of steam had given him a pretty accurate knowledge of its density; and he found himself authorised to say, that the quantity of steam employed did not exceed twice as much as would fill the cylinder, so that not above one-half was unavoidably wasted. But before he could bring the engine to this degree of perfection, he had many difficulties to overcome: He inclosed the cylinder in an outer wooden case at a small distance from it. This diminished the expense of heat by communication to surrounding bodies. Sometimes he allowed the steam from the boiler to occupy this interval. This undoubtedly prevented all dissipation from the inner cylinder; but in its turn it dissipated much heat by the outer case, and a very sensible condensation was observed between them. This has occasioned him to omit this circumstance in some of his best engines. We believe it was omitted in the Albion mills.

The greatest difficulty was to make the great piston tight. The old and effectual method, by water lying on it, was inadmissible. He was therefore obliged to have his cylinders most nicely bored, perfectly cylindrical, and finely polished; and he made numberless trials of different soft substances for packing his piston, which should be tight without enormous friction, and which should long remain so, in a situation perfectly dry, and hot almost to burning.

After all that Mr. Watt has done in this respect, he thinks that the greatest part of the waste of steam which he still perceives in his engines arises from the unavoidable escape by the sides of the piston during its descent.

But the fact is, that an engine of this construction, of the same dimensions with a common engine, making the same number of strokes of the same extent, does not consume above one-fourth part of the fuel that is consumed by the best engines of the common form. It is also a very fortunate circumstance, that the performance of the engine is not immediately destroyed, nor indeed sensibly diminished, by a small want of tightness in the piston. In the common engine, if air get in, in this way, it immediately puts a stop to the work; but although even a considerable quantity of steam get past the piston during its descent, the rapidity of condensation is such, that hardly any diminution of pressure can be observed.

Mr. Watt's penetration soon discovered another most valuable property of this engine. When an engine of available power is erected, the engineer must make an accurate estimate of the work to be performed, and must proportion his engine accordingly. He must be careful that it be fully able to execute its task; but its power must not exceed its load in any extravagant degree. This would produce a motion which is too rapid, and which, being alternately in opposite directions, would occasion jolts which no building or machinery could withstand. Many engines have been shattered by the pumps drawing air, or a pump rod breaking; by which accidents the steam-piston descends with such rapidity that every thing gives way. But in most operations of mining, the task of the engine increases, and it must be so constructed at first as to be able to bear this addition. It is very difficult to manage an engine that is much superior to its task; and the easiest way is, to have it almost full loaded, and to work it only during a few hours each day, and allow the pit water to accumulate during its repose. This increases the first cost, and wastes fuel during the inaction of the engine.

But this new engine can at all times be exactly fitted, that it (at least during the working stroke) to the load of work can always be exactly fitted to the load which happens to be common boiling water; but when once the ebullition is fairly commenced, and the whole air expelled from all parts of the apparatus, it is evident, that by damping the fire, steam of half this elasticity may be continually supplied, and the water will continue boiling although its temperature does not exceed 18° of Fahrenheit's thermometer. This appears by inspecting our table of vaporous elasticity, and affords another argument for rendering that table more accurate by new experiments. We hope that Mr. Watt will not withhold from the public the knowledge which he has acquired on this subject. It may very possibly result from an accurate investigation, that it would be advisable to work our steam-engines with weak steam, and that the diminution of work may be more than compensated by the diminution of fuel. It is more probable indeed, and it is Mr. Watt's opinion, that the contrary is the case, and that it is much more economical to employ great heats. At any rate, the decision of this question is of great importance for improving the engine; and we see, in the mean time, that the engine can at all times be fitted so as to perform its task with a moderate and manageable motion, and that as the task increases we can increase the power of the engine.
STEAM-ENGINE.

3. But the method now proposed has a great inconvenience. While the steam is weaker than the atmosphere, there is an external force tending to squeeze in the sides and bottom of the boiler. This could not be resisted when the difference is considerable, and common air would rush in through every crevice of the boiler and soon choke the engine: it must therefore be given up.

But the same effect will be produced by diminishing the passage for the steam into the cylinder. For this purpose, the puppet valve by which the steam enters the cylinder was made in the form of a long taper spigot, and it was lodged in a cone of the same shape; consequently the passage could be enlarged or contracted at pleasure by the distance to which the inner cone was drawn up.

In this way several engines were constructed, and the general purpose of suiting the power of the engine to its task was completely answered: but (as the mathematical reader will readily perceive) it was extremely difficult to make this adjustment precise and constant. In a great machine like this going by jerks, it was hardly possible that every successive motion of the valve should be precisely the same. This occasioned very sensible irregularities in the motion of the engine, which increased and became hazardous when the joints worked loose by long use.

Mr. Watt's genius, always fertile in resources, found out a complete remedy for all these inconveniences. Making the valve of the ordinary form of a puppet clack, he adjusted the button of its stalk or tail so that it should always open full to the same height. He then regulated the pins of the plug-frame, in such a manner that the valve should shut the moment that the piston had descended a certain proportion (suppose one-fourth, one-third, one-half, &c.) of the cylinder. So far the cylinder was occupied by steam as elastic as common air. In pressing the piston farther down, it behaved the steam to expand, and its elasticity to diminish. It is plain that this could be done in any degree we please, and that the adjustment can be varied in a minute, according to the exigency of the case, by moving the plug pins.

In the mean time, it must be observed, that the pressure on the piston is continually changing, and consequently the accelerating force. The motion therefore will no longer be uniformly accelerated; it will approach much faster to uniformity; nay, it may be retarded, because although the pressure on the piston at the beginning of the stroke may exceed the resistance of the load, yet when the piston is near the bottom the resistance may exceed the pressure. Whatever may be the law by which the pressure on the piston varies, an ingenious mechanic may contrive the connecting machinery in such a way that the chains or rods at the outer end of the beam shall continually exert the same pressure, or shall vary their pressure according to any law he finds most convenient. It is in this manner that the watchmaker, by the form of the foize, produces an equal pressure on the wheel-work by means of a very unequal action of the mainspring. In like manner, by making the outer arch heads portions of a proper spiral instead of a circle, we can regulate the force of the beam at pleasure.

Thus we see how much more manageable an engine is in this form than Newcomen's was, and also more easily investigated in respect of its power in its various positions. The knowledge of this last circumstance was of mighty consequence, and without it no notion could be formed of what it could perform. This suggested to Mr. Watt the use of the barometer communicating with the cylinder; and by the knowledge acquired by these means has the machine been so much improved by its ingenious inventor.

We must not omit in this place one dedication made by Mr. Watt from his observations, which may be called a discovery of great importance in the theory of the engine.

Let ABCD (fig. 10.) represent a section of the cylinder of a steam-engine, and EF the surface of its piston. Let us suppose that the steam was admitted of great importance, while EF was in contact with AB, and that as soon as it had pressed it down to the situation EF the steam cock is shut. The steam will continue to press it down, and as the steam expands its pressure diminishes. We Fig. 10.

may express its pressure (exerted all the while the piston moves from the situation AB to the situation EF) by the line EF. If we suppose the elasticity of the steam proportional to its density, as is nearly the case with air, we may express the pressure on the piston in any other position, such as KL or DC, by K and D, the ordinates of a rectangular hyperbola, of which AE, AB are the asymptotes, and A the centre. The accumulated pressure during the motion of the piston from EF to DC will be expressed by the area AEFc DE, and the pressure during the whole motion by the area ABFE DA.

Now it is well known that the area AEc DE is equal to ABFE multiplied by the hyperbolic logarithm of \( \frac{AD}{AE} \), and the whole area ABFc DA is

\[ = ABFE \times \left(1 + \frac{AD}{AE}\right) \]

Thus let the diameter of the piston be 24 inches, and the pressure of the atmosphere on a square inch be 14 pounds; the pressure on the piston is 6333 pounds. Let the whole stroke be 6 feet, and let the steam be stopped when the piston has descended 18 inches, or 1.5 feet. The hyperbolic logarithm of \( \frac{6}{5} \) is 1.3862943.

Therefore the accumulated pressure AEFc DA is

\[ = 6333 \times 2.3862943 = 15114 \text{ pounds}. \]

As few professional engineers are possessed of a table of hyperbolic logarithms, while tables of common logarithms are or should be in the hands of every person who is much engaged in mechanical calculations, let the following method be practised. Take the common logarithm of \( \frac{AD}{AE} \), and multiply it by 2.3026; the product is the hyperbolic logarithm of \( \frac{AD}{AE} \).

The accumulated pressure while the piston moves from AB to EF is 6333 \times 1, or simply 6333 pounds. Therefore the steam while it expands into the whole cylinder adds a pressure of 8781 pounds.

Suppose that the steam had got free admission during the whole descent of the piston, the accumulated pressure would have been 6333 \times 4, or 25332 pounds.

Here Mr. Watt observed a remarkable result. The steam expended in this case would have been four times greater.
greater than when it was stopped at one-fourth, and yet the accumulated pressure is not twice as great, being nearly five-thirds. One-fourth of the steam performs nearly three-fifths of the work, and an equal quantity performs more than twice as much work when thus admitted during one-fourth of the motion.

This is a curious and an important information, and the advantage of this method of working a steam-engine increases in proportion as the steam is sooner stopped; but the increase is not great after the steam is raised four times. The curve approaches near to the axis, and small additions are made to the area. The expense of such great cylinders is considerable, and may sometimes compensate this advantage.

Let the steam be stopped at its performance is mult.

&c.

It is very pleasing to observe so many unlooked-for advantages resulting from an improvement made with the sole view of lessening the waste of steam by condensation. While this purpose is gained, we learn how to handle the steam which is not thus wasted. The engine becomes more manageable, and is more easily adapted to every variation in its task, and all its powers are more easily computed.

The active mind of its ingenious inventor did not stop here: It had always been matter of regret that one-half of the motion was unaccompanied by any work. It was a very obvious thing to Mr. Watt, that as the steam admitted above the piston pressed it down, so steam admitted below the piston pressed it up with the same force, provided that a vacuum were made on its upper side. This was easily done, by connecting the lower end of the cylinder with the boiler and the upper end with the condenser.

Fig. 11. is a representation of this construction exactly copied from Mr. Watt's figure accompanying his specification. Here BB is a section of the cylinder, surrounded at a small distance by the case 1111. The section of the piston A, and the collar of leathers which embraces the piston rod, gives a distinct notion of its construction, of the manner in which it is connected with the piston-rod, and how the packing of the piston and collar contributes to make all tight.

From the top of the cylinder proceeds the horizontal pipe. Above the letter D is observed the seat of the steam valve, communicating with the box above it. In the middle of this may be observed a dark shaded circle. This is the mouth of the upper branch of the steam pipe coming from the boiler. Beyond D, below the letter N, is the seat of the upper condensing valve. The bottom of the cylinder is made spherical, fitting the piston, so that they may come into entire contact. Another horizontal pipe proceeds from this bottom. Above the letter E is the seat of the lower steam valve, opening into the valve box. This box is at the extremity of another steam pipe marked G, which branches off from the upper horizontal part, and descends obliquely, com-

Plate DIII. Description of Mr. Watt's steam-engine in its most improved state.

At it is intended by this construction to give the piston a strong impulse in both directions, it will not be proper to suspend its rod by a chain from the great beam; for it must not only pull down that end of the beam, but also push it upwards. It may indeed be suspended by double chains like the pistons of the engines for extinguishing fires; and Mr. Watt has accordingly done so in some of his engines. But in his drawing from which this figure is copied, he has communicated the force of the piston to the beam by means of a toothed rack OO, which engages or works in the toothed sector QQ on the end of the beam. The reader will understand, without any farther explanation, how the impulse given to the piston in either direction is thus transmitted to the beam without diminution. The fly XX, with its pinion Y, which also works in the toothed arch QQ, may be supposed to be removed for the present, and will be considered afterwards.

We shall take the present opportunity of describing Mr. Watt's method of communicating the force of the steam-engine to any machine of the rotary kind. VV represents the rim and arms of a very large and heavy metallic fly. On its axis is the concentric toothed wheel U. There is attached to the end of the great beam a strong and stiff rod TT, to the lower end of which a toothed wheel W is firmly fixed by two bolts, so that it cannot turn round. This wheel is of the same size and in the same vertical plane with the wheel U; and an iron link or strap (which cannot be seen here, because it is on the other side of the two wheels) connects the centres of the two wheels, so that the one cannot quit the other. The engine being in the position represented in the figure, suppose the fly to be turned once round by any external force in the direction of the darts. It is plain, that since the toothed wheels cannot quit each other, being kept together by the
STEAM ENGINE.

It is evident that this form of the engine, by maintaining an almost constant and uninterrupted impulsion, is much fitter for driving any machinery of continued motion than any of the former engines, which were inactive during half of their motion. It does not, however, seem to have this superiority when employed to draw water: But it is equally fitted for this task. Let the engine be loaded with twice as much as would be proper for it if a single-stroke engine, and let a fly be connected with it. Then it is plain that the power of the engine during the rise of the steam-piston will be accumulated in the fly; and this, in conjunction with the power of the engine during the descent of the steam-piston, will be equal to the whole load of water.

In speaking of the steam and eduction-valves, we said that they were all puppet-valves. Mr. Watt employed cocks, and also sliding-valves, such as the regulator or steam-valves in the old engines. But be found them always lose their tightness after a short time. This is not surprising, when we consider that they are always perfectly dry, and almost burning hot. He was therefore obliged to change them all for puppet-clacks, which, when truly ground and nicely fitted in their motions at first, are not found to go out of order by any length of time. Other engineers now universally use them in the old form of the steam-engine, without the same reasons, and merely by servile and ignorant imitation.

The way in which Mr. Watt opens and shuts these valves is as follows. Fig. 13 represents a clack with Fig. its seat and box. Suppose it one of the eduction-valves. HH is part of the pipe which introduces the steam, and GG is the upper part of the pipe which communicates with the condenser. At EE may be observed a piece more faintly shaded than the surrounding parts. This is the seat of the valve, and is a brass or bell-metal ring turned conical on the outside, so as to fit exactly into a conical part of the pipe GG. These two pieces are fitted by grinding; and the conical being of a long taper, the ring sticks firmly in it, especially after having been there for some time and united by rust. The clack itself is a strong brass plate DD, turned conical on the edge, so as to fit the conical or sloping inner edge of the seat. These are very nicely ground on each other with emery. This conical joining is much more obtuse than the outer side of the ring; so that although the joint is air-tight, the two pieces do not stick strongly together. The clack has a round tail DG, which is freely movable up and down in the hole of a cross piece FF. On the upper side of the valve is a strong piece of metal DC firmly joined to it, one side of which is formed into a toothed rack. A is the section of an iron axle which turns in holes in the opposite sides of the valve-box, where it is nicely fitted by grinding, so as to be air-tight. Collets of thick leather, well soaked in melted tallow and rosin, are screwed on the outside of these holes to prevent all ingress of air. One end of this axis projects a good way without the box, and carries a spanner or handle, which is moved by the plug-frame. To this axis is fixed a strong piece of metal B, the edge of which is formed into an arch of a circle having the axis A in its centre, and is cut into teeth which mesh with the teeth of the rack DC. K is a cover which is fixed by screws to the top of the box HHJH, and may be taken off in order to get at the valve when it needs repairs.
From this description it is easy to see that by turning the handle which is on the axis A, the sector B must lift up the valve by means of its toothed rack D, till the upper end of the rack touch the knob or button K. Turning the handle in the opposite direction brings the valve down again to its seat.

This valve is extremely tight. But in order to open it for the passage of the steam, we must exert a force equal to the pressure of the atmosphere. This in a large engine is a very great weight. A valve of six inches diameter sustains a pressure not less than 400 pounds. But this force is quite momentary, and hardly impedes the motion of the engine; for the instant the valve is detached from its seat, although it has not moved the 400th part of an inch, the pressure is over. Even this little inconvenience has been removed by a delicate thought of Mr. Watt. He has put the spawner in such a position when it begins to raise the valve, that its mechanical energy is almost infinitely great. Let QR (fig. 14.) be part of the plug-frame descending, and P one of its pins just going to lay hold of the spawner NO moveable round the axis N. On the same axis is another arm NM connected by a joint with the leader M L, which is connected also by a joint with the spawner LA that is on the axis A of the sector within the valve box. Therefore when the pin P pushes down the spawner NO, the arm MN moves sidewise and pulls down the spawner AL by means of the connecting rod. Things are so disposed, that when the cock is shut, LM and MN are in one straight line. The intelligent mechanic will perceive that, in this position, the force of the lever ONM is insuperable. It has this further advantage, that if any thing should tend to force open the valve, it would be ineffectual; for no force exerted at A, and transmitted by the rod LM, can possibly push the joint M out of its position. Of such one is it to practical mechanics, that its professors should be persons of penetration as well as knowledge. Yet this circumstance is unheeded by hundreds who have servily copied from Mr. Watt, as may be seen in every engine that is puffed on the public as a discovery and an improvement. When these puppet-valves have been introduced into the common engine, we have not seen one instance where this has been attended to; certainly because its utility has not been observed: and there is one situation where it is of more consequence than in Mr. Watt's engine, viz. in the injection cock. Here the valve is drawn back into a box, where the water is so awkwardly disposed round it that it can hardly get out of its way, and where the pressure even exceeds that of the atmosphere. Indeed this particular substitution of the button valve for the cock is most injudicious.

We postponed any account of the office of the fly XX (fig. 11.), as it is not of use in an engine regulated by the fly YY. The fly XX is only for regulating the reciprocating motion of the beam when the steam is not admitted during the whole descent of the piston. This it evidently must render more uniform, accumulating a momentum equal to the whole pressure of the full supply of steam, and then sharing it with the beam during the rest of the descent of the piston.

When a person properly skilled in mechanics and chemistry reviews these different forms of Mr. Watt's steam-engine, he will easily perceive them susceptible of many intermediate forms, in which any one or more of the distinguishing improvements may be employed. The first great improvement was the condensation in a separate vessel. This increased the original powers of the engine, giving to the atmospheric pressure and to the counter-weight their full energy; at the same time the waste of steam is greatly diminished. The next improvement, by employing the pressure of the steam instead of that of the atmosphere, aimed only at a still further diminution of the waste; but was fertile in advantages, rendering the machine more manageable, and particularly enabled us at all times, and without trouble, to suit the power of the engine to its load of work, however variable and increasing; and brought into view a very interesting proposition in the mechanical theory of the engine, viz. that the whole performance of a given quantity of steam may be augmented by admitting it into the cylinder only during a part of the piston's motion. Mr. Watt has varied the application of this proposition in a thousand ways; and there is nothing about the machine which gives more employment to the sagacity and judgment of the engineer. The third improvement of the double impulse may be considered as the finishing touch given to the engine, and renders it as uniform in its action as any water-wheel. In the engine in its most perfect form there does not seem to be above one-fourth of the steam wasted by warming the apparatus; so that it is not possible to make it one-fourth part more powerful than it is at present. The only thing that seems susceptible of considerable improvement is the great beam. The enormous strains exerted on its arms require a proportional strength. This requires a vast mass of matter, not less indeed in an engine with a cylinder of 54 inches than three tons and a half, moving with the velocity of three feet in a second, which must be communicated in about half a second. This mass must be brought into motion from a state of rest, must again be brought to rest, again into motion, and again to rest, to complete the period of a stroke. This consumes much power; and Mr. Watt has not been able to load an engine with more than 10 or 11 pounds on the inch and preserve a sufficient quantity of motion, so as to make 12 or 15 six-foot strokes in a second. Many attempts have been made to lessen this mass by using a light framed wheel, or a light frame of carpentry, in place of a solid beam. These have generally been constructed by persons ignorant of the true scientific principles of carpentry, and have fared accordingly. Mr. Watt has made similar attempts; but found, that although at first they were abundantly strong, yet after a short time's employment the straps and beams with which the wooden parts were connected cut their way into the wood, and the framing grew loose in the joints, and, without giving any warning, went to pieces in an instant. A solid massy simple beam of sufficient strength, bends, and sensibly complains (as the carpenters express it), before it breaks. In all great engines, therefore, such only are employed, and in smaller engines he sometimes uses cast-iron wheels or pulleys; nay, he frequently uses no beam or equivalent whatever, but employs the steam-piston rod to drive the machinery to which the engine is applied.

We presume that our thinking readers will not be displeased with this rational history of the progress of this engine in the hands of its ingenious and worthy inventor. We owe it to the communications of a friend, well
well acquainted with him, and able to judge of his merits. The public see him always associated with the no less celebrated mechanic and philosopher Mr Boulton of Soho near Birmingham. They have shared the royal patent from the beginning; and the alliance is equally honourable to both.

The advantages derived from the patent right show both the superiority of the engine and the liberal minds of the proprietors. To secure the engines at the expense of the employers, or give working drafts of all the parts, with instructions, by which any resident engineer may execute the work. The employers select the best engine of the ordinary kind in the kingdom, compare the quantities of fuel expended by each, and pay to Messrs Watt and Boulton one-third of the annual savings for a certain term of years. By this the patentees are excited to do their utmost to make the engine perfect; and the employer pays in proportion to the advantage he derives from it.

It may not be here improper to state the actual performance of some of these engines, as they have been ascertained by experiment.

An engine having a cylinder of 31 inches in diameter, and making 17 double strokes per minute, performs the work of forty horses working night and day, (for which three relays or 120 horses must be kept), and burns 11,000 pounds of Staffordshire coal per day. A cylinder of 19 inches, making 25 strokes of 4 feet each per minute, performs the work of 12 horses working constantly, and burns 3700 pounds of coal per day. A cylinder of 24 inches, making 22 strokes of 5 feet, burns 5500 pounds of coal, and is equivalent to the constant work of 32 horses. The patentees think themselves authorized by experience to say in general, that these engines will raise more than 20,000 cubic feet of water 24 feet high for every hundred weight of good pit-coal consumed by them.

In consequence of the great superiority of Mr Watt's engines, both with respect to economy and manageableness, they have become of most extensive use; and in every demand of manufacture on a great scale they offer us an indefatigable servant, whose strength has no bounds. The greatest mechanical project that ever engaged the attention of man was on the point of being executed by this machine. The States of Holland were treating with Messrs Watt and Boulton for draining the Haerlem Meer, and even reducing the Zuider Zee: and we doubt not but that it will be accomplished whenever that unhappy nation has sufficiently felt the difference between liberty and foreign tyranny. Indeed such unlimited powers are afforded by this engine, that the engineer now thinks that no task can be proposed to him which he cannot execute with profit to his employer.

No wonder then that all classes of engineers have taken much of their attention to this engine; and seeing that it has done so much, that they try to make it do still more. Numberless attempts have been made to improve Mr Watt's engine; and it would occupy a volume to give an account of them, whilst that account would do no more than indulge curiosity. Our engineers by profession are in general miserably deficient in that accurate knowledge of mechanics and of chemistry which is necessary for understanding this machine; and we have not heard of one in this kingdom who can be put on a par with the present patentees in this respect. Most of the attempts of engineers have been made with the humbler view of avail themselves of Mr Watt's discoveries, so as to construct a steam-engine superior to Newcomen's, and yet of a form sufficiently different from Watt's to keep it without the reach of his patent. This they have in general accomplished by performing the condensation in a place which, with a little stretch of fancy, not unfrequent in a court of law, may be called part of the cylinder.

The success of most of these attempts has interfered and the so little with the interest of the patentees, that these has not hindered the erection of many engines which the law would have deemed encroachments. We think it our duty to give our opinion on this subject without reserve. These are most expensive undertakings, and few employers are able to judge accurately of the merits of a project presented to them by an ingenious artist. They may see the practicability of the scheme, by having a general notion of the expansion and condensation of steam, and they may be misled by the ingenuity apparent in the construction. The engineer himself is frequently the dupe of his own ingenuity; and it is not always dishonesty, but frequently ignorance, which makes him prefer his own invention (as he thinks it) improvement. It is a most delicate engine, and requires much knowledge to see what does and what does not improve its performance. We have gone into the preceding minute investigation of Mr Watt's progress with the express purpose of making our readers fully masters of its principles, and have more than once pointed out the real improvements, that they may be firmly fixed and always ready in the mind. By having recourse to them, the reader may pronounce with confidence on the merits of any new construction, and will not be deceived by the puff of an ignorant or dishonest engineer.

We must except from this general criticism an construction by Mr Jonathan Hornblower near Bristol, on account of its singularity, and the ingenuity and real skill which appears in some particulars of its construc- tion. The following short description will sufficiently explain its principle, and enable our readers to appreciate its merit.

A and B (fig. 15) represent two cylinders, of which A is the largest. A piston moves in each, having their rods C and D moving through collars E and F. These cylinders may be supplied with steam from the boiler of his pipe C, which has a flange steam- to connect it with the rest of the steam-pipe. This pipe pipe square part is represented as branching off to both cylinders. c and d are two cocks, which have handles and tumbler as usual, worked by the plug-beam W. On the fore-side (that is, the side next the eye) of the cylinders is represented another communicating pipe, whose section is also square or rectangular, having also two cocks a, b. The pipe Y, immediately under the cock b, establishes a communication between the upper and lower parts of the small cylinder B, by opening the cock b. There is a similar pipe on the other side of the cylinder A, immediately under the cock d. When the cocks c and d are open, and the cocks b and d are shut, the steam from the boiler has free admission into the upper part of the cylinder B, and the steam from the lower part of B has a free admission into the upper part of A; but the upper part of each cylinder has no communication with its lower part.

From the bottom of the great cylinder proceeds the reduction-pipe K, having a valve at its opening into the...
STEAM-ENGINE.

Steam-engine.

cylinder, which bends downwards, and is connected with the conical condenser L (c). The condenser is fixed on a hollow box M, on which stand the pumps N and O, for extracting the air and water; which last runs along the trough T into a cistern U, from which it is raised by the pump V for recruiting the boiler, being already nearly boiling hot. Immediately under the condenser there is a spigot-valve at S, over which is a small jet-pipe, reaching to the bend of the eduction-pipe. The whole of the condensing apparatus is contained in a cistern R of cold water. A small pipe P comes from the side of the condenser, and terminates on the bottom of the trough T, and is there covered with a valve Q, which is kept tight by the water that is always running over it. Lastly, the pump-rods X cause the outer end of the beam to preponderate, so that the quiescent position of the beam is that represented in the figure, the pistons being at the top of the cylinders.

Suppose all the cocks open, and steam coming copiously from the boiler, and no condensation going on in L; the steam must drive out all the air, and at last follow it through the valve Q. Now shut the valves b and d, and open the valve S of the condenser. The condensation will immediately commence. There is now no pressure on the under side of the piston of A, and it immediately descends. The communication between the lower part of B and the upper part of A being open, the steam will go from B into the space left by the piston of A. It must therefore expand, and its elasticity must diminish, and will no longer balance the pressure of the steam above the piston of B. This piston therefore, if not withheld by the beam, would descend till it is in equilibriu, having steam of equal density above and below it. But it cannot descend so far; for the cylinder A is wider than B, and the arm of the beam at which its piston hangs is longer than the arm which supports the piston of B; therefore when the piston of B has descended as far as the beam will permit it, the steam between the two pistons occupies a larger space than it did when both pistons were at the tops of their cylinders. Its density, therefore, and its elasticity, diminish as its bulk increases. It is therefore not a balance; for the steam on the upper side of B, and the piston B, pulls at the beam with all the difference of these pressures. The slightest view of the subject must show the reader, that as the pistons descend, the steam that is between them will grow continually rarer and less elastic, and that both pistons will pull the beam downwards.

Suppose now that each has reached the bottom of its cylinder. Shut the cock c and the eduction-cock at the bottom of A, and open the cocks b and d. The communication being now established between the upper and lower part of each cylinder, nothing hinders the counter weight from raising the pistons to the top. Let them arrive there. The cylinder B is at this time filled with steam of the ordinary density, and the cylinder A with an equal absolute quantity of steam, but expanded into a larger space.

Shut the cocks b and d, and open the cock c, and the eduction-cock at the bottom of A; the condensation will again operate, and the pistons descend. And thus the operation may be repeated as long as steam is supplied; and one full of the cylinder B of ordinary steam is expended during each working stroke.

Let us now examine the power of this engine. It is evident, that when both pistons are at the top of their respective cylinders, the active pressure (that is, the difference of the pressure on its two sides) on the piston of B is nothing, while that on the piston of A is equal to the full pressure of the atmosphere on its area. This, multiplied by the length of the arm by which it is supported, gives its mechanical energy. As the pistons descend, the pressure on the piston of B increases, while that on the piston of A diminishes. When both are at the bottom, the pressure on the piston of B is at its maximum, and that on the piston of A at its minimum.

Mr Hornblower saw that this must be a beneficial employment of steam, and preferable to the practice of condensing it while its full elasticity remained; but he has not considered it with the attention necessary for ascertaining the advantage with precision.

Let a and b represent the areas of the pistons of A and B, and let m and n be the lengths of the arms by which they are supported. It is evident, that when both pistons have arrived at the bottoms of their cylinders, the capacities of the cylinders are as m and n, a and b. Let this be the ratio of m to n. Let g h i k (Fig. 16.) and l m n o be two cylinders of equal length, communicating with each other, and fitted with a piston-rod p q, on which are fixed two pistons a and b b, whose areas are as m and n. Let the distance between the pistons be precisely equal to the height of each cylinder, which height we shall call h. Let x be the space g h or b q, through which the pistons have descended. Let the upper cylinder communicate with the boiler, and the lower cylinder with the condenser or vacuum V.

Any person in the least conversant in mechanics and pneumatics will clearly see that the strain or pressure on the piston-rod p q is precisely the same with the united energies of the two piston rods of Mr Hornblower's engine, by which they tend to turn the working beam round its axis.

The base of the upper cylinder being r, and its height h, its capacity or bulk is r h or h; and this expresses the natural bulk of the steam which formerly filled it, and is now expanded into the space b h i a m s b. The part b h i b is plainly = h x, and the part i a m s = m x. The whole space, therefore, is m x + h x = h + m x, or h + m - 1 x. Therefore the density of the steam between the pistons is = h h + m - 1 x.

Let p be the downward pressure of the steam from the boiler on the upper piston b b. This piston is also pressed up with a force = p h h + m - 1 x by the steam between the pistons. It is therefore, on the whole, pressed downward with a force = p (1 - h h + m - 1 x).

The

(c) This, however, was stopped by Watt's patent; and the condensation must be performed as in Newcomen's engine, or at least in the cylinder A.
The lower piston $a$, having a vacuum below it, is pressed downwards with a force $\frac{p}{m}$ due to the pressure $p$ on the piston rod downwards.

Therefore, the whole pressure on the piston rod downwards is $p \left(1 + \frac{m}{h + m - 1} \frac{1}{x} + \frac{1}{h + m - 1} \frac{1}{x}ight) = p \left(1 + \frac{m - 1}{h + m - 1} \frac{1}{x} + \frac{1}{h + m - 1} \frac{1}{x}ight)$.

This is the momentary pressure on the piston rod corresponding to its descent $x$ from its highest position. When the pistons are in their highest position, this pressure is equal to $mp$. When they are in their lowest position, it is $\frac{2m - 1}{m}$. Here therefore is an accession of power. In the beginning, the pressure is greater than on a single piston in the proportion of $m$ to $1$; and at the end of the stroke, where the pressure is weakest, it is still much greater than the pressure on a single piston. Thus, if $m$ be 4, the pressure at the beginning of the stroke is 4$p$, and at the end it is $\frac{7}{4}p$, almost double, and in all intermediate positions it is greater. It is worth while to obtain the sum total of all the accumulated pressures, that we may compare it with the constant pressure on a single piston.

We may do this by considering the momentary pressure $p + \frac{m}{h + m - 1} \frac{1}{x} + \frac{1}{h + m - 1} \frac{1}{x}$, as equal to the ordinate $GF$, $Hb$, $m - 1$ + $x$, or $M$, of a curve $F b c$ (fig. 10), which has for its axis the line $GM$ equal to $h$ the height of our cylinder. Call this ordinate $y$. We have $y = p + \frac{m}{h + m - 1} \frac{1}{x} + \frac{1}{h + m - 1} \frac{1}{x}$. Now it is plain that $p + \frac{m}{h + m - 1} \frac{1}{x}$ is the ordinate of an equilateral hyperbola, $\frac{1}{h + m - 1} \frac{1}{x}$ is the ordinate of an equilateral hyperbola, which is that on which $p$, the power or rectangle of the orifice and abscissa, and of which the abscissa reckoned from the centre is $h = \frac{m - 1}{h + m - 1} + \frac{1}{x}$. Therefore make $GE = p$, and draw $DEA$ parallel to $MG$, and make $EA = \frac{GM}{m - 1}$.

The curve $F b c$ is an equilateral hyperbola, having $A$ for its centre and $AD$ for its asymptote. Draw the other asymptote $AB$, and its ordinate $FB$. Since the power of the hyperbola is $\frac{L}{p} h = \frac{L}{G E} \frac{M}{m - 1}$, and since all the inscribed rectangles, such as $AEFB$, are equal to $p h$, it follows that $AEFB$ is equal to $\frac{L}{G E} \frac{M}{m - 1}$, and that the area $ABF c DA$ is equal to the area $GF c MG$, which expresses the accumulated pressure in Hornblower's engine.

We can now compute the accumulated pressure very easily. It is evidently $\frac{L}{p} h \times \left(1 + \frac{AD}{AE}ight)$.

The intelligent reader cannot but observe that this is precisely the same with the accumulated pressure of a quantity of steam admitted in the beginning, and stop-

ped in Mr. Watt's method, when the piston has descended through the $m$th part of the cylinder. In considering Mr. Hornblower's engine, the thing was presented in so different a form that we did not perceive the analogy at first, and we were surprised at the result formulated.

We could not help regretting it, because it had the pressure appearance of a new principle and an improvement; and we doubt not that it appeared so to the ingenious author; for we have had such proofs of his liberal mind as to permit us not to suppose he saw it from the beginning, and saved himself of the difficulty of tracing the analogy. And as the thing may mislead others in the same way, we have done a service to the public by showing that this engine, so costly and so difficult in its construction, is no way superior in power to Mr. Watt's simple method of stopping the steam. It is even inferior, because there must be a condensation in the communicating passages. We may add, that if the condensation is performed in the cylinder $A$, which it must be unless with the permission of Watt and Boulton, the engine cannot be much superior to a common engine; for much of the steam from below $B$ will be condensed between the pistons by the coldness of the cylinder $A$; and this diminishes the downward pressure on $A$ more than it increases the downward pressure on $B$. We learn however that, by confining the condensation to a small part of the cylinder $A$, Mr. Hornblower has erected engines clear of Mr. Watt's patent, which are considerably superior to Newcomen's; so has Mr. Symington.

We said that there was much ingenuity and real skill observable in many particulars of this engine. The engine disposition and connection of the cylinders, and the whole condensing apparatus, are contrived with peculiar ingenuity and neatness. The cocks are very ingenious; they are also composed of two flat circular plates ground very true to each other, and one of them turns round on a pin through their centres; each is pierced with three sectoral apertures, exactly corresponding with each other, and occupying a little less than one-half of their surfaces. By turning the movable plate so that the apertures coincide, a large passage is opened for the steam; and by turning it so that the solid of the one covers the aperture of the other, the cock is shut. Such regula-

ators are now very common in the cast iron stoves for warming rooms.

Mr. Hornblower's contrivance for making the collars for the piston rods air-tight is also uncommonly ingenious. This collar is in fact two, at a small distance from each other. A small pipe, branching off from the main steam-pipe, communicates with the space between the collars. This steam, being a little stronger than the pressure of the atmosphere, effectually hinders the air from penetrating by the upper collar; and though a little steam should get through the lower collar into the cylinder $A$, it can do no harm. We see many cases in which this pretty contrivance may be of signal service.

But it is in the framing of the great working beam that Mr. Hornblower's scientific knowledge is most conspicuous, and we have no hesitation in affirming that it is a thing stronger than a beam of the common form, and containing twenty times its quantity of timber. There is the work-hardening of the metal throughout, if we use the term strain, except the strain of the pump $V$ on the struts by which it is worked. Every piece is either pushed or pulled in the direction of its length. We only fear that the bolts...
Steam-Engine.

The reciprocating motion of the steam-engine has always been considered as a great defect; for though it be now obviated by connecting it with a fly, yet, unless it is an engine of double stroke, this fly must be an enormous mass of matter moving with great velocity.

Any accident happening to it would produce dreadful effects: A part of the rim detaching itself would have the force of a bomb, and no building could withstand it. Many attempts have been made to produce a circular motion at once by the steam. It has been made to blow on the vanes of a wheel of various forms. But the rariety of steam is such, that even if none is condensed by the cold of the vanes, the impulse is exceedingly feeble, and the expense of steam, so as to produce any serviceable impulse, is enormous. Mr. Watt, among his first speculations on the steam engine, made some attempts of this kind. One in particular was uncommonly ingenious. It consisted of a drum turning air-tight within another, with cavities so disposed that there was a constant and great pressure urging it in one direction. But no packing of the common kind could preserve it air-tight with sufficient mobility. He succeeded by immersing it in mercury, or in an amalgam which remained fluid in the heat of boiling water; but the continual titration soon calcined the fluid and rendered it useless. He then tried Parent’s or Dr. Barker’s mill, inclosing the arms in a metal drum, which was immersed in cold water. The steam rushed rapidly along the pipe which was the axis, and it was hoped that a great reaction would have been exerted at the ends of the arms; but it was almost nothing. The reason seems to be, that the greatest part of the steam was condensed in the cold arms. It was then tried in a drum kept boiling hot; but the impulse was now very small in comparison with the expense of steam. This must be the case.

Mr. Watt has described in his specification to the patent office some contrivances for producing a circular motion by the immediate action of the steam. Some of these produce alternate motions, and are perfectly analogous to his double-stroke engine. Others produce a continued motion. But he has not given such a description of his valves for this purpose as can enable an engineer to construct one of them. From any guess that we can form, we think the machine very imperfect; and we do not find that Mr. Watt has ever erected a continuous circular engine. He has doubtless found all the case is not desperate, for a very crude scheme of this kind may be seen in the Transactions of the Royal Society of Dublin 1787.

But although our attempts have hitherto failed, we hope ciples may be employed.

Mr. Watt’s attempts to produce a circular motion by steam unsuccessful.

Steam-engine.

STEAM-KITCHEN. Ever since Dr. Papin contrived his digester (about the year 1690), schemes have been proposed for dressing victuals by the steam of boiling water. A philosophical club used to dine at Saltoro’s coffee-house, Chelsea, about 40 years ago, and bad their victuals dressed by hanging them in the boiler of the steam-engine which raises water for the supply of Picadilly and its neighbourhood. They were completely dressed, and both expeditiously and with high flavour.

A patent was obtained for an apparatus for this purpose by a tin-man in London; we think of the name of Tate. They were afterwards made on a much more effective plan by Mr. Gregory, an ingenious tradesman in Edinburgh, and are coming into very general use.

It is well known to the philosopher that the steam of boiling water contains a prodigious quantity of heat, which it retains in a latent state readily to be faithfully accounted for, and communicated to any colder body. Every cook knows the great scalding power of steam, and is disposed to think that it is much hotter than boiling water. This, however, is a mistake; for it will raise the thermometer no higher than the water from which it comes. But we can assure the cook, that if he make the steam from the spout of a tea-kettle pass through a great body of cold water, it will be condensed or changed into water; and when one pound of water has in this manner been boiled off, it will have heated the mass of cold water as much as if we had thrown into it seven or eight hundred pounds of boiling hot water.

If, therefore, a boiler be properly fitted up in a furnace, and if the steam of the water boiling in it be conveyed by a pipe into a pan containing victuals to be dressed, every thing can be cooked that requires no higher degree of heat than that of boiling water. And this will be done without any risk of scorching, or any kind of overheating, which frequently spoils our dishes, and proceeds from the burning heat of air coming to those parts of the pot or pan which is not filled with liquor, and is covered only with a film, which quickly burns and taints the whole dish. Nor will the cook be scorched by the great heat of the open fire that is necessary for dressing at once a number of dishes, nor have his
his person and clothes soiled by the smoke and soot unavoidably in the cooking on an open fire. Indeed the whole process is so neat, so manageable, so open to inspection, and so cleanly, that it need neither fatigue nor offend the delicacy of the nicest lady.

We had great doubts, when we first heard of this as a general mode of cookery, as to its economy; we had none as to its efficacy. We thought that the steam, and consequently the fuel expended, must be vastly greater than by the immediate use of an open fire; but we have seen a large tavern dinner expeditiously dressed in this manner, seemingly with much less fuel than in the common method. The following simple narration of facts will show the superiority. In a paper manufacturer in this neighborhood, the vats containing the pulp into which the frames are dipped are about six feet diameter, and contain above 200 gallons. This is brought to a proper heat by means of a small cockle or furnace in the middle of the liquor. This is heated by putting in about one hundred weight of coal about eight o'clock in the evening, and continuing this till four next morning, renewing the fuel as it burns away. This method was lately changed for a steam heater. A furnace, having a boiler of five or six feet diameter and three feet deep, is heated about one o'clock in the morning with two hundred weight of coal, and the water kept in brisk ebullition. Pipes go off from this boiler to six vats, some of which are at 90 feet distance. It is conveyed into a flat box or vessel in the midst of the pulp, where it condenses, imparting its heat to the sides of the box, and thus heats the surrounding pulp. These six vats are as completely heated in three hours, expending about three hundred weight of coal, as they were formerly in eight hours, expending near eighteen hundred weight of coal. Mr. Gregory, the inventor of this steam-heater, has obtained (in company with Mr. Scott, plumber, Edinburgh) a patent for the invention; and we are persuaded that it will come into very general use for many similar purposes. The dyers, hatters, and many other manufacturers, have occasion for large vats kept in a continual heat; and there seems no way so effectual.

Indeed when we reflect seriously on the subject, we see that this method has immense advantages considered merely as a mode of applying heat. The steam may be applied to the vessel containing the victuals in every part of its surface: it may even be made to enter the vessel, and apply itself immediately to the piece of meat that is to be dressed, and this without any risk of scorching or overdoing.—And it will give out about 75% of the heat which it contains, and will do this only if it be wanted; so that no heat whatever is wasted except what is required for heating the apparatus. Experience shows that this is a mere trifle in comparison of what was supposed necessary. But with an open fire we only apply the flame and hot air to the bottom and part of the sides of our boiling vessels: and this application is hurried in the extreme; for to make a great heat, we must have a great fire, which requires a prodigious and most rapid current of air. This air, too hot to come into our pans but for a moment, imparts to them but a small portion of its heat; and we are persuaded that three-fourths of the heat is carried up the chimney, and escapes in pure waste, while another great portion beams out into the kitchen to the great annoyance of the scorched cook.

We think, therefore, that a page or two of this work will not be thrown away in the description of a contrivance by which a saving may be made to the enter-tainer, and the providing the pleasures of his table prove a less fatiguing task to this valuable corps of practical chemists.

Let A (fig. 1.) represent a kitchen-boiler, either properly fitted up in a furnace, with its proper fire-place, ash-pit, and flue, or set on a tripod on the open fire, or built up in the general fire-place. The steam-pipe B C rises from the cover of this boiler, and then is led away with a gentle ascent in any convenient direction. C represents the section of this conducting steam-pipe. Branches are taken off from the side at proper distances. One of these is represented at C D E, furnished with a cock D, and having a tap or nozzle L, fitted by grinding into a conical piece F, which communicates with an upright pipe G H, which is soldered to the side of the stewing vessel P Q R S, communicating with it by the short pipe I. The vessel is fitted with a cover O T, having a staple handle V. The piece of meat M is laid on a tin-plate grate K L, pierced with holes like a cullender, and standing on three short feet n n n.

The steam from the boiler comes in by the pipe I, and is condensed by the meat and by the sides of the vessel, communicating to them all its heat. What is not so condensed escapes between the vessel and its cover. The condensed water lies on the bottom of the vessel, mixed with a very small quantity of gravy and fatty matter from the victuals. Frequently, instead of a cover, another stew-vessel with a cullender bottom is set on this one, the bottom of the one fitting the mouth of the other: and it is observed, that when this is done, the dish in the under vessel is more expeditiously and better dressed, and the upper dish is more slowly, but as completely, stewed.

This description of one stewing vessel may serve to give a notion of the whole; only we must observe, that when broths, soups, and dishes with made sauces or containing liquids, are to be dressed, they must be put into a smaller vessel, which is set into the vessel P Q R S, and is supported on three short feet, so that there may be a space all around it of about an inch or three quarters of an inch. It is observed, that dishes of this kind are not so expeditiously cooked as on an open fire, but as completely in the end, only requiring to be turned up now and then to mix the ingredients; because as the liquids in the inner vessel can never come into ebullition, unless the steam from the boiler be made of a dangerous heat, and every thing be close confined, there cannot be any of that tumbling motion that we observe in a boiling pot.

The performance of this apparatus is far beyond any expectation we had formed of it. In one which we examined, six pans were stewing together by means of a boiler 15½ inches in diameter, standing on a brisk open fire. It boiled very briskly, and the steam pulled frequently through the chinks between the stew-pans and their covers. In one of them was a piece of meat considerably above 20 pounds weight. This required above four hours stewing, and was then very thoroughly and equally cooked; the outside being no more done than the heart, and it was near two pounds heavier than when put in, and greatly swelled. In the mean time, several dishes had been dressed in the other pans. As
far as we could judge, this cooking did not consume
one-third part of the fuel which an open fire would
have required for the same effect.

When we consider this apparatus with a little more
knowledge of the mode of operation of fire than falls
to the share of the cooks (we speak with deference),
and consider the very injudicious manner in which the
steam is applied, we think that it may be improved so
as to surpass any thing that the cook can have a notion
of.

When the steam enters the stew-pan, it is condensed
on the meat and on the vessel; but we do not want it
to be condensed on the vessel. And the surface of the
vessel is much greater than that of the meat, and con-
tinues much colder; for the meat grows hot, and con-
tinues so, while the vessel, made of metal, which is a
very perfect conductor of heat, is continually robbed
of its heat by the air of the kitchen, and carried off by
it. If the meat touch the side of the pan in any part,
no steam can be applied to that part of the meat, while
it is continually imparting heat to the air by the inter-
medium of the vessel. Nay, the meat can hardly be
dressed unless there be a current of steam through it;
and we think this confirmed by what is observed above,
that when another stew-pan is set over the first, and thus
gives occasion to a current of steam through its cullen-
deer bottom to be condensed by its sides and contents,
the lower dish is more expeditiously dressed. We ima-

...
ROOFS Heated by STEAM.
STEAM applied to Heating Rooms. Steam has been successfully applied as a substitute for open fires in heating manufactories, and promises to be highly beneficial, not only in point of economy in saving fuel, but also in lessening the danger of accidental fire. The following mode of heating a cotton mill by steam was proposed and practised in 1799 by Mr. Neil Snodgrass of Paisley.

We shall give an account of it in his own words.

"Fig. 1. presents a view of an inner gable, which is at one extremity of the preparation and spinning rooms of the mill. On the other side of this gable there is a space of 17 feet, enclosed by an outer gable, and containing the water-wheel, the staircase, and small rooms for the accommodation of the work. In this space the furnace and boiler are placed on the ground. The boiler cannot be shown here, as it lies behind the gable exhibited; nor is it of any consequence, as there is nothing peculiar in it. It may be of any convenient form. The feeding apparatus, &c. are in every respect the same as in the boiler of a common steam-engine. A circular copper boiler, two feet diameter by two feet deep, containing 32 gallons of water, with a large copper head as a reservoir for the steam, was found to answer in the present instance. The steam is conveyed from the boiler through the gable, by the copper pipe B, into the tin pipe, C, C. From C it passes to the centres of the perpendicular pipes E, E, E, by the small bent copper tubes D, D, D. The pipes E, E, E, are connected under the garret floor by the tubes F, F, for the more easy circulation of the steam. The middle pipe, E, is carried through the garret floor, and communicates with a lying pipe, 36 feet in length (the end of which is seen at G), for heating the garret. At the further extremity of the pipe G, there is a valve falling inwards to prevent a vacuum being formed on the cooling of the apparatus; the consequence of which would be the crushing of the pipes by the pressure of the atmosphere. Similar valves K, K, are placed near the top of the perpendicular pipes, E, E, E, and from the middle one E, the small pipe passes through the roof, and is furnished with a valve at I, opening outwards, to suffer the air to escape while the pipes are filling with steam, or the steam itself to escape when the charge is too high.

The water condensed in the perpendicular pipes E, E, E, tricks down their sides into the three funnels L, L, L, the necks of which may either pass through or round the pipe C, into the copper tube M, M, which also receives the water condensed in C, C by means of the short tubes N, N. The pipe C, C, is itself so much inclined as to cause the water to run along it to the tubes N, N, and the pipe G in the garret has an inclination of 18 inches in its length, to bring the water condensed in it back to the middle pipe E. The tube M, M, carries back the water through the gable to the boiler, which stands five feet lower than this tube. It is material to return the water to the boiler, as, being nearly at a boiling heat, a considerable expence of fuel is thereby saved.

"The large pipes are ten inches in diameter, and are made of the second kind of tinned iron plates. The dimensions of the smaller tubes may be seen by their comparative size in the engraving, and perhaps they might be varied without inconvenience.

"The apparatus erected as here described, has been found sufficiently strong, and has required no material repairs.
Steam repairs since the first alterations were made. The leading object in the instance under consideration being to save fuel, in order to derive as much heat as possible from a given quantity of fuel, the flue from the furnace, which heats the boiler, is conveyed into common stone pipes placed in the gable. These are erected so as to prevent any danger of fire, in the manner shown in the engraving, fig. 2. The steam with this auxiliary communicates a heat of about 70° to the mill, the rooms of which are 50 feet long, 32 feet wide, and 86 feet high, except the lower story and garret; the former of which is 11, and the latter seven feet high. The rooms warmed in this manner are much more wholesome and agreeable than those heated by the best constructed stoves, being perfectly free from vapour or contaminated air.

The application of the principle to buildings already constructed, it is presumed, will be sufficiently obvious from the foregoing details. In new manufactories, where the mode of heating may be made a part of the original plan, a more convenient apparatus may be introduced. This will be best explained by a description of fig. 2, which gives a section of a cotton-mill constructed so as to apply the steam apparatus to a new building.

The furnace for the boiler is shown at a (fig. 2.) The flue of the furnace conveys the smoke into the cast iron stove pipes, 1, 2, 3, 4. These pipes are placed in a space in the gable, entirely inclosed with brick, except at the small apertures, 5, 6, 7, 8. A current of air is admitted below at g, and thrown into the rooms by those openings, after being heated by contact with the pipes. This part of the plan is adopted with a view to prevent, as much as possible, any of the heat, produced by the fuel used, from being thrown away. It may be omitted where any accident of fire is apprehended from it, and the smoke may be carried off in any way that is considered absolutely secure. So far, however, as appears from experience, there seems to be little or no danger of fire from a stove of this construction. The greatest inconvenience of a common stove is, that the coakle or metal furnace is liable to crack from the intensity of the heat. By the continuity of the metal from the fireplace, an intense heat is also conducted along the pipes, which exposes them to the same accident. Here the smoke being previously conveyed through a brick flue, can never communicate to the pipes a degree of heat sufficient to crack them. In like manner the pipes, having no communication with the rooms but by the small apertures, cannot come in contact with any combustible substance; and from being surrounded with air, which is constantly changing, can impart only a very moderate degree of heat to the walls. The iron supporters of the pipes may be imbedded in some substance which is a bad conductor of heat, as furnace ashes and lime, &c. The emission of heated air into the rooms may be regulated by valves. As the pipes are not exposed to cracking, there is no risk of their throwing smoke or vapour into the rooms.

The boiler b, b, is six feet long, three and a half broad, and three feet deep. As there is nothing peculiar in the feeding apparatus, it is omitted. The boiler may be placed in any convenient situation. Where a steam engine is used for other purposes, the steam may be taken from its boiler. The pipe c, c, conveys the steam from the boiler to the first perpendicular pipe d, d, d, d. There is an expanding joint at g, stuffed, to make it steam-tight. The steam ascending in the first pipe d, d, d, enters the horizontal pipe f, f, f, f, (which is slightly inclined) expelling the air, which partly escapes by the valve g, and is partly forced into the other pipes. The valve g being considerably loaded, forces the accumulating steam down into the rest of the pipes d, d, d. The air in these pipes recedes before the steam, and is forced through the tubes h, h, h, into the pipe m, m, m, whence it escapes at the valve k, and the syphon k. The water, condensed in the whole of the pipes, passes also through the tubes h, h, h, h, into the pipe m, m, m, which has such a declivity as to discharge the water at the syphon k, into the hot well n, whence it is pumped back into the boiler.

The whole of the pipes are of cast iron, except m, m, m, which is of copper. The perpendicular pipes serve as pillars for supporting the beams of the house, by means of the projecting pieces o, o, o, which may be raised or lowered at pleasure by the wedges p, p, p. The pipes are sunk in the beams about an inch, and are made fast to them by the iron straps q, q. Those in the lower story rest on the stones, s, s, s, s, and are made tight at the junction with stuffing. The pipe in each story supports the one in the story above by a stuffed joint as shown at r. The pipes in the lower story are seven inches in diameter; those in the higher six inches; those in the other two are of intermediate diameters. The thickness of the metal is three-eighths of an inch. The lower pipes are made larger than the upper, in order to expose a greater heated surface in the lower rooms, because the steam being thrown from above into all the pipes, except the first, would otherwise become incapable of imparting an equal heat as it descends. There is no necessity for valves, opening inwards in this apparatus, the pipes being strong enough to resist the pressure of the atmosphere.

The cotton mill is 60 feet long, 33 wide, and four stories high, the upper being a garret story. In the engraving, five parts out of nine in the length of the building are only shown. The apparatus will heat the rooms to 85° in the coldest season. It is evident that, by increasing the size or the number of the pipes, and the supply of steam, any degree of heat up to 212° may be easily produced. It may even be carried beyond that point by an apparatus strong enough to compress the steam: this, however, can seldom be wanted. At first it was objected to this construction, that the expansion of the pipes, when heated, might damage the building; but experience has proved, that the expansion occasioned by the heat of steam is quite insensible.

Steam has also been advantageously employed in drying muslin goods, when the state of the weather interrupts this process out of doors. This application of steam, we understand, was the invention of an ingenious mechanic in Paisley, who never derived the smallest benefit from the discovery. It was adopted immediately by some bleachers in the neighbourhood, and has now come into very general use. The steam is introduced into cylinders of tin plate, and the goods to be dried are wrapped round the cylinders which communicate to them a heat equal at least to the temperature of boiling water, and in this way the process of drying is expeditiously accomplished.

STEATITES, or Soap-earth, a species of mineral belonging
STEEL, iron united with carbon, from which it possesses properties distinct from those of iron, and which render it of superior value. From its higher degree of hardness, it admits a finer polish and assumes a brighter colour. When tempered, it possesses a higher degree of elasticity, and is also more sonorous. It is more weakly attracted by the lodestone, it receives more slowly the magnetic power, but it preserves it longer. When exposed to a moist air, it does not contract rust so easily as iron. See Iron, Chemistry Index.

Steel-Bow Tenants. See Tenure.

Steel-Yard, is one of the most ancient presents which science has made to society; and though long in desuetude in this country, is in most nations of the world the only instrument for ascertaining the weight of bodies. What is translated balance in the Pentateuch, is in fact steeleward, being the word used by the Arabs to this day for their instrument, which is a steeleward. It is in common use in all the Asiatic nations. It was the staterea of the Greeks and Romans, and seems to have been more confided in by them than the balance; for which reason it was used by the goldsmiths, while the balance was the instrument of the people. —Non aurifexi staterea sed populi trutina examinare. Cic. de Orat. 238.

The steeleward is a lever of unequal arms, and, in its most perfect form, is constructed much like a common balance. It hangs in sheers E (fig. 1. resting on the nail C, and the scale L for holding the goods hangs by a nail D on the short arm BC. The counter weight P hangs by a ring of tempered steel, made sharp in the inside, that it may bear by an edge on the long arm CA of the steeleward. The under edge of the centre nail C, and the upper edge of the nail D, are in the straight line formed by the upper edge of the long arm. Thus the three points of suspension, as the weight P, the head of the needle, and the edge of the short arm, are on parallel lines. The needle or index of the steeleward is perpendicular to the line of the arms, and plays between the sheers. The short arm may be made so massive, that, together with the scale, it will balance the long arm unloaded. When no goods are in the scale, and the counter weight with its hook are removed, the steeleward acquires a horizontal position, in consequence of its centre of gravity being below the axis of suspension. The rules for its accurate construction are the same as for a common balance.

The instrument indicates different weights in the following manner: The distance CD of the two nails is considered as an unit, and the long arm is divided into a number of parts equal to it; and these are subdivided as low as is thought proper; or in general, the long arm is made a scale of equal parts, commencing at the edge of the nail C, and the short arm contains some determined number of those equal parts. Suppose, then, that a weight A of 10 pounds is put into the scale L. The counterpoise P must be of such a weight, that, when hanging at the division 10, it shall balance this weight A. Now let any unknown weight W be put into the scale. Slide the hook of the counterpoise along the long arm till it balances this weight. Suppose it then hanging at the division 38. We conclude that there is 38 pounds in the scale. This we do on the authority of the fundamental property of the lever, that forces acting on it, and balancing each other, are in the inverse proportion of the distances from the fulcrum to their lines of direction. Whatever weight the counterpoise is, it is to A as CD to 10, and it is to the weight W as CD to 38: therefore A is to the weight W as 10 to 38, and W is 38 pounds: and thus the weight in the scale will always be indicated by the division at which it is balanced by the counterpoise.

Our well-informed readers know that this fundamental property of the lever was discovered by the renowned Archimedes, or at least first demonstrated by him; and that his demonstration, besides the defect of being applicable only to commensurable lengths of the arms, has been thought by metaphysicians of the first note to proceed on a postulate which seems equally to need a demonstration. It has accordingly employed the utmost refinement of the first mathematicians of Europe to furnish a demonstration free from objection. Mr D'Alembert has given two, remarkable for their ingenuity and subtlety; Fouchez has done the same; and Professor Hamilton of Trinity College, Dublin, has given one which is thought the least exceptional. But critics have even objected to this, as depending on a postulate which should have been demonstrated.

The following demonstration by Mr Vince, we think unexceptionable, and of such simplicity that it is aston-Phil.Trans. Phishing that it has not occurred to any person who thinks 1794. on the subject.

Let AE (fig. 2.) be a mathematical lever, or inclinable straight line, resting on the prop A, and supported at D by a force acting upwards. Let two equal weights b and d be hung on at B and D, equidistant from A and E. Pressures are now exerted at A and E; and because every circumstance of weight and distance is the same, the pressure at E, arising from the action of the weight b on the point B, must be the same with the pressure at A, arising from the action of the weight d on the point D; and the pressure at E, occasioned by the weight b, must be the same with the pressure at A, occasioned by the weight d. This must be the case wherever the weights are hung, provided that the distances AB and DE are equal. Moreover, the sum of the pressures at A and E is unquestionably equal to the sum of the weights, because the weights are supported solely at A and E. The two weights are hung on at C the middle point; the pressure at E is still the same. Therefore, in general, the pressure excited at the point E, by two equal weights hanging at any points B and D, is the same as if they were hung on at the middle point between them; but the pressure excited at E is a just measure of the effort or energy of the weights b and d to urge the lever round the point A. It is, at least, a measure of the opposite force which must be applied at E to sustain or balance this pressure. A very fastidious metaphysician may still say, that the demonstration is limited to a point E, whose distance from A is twice AC, or =AB + AD. But it extends to any other point, on the authority of a postulate which cannot be refused, viz. that in whatever proportion the pressure at E is augmented or diminished, the pressure at this other point must augment or diminish in the same proportion. This being proved, the general theorem may be demonstrated.
Steel yarded in all proportions of distance, in the manner of Archimedes, at once the most simple, perspicuous, and elegant of all.

We cannot help observing, that all this difficulty (and it is a real one to the philosopher who aims at rendering mechanics a demonstrative science) has arisen from an improper search after simplicity. Had Archimedes taken a lever as it really exists in nature, and considered it as material, consisting of atoms united by cohesion; and had he traced the intermediate pressures by whose means the two external weights are put in opposition to each other, or rather to the support given to the fulcrum; all difficulty would have vanished. (See what is said on this subject in the article STRENGTH of TIMBER, &c.).

The quantity of goods which may be weighed by this instrument depends on the weight of the counterpoise, and on the distance CD from the fulcrum at which the goods are suspended. A double counterpoise hanging at the same division will balance or indicate a double quantity of goods hanging at DC; and any counterpoise will balance and indicate a double quantity of goods, if the distance CD be reduced to one half. And it sometimes occurs that steelyards are so constructed that they have two or more points of suspension D, to which the scale may occasionally be attached. It is evident, that in this case the value or indication of the division of the long arm will be different, according to the point from which the scale is suspended. The same division which would indicate 20 pounds when CD is three inches, will indicate 30 pounds when it is two inches. As it would expose to chance of mistakes, and be otherwise troublesome to make this reduction, it is usual to make as many divided scales on the long arm as there are points of suspension D on the short arm; and each scale having its own numbers, all trouble and all chance of mistake is avoided.

But the range of this instrument is not altogether at the pleasure of the maker. Beside the inability of a slender beam to carry a great load, the divisions of the scale answering to pounds or half-pounds become very minute when the distance CD is very short; and the balance becomes less delicate, that is, less sensibly affected by small differences of weight. This is because in such cases the thickness which is necessary to give the edges of the nails does then bear a sensible proportion to the distance CD between them; so that when the balance inclines to one side, that arm is sensibly shortened, and therefore the energy of the preponderating weight is lessened.

We have hitherto supposed the steelyard to be in equilibrio when not loaded. But this is not necessary, nor is it usual in those which are commonly made. The long arm commonly preponderates considerably. This makes no difference, except in the beginning of the scale. The preponderancy of the long arm is equivalent to some goods already in the scale, suppose four pounds. Therefore when there are really 10 pounds in the scale, the counterpoise will balance it when hanging at the division 6. This division is therefore reckoned 10, and the rest of the divisions are numbered accordingly.

A scientific examination of the steelyard will convince us that it is inferior to the balance of equal arms in point of sensibility: But it is extremely comprehensible and convenient; and when accurately made and extensively used, it is abundantly exact for most commercial purposes. We have seen one at Leipzig which has been in use since the year 1718, which is very sensible to a difference of one pound, when loaded with nearly three tons on the short arm; and we saw a wagon loaded with more than two tons weighed by it in about six minutes.

The steelyard in common use in the different countries of Europe is of a construction still simpler than what we have described. It consists of a batten of hard wood, having a heavy lump A (fig. 3.) at one end, and fig. 5 a swivel-hook B at the other. The goods to be weighed are suspended on the hook, and the whole is carried in a loop of whip-cord C, in which it is slid backward and forward, till the goods are balanced by the weight of the other end. The weight of the goods is estimated by the place of the loop on a scale of divisions in harmonic progression. They are marked (we presume) by trial with known weights.

The chief use that is now made of the steelyard in these kingdoms is for the weighing of loaded waggons and carts. For this it is extremely convenient, and more than sufficiently exact for the purpose in view. We shall describe one or two of the most remarkable; and we shall begin with that at Leipzig already mentioned.

This steelyard is represented in fig. 4. as run out, Fig. 4. and just about to be hooked for lifting up the load. The steelyard itself is OPQ, and is about 12 feet long. The short arm PQ has two points of suspension c and b; and the stirrup which carries the chains for holding the load is made with a double hook, instead of a double eye, that it may be easily removed from the one pin to the other. For this purpose the two hooks are connected above an haup or staple, which goes over the arm of the steelyard like an arch. This is represented in the little figure above the steelyard. The suspension is shifted when the steelyard is under cover, by hooking to this staple the running block of a small tackle which hangs in the door through which the steelyard is run out and in. This operation is easy, but necessary, because the stirrup, chains, and the stage on which the load is placed, weigh some hundreds.

The outer pin b is 14 inches, and the inner one c is seven inches, distant from the great nail which rests in the sheers. The other arm is about 105 feet long, formed with an obtuse edge above. On the inclined plane on each side of the ridge is drawn the scale of weights adapted to the inner pin c. The scales corresponding to the outer pin b are drawn on the upright sides. The counterpoise slides along this arm, hanging from a saddle-piece made of brass, that it may not contract rust. The motion is made easy by means of rollers. This is necessary, because the counterpoise is greatly above a hundred weight. This saddle-piece has like two laps on each side, on which are engraved vernier scales, which divide their respective scales on the arm to quarters of a pound. Above the saddle is an arch, from the summit of which hangs a little plummet, which shows the equilibrium of the steelyard to the weigher, because the sheers are four feet out of the house; and he cannot see their coincidence with the needle of the steelyard. Lastly, near the end of the long arm, are
Sheet-yard are two pins $d$ and $e$, for suspending occasionally two eke weights for continuing the scale. These are kept hanging on adjoining hooks, ready to be lifted on by a little tackle, which is also hooked immediately above the pin $d$ and is the counterpoise $C$. Although the stirrup with its chains and stage weighs some hundreds, yet the length and size of the arm $OP$ gives it a preponderancy of 300 pounds. Here, then, the scale of weights must commence. The counterpoise weighs about 125 pounds. Therefore:

1. When the load hangs by the pin $d$, 14 inches from the centre, the distance from one hundred to another on the scale is about 11 inches, and the first scale (on the side of the arm) reaches from 300 to 1200. In order to repeat or continue this, the eke-weight $E$ is hung on the pin $c$, and the counterpoise $C$ is brought back to the mark 300; and the two together balance 1100 pounds hanging at $d$. Therefore a second scale is begun on the side of the arm, and continued as far out as the first, and therefore its extremity marks 2000; that is, the counterpoise $C$ at 2000 and the eke-weight $E$ at $c$ balance 2900 hanging at $a$. This is a scale and its balance.

2. To continue the scale beyond 2000, the load must be hung on the inner pin $c$. The eke-weight $E$ is taken off, and the eke-weight $D$ is hung on its pin $d$. The general counterpoise being now brought close to the sheers, it, together with the weight $D$ at $d$, balance 2000 pounds hanging at $c$. A scale is therefore begun on one of the inclined planes $a$-top, and continued out to 4000, which falls very near to the pin $d$, each hundred pounds occupying about five inches on the arm. To complete the scale, hang on the eke-weight $E$ on its pin $c$, and bring back the counterpoise to the sheers, and the three together balance 3800 hanging at $c$. Therefore when the counterpoise is now slid out to 4000, it must complete the balance with 3800 hanging at $c$.

It required a little consideration to find out what proportion of the three weights $C$, $D$, and $E$, would make the repetitions of the scale extend as far as possible, having very little of it expressed twice, or upon two scales, as is shown here. We see that the space corresponding to a single pound is a very sufficient quantity on both scales, being one-ninth of an inch on the first two scales, and one-twentieth on the last two. This very ponderous machine, with its massive weights, cannot be easily managed without some assistance from mechanics. It is extremely proper to have it susceptible of motion out and in, that it may be protected from the weather, which would soon destroy it by rust. The contrivance here is very effectual, and abundantly simple.

When the steel-yard is not in use, it is supported at one end by the iron rod $F$, into which the upper end of the sheers is hooked. The upper end of this rod has a strong hook $E$, and a little below at $a$ it is pierced with a hole, in which is a very strong bolt or pin of tempered steel, having a roller on each end close to the rod on each side. These rollers rest on two joists, one of which is represented by $MN$, which traverse the building, with just room enough between them to allow the rod $F$ to hang freely down. The other end $O$ of the steel-yard rests in the bight of a large flat hook: at the end of a chain $W$, which hangs down between steel-yard, the joists, and is supported on them by a frame with rollers $H$. This is connected with the rollers at $C$, which carry the sheers by means of two iron-rod, of which one only can be seen. These connect the two sets of rollers in such a manner that they must always move together, and keep their distance invariable. This motion is produced by means of an endless rope $HI$ ZLKVH passing over the pulleys $I$ and $K$, which turn between the joists, and hanging down in a height between them. It is evident that by pulling on the part $LZ$ we pull the frame of rollers in the direction $GH$, and thus bring the whole in the position marked by the dotted figure. It is also plain, that by pulling on the part $LK$ we force the roller frame and the whole apparatus out again.

It remains to show how the load is raised from the ground and weighed. When the steel-yard is run out for use, the upper hook $E$ just enters into the ring $D$, which hangs from the end of the great ashen lever $BCA$ about 23 feet long, turning on gudgeons at $C$ about 3 feet from this end. From the other end $A$ descends a long iron-rod $SR$, which has one side formed into a toothed rack that is acted on by a head of wheel-work turned by an endless screw and winch $Q$. Therefore when the hook $E$ is well engaged in the ring $D$, a man turns the winch, and then brings down the end $A$ of the great lever, and raises the load two or three inches from the ground. Everything is now at liberty, and the weigher now manages his weights on the arm of the steel-yard till he has made an equilibrium.

We need not describe the operation of letting down the load, disengaging the steel-yard from the great lever, and bringing it again under cover. The whole of this service is performed by two men, and may be done in succession by one, and is over in five or six minutes.

The most compendious and economical machine of this kind that we have seen is one, first used (we have heard) for weighing the riders of race-horses, and afterwards applied to the more reputable service of weighing loaded carriages. Fig. 5 is a plan of the machine. KLMN is the plan of a rectangular box, which has a platform lid or cover, of size sufficient for placing the wheels of a cart or waggon. The box is about a foot deep, and is sunk into the ground till the platform cover is even with the surface. In the middle of the box is an iron lever supported on the fulcrum pin $i$, formed like the nail of a balance, which rests with its edge on arches of hardened steel firmly fastened to the bottom of the box. The lever goes through one side of the box, and is furnished at its extremity with a hard steel pin $l$, m, also formed to an edge below. In the very middle of the box it is crossed by a third nail of hardened steel $g$, also formed to an edge, but on the upper side. These three edges are in one horizontal plane, as in a well-made balance.

In the four corners $A$, $A'$, $E'$, $E$, of the box are firmly fixed four blocks of tempered steel, having their upper surfaces formed into spherical cavities, well polished and hard tempered. ABCDE represents the upper edge of an iron bar of considerable strength, which rests on the cavities of the steel blocks in $A$ and $E$, by means
Steel-yard. One of two hard steel studs projecting from its under edge, and formed into obtuse-angled points or cones. These points are in a straight line parallel to the side KN of the box. The middle part C of this crooked bar is faced with hard tempered steel below, and there formed into an edge parallel to AE and KN, by which it rests on the upper edge of the steel pin g h which is in the lever. In a line parallel to AE, and on the upper side of the crooked bar ACE, are fixed two studs or points of hardened steel B and D projecting upwards above half an inch. The platform-cover has four short feet like a stool, terminated by hard steel studs, which are shaped into spherical cavities and well polished. With these it rests on the four steel points B, B', D, D'. The bar ACE is kneed in such a manner vertically, that the points A, B, D, E and the edge C are all in a horizontal plane. These particulars will be better understood by looking at the elevation in fig. 6. What has been said of one point must be understood as also said of the bar A'C'E'.

Draw through the centre of the box the line a'b'c' perpendicular to the line AE, BD. It is evident that the bar ACE is equivalent to a lever a'b'c', having the fulcrum or axis AE resting with its extremity C on the pin g h and loaded at b. It is also evident that c C is to a b as the load on this lever to the pressure which it exerts on the pin g h, and that the same proportion subsists between the whole load on the platform and the pressure which it exerts on the pin g h. It will also appear, on an attentive consideration, that this proportion is nowhere deranged in whatever manner the load is placed on the platform. If very unequally, the two ends of the pin g h may be unequally pressed, and the lever wrenched and strained a little; but the total pressure is not changed.

If there be now placed a balance or steelyard at the side LK, in such a manner that one end of it may be directly above the pin lm in the end of the lever EOF, the same may be connected by a wire or slender rod, and a weight on the other arm of the balance or steelyard may be put in equilibrio with any load that can be laid on the platform. A small counterpoise being first hung on to balance the apparatus when unloaded, any additional weight will measure the load really laid on the platform. If a b be to a c as 1 to 8, and EO to EP, also as 1 to 8, and if a common balance be used above, 64 pounds on the platform will be balanced by one pound in the scale, and every pound will be balanced by \(\frac{1}{4}\)th of an ounce. This would be a very convenient partition for most purposes, as it would enable us to use a common balance and common weights to complete the machine: Or it may be made with a balance of unequal arms, or with a steelyard.

Some have thought to improve this instrument by using edges like those of the nails of a balance, instead of points. But unless made with uncommon accuracy, they will render the balance very dull. The small deviation of the two edges A and E, or of B' and D', from perfect parallelism to KN, is equivalent to a broad surface equal to the whole deviation. We imagine that, with no extraordinary care, the machine may be made to weigh within \(\frac{1}{4}\)th of the truth, which is exact enough for any purpose in commerce.

It is necessary that the points be attached to the bars. Some have put the points at A and E in the blocks of steel fastened to the bottom, because the instrument there lodged water or dirt, which soon destroyed the steel with rust. But this occasions a change of proportion in the first lever by any shifting of the crooked bars; and this will frequently happen when the wheels of a loaded cart are pushed on the platform. The cavity in the steel should have a little rim round it, and it should be kept full of oil. In a nice machine a quarter of an inch of quicksilver would effectually prevent all these inconveniences.

The simplest and most economical form of this machine is to have no balance or second steelyard; but make the first steelyard EOF a lever of the first kind, viz. having the fulcrum between O and F, and allow it to project far beyond the box. The long or outward arm of this lever is then divided into a scale of weights, commencing at the side of the box. A counterpoise must be chosen, such as will, when at the beginning of the scale, balance the smallest load that will probably be examined. It will be convenient to go on carry on this scale by means of eke-weights hung on at the extremity of the lever, and to use but one moveable weight. By this method the divisions of the scale will always have one value. The beginning of the arrangement is as follows: Place the mark O at the beginning of the scale, and let it extend only to 100, if for pounds; or to 112, if for cwt.s; or to 10, if for stones; and let the eke-weight be numbered 1, 2, 3 &c. Let the lowest weight be marked on the beam. This is always to be added to the weight shown by the operation. Let the eke-weights stand at the end of the beam, and let the general counterpoise always hang at O. When the cart is put on the platform, the end of the beam tilts up. Hang on the heaviest eke-weight that is not sufficient to press it down. Now complete the balance by sliding out the counterpoise. Suppose the constant load to be 31 lb. and that the counterpoise stands at 86, and that the eke-weight is 9 lbs.; we have the load \(208 + 31.2 = 239.2\). STEELE, Sir Richard, was born about the year 1676 in Dublin; in which kingdom one branch of the family was possessed of a considerable estate in the county of Wexford. His father, a counsellor at law in Dublin, was private secretary to James duke of Ormond; but he was of English extraction: and his son, while very young, being carried to London, he put him to school at the Charter-house, whence he was removed to Merton College in Oxford. Our author left the university, which he did without taking any degree, in the full resolution to enter into the army. This step was highly displeasing to his friends; but the ardour of his passion for a military life rendered him deaf to any other proposal. Not being able to procure a better station, he entered as a private gentleman in the house guards, notwithstanding he thereby lost the succession to his Irish estate. However, as he had a flow of good nature, a generous openness and frankness of spirit, and a sparkling vivacity of wit, these qualities rendered him the delight of the soldiery, and procured him an ensign’s commission in the guards. In the mean time, as he had made choice of a profession which set him free from all the ordinary restraints in youth, he spared not to indulge his inclinations in the wildest excesses. Yet his gaieties and revels did not pass without some cool hours of reflection; it was in these that he drew up his little treatise entitled...
The Christian Hero, with a design, if we may believe himself, to be a check upon his passions. For this purpose it had lain some time by him, when he printed it in 1701, with a dedication to Lord Clive, who had not only appointed him his private secretary, but procured for him a company in Lord Lucas’s regiment of fusiliers.

The same year he brought out his comedy called The Funeral, or Grief à la Mode. This play procured him the regard of King William, who resolved to give him some essential marks of his favour; and though, upon that prince’s death, his hopes were disappointed, yet, in the beginning of Queen Anne’s reign, he was appointed to the profitable place of gazetteer. He owed this post to the friendship of Lord Halifax and the earl of Sunderland, to whom he had been recommended by his schoolfellow Mr Addison. That gentleman also lent him a helping hand in promoting the comedy called The Tender Husband, which was acted in 1704 with great success. But his next play, The Lying Lover, had a very different fate. Upon this rebuff from the stage, he turned the same humorous current into another channel; and early in the year 1709, he began to publish the Tatler: which admirable paper was undertaken in concert with Dr Swift. His reputation was perfectly established by this work; and, during the course of it, he was made a commissioner of the stamp duties in 1710. Upon the change of the ministry the same year, he joined the duke of Marlborough, who had several years entertained a friendship for him; and upon his Grace’s dismissal from all employments in 1711, Mr Steele addressed a letter of thanks to him for the services which he had done to his country. However, as our author still continued to hold his place in the stamp-office under the new administration, he wisely declined the discussion of political subjects; and, adhering more closely to Mr Addison, he dropped the Tatler, and afterwards, by the assistance chiefly of that steady friend, he carried on the same plan, much improved, under the title of The Spectator. The success of this paper was equal to that of the former; which encouraged him, before the close of it, to proceed upon it. Upon Stockbridge in Hampshire, took his seat accordingly in the house of commons; but was expelled thence in a few days after, for writing the close of the paper called the Englishman, and one of his political pieces intitled the Crisis. Presently after his expulsion, he published proposals for writing the history of the duke of Marlborough; at the same time he also wrote the Spinster; and, in opposition to the Examiner, he set up a paper called the Reader, and continued publishing several other things in the same spirit till the death of the queen. Immediately after which, as a reward for these services, he was taken into favour by her successor to the throne, King George I. He was appointed surveyor of the royal stables at Hampton Court, governor of the royal company of comedians, put into the commission of the peace for the county of Middlesex, and in 1715 received the honour of knighthood. In the first parliament of that king, he was chosen member for Boroughbridge in Yorkshire; and, after the suppression of the rebellion in the north, was appointed one of the commissioners of the forfeited estates in Scotland. In 1718, he buried his second wife, who had brought him a handsome fortune and a good estate in Wales; but neither this, nor the ample additions lately made to his income, were sufficient to answer his demands. Their best hopes, however, and his spirit often reduced him to little shifts of wit for its support; and the project of the fish-pool this year owed its birth chiefly to the projector’s necessities.

This vessel was intended to carry fish alive, and without wasting, to any part of the kingdom: but notwithstanding all his towering hopes, the scheme proved very ruinous to him; for after he had been at an immense expense in contriving and building his vessel, besides the charge of the patent, which he had procured, it turned out upon trial to be a mere project. His plan was to bring salmon alive from the coast of Ireland; but these fish, though supplied by this contrivance with a continual stream of water while at sea, yet uneasy at their confinement, shattered themselves to pieces against the sides of the pool; so that when they were brought to market they were worth very little.

The following year he opposed the remarkable peerage bill in the house of commons; and, during the course of this opposition to the amending acts was revoked, and his patent rendered ineffectual, at the instance of the lord chamberlain. He did his utmost to prevent so great a loss; and finding every direct avenue of approach to his royal master effectually barred against him by his powerful adversary, he had recourse to the method of applying to the public, in hopes that his complaints would reach the ears of his sovereign, though in an indirect course, by that canal. In this spirit he formed the plan of a periodical paper, to be published twice a week, under the title of the Theatre; the first number of which came out on the 2d of January 1719-20. In the mean time, the misfortune of being out of favour at court, like other misfortunes, drew after it a train of more. During the course of this paper, in which he had assumed the cognomen of Sir John Edgar, he was outrageously attacked by Mr Dennis, the noted critic, in a very abusive pamphlet, entitled The character and Conduct of Sir John Edgar. This insult our author made a proper reply in the Theatre.

While he was struggling with all his might to save himself from ruin, he found time to turn his pen against the mischievous South Sea scheme, which had nearly brought...
brought the nation to ruin in 1720; and the next year he was restored to his office and authority in the play-house in Drury-Lane. Of this it was not long before he made an additional advantage, by bringing his celebrated comedy called the Conscious Lovers upon that stage, where it was acted with prodigious success; so that the receipt there must have been very considerable, besides the profits accruing by the sale of the copy, and a purse of 200l. given to him by the king, to whom he dedicated it. Yet notwithstanding these ample supplies, about the year following being reduced to the utmost straitness, he sold his house in the play-house; and soon after commenced a suit-law in the courts, which in 1726 was decided against him. Having now, again, for the last time, brought his fortune by the most heedless profusion, into a desperate condition, he was rendered altogether incapable of retrieving the loss, by being seized with a paralytic disorder, which greatly impaired his understanding. In these unhappy circumstances, he retired to his seat at Langasco near Caermarthens in Wales, where he died on the 21st of September 1729, and was privately interred, according to his own desire, in the church of Caermarthens. Among his papers were found the manuscripts of two plays, one called The Gentlemen, founded upon the Eunuch of Tarsace, and the other intituled The School of Action, both nearly finished.

Sir Richard was a man of undissembled and extensive benevolence, a friend to the friendless, and, as far as his circumstances would permit, the father of every orphan. His works are chaste and manly. He was a stranger to the most distant appearance of envy or malevolence; never jealous of any man growing reputation; and so far from arrogating any praise to himself from his conjunction with Mr. Addison, that he was the first who desired him to distinguish his papers. His great fault was want of economy; and it has been said of him, he was certainly the most agreeable and the most innocent rake that ever trolled the rounds of dissipation.

STEEPLE, an appendage erected generally on the western end of churches, to hold the bells. Steeples are denominated from their form, either spires or towers: the first are such as ascend continually diminishing either conically or pyramidal; the latter are mere parallellopedoids, and are covered a-top platform-like.

STEEERING, on board a ship, that part of the ship next below the quarter-deck, before the bulk-head of the great cabin, where the steer-man stands, in most ships of war. See STEERING.

STEERING, in Navigation, the art of directing the ship's way by the movements of the helm; or of applying its effects to regulate her course when she advances.

The perfection of steering consists in a vigilant attention to the motion of the ship's head, so as to check every deviation from the line of her course in the first instant of its motion; and in applying as little of the power of the helm as possible. By this she will run more uniformly in a straight path, as declining less to right and left; whereas, if a greater effort of the helm is employed, it will produce a greater declination from the course, and not only increase the difficulty of steering, but also make a crooked and irregular track through the water. See HELM.—The helmsman should diligently watch the movements of the head by

the land, clouds, moon, or stars; because although steering, the course is in general regulated by the compass, yet Steerees the vibrations of the needle are not so quickly perceived as the silents of the ship's head to the right or left, which, if not immediately restrained, will acquire additional velocity in every instant of their motion, and demand a more powerful impulse of the helm to reduce them; the application of which will operate to turn her head as far on the contrary side of her course. —The phrases used in steering a ship vary according to the relation of the wind to her course. Thus, if the wind is fair or large, the phrases used by the pilot or officer who superintends the steering are, port, sternboard, and steady. The first is intended to direct the ship's course farther to the right; the second to guide her farther to the left; and the last is designed to keep her exactly in the line wherein she advances, according to the course prescribed. The excess of the first and second movements is called hard-to-port, and hard-to-sternboard; the former of which gives her the greatest possible inclination to the right, and the latter an equal tendency to the left.—If, on the contrary, the wind is foul or scant, the phrases are left, there, and no nearer; the first of which is the order to keep her close to the wind; the second, to retain her in her present situation; and the third to keep her sails full.

In a ship of war, the exercise of steering the ship is usually divided amongst a number of the most expert sailors, who attend the helm in their turns; and are accordingly called timoniers, from the French term timo nier, which signifies "helmsman." The steering is constantly superintended by the quarter-masters, who also attend the helm by rotation. In merchant ships, every seaman takes his turn in this service, being directed therein by the mate of the watch, or some other officer. As the safety of a ship, and all contained therein, depends in a great measure on the steerage or effects of the helm, the apparatus by which it is managed should often be diligently examined by the proper officers. Indeed, a negligence in this important duty appears almost unpardonable, when the fatal effects which may result from it are duly considered.

STEEVENS, GEORGE, the most successful of all the editors and commentators of Shakespeare, was born in the year 1735. We knew nothing respecting his parents, but they appear to have been in affluent circumstances. Our author received the rudiments of his education at Kingston-upon-Thames, and had Gibbon the historian for a companion at that school. From thence he went to Eton, and in a few years was admitted a fellow commoner of King's college, Cambridge; but no mention is made of his peculiar course of studies. It appears, however, that he had little relief for the mathematics, which lead at Cambridge to academical honours. On the first establishment of the Essex militia, he accepted of a commission; but he spent the concluding years of his life in almost total seclusion from the world, seldom mingling with society, but in the shops of booksellers, in the Shakespeare gallery, or in the morning conversations of Sir Joseph Banks.

Although not an original writer, we cannot in justice refuse him a place among the first literary characters of the age, when we consider the works he illustrated, and the learning, sagacity, taste, and general knowledge which he brought to the task. With a versatility of talents,
lents, he was eminent both by his pen and his pencil, but his chief excellence lay in his critical knowledge of an author’s text; and the best specimen of his great abilities is his edition of Shakespeare, in which he has left every competitor far behind him. He had studied the age of Shakespeare, and employed his persevering industry in becoming acquainted with the writings, manners, and laws of that period, as well as the provincial peculiarities, whether of language or customs, which prevailed in different parts of the kingdom, but more particularly in those where Shakespeare passed the early years of his life. He was continually increasing his store of knowledge, by the acquisition of the obsolete publications of a former age, which he spared no expense to obtain. His critical sagacity and observation were constantly employed in calling forth the hidden meanings of the dramatic bard, and of course enlarging the display of his beauties. This advantage is apparent from his last edition of Shakespeare, which contains so large a portion of new, interesting, and accumulated instruction. In preparing it for the press, he gave an instance of activity and perseverance without example. In this work he exclusively devoted a period of 18 months, during which he left his house every morning at one o’clock, going to his friend Mr. Isaac Read’s chambers in Barnard’s-inn, without any consideration of the weather or the season, and there he found a sheet of the Shakespeare letter-press ready for correction. Thus, while the printers slept the editor was awake, by which means he completed, in less than 20 months, his splendid edition of Shakespeare in 15 vols octavo; a labour almost incredible, and by which the energy and persevering powers of his mind were fully proved.

He probably rested satisfied with being a commentator from the particular habits of his life, and his devotion to the name of Shakespeare. But at the same time he was a classical scholar of the first order, and well acquainted with the belles lettres of Europe. He studied ancient and modern history; and particularly that of his own country. His genius was strong and original; his wit abundant; his imagination of every colour; and his sentiments enlivened with the most brilliant expressions. His eloquence was logical and animated; his descriptions were so true to nature, his figures so curiously selected, and so happily grouped, that he might be regarded as a speaking Hogarth. He scattered his wit and his humour too freely around him, and they were not lost for want of gathering.

Mr. Steevens had a very handsome fortune, which he managed with discretion. His generosity was equal to his fortune; and though not profuse of his money to sturdy beggars, few persons distributed with more liberality to truly deserving objects. He possessed all the graces of outward accomplishment, at a period when civility and politeness were characteristics of a gentleman.

He bequeathed his valuable Shakespeare, illustrated with about 1,500 prints, to Lord Spencer; his Hogarth perfect, with the exception of one or two pieces, to Mr. Windham; and his corrected copy of Shakespeare, with 200 guineas, to his friend Mr. Read. He died in the month of January 1800, about 65 years of age.

STEGANOGRAPHY, the art of secret writing, or of writing in cyphers, known only to the persons corresponding. See Cipher.

STELLARIA, a genus of plants belonging to the class decandria, and in the natural system arranged under the 22d order, Caryophyllaeæ. See Botany Index.

STELLATE, in Botany, a term applied to leaves which grow not less than six at a joint, and are arranged like the rays of a star.

STELLARIA, German Groundsel, a genus of plants belonging to the class octandria; and in the natural system arranged under the 31st order, Nepetoceæ. See Botany Index.

STELLATION, in the civil law, a kind of crime committed by a fraudulent bargain, where one of the parties sells a thing for what it is not; as if I sell my estate for my own which belongs to another, or convey a thing as free and clear which is already engaged in another, or put off copper for gold, &c.

STEM, in Botany, that part of a plant arising out of the root, and which sustains the leaves, flowers, fruits, &c. By washing and rubbing the stems of trees, their annual increase is promoted; for the method of doing which, see the article Tree.

STEM of a Ship, a circular piece of timber into which the two sides of a ship are united at the fore-end: the lower end of which is scarfed to the keel, and the bowsprit rests upon its upper end. The stem is formed of one or two pieces, according to the size of the vessel; and as it terminates the ship forward, the ends of the wales and planks of the sides and bottom are let into a groove or channel, in the midst of its surface, from the top to the bottom; which operation is called rabiting. The outside of the stem is usually marked with a scale, or division of feet, according to its perpendicular height from the keel. The intention of this is to ascertain the draught of water at the forecastle, when the ship is in preparation for a sea-voyage, &c. The stem at its lower end is of equal breadth and thickness with the keel, but it grows proportionally broader and thicker towards its upper extremity. See Ship-Building.

STEMMATA, in the history of insects, are three smooth hemispheric dots, placed generally on the top of the head, as in most of the hymenoptera and other classes. The name was first introduced by Linnaeus.

STEMODIA, a genus of plants belonging to the class didynamia; and in the natural system ranging under the 40th order, Personatoæ. See Botany Index.

STEMPHYLA, a word used by the ancients to express the husks of grapes, or the remains of the pressings of wine. The same word is also used by some to express the remaining mass of the olives, after the oil is pressed out.

STEMPHYLITES, a name given by the ancients to a sort of wine pressed hard from the husks.

STEMPLES, in mining, cross bars of wood in the shafts which are sunk to mines.

In many places the way is to sink a perpendicular hole, or shaft, the sides of which are strengthened from top to bottom with wood-work, to prevent the earth from falling in; the transverse pieces of wood are called stemples, and by means of these the miners in some places descend, without using any rope.

STEMSON, in a ship, an arching piece of timber fixed within the apron, to reinforce the scarf thereof, in the same manner as the apron supports the scarf of the stern. In large ships it is usually formed of two pieces.
STENOGRAPHY (A).

CHAP. I.

The art of stenography, or short writing, was known and practised by most of the ancient civilized nations. The Egyptians, who were distinguished for learning at an early period, at first expressed their words by a delineation of figures called hieroglyphics. A more concise mode of writing seems to have been afterwards introduced, in which only a part of the symbol or picture was drawn. This answered the purpose of shorthand in some degree. After them the Hebrews, the Greeks, and the Romans, adopted different methods of abbreviating their words and sentences, suited to their respective languages. The initials, the finals, or radicals, often served for whole words; and various combinations of these sometimes formed a sentence. Arbitrary marks were likewise employed to determine the meaning, and to assist legibility; and it seems probable that every writer, and every author of antiquity, had some peculiar method of abbreviation, calculated to facilitate the expression of his own sentiments, and intelligible only to himself.

It is also probable, that some might by these means take down the heads of a discourse or oration; but few, very few, it is presumed, could have followed a speaker through all the meanders of rhetoric, and noted with precision every syllable, as it dropped from his mouth, in a manner legible even to themselves.

To arrive at such consummate perfection in the art was reserved for more modern times, and is still an acquisition by no means general.

In every language of Europe, till about the close of the 16th century, the Roman plan of abbreviating (viz. substituting the initials or radicals, with the help of arbitraries, for words) appears to have been employed. Till then no regular alphabet had been invented expressly for stenography, when an English gentleman of the name of Willis invented and published one (b). His plan was soon altered and improved, or at least pretended to be so. One alteration succeeded another; and at intervals, for a series of years past, some men of ingenuity and application have composed and published systems of stenography, and doubtless have themselves reaped all the advantages that attend it. But among the various methods that have been proposed, and the different plans that have been adopted by individuals, none has yet appeared fortunate enough to gain general approbation; or proved sufficiently simple, clear, and concise, to be universally studied and practised.

Some systems are replete with meaningless symbols, perplexing arbitraries, and ill-judged contractions, which render them so difficult to be attained by a common capacity, or ordinary application, that it is not to be wondered at if they have sunk into neglect, and are now no longer known (c). Other systems, by being too prolix, by containing a multiplicity of characters, and those characters not simple or easily remembered, become ineffectual to the purpose of expedient, and are only superior in obscurity to a common hand. Some, again, not only reject all arbitraries and contractions, but even prepositions and terminations; which fast, if not too lavishly employed and badly devised, highly contribute to promote both expedition and legibility; and though they reduce their characters to fewer than can possibly express the various modifications of sound, yet they make nearly one half of them complex. In the disposition of the vowels there is the greatest perplexity in most systems. A dot is sometimes substituted for all the vowels indiscriminately, and the judgment is left to determine which letter out of six any dot is intended to express; or a minute space is allotted them; so that unless they be arranged with mathematical precision they cannot be distinguished from one another: but such a minute attention is inconsistent with the nature of shorthand, which should teach us to write down in a short time, as well as in small bounds, what we wish to preserve of what we hear. Nor is the plan of lifting the pen and putting the next consonant in the vowel's place, in the middle of words, less liable to objections; or that of representing all the vowels by distinct characters, being obviously ill calculated for facility and dispatch.

(a) The value of stenography is not unknown to the learned; and the care and success with which it has been lately cultivated in these kingdoms will, in all probability, soon render it an object of general attention. No one, however, appears to us to have simplified and improved the art so much as Dr Mavor, author of Universal Stenography, who has liberally permitted us to present our readers with a complete view of his scheme. To those who wish to become proficient in Short-Writing, we earnestly recommend his entire publication (printed for Cadell and Davis, Strand, London), which in many schools of the first reputation now forms a deserved class-book.

(b) Mr Locke says, a regular method of short-writing seems to be known and practised only in Britain. This is not now the case; and indeed there is no reason to doubt whether characters may not be invented to express the various sounds, or letters, employed in any language, either ancient or modern.

STENOGRAPHY.

dispatch, and consequently inadmissible into any useful system.

It is to be confessed, that the person who first proposed the omission of vowels in the middle of words (D), which it is obvious are not wanted, and invented letters, which could be connected as in a running hand without lifting the pen in the middle of the word, made a real improvement on the works of his predecessors. But, in fine, most systems, either in their plan or execution, labour under some capital defect, attended with circumstances highly discouraging to the learner, and which in a great measure defeat the end of their invention, by being too complicated to be learned with ease and remembered with accuracy, or to be practised with the expedition which is requisite; and so difficult to be deciphered, that a man can scarcely read what he has just written.

To obviate these defects; to provide against prolixity and conciseness, which might occasion obscurity; to exhibit a system founded on the simplest principles, which might be easily learned and read, and yet be capable of the utmost expedition—were the motives that gave rise to the present attempt.

This method will be found different from any yet published, and superior to all in the disposition of the vowels and the facility of arranging them; the confusion in placing which seems to detract from the merit of the best performances on the subject; and it may be affirmed, without ostentation, that characters simpler in their form, and more perfect in their union, have not been applied to the art of stenography.

As well as it could be determined, the simplest characters are appropriated to the letters most usually employed: indeed, as far as possible, those which are complex have been rejected; but as it was an object always kept in view that the writing should be on a line, a few are admitted into the alphabet for that reason.

The characters for the double and triple consonants are the easiest that could be invented, consistent with perspicuity (E); for care has been taken to provide against all obscurity which might arise by adopting letters too similar in their formation; and with respect to the prepositions and terminations, those which occur most frequently are expressed by the simplest characters, which will be found perfectly easy in their application.

The arbitraries are few in number (F), and the arbitrary abbreviations, as they are entirely from the letters of the alphabet, and chosen from some thousands of words in common use, will well repay the learner for an hour's trouble in committing them to memory.

The last chapter lays down a scheme of abbreviation, comprised in a few rules, perfectly easy to be understood and practised by proficients in this art, which we hope will answer the expectation of the author, and will be found free from the perplexity complained of in many systems where abbreviation is admitted. The principal rules are new, are so easy, so extensive in their use, and so consistent with expedition and legibility, if applied with judgment, that they alone might suffice. The learner is, however, advised by no means to adopt any of them, till experience has convinced him that they may be used without error or injury to legibility. All abbreviating rules are suited to those only who have made some progress in the stenographic art; for although they certainly promote expedition in a wonderful manner, and afford the greatest ease to a proficient, yet a learner, as expedition is not his first, though his ultimate view, should admit of nothing that in the least renders the reading difficult.

CHAP. II.

The English alphabet consists of twenty-six letters; the gross six of which are vowels, a, e, i, o, u, and y; and the remaining other twenty consonants, s, c, ch, f, g, h, k, l, m, n, p, q, plex of steno-
graphy.

This alphabet, as is observed by the best grammarians that have written on the language, is both defective and redundant in expressing the various modifications of sound.

Custom or prejudice has assigned some letters a place, (G) when others would with much more propriety press the same sound: and to this may be added, that several letters, sometimes in one word, seem to be admitted for no other reason than to perplex a young beginner or a foreigner, as an obstruction to true pronunciation, and to add to the apparent length of the word, when they are entirely quiescent and useless. That this is the genius of the orthography of our language must be perceived by the most superficial observer; but no modern tongue is absolutely free from the same exceptions. In particular, the French has a great number of dormant letters, which, it is obvious, render the pronunciation more difficult and perplexing to learners (C).

But as it is neither our business nor our intention to propose a mode of spelling different from that in common use, when applied to printing or long hand writing (since several innovators in orthography have fallen into contempt, and their plans have been only preserved as beacons to warn others of the folly of endeavouring to subvert established principles); we shall only observe that in stenography, where the most expeditious and conci-

(D) Mr Byrom rejected vowels entirely in the middle of words, as others before him had only done partially. Without critically examining the executive part of his performance, which is very defective, it must be owned, that it is above the reach of human ingenuity to exceed his general plan; which for ever must be the basis of every future rational system.

(E) Those for th and ch may be either made upright or sloping to the right.

(F) Those are not by any means prescribed; they may be employed or not according to the fancy of the learner.

(G) The Latin and Greek claim a just superiority over the modern tongues in this respect. In them no confusion or doubt can arise from the manner of spelling; and the reader can scarcely be wrong (unless in quantity) in sounding all the letters he sees.

482
STENOGRAPHY.

Rule I. All quiescent consonants in words are to be dropped; and the orthography to be directed only by the pronunciation; which being known to all, will render this art attainable by those who cannot spell with precision in long hand.

Rule II. When the absence of consonants, not entirely dormant, can be easily known, they may often be omitted without the least obscurity.

Rule III. Two or sometimes more consonants may, to promote greater expedition, be exchanged for a single one of nearly similar sound; and no ambiguity as to the meaning ensue (H).

Rule IV. When two consonants of the same kind or same sound come together, without any vowel between them, only one is to be expressed; but if a vowel or vowels intervene, both are to be written: only observe, if they are perpendicular, horizontal, or oblique lines, they must only be drawn a size longer than usual; and characters with loops must have the size of their heads doubled.

Might be written mit, sight sit, machine masheen, enough eanf, laugh laf, prophet profet, physics fisiks, through thro, foreign foren, sovereign sovern, psalm sam, receipt retseet, write rite, bright rit, island island, knavery novery, temptation temptation, knife nife, stick stik, thigh thil, honour ovour, indirectment indirectment, acquaint aquaint, chaos kosa, &c.

Second rule exemplified.

Strength strength, length lenth, friendship frienship, connect conk, commandment commanment, conjunct conjunct, humble humble, lumber lumer, slumber slumer, number numer, exemplary exemplary, &c.

Third rule exemplified.

Rocks raks, acts aks or ax, facts faks or fax, districts district or districk, affects ofeks or ofes, afflicts ofiks or ofiks, conquer conquer, &c.

Fourth rule exemplified.

Letter letter, little little, command conmand, error error, terror terror, &c. But in remember, moment, sister, and such like words, where two consonants of the same name have an intervening vowel, both of them must be written.

These four rules, with their examples, being carefully considered by the learner, will leave him in no doubt concerning the disposition and management of the consonants in this scheme of short-writing; we shall therefore proceed to lay down rules for the application of the vowels with ease and expedition.

Rule I. Vowels, being only simple articulate sounds, though they are the connectives of consonants, and employed in every word and every syllable, are not necessary to be inserted in the middle of words; because the consonants, if fully pronounced, with the assistance of connection, will always discover the meaning of a word, and make the writing perfectly legible.

Rule II. If a vowel is not strongly accented in the incipient syllable of a word, or if it is mute in the final, it is likewise to be omitted; because the sound of the incipient vowel is often implied in that of the first consonant, which will consequently supply its place.

Rule III. But if the vowel constitutes the first or last syllable of a word, or is strongly accented at its beginning or end, that vowel is continually to be written.

Rule IV. If a word begins or ends with two or more vowels though separated, or when there is a coalition of vowels, as in diphthongs and triphthongs; only one of them is to be expressed, which must be that which agrees best with the pronunciation.

Rule V. In monosyllables, if they begin or end with a vowel, it is always to be inserted, unless the vowel be mute at the end of a word.

Such are the general principles of this art; in vindication and support of which it will be needless to offer any arguments, when it is considered that brevity and expedition are the chief objects, if consistent with legibility and the subsequent specimen in the orthography recommended will, we hope, be sufficient to show that there is no real deficiency in the last mentioned particular.

He who m'd us mst be etnal, grt, nd mmptr. It is Species or dby, as mnl borgs, to swv, lw vs nd oby bms.—A mnt wth wld nd bm, shd be mksnshp in lk bsm, nd ndr wth, in stnegrph. But sl prd of ths rt frs, nd evr fr sl evd.

CHAP. III.

As the whole of this art depends upon a regular method and a simple alphabet, we have not only endeavoured to establish the former on satisfactory principles, but have been careful to appropriate, according to the comparative frequency of their occurrence, each character.
STENOGRAPHY.

The stenographic alphabet consists of 18 distinct characters (viz., two for the vowels and the rest for the consonants), taken from lines and semicircular curves; the formation and application of which we shall now explain, beginning with the vowels.

For the three first vowels, \( a, e, \) and \( i \), a comma is appropriated in different positions; and for the other three, \( o, u, \) and \( y \), a point. The comma and point, when applied to \( a \) and \( o \), is to be placed, as in the Plate DVII, at the top of the next character; when for \( e \) and \( u \), opposite to the middle; and when for \( i \) and \( y \), at the bottom.

This arrangement of the vowels is the most simple and distinct that can easily be imagined. Places at the top, the middle, and the bottom of characters, which make three different positions, are as easily distinguished from one another as any three separate characters could be; and a comma is made with the same facility as a point.

Simple lines may be drawn four different ways; perpendicular, horizontal, and with an angle of about 45 degrees to the right and left. An ascending oblique line to the right, which will be perfectly distinct from the rest when joined to any other character, may likewise be admitted. These characters being the simplest in nature, are assigned to those five consonants which most frequently occur, viz., \( l, r, t, h \), hard or \( k \), and \( c \), soft or \( s \).

Every circle may be divided with a perpendicular and horizontal line, so as to form likewise four distinct characters. Those being the next to lines in the simplicity of their formation, we have appropriated them for \( b, d, n, \) and \( m \).

The characters expressing nine of the consonants are all perfectly distinct from one another; eight only remain which are needful, viz., \( f, g, r, j, k, p, q, v, \) and \( x \); to find characters for which we must have recourse to mixed curves and lines. The characters which we have adopted are the simplest in nature after those already applied, admit of the easiest joining, and tend to preserve lineality and beauty in the writing.

It must be observed that we have no character for \( k \) when it has a hard sound, as in castle; or soft, as in city; for it naturally takes the sound of \( k \) or \( s \) which in all cases will be sufficient to supply its place.

\( R \) likewise is represented by the same character as \( l \); only with this difference, \( r \) is written with an ascending stroke (1), and \( l \) with a descending; which is always to be known from the manner of its union with the following character; but in a few monosyllables where \( r \) is the only consonant in the word, and consequently stands alone, it is to be made as is shown in the alphabet for distinction's sake.

\( Z \), as it is a letter seldom employed in the English language, and only a coarser and harder expression of \( s \) must be supplied by \( s \) whenever it occurs; as for Zedekiah write Sedekiah, &c.

CHAP. IV.

The prepositions and terminations in this scheme are so simple, that the greatest benefit may be reaped from them, and very little trouble required to attain them; as the incipient letter or the incipient consonant of all the prepositions and of several of the terminations is used to express the whole. But although in Plate DVII. sufficient specimens are given of the manner of their application, that the learner of less ingenuity or more slow perception may have every assistance, we have subjoined the following directions.

GENERAL RULES FOR PREPOSITIONS AND TERMINATIONS.

1. The preposition is always to be written without joining, yet so near as plainly to show what word it belongs to; and the best way is to observe the same order as if the whole was to be connected.

2. A preposition, though the same letters that constitute it may be met with in the middle or end of a word, is never to be used, because it would expose to obscurity.

3. Observe that the preposition omni is expressed by the vowel \( o \) in its proper position; and for anti, ante, ante; by the vowel \( a \) which the radical part of the word will easily distinguish from being only simple vowels.

The first rule for the prepositions is (allowing such exceptions as may be seen in the Plate) to be observed for the terminations; and also the second, mutatis mutandis; except that whenever \( xis, sus, yis, eis, tions, tiins, \) and \( csr \) occur, they are to be expressed as directed in the fourth rule for the consonants, whether in the beginning, middle, or end of words (k).

4. The terminative character for \( tion, sion, cion, cian, cian, tian \), is to be expressed by a small circle joined to the nearest letter, and turned to the right, and the plurals \( tions, cions, cians, tians, tience \), by a dot on the same side.

5. The terminative character for \( ing \), is to be expressed likewise by a small circle, but drawn to the left hand; and its plural \( ings \) by a dot (l).

6. The plural sign \( s \) is to be added to the terminative characters when necessary.

7. The separated terminations are never to be used but in polysyllables or words of more syllables than one.

These rules duly observed will point out a method as concise and elegant as can be desired, for expressing the most
most frequent and longest prepositions and terminations
in the English language. If it should be thought ne-
cessary to increase their number by the addition of
others, it will be an easy matter for any one of the least
discernment to do so, by proceeding on the principles
before laid down.

CHAP. V.

THOUGH a more concise method of writing, or more
numerous abbreviations, may not be indispensably ne-
cessary, if the foregoing directions be practised for a
considerable time, yet contractions will be found ex-
tremely useful and convenient to those who have attain-
ed a proper knowledge of the subject, and lead to a
greater degree of expedition, at the same time that they
diminish the labour of writing. It has been observed in
the introduction, that abbreviations are only to be em-
ployed by proficients in this art; because expedition is
not the first, though the ultimate, object in view; and
that an easy legibility is of the utmost consequence to
the learner; which, however, cannot be preserved, if
he adopts too soon those very rules which in time will
afford him the greatest ease when applied with judge-
ment.

The following short and practical rules will be found,
we hope, fully adequate to every purpose for which they
were intended, and are far superior in the facility of
their application to any which we have seen.

RULE I. The usual abbreviations in long hand are al-
tways to be followed; as Mr for Master, M. D. for Doc-
tor of Physick, and Abp. for Archbishop, &c.

RULE II. Substantives, adjectives, verbs, and partic-
iples, whence the sense will direct to the meaning, are
to be expressed by their initial consonant with the di-
s'tinguishing marks exhibited in Plate DV. viz. a sub-
stantive must have the dot exactly over its initial con-
sontant; an adjective must have a dot under it; a verb
is to be expressed by a comma over its initial consonant;
and a participle by a comma under (m). These being
the four principal parts of speech will be sufficient; and
an adept will never be at a loss to know when he can
with safety apply this rule to them.

RULE III. To render the writing more legible, the last
letter of the word may be joined to the first, and
the proper mark applied.

RULE IV. The constituent or radical part of words,
especially if they are long, will often serve for the whole
or sometimes the first syllable; as, we ought to mod-
erate our ex. by our circum.; a man's man. commonly
shape his for.

RULE V. All long words without exception may
have their prepositions or terminations expressed by the
incipient consonant of such preposition or termination.

RULE VI. When there is a great dependence be-
tween the parts of a sentence, the initial letter will often
suffice; as, L. is the capital of Great B. the eldest S.
of the king of Great B. is styled prince of W. Every
one, it is presumed, will allow this to be perfectly le-
gible in long-hand, then why may it not in stenogra-
phy?

RULE VII. The terminations ness and less may be
omitted; as, faithfulness is only to be written faithful;
forwardness, forward; needess, need; stubbornness,
stubborn, &c.

RULE VIII. The second and third persons of verbs,
ending in eth and est, may be expressed by s; as, he
loves, thou teachest; instead of he lovest, thou teac'est;
or even without s; as, he love, &c.

RULE IX. Words may often be entirely omitted,
yet no ambiguity ensue; as, In beginning God cre-
ated heaven and earth, for In the beginning God created
the heaven and the earth.

RULE X. When there is an immediate repetition of
a sentence or word, a line is to be drawn under the sen-
tence or word to be repeated; as, Amen, Amen, is to be
written Amen; but if any words intervene before a
word or sentence is to be repeated, the line must be
drawn as before, and a A or mark of omission placed
where the repetition should begin; as, Is it just the in-
ocents should be condemned A reviled?

Fabricius's Reply to Pyrrhus. Plate

As to my poverty, you have indeed, Sir, been rightly
informed. My whole estate consists in a house of but
mean appearance, and a little spot of ground, from
which by my own labour I draw my support. But if
by any means you have been persuaded to think, that
this poverty makes me less considered in my country,
or in any degree unhappy, you are extremely deceived.
I have no reason to complain of fortune, she supplies me
with all that nature requires; and if I am without su-
perfluities, I am also free from the desire of them.
With these I confess I should be more able to succour
the necessitous, the only advantage for which the weal-
thy are to be envied; but as small as my possessions are,
I can still contribute something to the support of the
state and the assistance of my friends. With regard to
honours, my country places me, poor as I am, upon a
level with the richest: for Rome knows no qualifica-
tions for great employments but virtue and ability. She
appoints me to officiate in the most august ceremonies
of religion; she entrusts me with the command of her
armies; she confides to my care the most important ne-
gociations. My poverty does not lessen the weight and
influence of my counsels in the senate; the Roman
people honour me for that very poverty which you con-
sider as a disgrace; they know the many opportunities
I have had in war to enrich myself without incurring
censure; they are conscious of my disinterested zeal
for their prosperity; and if I have any thing to com-
plain of in the return they make, it is only the excess
of their applause. What value then can I set upon
your gold and silver! What king can add any thing to
my fortune! Always attentive to discharge the duties
incumbent

(m) The dot or comma being placed thus will never occasion them to be mistaken for vowels, because they
should always be on one side or other; whereas the mark for parts of speech may constantly be placed exactly
over or under.

incumbent on me, I have a mind free from self-reproach, and I have an honest fame. Dodges's Preceptor.

Letter to a Friend against waste of Time.

Conversely often with yourself, and neither lavish your time, nor suffer others to rob you of it. Many of our hours are stolen from us, and others pass insensibly away; but of both these losses the most shameful is that which happens through our own neglect. If we take the trouble to observe we shall find that one considerable part of our life is spent in doing evil, and the other in doing nothing, or in doing what we should not do. We don't seem to know the value of time, nor how precious a day is; nor do we consider that every moment brings us nearer our end. Reflect upon this I entreat you, and keep a strict account of time. Procrastination is the most dangerous thing in life. Nothing is properly ours but the instant we breathe in, and all the rest is nothing; it is the only good we possess; but then it is fleeting, and the first comer robs us of it. Men are so weak, that they think they oblige by giving of trifles, and yet reckon that time as nothing for which the most grateful person in the world can never make amends. Let us therefore consider time as the most valuable of all things; and every moment spent, without some improvement in virtue or some advancement in goodness, as the greatest subliminal loss.

St Paul's Speech before Agrippa and Festus...

I think myself happy, King Agrippa, that I shall answer for myself this day before thee, touching all things whereof I am accused of the Jews: especially because I know thee to be expert in all customs and questions which are among the Jews, wherefore I beseech thee to hear me patiently. My manner of life from my youth, which was at first among mine own nation at Jerusalem, know all the Jews, which knew me from the beginning (if they would testify), that, after the straitest sect of our religion, I lived a Pharisee. And now I stand and am judged for the hope of the promise made by God unto our fathers; unto which promise our twelve tribes instantly serving God day and night hope to come; for which hope's sake, King Agrippa, I am accused of the Jews. Why should it be thought a thing incredible with you, that God should raise the dead, when God himself has given assurance of it unto all men, in that he hath raised Christ from the dead? As for my own part, most noble Festus, I own I once verily thought that even I myself ought to do many things contrary to the name of Jesus of Nazareth. Which thing I also did in Jerusalem. I punished the saints oft in every synagogue, and compelled them to blaspheme; and being exceedingly mad against them, I persecuted them even unto strange cities. In pursuit of which, as I went to Damascus, with authority and commission from the chief priests: At mid-day, O king, I saw in the way a light from heaven, above the brightness of the sun, shining about me, and them which journeyed with me. And when we were all fallen to the earth, I heard a voice speaking unto me, and saying in the Hebrew tongue, Saul, Saul, why persecutest thou me? It is hard for thee to kick against the pricks. And I said, Who art thou, Lord? And he said, I am Jesus whom thou persecutest. But rise, and stand upon thy feet: for I have appeared unto thee for this purpose, to make thee a minister and a witness both of these things which thou hast seen, and of those things in which I will appear unto thee. Whereupon, O king Agrippa, I was not disobedient to the heavenly vision; but shewed first unto them of Damascus, and at Jerusalem, and throughout all the coasts of Judea, and then to the Gentiles, that they should repent and turn to God. For these causes the Jews caught me in the temple, and went about to kill me. Having therefore obtained help of God, I continued unto this day, witnessing both to small and great, saying none other things than those which the prophets and Moses did say should come: That Christ should suffer, and that he should be the first that should rise from the dead, and should show light unto the people, and to the Gentiles. This is the real truth: Believe me, I am no pestilent fellow, nor mover of sedition; but always endeavour all that lies in me to preserve a conscience void of offence towards God and towards man: nor can the Jews prove the things whereof they now accuse me. Neither am I, Festus, besides myself; but speak thus freely before the king; because he knows these things to be fact: yea, I am fully persuaded the king knows them all to be fact: for they were not done in a corner. King Agrippa, believe thou the prophets? I know that thou believest. And would to God that not only thou, but also all that hear me this day, were altogether such as I am except those bonds. Holmier's Rhetoric.

Pope to Atterbury.

Once more I write to you, as I promised, and this once I fear will be the last; the curtain will soon be drawn between my friend and me, and nothing left but to wish you a long good night; may you enjoy a state of repose in this life not unlike that sleep of the soul which some have believed is to succeed it, where we lie utterly forgetful of that world from which we are gone, and ripening for that to which we are to go. If you retain any memory of the past, let it only image to you what has pleased you best; sometimes present a dream of an absent friend, or bring you back an agreeable conversation. But, upon the whole, I hope you will think less of the time past than the future; as the former has been less kind to you than the latter infallibly will. Do not envy the world your studies: They will tend to the benefit of men, against whom you can have no complaint; I mean, of all posterity: and, perhaps, at your time of life, nothing else is worth your care. What is every year of a wise man's life but a censure or criticism past? Those whose date is the shortest, live long enough to laugh at one half of it: The boy despises the infant, the man the boy, the philosopher both, and the Christian all. You may now begin to think your manhood was too much a puissance; and you will never suffer your age to be but a second infancy. The toys and babbles of your childhood are hardly now more below you than those toys of our riper and our declining years; the drums and rattles of ambition, and the dirt and bubbles of avarice. At this time, when you are cut off from a little society, and made a citizen of the world at large, you should bend your talents not to serve a party, or a few, but all mankind. Your genius should mount above that mist, in which its participation and neighbourhood with earth hath long involved it: To shine abroad, and to heaven, outh.
ought to be the business and the glory of your present situation. Remember it was at such a time that the greatest lights of antiquity dazzled and blazed the most; in their retreat, in their exile, or in their death. But why do I talk of dazzling or blazing? it was then that they did good, that they gave light, and that they became guides to mankind. Those arts alone are worthy of spirits truly great, and such I therefore hope will be yours. Resentment indeed may remain, perhaps cannot be quite extinguished, in the noblest minds; but revenge will never harbour there: Higher principles than those of the first, and better principles than those of the latter, will infallibly influence men whose thoughts and whose hearts are enlarged, and cause them to prefer the whole to any part of mankind, especially to so small a part as one's single self. Believe me, my Lord, I look upon you as a spirit entered into another line, as one just upon the edge of immortality, where the passions and affections must be much more exalted, and where you ought to despise all little views and all mean retrospects. Nothing is worth your looking back: and therefore look forward, and make (as you can) the world look after you; but take care it be not with pity, but with esteem and admiration. I am, with the greatest sincerity and passion for your fame as well as happiness, your, &c.

The above most charming and most affectionate letter was written about a month before Atterbury bishop of Rochester was sent into banishment, and is universally admired.

FABRICIUS' Reply to PYRRHUS.

PLATE VII.

St. Paul's Speech.

LETTER.

POPE to ATTERBURY.
not only to understand, but even to speak with tolerable ease.

In 1531 he published his Latin "Thesaurus," a work of great importance, which he laboured at for two years. The mark which he put upon all his books was a tree branched, with a man looking upon it, and these words, noli altum sperare, to which he sometimes added sed time. In 1539, Francis I. made him his printer, and ordered a new set of elegant types to be founded for him. His frequent editions of the New Testament gave great offence to the doctors of the Sorbonne, who accused him of heresy for his annotations, and insisted upon the suppression of some of his books. Although Henry the French king in some measure protected him, the persecution of these divines rendered him so unhappy, not to mention the expense and loss of time which an almost constant attendance at court unavoidably occasioned, that in 1552 he abandoned his country and went to Geneva. Here he embraced the Protestant religion, and thus justified in some measure the suspicions of his theological enemies. It has been affirmed by several writers that he carried along with him the royal types, and the moulds also in which they were cast; but it is certain that he never afterwards made use of those types. Besides is it possible that the author of so daring a theft could have been not only protected in Geneva, but even courted and honoured by the most eminent men of the age? Is it credible that such a crime could have been concealed for 60 years; or that Henry, the son and heir of the perpetrator, would have enjoyed the favour of the French king, if Robert Stephens had acted such a shameful part? If he was burnt in effigy at Paris, it was not for theft, but for having changed his religion. After his arrival at Geneva, he published an account of the dispute between him and the Paris divines, which does as much honour to his abilities as his Thesaurus does to his learning. He died in 1559, after a life of the most extraordinary industry. The books of which he was the editor were not fewer than 360. Many of them were ancient classics in different languages. Several were accompanied with annotations which he collected, and all of them were corrected by collating manuscripts. He was so anxious to obtain perfect accuracy, that he used to expose his proofs in public, and reward those who discovered a mistake. His books consequently were very correct. It is said that his New Testament, called Omirifical (because the preface begins with these words), has not a single fault.

It was Robert Stephens who first divided the New Testament into verses during a journey between Paris and Lyons. The advantages of this improvement are fully counterbalanced by its defects. It has destroyed the unity of the books, and induced many commentators to consider every verse as a distinct and independent aphorism. To this in some measure is to be ascribed the many absurd interpretations and creeds that have been forced out of that book.

By his last will his estate was left exclusively to such of his children as should settle at Geneva. He left behind him three sons, Henry, Robert, and Francis.

Charles Stephens, the third son of Henry, was, like the rest of his family, familiarly acquainted with the learned languages. This recommended him to Lazarus de Bail, who made him tutor to his son, and in 1540 carried him along with him to Germany. He studied medicine, and practised it with success in France. He did not, however, forsake the profession of his family, but exercised it in Paris, where he became the editor of many books remarkable for neatness and elegance. He wrote above thirty treatises on different subjects, particularly on botany, anatomy, and history. He died in 1564.

Robert Stephens, the son of Robert the first of that name, did not accompany his father to Geneva, but continued to profess the Catholic religion, and to reside at Paris. His letters were remarkably beautiful. He was made king's printer, and died about 1580.

His brother Francis was also a printer. He embraced the Protestant religion, and resided at Geneva.

Henry Stephens, the remaining son of Robert, was born at Paris in 1528. He became the most learned and most celebrated of all his family. From his very birth he received proofs of uncommon abilities, and displayed an ardent passion for knowledge. The Medea of Euripides, which he saw acted while at school, kindled his love for poetry, and inspired him with the desire of acquiring the language in which that tragedy is written. He interested his father not to condemn him to study Latin, which he already understood from conversation, but to initiate him at once into the knowledge of Greek. His father willingly granted his request; and Henry applied with such vigour, that in a short time he could repeat the Medea by heart. He afterwards studied Greek under Peter Dainesius, who was tutor to the Dauphin, and finally heard the lectures of Tusanus and Turnebus. He became eager at an early age to understand astrology, and accordingly attended a professor of that mysterious art; but he was not long in discovering its absurdity. At 19 he began his travels, which he undertook in order to examine foreign libraries, and to become acquainted with learned men. He spent two years in Italy, and returned into France completely master of Italian, and bringing along with him copies of several scarce authors, particularly a part of Anacreon, which before was thought lost.

He found his father publishing an edition of the New Testament, to which he prefixed some Greek verses.—Soon after, he visited England and the Netherlands, where he met with John Clement, an Englishman, to whom he was indebted for the remaining odes of Anacreon. During this journey he learned the Spanish language, which was very much spoken at that time in the Low Countries.

Whether Henry accompanied his father to Geneva or not is uncertain; at least he must have returned immediately to France, for we find him soon after established at Paris, and publishing the odes of Anacreon. In 1554 he went to Rome, and thence to Naples. This journey was undertaken at the request, and in the service, of the French government. He was discovered, and would have been arrested as a spy, had he not by his address and skill in the language of the country been able to pass himself for a native of Italy. On his return to France he assumed the title of printer to Ulric Fugger, a very rich and learned German nobleman, who allowed him a considerable pension.

In 1560 he married a relation, as is generally supposed, of Henry Scrimgeour, a Scotch nobleman, with whom he was intimately acquainted. She was a woman, as he himself informs us, endowed with the noblest spirit.
S T E

S T E

Stephens. spirit and the most amiable dispositions. Her death, which happened in 1586, brought on a disease that had twice attacked him before. It was a disgust at all those pursuits which had formerly charmed him, an aversion to reading and the sight of books. It was probably occasioned by too constant and severe an application to literary pursuits. In 1572 he published his Thesaurus Linguae Graecae, one of the greatest works, perhaps, that ever was executed by one man, if we consider the wretched materials which more ancient dictionaries could furnish, if we consider the size and perfection of the work, and the immense labour and learning which must have been employed in the compilation. This work had been carried on at a greater expense than he could well bear. He expected to be reimbursed by the sale of the book, but he was unfortunately disappointed. John Scapula, one of his own servants, extracted from it whatever he thought would be most serviceable to students, and published it beforehand in 1610. By this act of treachery Henry was reduced to poverty.

About this time he was much beloved by Henry III. of France, who treated him so kindly, and made him such flattering promises, that he resided frequently at court. But these promises were never fulfilled, owing to the civil wars which soon after distracted France, and the unfortunate death of King Henry himself. During the remainder of his life his situation was very unsettled. We find him sometimes in Paris, sometimes in Geneva, in Germany, and even in Hungary. He died at Lyons in 1598, at the age of 70. He was fond of poetry from his very infancy. It was a custom of his to compose verses on horseback, and even to write them, though he generally rode a very mettlesome steed. His Thesaurus was his great work, but he was also the author of several other treatises. His poems are numerous: His Apology for Herodotus is a witty satire on the Roman Catholics. His Concordance to the New Testament must have been a laborious work, and has deservedly endeared him to every Christian who wishes to acquire a rational and critical knowledge of the Scriptures. The number of books which he published, though fewer than his father's, was great, and superior in elegance to any thing which the world had then seen. A great proportion of them were Greek; he was the editor, however, of many Roman and even of some eastern writings. His Greek classics are remarkably correct; the principal of them are Homer, Anacreon, Æschylus, Maximus Tyrius, Diondorus Siculus, Pindar, Xenophon, Thucyldides, Herodotus, Sophocles, Diogenes Laertius, Plutarch, Plato, Apollonius Rhodius, Æschines, Lysias, Callimachus, Theocritus, Herodian, Dionysius Halicarnassensis, Dion Cassius, Isocrates, Appian, Xiphilin, &c. His temper in the latter part of his life is represented as haughty and severe, owing probably to his disappointments. He left behind him a son and two daughters, one of whom was married to the learned Isaac Casaubon.

Paul Stephens, the son of Henry, continued his father's profession at Geneva. He was a man of learning, and wrote translations of several books, and published a considerable number of the ancient classics; but his editions possess little of his father's elegance. He died in 1627, at the age of 60, after selling his types to one Chouet a printer.—His son Antony, the last printer of the family, abandoned the Protestant religion, and returned to France, the country of his ancestors. He received letters of naturalization in 1612, and was made printer to the king; but managing his affairs ill, he was reduced to poverty, and obliged to retire into an hospital, where he died in 1674, miserable and blind, at the age of 80.

STERICANARIANS, or STERICANISTAE, formed from sterco, "dung," a name which those of the Romish church anciently gave to such as held that the host was liable to digestion, and all its consequences, like other food.

STERICULIA, a genus of plants belonging to the class monoezae; and in the natural system ranging under the 38th order, Tricocereae. See Botany Index.

STEREOGRAPHIC PROJECTION, is the projection of the circles of the sphere on the plane of some one great circle, the eye being placed in the pole of that circle. See Projection of the Sphere.

STEREOCONTACT, an instrument invented in France for measuring the volume of a body, however irregular, without plunging it in any liquid. If the volume of air contained in a vessel be measured, when the vessel contains air only, and also when it contains a body whose volume is required to be known, the volume of air ascertained by the first measurement, deducting the volume ascertained by the second, will be the volume of the body itself. Again, if the volume of any mass of air be inversely as the pressure to which it is subjected, the temperature being supposed constant, it will be easy to deduce, from the mathematical relations of quantity, the whole bulk if the difference between the two bulks under two known pressures be obtained by experiment.

Suppose that the first pressure is double the second, or the second volume of air double the first, and the difference equal to 50 cubic inches; the first volume of air will likewise be 50 cubic inches. The design of the stereometer is to ascertain this difference at two known pressures.

The instrument is a kind of funnel A B (fig. 1.) composed of a capsule A, in which the body is placed, and the tube B as uniform in the bore as can be procured. The upper edge of the capsule is ground with emery, so that it may be hermetically closed with a glass cover M slightly greased. A spiral scale is pasted on the tube, having two sets of graduations; one to denote the length, and the other the capacities, as determined by experiment.

When this instrument is used, it must be plunged into a vessel of mercury, with the tube very upright, till the mercury rise within and without to a point C of the scale. See fig. 2.

The capsule is then closed with the cover, which being greased will prevent its communication between the external air and that contained within the capsule and tube.

In this situation of the instrument, the internal air is compressed by the weight of the atmosphere, expressed by the length of the mercury in the tube of the common barometer.

The instrument is then elevated, still keeping the tube in the vertical position. It is thus represented, fig. 2, second position. The mercury descends in the tube, but not to the level of the external surface, and a column of mercury D E remains suspended in the tube, the height of which is known by the scale. The interior air is less compressed.
compressed than before, the increase of its volume being equal to the whole capacity of the tube from C to D, indicated by the second scale.

It is therefore known that the pressures are in proportion to the barometrical column, and to the same column — DE. The bulks of the air in these two states are inversely in the same proportion; and the difference between these bulks is the absolute quantity left void in the tube by the fall of the mercury; from which data the following rule is deduced. Multiply the number expressing the less pressure by that which denotes the augmentation of capacity, and divide the product by the number which denotes the difference of the pressures. The quotient is the bulk of the air when subject to the greater pressure.

Suppose the height of the mercury in the barometer to be 78 centimetres, and the instrument being empty to be plunged into the mercury to the point C. It is then covered and raised till the small column of mercury DE is suspended, say at the height of six centimetres. The internal air at first compressed by a force represented by 78 centimetres, is now only compressed by a force = 72 centimetres, or 78-6 = 72.

Suppose that the capacity of the part CD of the tube which the mercury has quitted is two cubic centimetres. Then \( \frac{72}{6} = 24 \) cubic centimetres, the volume of the air included in the instrument when the mercury rose as high as C in the tube.

The body of which the volume is to be ascertained must then be placed in the capsule, and the operation repeated. Let the column of mercury suspended be =8 centimetres, when the capacity of the part CD of the tube is = 2 centimetres cubic. Then the greatest pressure being denoted by 78 centimetres, the least will be 70 centimetres, the difference of pressure being 8, and difference of the volumes two cubic centimetres.

Hence \( \frac{70}{8} \times 2 \) gives the bulk of the included air under the greatest pressure 17.5 cubic centimetres. Then 24-17.5 = 6.5 the volume of the body introduced.

If the absolute weight of the body be multiplied by its bulk in centimetres, and divided by the absolute weight of one cubic centimetre of distilled water, the quotient will be = the specific gravity of the body in the common form of the tables, where distilled water is taken as unity, or the term of comparison.

Mr Nicholson supposes that the author of the invention had not finished his meditations on the subject. If he had, it is probable that he would have determined his pressures, as well as the measures of bulks, by weight. For if the whole instrument were set to its positions by suspending it from one arm of a balance at H (fig. 3.) the quantity of counterpoise, when in equilibrio, might be applied to determine the pressures to a degree of accuracy much greater than can be obtained by linear measurement.

STEREOMETRY, Στρερομέτρια, formed of στρογγολ İn, solid, and μέτρον, measure, that part of geometry which teaches how to measure solid bodies, i.e. to find the solidity or solid contents of bodies; as globes, cylinders, cubes, vessels, ships, &c.

STEREOTOMY, formed from στρογγολ İn, and τομή, section, the art or act of cutting solids, or making sections thereof; as walls and other membranes in the profiles of architecture.

STEREOTYPE PRINTING, a method of printing, which was introduced into this country by William Ged of Edinburgh before the middle of the 18th century, and which has been revived of late, and greatly improved by the French. It has also been brought into practice in Britain by Earl Stanhope, who has produced some beautiful specimens of it. Some persons seem disposed to dispute the invention of Ged, seeing that the same method of printing by wooden blocks was practised by the Chinese and Japanese many hundreds years ago. See Ged, life of, and Printing.

STERILITY, barrenness, in opposition to fertility. It has been asserted by many authors, that all monsters produced by a mixture of different species of animals, such as mules, are barren; but this does not hold universally, even with the mule, which is the instance most generally adduced.

Sterility in women sometimes happens from miscarriage, or violent labour injuring some of the genital parts; but one of the most frequent causes is the suppression of the menstrual flux.—There are other causes arising from various diseases incident to those parts, by which the uterus may be unfit to receive or retain the male seed; — from the tube fallopian being too short, or having lost their erectile power; or in either of which cases no conception can take place; — from universal debility and relaxation; or a local debility of the genital system; by which means, the parts having lost their tone or contractile power, the semen is thrown off immediately post coitum; — from imperfection of the vagina, the uterus, or the tube, or from diseased ovaries, &c. Hence medical treatment can only avail in cases arising from topical or universal debility; in correcting irregularities of the menstrual flux, or in removing tumors, cicatrizes, or constrictions of the passage, by the art of surgery.

STERIS, a genus of plants belonging to the class pentandria. See Botany Index.

STERLING, an epithet by which genuine English money is distinguished. It is unnecessary to mention the various conjectures of antiquaries about the origin and meaning of this appellation. The most probable opinion seems to be this, that some artists from Germany, who were called Esterlings, from the situation of their country, had been employed in fabricating our money, which consisted chiefly of silver pennies; and that from them the penny was called an esterling, and our money esterling or sterling money.

STERN, the posterior face of a ship; or that part which is represented to the view of a spectator, placed on the continuation of the keel behind. The stern is terminated above by the taffarel, and below by the counters; it is limited on the sides by the quarter-pieces, and the intermediate space comprehends the galleries and windows of the different cabins. See Quarter of a Ship, Ship, and Ship-building.

STERN-FAST, a rope used to confine the stern of a ship or boat to any wharf or jetty head, &c.

STERN-MOST, in sea language, usually denotes that part of a fleet of ships which is in the rear, or firthest a-stern, as opposed to head-most.
STERNE, Laurence, an English writer of a very peculiar cast, was born at Clonmel, in the south of Ireland, on the 24th November 1713. His father Roger Sterne was the grandson of Sterne archbishop of York, who has been supposed, we know not upon what grounds, to have been the author of the excellent book entitled "The Whole Duty of Man." Laurence inherited nothing of his ancestor's manner of writing, but rather resembled Rabelais, whose wit he carried with him even into the pulpit.

In 1722 he was sent to school at Halifax in Yorkshire, where he continued till 1732, when he was removed to Jesus College in Cambridge. How long he resided in college, or what progress he made in literature or science, is not known; his works display rather native genius than profound erudition. Upon quitting the university he went to York, and being in orders was presented to the living of Sutton by the interest of his uncle Dr. Sterne, a prebendary of that church. In 1741 he married, and was soon afterwards made a prebendary of York, by the interest also of his uncle, who was then upon very good terms with him; but "quickly quarrelled with him (he says), and became his bitterest enemy, because he would not be a party man, and write paragraphs in the newspapers." By his wife's means he got the living of Stillington, but remained nearly 20 years at Sutton, doing duty at both places. He was then in very good health, which, however, soon after forsook him; and books, painting, fiddling, and shooting, were, as he tells us, his amusements.

In 1760, he went to London to publish his two first volumes of "Tristram Shandy;" and was that year presented to the curacy of Coxwold. In 1762 he went to France, and two years after to Italy, for the recovery of his health; but his health never was recovered. He languished under a consumption of the lungs, without the slightest depression of spirits, till 1768, when death put a period to his terrestrial existence.

The works of Sterne are very generally read. They consist of, 1. The Life and Opinions of Tristram Shandy; 2. Sermons; 3. A Sentimental Journey; 4. Letters, published since his death. In every serious page, and in many of much levity, the author writes in praise of benevolence, and declares that no one who knew him could suppose him one of those wretches who heap misfortune upon misfortune: But we have heard anecdotes of him extremely well authenticated, which proved that it was easier for him to praise this virtue than to practise it. His wit is universally allowed; but many readers have persuaded themselves that they found wit in his blank pages, while it is probable that he intended nothing but to amuse himself with the idea of the sage conjectures to which these pages would give occasion.

Even his originality is not such as is generally supposed by those fond admirers of the Shandean manner, who have presumed to compare him with Swift, Arbuthnot, and Butler. He has borrowed both matter and manner from various authors, and in particular from an old work, "The Anatomy of Melancholy" by Burton," as every reader may be convinced by the learned, elegant, and candid comments on this work published by Dr. Ferris, in the fourth volume of the Memoirs of the Literary and Philosophical Society of Manchester.

STERNOHYOIDÆUS, in Anatomy. See Table of the Muscles, under the article ANATOMY.

STERNOWASTODEUS, in Anatomy. See Table of the Muscles, under the article ANATOMY.

STERNOCOSTALES, commonly called the musculi triangulares sterni, in Anatomy, are five pairs of fleshy planes, disposed more or less obliquely on each side the sternum, on the inside of the cartilages of the second, third, fourth, fifth, and sixth true ribs.

STERNOHYOIDÆUS, a muscle. See Table of the Muscles, under ANATOMY.

STERNOTHYROIDÆUS, a muscle. See Table of the Muscles, under ANATOMY.

STERNUM. See Anatomy Index.

STERNUTATIVE, or STERNUTATORY, a medicine proper to produce sneezing. See Sneezing.

STETIN, or STETTIN, a sea-port town of Germany, belonging to Prussia, and capital of Hither Pomerania, with the title of a duchy, and a castle. It has long been a famous school, which the wars of Germany never disturbed. The ancient dukes of Pomerania resided here; and it was taken by the elector of Brandenburg in 1676, but given to Sweden by the treaty of Nimegein. In 1713 it submitted to the allies; and then the said elector was put in possession again of this important place, which is a bulwark to the march of Brandenburg; and the fortifications have been greatly improved. It is now a flourishing place, and carries on a considerable trade. It is seated on the river Oder, 72 miles north of Francfort, and 70 north by east of Berlin. E. Long. 14. 38. N. Lat. 53. 35. The duchy is 325 miles in length, and borders upon Mecklenburg, and partly upon Brandenburg. The breadth is from 17 to 25 miles, and it is divided by the river Oder into two parts.

STEW, a small kind of fish-pond, the peculiar use of which is to maintain fish, and keep them in readiness for the daily use of the family, &c. STEUWS (from the French estuée, i. e. therme, balneum), those places which were permitted in England to women of professed incontinency; so called, because dissolute persons are wont to resort and immerse themselves in warm baths by bathing; and hot baths were by Homer reckoned among the effeminate sorts of pleasures. These stews were suppressed by King Henry VIII. about the year 1546.

STEWARD (seneschallus, compounded of the Saxon steda, i. e. "room" or "stede," and tegard, "a ward" or "keeper"), an officer appointed in another's stead or place, and always taken for a principal officer within his jurisdiction.
The greatest officer under the crown is the lord high-steward of England, an office that was anciently the inheritance of the earls of Leicester, till forfeited by Simon de Montfort to King Henry III. But the power of this officer is so very great, that it has not been judged safe to trust it any longer in the hands of a subject, excepting only pro hac vice, occasionally: as to officiate at a coronation, at the arraignment of a nobleman for high treason, or the like. During his office, the steward bears a white staff in his hand; and the trial, &c. ended, he breaks the staff, and with it his commission expires. There is likewise a lord-steward of the king's household, who is the chief officer of the king's court, has the care of the king's house, and authority over all the officers and servants of the household, except such as belong to the chapel, chamber, and stable.

Steward, an officer in a ship of war, appointed by the purser to distribute the different species of provisions to the officers and crew; for which purpose he is furnished with a mate and proper assistants.

Court of the Lord High Steward of Great Britain, is a court instituted for the trial of peers indicted for treason or felony, or for misprison of either. The office of this great magistrate is very ancient, and was formerly hereditary, or at least held for life, or dum bene se gesserit; but now it is usual, and hath been for many centuries past, granted pro hac vice only; and it hath been the constant practice (and therefore seems now to have become necessary) to grant it to a lord of parliament, else he is incapable to try such delinquent peer.

When such an indictment is therefore found by a grand jury of freeholders in the King's bench, or at the assizes before the justices of oyer and terminer, it is to be removed by a writ of certiorari into the court of the lord high-steward, which has the only power to determine it. A peer may plead a pardon before the court of King's bench, and the judges have power to allow it, in order to prevent the trouble of appointing an high-steward merely for the purpose of receiving such plea: but he may not plead in that inferior court any other plea, as guilty or not guilty of the indictment, but only in this court; because, in consequence of such plea, it is possible that judgment of death might be awarded against him. The king, therefore, in case a peer be indicted of treason, felony, or misprison, creates a lord high-steward pro hac vice by commission under the great seal; which recites the indictment so found, and gives his Grace power to receive and try it secundum legem et consuetudinem Angliae. Then when the indictment is regularly removed by writ of certiorari, commanding the inferior court to certify it up to him, the lord high-steward directs a precept to a serjeant at arms, to summon the lords to attend and try the indicted peer. This precept was formerly issued to summon only 18 or 20 selected from the body of the peers; then the number came to be indefinite; and the custom was for the lord high-steward to summon as many as he thought proper (but of late years not less than 23); and that those lords only should sit upon the trial; which threw a monstrous weight of power into the hands of the crown, and this its great officer, of selecting only such peers as the then predominant party should most approve of. And accordingly, when the earl of Clarendon fell into disgrace with Charles II. there was a design formed to prorogue the parliament, in order to try him by a select number of peers; it being doubted whether the whole house could be induced to fall in with the views of the court. But now, by statute 7 W. III. c. 3. upon all trials of peers for treason or misprison, all the peers who have a right to sit and vote in parliament shall be summoned at least 20 days before such trial, to appear and vote therein; and every lord appearing shall vote in the trial of such peer, first taking the oaths of allegiance and supremacy, and subscribing the declaration against popery.

During the session of parliament, the trial of an indicted peer is not properly in the court of the lord high-steward, but before the court last mentioned of our lord the king in parliament. It is true, a lord high-steward is always appointed in that case to regulate and add weight to the proceedings: but he is rather in the nature of a speaker pro tempore, or chairman of the court, than the judge of it; for the collective body of the peers are therein the judges both of law and fact, and the high-steward has a vote with the rest in right of his peerage. But in the court of the lord high-steward, which is held in the recess of parliament, he is the sole judge of matters of law, as the lords triors are in matters of fact; and as they may not interfere with him in regulating the proceedings of the court, so he has no right to intermix with them in giving any vote upon the trial. Therefore, upon the conviction and attaint of a peer for murder in full parliament, it hath been held by the judges, that in case the day appointed in the judgment for execution should lapse before execution done, a new time of execution may be appointed by either the high court of parliament during its sitting, though no high steward be existing, or, in the recess of parliament, by the court of King's bench, the record being removed into that court.

It has been a point of some controversy, whether the bishops have now a right to sit in the court of the lord high-steward to try indictments of treason and misprison. Some incline to imagine them included under the general words of the statute of King William "all peers who have a right to sit and vote in parliament;" but the expression had been much clearer, if it had been "all lords," and not "all peers;" for though bishops, on account of the baronies annexed to their bishoprics, are clearly lords of parliament, yet their blood not being ennobled, they are not universally allowed to be peers with the temporal nobility: and perhaps this word might be inserted purposely with a view to exclude them. However, there is no instance of their sitting on trials for capital offences, even upon impeachments or indictments in full parliament, much less in the court we are now treating of; for indeed they usually withdraw voluntarily, but enter a protest, declaring their right to stay. It is observable, that in the 11th chapter of the constitutions of Clarendon, made in parliament 11th Henry II. they are expressly excused, rather than excluded, from sitting and voting in trials, which concern life or limb: episcopi, sicut caetera barones, debent interesse judiciis cum baronibus, quoque perveniatur ad diminutionem membrorum vel ad mortem. And Becket's quarrel with the king hereupon was not on account of the exception (which was agreeable to the canon law), but of the general rule, that compelled the bishops to attend at all. And the determination of the house of lords
lords in the earl of Danby's case, which hath ever since been adhered to, is consonant to these constitutions; that the lords spiritual have a right to stay and sit in court in capital cases, till the court proceeds to the state of guilty or not guilty. It must be noted, that this resolution extends only to trials in full parliament; for to the court of the lord high-steward (in which no vote can be given, but merely that of guilty or not guilty), no bishop, as such, ever was or could be summoned: and though the statute of King William regulates the proceedings in that court, as well as in the court of parliament, yet it never intended to new-model or alter its constitution; and consequently does not give the lords spiritual any right, in cases of blood, which they had not before. And what makes their exclusion more reasonable is, that they have no right to be tried themselves in the court of the lord-high-steward, and therefore surely ought not to be judges there. For the privilege of being thus tried depends upon nobility of blood rather than a seat in the house, as appears from the trials of the popish lords, of lords under age, and (since the union) of the Scotch nobility, though not in the number of the sixteen; and from the trials of females, such as the queen consort or dowager, and of all peeresses by birth; and peeresses by marriage also, unless they have, when dowagers, disparaged themselves by taking a commoner to their second husband.

Steward of the Chiltern Hundreds. See Chiltern Hundreds.

Stewart, Dr Matthew, an eminent mathematician, was in 1717 born at Bothsay in the isle of Bute, of which parish his father was minister. Being intended for the church, he went through the usual course of a grammar-school education, and was in 1734 received as a student into the university of Glasgow. There he had the happiness of having for his preceptors in moral science and in mathematics the celebrated professors Hutcheson and Simson; by the latter of whom he was instructed in what may not improperly be called the arca of the ancient geometry.

Mr Stewart's views making it necessary for him to remove to Edinburgh, he was introduced by Dr Simson to Mr Maclaurin, that his mathematical studies might suffer no interruption; and he attended the lectures of that great master with such advantage as might be expected from eminent abilities, directed by the judgement of him who made the philosophy and geometry of Newton intelligible to ordinary capacities. Mr Stewart, however, had acquired, from his intimacy with Dr Simson, such a predilection for the ancient geometry, as the modern analysis, however powerfully recommended, could not lessen; and he kept up a regular correspondence with his old master, giving him an account of his progress and his discoveries in geometry, and receiving in return many curious communications respecting the Loci Plani and the porisms of Euclid. See Porism and Simson.

While the second invention of porisms, to which more genius was perhaps required than to the first discovery of them, employed Dr Simson, Mr Stewart pursued the same subject in a different and new direction. In doing so, he was led to the discovery of those curious and interesting propositions which were published under the title of General Theorems in 1746. They were given without the demonstrations; but did not fail to place their discoverer at once among the geometers of the first rank. They are for the most part porisms, though Mr Stewart, careful not to anticipate the discoveries of his friend, gave them no other name than that of theorems.

Our author had before this period entered into the church; and obtained, through the patronage of the duke of Argyle and the earl of Bute, the living of Rosneath, a retired country parish in the west of Scotland: but in 1747 he was elected to the mathematical chair in the university of Edinburgh, which had become vacant the year before by the death of Mr Maclaurin. The duties of this office gave a turn somewhat different to his pursuits, and led him to think of the most simple and elegant means of explaining those difficult propositions which were hitherto only accessible to men deeply versed in the modern analysis. In doing this, he was pursuing the object which of all others he most ardently wished to attain, viz. the application of geometry to such problems as the algebraic calculus alone had been thought able to resolve. His solution of Kepler's problem was the first specimen of this kind which he gave to the world; and it was impossible to have produced one more to the credit of the method he followed, or of the abilities with which he applied it. On this problem the utmost resources of the integral calculus had been employed. But though many excellent solutions had been given, there was none of them at once direct in its method and simple in its principles. Mr Stewart was so happy as to attain both these objects; and his solution appeared in the second volume of the Essays of the Philosophical Society of Edinburgh for the year 1756. In the first volume of the same collection there are some other propositions of Mr Stewart's, which are an extension of a curious theorem in the fourth book of Pappus. They have a relation to the subject of porisms, and one of them forms the gist of Dr Simson's Restoration. They are besides very beautiful propositions, and are demonstrated with all the elegance and simplicity of the ancient analysis.

The prosecution of the plan which he had formed of introducing into the higher parts of mixed mathematics the strict and simple form of ancient demonstration, produced the Tracts Physical and Mathematical, which were published in 1761, and the Essay on the Sun's Distance, which was published in 1763. In this last work it is acknowledged that he employed geometry on a task which geometry cannot perform; but while it is granted that this determination of the sun's distance is by no means free from error, it may safely be asserted that it contains a great deal which will always interest geometers, and will always be admired by them. Few errors in science are redeemed by the display of so much ingenuity, and what is more singular, of so much sound reasoning. The investigation is everywhere elegant, and will probably be long regarded as a specimen of the most arduous inquiry which has been attempted by mere geometry.

The Sun's Distance was the last work which Dr Stewart published; and though he lived to see several animadversions on it made public, he declined entering into any controversy. His disposition was far from polemical; and he knew the value of that quiet which a literary man should rarely suffer his antagonists to interrupt. He used to say, that the decision of the point in
in question was now before the public; that if his investigation was right it would never be overthrown, and that if it was wrong it ought not to be defended. A few months before he published the essay just mentioned, he gave to the world another work, intitled Propositiones Geometricae More Veterum Demonstratae. This title, it is said, was given to it by Dr Simson, who rejoiced in the publication of a work so well calculated to promote the study of the ancient geometry. It consists of a series of geometrical theorems, for the most part new; investigated first by an analysis, and afterwards synthetically demonstrated by the inversion of the same analysis.

Dr Stewart's constant use of the geometrical analysis had put him in possession of many valuable propositions which did not enter into the plan of any of the works that have been enumerated. Of these not a few have found a place in the writings of Dr Simson, where they will for ever remain to mark the friendship of these two mathematicians, and to evince the esteem which Dr Simson entertained for the abilities of his pupil.

Soon after the publication of the Sun's Distance, Dr Stewart's health began to decline, and the duties of his office became burdensome to him. In the year 1772 he retired to the country, where he afterwards spent the greater part of his life, and never resumed his labours in the university. But though mathematics had now ceased to be his business, they continued to be his amusement till a very few years before his death, which happened on the 23rd of January 1785, at the age of 68.

The habits of study, in a man of original genius, are objects of curiosity, and deserve to be remembered. Concerning those of Dr Stewart, his writings have made it unnecessary to remark, that from his youth he had been accustomed to the most intense and continued application. In consequence of this application, added to the natural vigour of his mind, he retained the memory of his discoveries in a manner that will hardly be believed. He rarely wrote down any of his investigations till it became necessary to do so for the purpose of publication. When he discovered any proposition, he would put down the enunciation with great accuracy, and on the same piece of paper would construct very nearly the figure to which it referred. To these he trusted for recalling to his mind at any future period the demonstration or the analysis, however complicated it might be. Experience had taught him, that he might place this confidence in himself without any danger of disappointment; and for this singular power he was probably more indebted to the activity of his invention than the mere tenaciousness of his memory. Though he was extremely studious, he read few books, and verified the observation of M. D'Alembert, that of all men of letters, mathematicians read least of the writings of one another. His own investigations occupied him sufficiently; and indeed the world would have had reason to regret the misapplication of his talents, had he employed in the mere acquisition of knowledge that time which he could dedicate to works of invention.

STEWART, in Scots Law. See Law Index.

STEWARDIA, a genus of plants belonging to the class monadelphia, and in the natural system ranging under the 37th order, Columniferae. See Botany Stewart Index.

STIBADIUM, among the Romans, a low kind of table couch or bed of a circular form, which succeeded to the triclinia, and was of different sizes according to the number of guests for which it was designed. Tables of this kind were called hexacлина, octacлина, or enneacлина, according as they held six, eight, or nine guests, and so of any other number.

STIBIUM, a name for Antimony.

STICHOS, a name given by the old writers to a pectoral confection, the principal ingredient of which was the herb marrubium or horchourd.

STICKLEBACK, a genus of fishes. See Gasterosteus, Ichthyology Index.

FOOT-STICKS, in Printing, slips of wood that lie between the foot of the page and the chase, to which they are wedged fast by the quoins, to keep the form firm, in conjunction with the side-sticks, which are placed at the side of the page, and fixed in the same manner by means of quoins.

STIFFLE, or GREAT MUSCLE, in the manege, is the part of the hind-leg of a horse which advances towards his belly. This is a most dangerous part to receive a blow upon.

STIGMA, a brand or impression with a hot iron; a mark of infamy. See Stigmatizing.

STIGMA, in Botany, the summit or top of the style, accounted by the sexualists the female organ of generation in plants, which receives the fecundating dust of the tops of the stamens, and transmits its vapour or effluvia through the style into the heart of the seed-bud, for the purpose of impregnating the seeds.

STIGMATA, in Natural History, the apertures in different parts of the bodies of insects communicating with the trachea or air-vessel, and serving for the office of respiration.

STIGMATA, in antiquity, certain marks impressed on the left shoulders of the soldiers when listed.

STIGMATA, were also a kind of notes or abbreviations, consisting only of points disposed various ways; as in triangles, squares, crosses, &c.

STIGMATIZED, is also a term used among the Franciscans, to express the marks or prints of our Saviour's wounds, said to have been miraculously impressed by him on the body of their seraphic father St Francis.

STIGMATIZING, among the ancients, was inflicted upon slaves as a punishment, but more frequently as a mark to know them by: in which case, it was done by applying a red-hot iron marked with certain letters to their foreheads, till a fair impression was made; and then pouring ink into their furrows, that the inscription might be the more conspicuous.

Soldiers were branded in the hand with the name or character of their general.

After the same manner, it was customary to stigmatize the worshippers and votaries of some of the gods. The marks used on these occasions were various; sometimes they contained the name of the god, sometimes his particular ensign, as the thunderbolt of Jupiter, the trident of Neptune, the ivy of Bacchus, &c. or they marked themselves with some mystical number, whereby the god's name was described. To these three ways of stigmatizing St John is supposed to refer (Rev. chap. xiii. ver. 16, 17.). Theodore is of opinion, that the Jews...
Jews were forbidden to brand themselves with stigmata, because the idolaters, by that ceremony, used to consecrate themselves to their false gods.

Among some nations, stigmatizing was considered as a distinguishing mark of honour and nobility. In Thrace, as Herodotus tells us, it was practised by none but persons of credit, nor omitted by any but persons of the meanest rank. The ancient Britons are also said to have imprinted on the bodies of their infants the figures of animals, and other marks, with hot irons.

STIL DE GRAIN, in the colour trade, the name of a composition used for painting in oil or water, and is made of a decoction of the liquor or Avignon berry, in alum-water, which is mixed with whiting into a paste, and formed into twisted sticks. It ought to be chosen of a fine gold yellow, very fine, tender, and friable, and free from dirt.

STILAGO, a genus of plants belonging to the class gynandra. See Botany Index.

STILBE, a genus of plants belonging to the class polygama, and order dioecia. See Botany Index.

STILBATE, a species of mineral, or variety of zeolite. See Zeolite, Mineralogy Index.

STILE. See Style.

STILL, the name of an apparatus used in chemistry for various purposes, and in the distillation of ardent spirits.

STILL-Bottoms, in the distillery, a name given by the traders to what remains in the still after working the wash into low wines. These bottoms are procured in the greatest quantity from the malt-wash, and are of so much value to the distiller in the fattening of hogs, &c. that he often finds them one of the most valuable articles of the business.

STILLINGFLEET, EDWARD, bishop of Worcester, was the son of Samuel Stillingsfleet, gentleman, and was born at Cranbourn in Dorsetshire in 1633. He was educated at St John's College, Cambridge; and having received holy orders, was, in 1657, presented to the rectory of Sutton in Nottinghamshire. By publishing his Origins Sacrae, one of the ablest defences of revealed religion that has ever been written, he soon acquired such reputation, that he was appointed preacher of the Rolls Chapel; and in January 1655 was presented to the rectory of St Andrew's, Holborn. He was afterwards chosen lecturer at the Temple, and appointed chaplain in ordinary to King Charles II. In 1668 he took the degree of doctor of divinity; and was soon after engaged in a dispute with those of the Romish religion, by publishing his discourse concerning the idolatry and fanaticism of the church of Rome, which he afterwards defended against several antagonists. In 1680 he preached at Guildhall a sermon on Phil. iii. 26, which he published under the title of The Mischief of Separation; and this being immediately attacked by several writers, he in 1683 published his Unreasonableness of Separation. In 1685 appeared his Origins Britannicae, or the Antiquities of the British Church, in folio. During the reign of King James IV, he wrote several tracts against popery, and was prolocutor of the convocation, as he had likewise been under Charles II. After the revolution he was advanced to the bishopric of Worcester, and was engaged in a dispute with the Socinians, and also with Mr Locke; in which last contest he is generally thought to have been unsuccessful. He died at Westminster in 1699, and was interred in the cathedral of Worcester, where a monument was erected to his memory by his son. Dr Stillingfleet wrote other works besides those here mentioned, which, with the above, have been reprinted in 6 vols. folio.

STILLINGFLEET, BENJAMIN, an ingenious naturalist, was grandson of the preceding. His father Edward was fellow of St John's College in Cambridge, F. R. S. M. D. and Gresham professor of physic; but marrying in 1602, he lost his lucrative offices and his father's favour; a misfortune that affected both himself and his posterity. However, going into orders, he obtained, by his father's means, the living of Newton-Butts, which he immediately exchanged for those of Wood Norton and Swanton in Norfolk. He died in 1708.

Benjamin, his only son, was educated at Norwich school, which he left in 1720, with the character of an excellent scholar. He then went to Trinity-College in Cambridge, at the request of Dr Bentley, the master, who had been private tutor to his father, domestic chaplain to his grandfather, and much indebted to the family. Here he was a candidate for a fellowship, but was rejected by the master's influence. This was a severe and unexpected disappointment, and but little alleviated afterwards by the Doctor's apology, that it was a pity that a gentleman of Mr Stillingfleet's parts should be buried within the walls of a college.

Perhaps, however, this ingratitude of Dr Bentley was not of any real disservice to Mr Stillingfleet. By being thrown into the world, he formed many honourable and valuable connections. He dedicated some translations of Linnaeus to the late Lord Lyttleton, partly, he says, from motives of private respect and honour. Lord Barrington gave him, in a very polite manner, the place of the master of the barracks at Kennington; a favour to which Mr Stillingfleet, in the dedication of his Calendar of Flora to that nobleman, alludes with equal politeness, as well as with the warmest gratitude. His Calendar of Flora was formed at Stratton in Norfolk in the year 1755, at the hospitable seat of his very worthy and ingenious friend Mr Marsham, who had made several observations of that kind, and had communicated to the public his curious observations on the growth of trees. But it was to Mr Wyndham of Felbrigg in Norfolk that he appears to have had the greatest obligation: he travelled abroad with him, spent much of his time at his house, and was appointed one of his executors (Mr Garrick was another); with a considerable addition to an annuity which that gentleman had settled upon him in his lifetime.

Mr Stillingfleet's genius seems, if we may judge from his works, to have led him principally to the study of natural history; which he prosecuted as an ingenious philosopher, an useful citizen, and a good man. In this walk of learning he mentions, as his friends, Dr Watson, Mr (afterwards Dr) Sander, Mr Hudson, Mr Price of Foxley, and some others; to whom may be added the ingenious Mr Pennant. Nor can we omit the flattering mention which Mr Gray makes of him in one of his letters, dated from London in 1761: "I have lately made an acquaintance with this philosopher, who lives in a garret here in the winter, that he may support some near relations who depend upon him. He is always employed, consequently (according to my old maxim)
maxim) always happy, always cheerful, and seems to me a very worthy honest man. His present scheme is to send some person, properly qualified, to reside a year or two in Attica, to make themselves acquainted with the climate, productions, and natural history of the country, that we may understand Aristotle, Theophrastus, &c. who have been heathen Greek to us for so many ages; and this he has got proposed to Lord Bute, no unlikely person to put it in execution, as he is himself a botanist.

Mr Stillingfleet published a volume of miscellaneous tracts, which is in much esteem, and does great honour to his head and heart. They are chiefly translations of some essays in the Aemnatiates Academicae, published by Linneus, interspersed with some observations and additions of his own. In this volume he shows also a taste for classical learning, and entertains us with some elegant poetic effusions of his own. But his Essay on Conversation, published in the first volume of Dodsley’s Collection of Poems, entitles him to a distinguished rank among our English poets. This poem is addressed to Mr Wyndham, with all that warmth of friendship which distinguishes Mr Stillingfleet. As it is chiefly didactic, it does not admit of so many ornaments as some compositions of other kinds. However, it contains much good sense, shows a considerable knowledge of mankind, and has several passages that in point of harmony and easy versification would not disgrace the writings of our most admired poets. Here more than once Mr Stillingfleet shows himself still sore for Dr Bentley’s cruel treatment of him; and towards the beautiful and moral close of it where it is supposed he gives us a sketch of himself) seems to hint at a mortification of a more delicate nature, which he is said to have suffered from the other sex.

To these disappointments it was perhaps owing that Mr Stillingfleet neither married nor went into orders. His London residence was at a saddler’s in Piccadilly; where he died in 1771, aged above 70, leaving several valuable papers behind him. He was buried in St James’s church, without the slightest monument to his memory.

STILLINGIA, a genus of plants belonging to the class monoeccia, and to the order of monadelphia. See BOTANY Index.

STILYARD. See STEEL-YARD.

STILPO, a celebrated philosopher of Megara, flourished under the reign of Poltemy Euergetes. In his youth he had been addicted to licentious pleasures, from which he religiously refrained from the moment that he ranked himself among philosophers. When Poltemy Soter, at the taking of Megara, offered him a large sum of money, and requested that he would accompany him into Egypt, he accepted but a small part of the offer, and retired to the island of Eiga, whence, on Pote- my’s departure, he returned to Megara. That city being again taken by Demetrios the son of Anticonus, and the philosopher required to give an account of any effects which he had lost during the hurry of the plunder, he replied that he had lost nothing; for no one could take from him his learning and eloquence. So great was the fame of Stilpo, that the most eminent philosophers of Athens took pleasure in attending upon his discourses. His peculiar doctrines were, that spe-

cies or universals have no real existence, and that one thing cannot be predicated of another. With respect to the former of these opinions, he seems to have taught the same doctrine with the sect afterwards known by the appellation of Nominalists. To prove that one thing cannot be predicated of another, he said, that goodness and man, for instance, are different things, which cannot be confounded by assigning the one to be the other: he argued farther, that goodness is an universal, and universals have no real existence; consequently since nothing cannot be predicated of any thing, goodness cannot be predicated of man. Thus, whilst this subtle logician was, through his whole argument, predicating one thing of another, he denied that any one thing could be the accident or predicate of another.

If Stilpo was serious in this reasoning; if he meant any thing more than to expose the sophistry of the schools, he must be confessed to have been an eminent master of the art of wrangling; and it was not wholly without reason that Glycera, a celebrated courtezan, when she was reproved by him as a corruptor of youth, replied, that the charge might be justly retorted upon himself, who spent his time in filling their heads with sophistical quibbles and useless subtleties. In ethics he seems to have been a Stoic, and in religion he had a public and a private doctrine, the former for the multitude, and the latter for his friends. He admitted the existence of a supreme divinity, but had no reverence for the Greek superstitions.

STILOBATUM, in Architecture, denotes the body of the pedestal of any column.

STILTON, a town of England, in Huntingdonshire, 75 miles from London, south-west of Yaxley, on the Roman highway from Castor to Huntingdon, called Ermine-street, some parts of which, in this neighbourhood, appear still paved with stone. This place is famous for cheese called English Parmesan, which is generally kept till it is old before it is brought to table, and even the process of decay is accelerated by various means, to render it agreeable to a vitiated taste. For making Stilton cheese, the following receipt is given in the first volume of the Repository of Arts and Manufactures:

"Take the night’s cream, and put it to the morning’s new milk, with the rennet; when the curd is come, it is not to be broken, as is done with other cheeses, but take it out with a soil-dish altogether, and place it in a sieve to drain gradually; and as it drains, keep gradually pressing it till it becomes firm and dry; then place it in a wooden hoop; afterwards to be kept dry on boards turned frequently, with cloth binders round it, which are to be tightened as occasion requires, and changed every day until the cheese become firm enough to support itself; after the cloth is taken off, the cheese is rubbed every day all over, for two or three months, with a brush; and if the weather be damp or moist twice a day; and even before the cloth is taken off, the top and bottom are well rubbed every day."

STIMULANTS, in Medicine, substances which increase the action of certain parts of the body. In particular, they quicken the motion of the blood, increase the action of the muscular fibres, and affect the nervous system.

STIMULI, in Botany, a species of armature or offensive weapon, with which some plants, as nettle, cassa-

† 4 U da,
da, acalypha, and tragia, are furnished. Their use, says
Linnæus, is by their venomous punctures to keep off
naked animals that would approach to hurt them.

STING, an apparatus in the bodies of certain insects,
in the form of a little spear, serving them as a weapon
of offence.

STING-Ray. See RAIA, ICHTHYOLOGY Index.

STINK-FOG, an earthen jar or shell, charged with
powder, grenades, and other materials of an offensive
and suffocating smell. It is frequently used by priva-
teers, in the western ocean, in the attack of an enemy
whom he designs to board; for which purpose it is fur-
nished with a light fuse at the opening or touch-hole.
See BOARDING.

STINT, a species of bird. See TRINGA, ORNITHO-
LOGY Index.

STIPA, FLEATHER GRASS, a genus of plants belong-
ing to the class triandra, and order of digynia; and in
the natural system ranging under the 4th order, Grami-
na. See BOTANY Index.

STIPEND, among the Romans, signifies the same
with tribute; and hence stipendiarii were the same with
tributarii.

STIPEND, in Scots Law. See LAW, § clxx. 10.

STIPULA, in Botany, one of the fulica or props of
plants, defined by Linneæus to be a scale, or small leaf,
stationed on each side the base of the footstalks of the
flower and leaves, at their first appearance, for the
purpose of support. Elmgren restricts it to the footstalks
of the leaves only.

STIPULATION, in the civil law, the act of stipu-
lating, that is, of treating and concluding terms and
conditions to be inserted in a contract. Stipulations were
anciently performed at Rome, with abundance of cere-
monies; the first whereof was, that one party should in-
terrogate, and the other answer, to give his consent, and
oblige himself. By the ancient Roman law, nobody could
stipulate but for himself; but as the tabelliones were pub-
lic servants, they were allowed to stipulate for their mas-
ters; and the notaries succeeding the tabelliones have
inherited the same privilege.

STIRIA, a province of Germany, in the circle of
Austria, with the title of a duchy. It is bounded on
the north by the archduchy of Austria, on the east by
Hungary, on the south by Carniola, and on the west
by Carinthia and the archbishopric of Salzburg; it is
340 miles in length and 60 in breadth; it covers an
area of 8,500 square English miles, and contains, in
1817, 799,000 inhabitants. Though it is a mountain-
ous country, yet there is a great deal of land fit for til-
lage, and the soil is so good, that the inhabitants never
are in want of corn. It contains mines of very good
iron; whence the arms made there are in great esteem.
The women differ greatly from the Austrians, and are
very plain and ingenious. They have all swellings on
their throats, called bronchocele. The men are also very
simple, and are rather disposed to indulge in idleness.
The chief town is Graz.

STIRLING, a town of Scotland, situated on the
river Forth, 35 miles north-west of Edinburgh, in W.
Long. 3° 59'. N. Lat. 56° 6'. It is also called Sterling
and Striveling; from the former of which Boethius falsely
derives the name Sterling money; because, says be,
Osbert, a Saxon prince, after the overthrow of the Scots,
established a mint there. The name of Striveling is said
to have been derived from the frequency of strifes or
conflicts in the neighbourhood. The town contained,
in 1811, 582 inhabitlants, but including St Ninians
the population was 13,456. It has a manufacture of
tartans and shawloons, and employs about 30 looms in
that of carpets. In it is the tolbooth, where is kept the
standard for the wet measures of Scotland. Stirling is
in miniature a resemblance of Edinburgh; being built
on a rock of the same form, with a fortress on the
summit. The origin of the castle is unknown. The rock
of Stirling was strongly fortified by the Picts, amongst
whom architecture and several other useful arts had
made a considerable progress. As it lay in the ex-
tremities of their kingdom, the possession of it was the
occasion of frequent contests between them and their
neighbours the Scots and Northumbrians; each of whose
dominions did, for some time, terminate near it.

When the Scots, under Kenneth II. overthrew the
Pictish empire near the middle of the ninth century,
they endeavoured to obliterate every memorial of that
people. They not only gave new names to provinces
and towns, but, with all the rage of barbarians, demoli-
ished many magnificent and useful edifices which had
been reared up by them, and this fortress among the rest.
It was, however, soon rebuilt, though upon an occasion
not very honourable to the Scots.

Upon the death of Kenneth II. in 855, his brother
Donald V. mounted the throne of Scotland. In the
beginning of his reign the kingdom was invaded by
Osbright and Ella, two Northumbrian princes, who,
uniting their forces with the Cumbrians Britons, and a
number of Picts, who upon their expulsion from their
native country had taken refuge in England, advanced to
Edinburgh, where Donald encountered them; and, af-
after a fierce and bloody battle, obtained a complete
victory: but, having taken up his station in Berwick, in
supine security, the Northumbrians, informed of the care-
less posture in which the Scottish army lay, surprised
them by a hasty march, dispersed them, and made a pri-
soner of the king. Pursuing the advantage they had
gained, they marched northward, and subdued all be-
fore them to the frith of Forth and the town of Stirl-
ing. But the forlorn situation of the Scots, without a
king and without an army, obliging them to sue for
peace, they obtained it, upon condition that they should
pay a sum of money for the ransom of the king, and
yield up all their dominions upon the south side of the
Forth to the conquerors.

The Northumbrians taking possession of the territo-
rious ceded to them by this treaty, rebuilt the castle of
Stirling, and planted it with a strong garrison, in order
to preserve their new conquests, upon the frontiers of
which it was situated. Our authorities also inform us,
that they erected a stone bridge over the Forth, upon the
summit of which a cross was raised, with the following
inscription in monkish rhyme.

Anglos a Scotia separat crux xata remotis;
Armis hic stant Britti. Scoti stant hic, cruce tuti.

Which is thus translated by Bellenden:

I am free marche, as passagerris may ken,
To Scottis, to Britonis, and to Inglesmen.

None of the ancient English historians mentions this
conquest. The whole story, as well as the inscription,
S T I

S T I

wears much of a monkish garb; yet its authenticity is not a little confirmed by the arms of the town of Stirling, upon which is a bridge, with a cross, and the last line of the above Latin distich is the motto round it.

We must not, however, imagine, that in those times that fortress bore any resemblance to the present structure, which is adapted to the use of fire-arms. Its size and form probably resembled those castles which, under the feudal constitution, the English and Scottish barons used to erect upon their estates for dwelling-houses, and which, in those barbarous ages, they found necessary to fortify for their defence, not only against foreign invaders, but often against the attacks of their own neighbours. It is directly such a Gothic figure as this which represents the Costrum Strivelense upon the arms of Stirling.

This fortress, after it had continued in the possession of the Northumbrian Saxons about 20 years, was, together with the whole country upon the south side of the Forth, restored to the Scots, upon condition of their assisting the Saxons against their turbulent invaders the Danes. Upon the arms of Stirling are two branches of a tree, to represent the Nemus Strivelense; but the situation and boundaries of that forest, which was probably a wing of the Caledonian, cannot be ascertained. Upon the south of Stirling, vestiges of a forest are still discernible for several miles. Banks of natural timber still remain in the castle park, at Murray's wood, and near Nether Bannockburn; and stumps of trees, with much brushwood, are to be seen in all the adjacent fields.

When Kenneth III. received intelligence of the Danes having invaded his dominions, he appointed the castle of Stirling to be the place of rendezvous for his army; and he marched thence to the battle of Lornachity, where he obtained a victory over those rovers, in the end of the 10th century.

In the 12th century, this castle is spoken of as a place of great importance, and one of the strongest castles in the kingdom. In 1174, a calamity not unusual amongst the Scottish monarchs, befell William, who at that time occupied the throne. He was taken prisoner in an unsuccessful expedition which he made into England; and, after having been detained 12 months in captivity, was released, upon stipulating to pay a large sum of money for his ransom; and, until payment thereof, delivering into the hands of the English the four principal fortresses in the kingdom, which in those days were Stirling, Edinburgh, Roxburgh, and Berwick. This was the first great advent that England obtained over Scotland; and indeed the most important transaction which had passed between these kingdoms from the Norman conquest.

Though the Scottish monarchs, in their frequent parambulations through the kingdom, often visited Stirling, and held their courts for some time in the castle; yet it did not become a royal residence till the family of Stuart mounted the throne, and it was from different princes of this family that it received its present form. It was the place of the nativity of James II. and, when raised to the throne, he frequently kept his court in it. It is well known to have been the place where that prince perpetrated an atrocious deed, the murder of William earl of Douglas, whom he stabbed with his own hand. The royal apartments were at that time in the north-west corner of the castle, and are now the residence of the fort-major. The room where the murder was committed still goes by the name of Douglas's room.

James III. contracting a fondness for the castle on account of its pleasant situation, made it the chief place of his residence, and added several embellishments to it. He built within it a magnificent hall, which in those days was deemed a noble structure, and is still entire. It now goes by the name of the parliament-house, having been designed for the accommodation of that supreme court. It was covered with an octagonal cover, of exquisite workmanship, which, though very little decayed, was a few years ago removed to make way for one of more modern structure. James also erected a college of secular priests in the castle, which he called the chapel royal, and which proved one cause of his own ruin. As the expenses necessary for maintaining the numerous officers of such an institution were considerable, he annexed to it the revenues of the rich priory of Coldham in the Merse, which at that time happened to become vacant. This priory had for a long time been helden by persons connected with the family of Hume; and that family, considering it as belonging to them, strongly opposed the annexation. The dispute seems to have lasted several years; for one parliament had passed a vote, annexing the priory to the chapel-royal, and a subsequent one enacted a statute prohibiting every attempt that was contrary or prejudicial to that annexion.

James V. was crowned in the castle of Stirling; and the palace, which is the chief or monument of it, was the work of that prince. This is a stately and commodious structure, all of hewn stone, with much statutory work upon it. It is built in form of a square, with a small court in the middle, in which the king's lions are said to have been kept; and hence it still goes by the name of the lions den. The palace contains many large and elegant apartments; the ground story is now converted into barrack-rooms for the soldiers of the garrison; the upper affords a house for the governor, with lodgings for some of the subaltern officers.

Opposite to the palace, upon the north, stands an elegant chapel, which was built by James VI. for the baptism of his son, Prince Henry, in 1594. In this chapel is preserved the hulk of a large boat, which that whimsical monarch caused to be built and placed upon carriages, in order to convey into the castle the provisions for that solemnity.

A strong battery, with a tier of guns pointing to the bridge over the Forth, was erected during the regency of Mary of Lorraine, mother to Queen Mary. It is called the French battery, probably because constructed by engineers of that nation. The last addition was made to the fortifications in the reign of Queen Anne. Formerly they reached no farther than the old gate, upon which the flag-staff now stands: but in that reign they were considerably enlarged upon the side towards the town; and barracks which are bomb-proof, with several other conveniences for a siege were erected.

Upon the south side of the castle lies a park inclosed with a stone wall, called the king's park, and near to the foot of the rock on which the castle stands, lay the royal gardens; vestiges of the walks and parterres, with a few stumps of fruit trees, are still visible; but by long neglect, and the natural wetness of the soil, the place is now
now little better than a marsh. In the garden's is a mount of earth in form of a table, with benches of earth around it, where, according to tradition, the court sometimes held _fetes-champêtres_. In the castle-hill is an hollow, comprehending about an acre of ground, and having all the appearance of an artificial work, which was used for jousts, tournaments, and other feats of chivalry.

Northward of the castle lies the Govan, or perhaps more properly the Goiling hill (A); in the middle of which is a small mount called _Harly Haunky_, upon which Duke Murdoch and his two sons were executed for treasonable practices in the reign of James I.

The prospect from the castle is most delightful, as well as extensive, being greatly beautified, especially upon the east, by the windings of the Forth; which are so numerous, that though the distance by land from Stirling to Alloa is, in a straight line, not quite six miles, it is said to be 24 by water. As this river generally runs upon plain ground, it rolls its stream in so slow and silent a manner, that what Silvius Italicus saith of the Ticinum is applicable to it, if, instead of *lucents* in that poet, we should read *lutoso*; for the clay-banks, together with the tide, which flows above Stirling, render the Forth perpetually muddy:

Vix credas labi, ripis tam mitis opacis
_Somniferam ducit lutoso gurgite lympham._

The lordship and castle of Stirling were a part of the usual dowry of the queens of Scotland, at least after the family of Stuart came to the throne, in which they were invested in their marriage.

Robert Lord Erskine was appointed governor of the castle by King David II. and the office continued in that family till 1715.

This fortress hath been the scene of many transactions. Being by its situation considered as a key to the northern parts of the kingdom, the possession of it hath been always esteemed of great importance to those who sought to be masters of Scotland. It was undoubtedly a place of strength when the art of war by ordinance was in its infancy; but though it resisted the utmost efforts of the rebels in 1746, it could not now hold out three days if besieged by an army of a few thousand men conducted by an engineer of knowledge and integrity.

_STIRLINGSHIRE_, a county of Scotland, of which Stirling is the capital. It extends 20 miles in length and 12 in breadth; being bounded on the west by part of Lennox and Clydesdale; on the east, by Clackmannanshire, the river Forth, and part of Lothian; on the south-east by Lothian; and on the north by Monteth. The face of the country is open and agreeable, diversified by hill and dale, well watered with streams and rivers, the principal of which is the Forth, rising in the neighbourhood of a high mountain called Ben-Lomond, and, running eastward, forms the frith of Edinburgh. The southern part is hilly, affording plenty of game, and pastureage for sheep, horses, and black cattle. The eastern part is fertile, producing plentiful harvests of corn, and great abundance of coal. Lead-ore is found in different parts of the county; and the rivers abound with pike, trout, and salmon.

The population of this county at two different periods, and according to the different parishes, will be seen in the following table:

In 1811 the population was 38,174. See Stirling.

_STIRROP_, in the manage, a rest or support for the horseman's foot, for enabling him to mount, and for keeping him firm in his seat.

Stirrup was unknown to the ancients. The want of them in getting upon horseback was supplied by agility or art. Some horses were taught to stoop to take their riders up; but the riders often leapt up by the help of their spears, or were assisted by their slaves, or made use of ladders for the purpose. Gracchus filled the highways with stones, which were intended to answer the same end. The same was also required of the surveyors of the roads in Greece as part of their duty.

Menage observes, that St Jerome is the first author who mentions them. But the passage alluded to is not to be found in his epistles; and if it were there, it would prove nothing, because St Jerome lived at a time when stirrups are supposed to have been invented, and after the use of saddles. Montfaucon denies the authenticity of this passage; and, in order to account for the ignorance of the ancients with regard to an instrument so useful and so easy of invention, he observes, that while the cloths and housings only were laid upon the horses backs, on which the riders were to sit, stirrups could not have been used, because they could not have been fastened with the same security as upon a saddle. But it is more

(A) So called from the wailings and lamentations (in Scotch, _gowlings_) that were made for Duke Murdoch.
more probable, that in this instance, as in many others, the progress of human genius and invention is uncertain and slow, depending frequently upon accidental causes.

**Stirrup of a Ship**, a piece of timber put upon a ship's keel, when some of her keel happens to be beaten off, and they cannot come conveniently to put or fit in a new piece; then they patch in a piece of timber, and bind it on with an iron, which goes under the ship's keel, and comes up on each side of the ship, where it is nailed strongly with spikes; and this they call a stirrup.

**STOBÆUS, John**, a laborious Greek writer, who lived at the end of the fourth century, composed many works, of which there are only his Collections remaining, and these are not as he composed them; many things being inserted by later authors. This work contains many important sentiments collected from the ancient writers, poets, and philosophers.

**STOCK**, in gardening, &c. the stem or trunk of a tree. What stock is most proper for each kind of fruit, ought as well to be considered and known, as what soil is most suitable to trees; for on these two things the future vigour of trees, and the goodness of fruits, equally depend. The best way for those who intend to plant, is to raise their own stocks, by which they will be better assured of what they do; but if they should buy their trees of nurserymen, they should diligently inquire upon what stocks they were propagated. See **Grafting**.

**STOCK, in Trade.** See **Capital Stock**.

**STOCK-Broker.** See **Broker and Stocks**.

**STOCK-Dove.** See **Columba, Ornithology Index**.

**Stock-Jobbing.** See **Cheiranthus, Botany Index**.

**STOCKHOLM, the capital of Sweden, is situated in the province of Upland, in E. Long. 19. 32. and N. Lat. 59. 20. Its foundation is by the best Swedish writers generally attributed to Birger Jarl, regent of the kingdom about the middle of the 13th century during the minority of his son Waldemar, who had been raised to the throne by the states of the kingdom; but it was not before the 18th century that the royal residence was transferred from Upsala to this city.**

This capital, which is very long and irregular, occupies, beside two peninsulas, seven small rocky islands, scattered in the Maeler, in the streams which issue from that lake, and in a bay of the golf of Bothnia. A variety of contrasted and enchanting views are formed by numberless rocks of granite rising boldly from the surface of the water, partly bare and craggy, partly dotted with houses, or feathered with wood. The harbour is an inlet of the Baltic; the water is clear as crystal, and of such depth that ships of the largest burden can approach the quay, which is of considerable breadth, and lined with spacious buildings and warehouses. At the extremity of the harbour several streets rise one above another in the form of an amphitheatre; and the palace, a magnificent building, crowns the summit. Towards the sea, about two or three miles from the town, the harbour is contracted into a narrow strait, and, winding among high rocks, disappears from the sight; and the prospect is terminated by distant hills, overspread with forests. It is far beyond the power of words, or of the pencil, to delineate these singular views. The central island, from which the city derives its name, and the Ritterholm, are the handsomest parts of the town. Excepting in the suburbs, where the houses are of wood painted red, the generality of the buildings are of stone, or brick stuccoed white. The royal palace, which stands in the centre of Stockholm, and upon the highest spot of ground, was begun by Charles XI.: it is a large quadrangular stone edifice, and the style of architecture is both elegant and magnificent.

It is the habituation not only of the royal family, but also of the greater part of the officers belonging to the household. It likewise comprehends the national or supreme court of justice, the colleges of war, chancellery, treasury, and commerce; a chapel, armory, library, and office for the public records; but the greater number of inferior officers and servants belonging to the court, are, with the foot-guards, quartered on the burghers. The castle, and all the stately edifices in the kingdom, are covered with copper. The palace of the nobility, in which this order sits during the session of the diet, is an elegant building, adorned on the outside with marble statues and columns, and on the inside with painting and sculpture. This and three other palaces stand on the banks of the lake, and are built on the same model, so as to compose a uniform piece of architecture. The bank, built at the expense of the city, is a noble edifice, and joins with many sumptuous houses belonging to the nobility in exhibiting a splendid appearance. The houses of the burghers are generally built of brick in the city; but in the suburbs they are commonly made up of timber, and therefore very subject to conflagrations. These houses are often framed in Finland, according to the plan and dimensions prescribed: whence they are transported in pieces to Stockholm by water, and there set up by the carpenters. These wooden habitations, if kept in proper repair, will last 30 or 40 years, and are deemed warmer, neater, and more healthful, than those of brick or stone. To prevent the danger of conflagrations, the city is divided into 12 wards. In each of these there is a master and four assistants, who forthwith repair to the place where the fire breaks out; and all porters and labourers are obliged to range themselves under the master of the ward to which they belong. A fire-watch patrols the streets by night, to give warning or assistant as it may be wanted; and a sentinel is maintained in the steeple of every church, to toll the bell on the first appearance of any such accident. The police of Stockholm is entirely subjected to the regulations of the grand governor, assisted by a deputy and bailiff of the castle. This city is theemporium of Sweden, to which all the commodities of the kingdom are brought for exportation, and where almost all the imports from abroad are deposited. The port or haven formed by the lake Maeler is large enough to contain 1000 sail of shipping; and furnished with a key or wharf about an English mile in length, to which the vessels may lie with their broadsides. The greatest inconveniences attending this situation are, the distance from the sea, which is not within less than 12 miles of the town; the want of tide; and the winding of the river, which is remarkably crooked. It opens into the Baltic; and the entrance, which is dangerous and rocky, the Swedes have secured with two small forts: within, it is perfectly safe and commodious.
Their only means of support was the knitting of stockings, at which the woman was very expert: "But sitting constantly together from morning to night, and the scholar often fixing his eyes, with steadfast observation, on the motion of his wife's fingers in the dexterous management of her needles, he took it into his imagination, that it was not impossible to contrive a little loom which might do the work with much more expedition. This thought he communicated to his wife, and joining his head to her hands, the endeavour succeeded to their wish. Thus the ingenious stocking-loom, which is so common now, was first invented; by which he did not make himself and his family happy, but has left his nation indebted to him for a benefit which enables us to export silk stockings in great quantities, and to a vast advantage, to those very countries from whence before we used to bring them at considerable loss in the balance of our trade."

**STOCKS, or PUBLIC FUNDS in England.**

By the word *stock* was originally meant a particular sum of money contributed to the establishing a fund to enable a company to carry on a certain trade, by means of which the person became a partner in that trade, and received a share of the profits or losses, in proportion to the money employed. But this term has been extended farther, though improperly, to signify any sum of money which has been lent to the government, on condition of receiving a certain interest till the money is repaid, and which makes a part of the national debt. As the security both of the government and of the public companies is esteemed preferable to that of any private person, as the stocks are negociable and may be sold at any time, and as the interest is always punctually paid when due; so they are thereby enabled to borrow money on a lower interest than what could be obtained from lending it to private persons, where there must be always some danger of losing both principal and interest.

But as every capital stock or fund of a company is raised for a particular purpose, and limited by parliament to a certain sum, it necessarily follows, that when that fund is completed, no stock can be bought of the company; though shares already purchased may be transferred from one person to another. This being the case, there is frequently a great disproportion between the original value of the shares and what is given for them when transferred: for if there are more buyers than sellers, a person who is indifferent about selling will not part with his share without a considerable profit to himself; and on the contrary, if many are disposed to sell, and few inclined to buy, the value of such shares will naturally fall in proportion to the impatience of those who want to turn their stock into specie.

A stock may likewise be affected by the court of chancery: for if that court should order the money, which is under their direction, to be laid out in any particular stock, that stock, by having more purchasers, will be raised to a higher price than any other of the like value.

By what has been said, the reader will perceive how much the credit and interest of the nation depends on the support of the public funds. While the annuities and interest for money advanced is there regularly paid, and the principal insured by both prince and people (a security...
Stocks, a frame erected on the shore of a river or harbour, wherein to build shipping. It generally consists of a number of wooden blocks, ranged parallel to each other at convenient distances, and with a gradual declivity towards the water.

Stocks, a wooden machine to put the legs of offenders in, for securing disorderly persons, and by way of punishment in divers cases, ordained by statute, &c.

STOCKTON upon Tees, a handsome town in the county of Durham, about 16 miles south of the city of Durham. It is now a port of considerable trade; though at the restoration, it was a despicable village, the best house in which could hardly boast of any thing better than clay-walls and a thatched roof. The population of this place in 1801 was 4,000, and in 1811, 4,229.

STOEBE, BASTARD ETHIOPIAN, a genus of plants belonging to the class synogenesis; and in the natural system ranging under the 49th order, Composite. See BOTANY INDEX.

STOKESIA, a genus of plants belonging to the synogenesis class, and order of polyanthae. The corollas in the ray are disposed in the shape of a funnel, and are long and irregular. The down is four-bristled, and the receptacle is naked. One species only is known, which is a herbaceous plant, and a native of South Carolina.

STOICS, the name given to a sect of Grecian philosophers, from Stoas, "the porch in Athens," which the founder of the sect chose for his school. For the peculiar tenets of this sect, see METAPHYSICS, Chap. IV. Part 3. MORAL PHILOSOPHY, No. 8. and ZENO.

STOLBERG, a small town in Germany, in the circle of Upper Saxony, and territory of Thuringia, of which it is the capital. It is situated between two mountains, 50 miles north-west of Leipzig. E. Long. 11° 8' N. Lat. 51° 42'.

STOLE, a sacerdotal ornament worn by the Roman parish priests above their surplice, as a mark of superiority in their respective churches; and by other priests over the alb, at celebrating of mass, in which case it goes across the stomach; and by deacons, over the left shoulder, scarf-wise: when the priest reads the gospel for any one, he lays the bottom of his stole on his head. The stole is a broad swath, or slip of stuff, hanging from the neck to the feet, with three crosses thereon.

Groom of the Stole, the eldest gentleman of his Majesty's bedchamber, whose office it is to present and put on his Majesty's first garment, or shirt, every morning, in order to the things in the closet.

STOMACH, in Anatomy. See ANATOMY, No. 91.

STOMACHIC MEDICINES are such as strengthen the stomach and promote digestion, &c.

Stomachic corroboratives are such as strengthen the tone of the stomach and intestine; among which are carminatives, as the roots of galangals, red gentian, zedoary, pimpiuella, calamus aromaticus, and arum. Of barks and rinds, those of cancilia alba, sassafras, citrons, Seville and China oranges, &c. Of spices, pepper, Stomachic ginger, cloves, cinnamon, cardamoms, and mace.

STOMOXYS, a genus of insects belonging to the order of diptera. See ENTOMOLOGY, p. 214.

STONE, EDMUND, a distinguished self-taught mathematician, was born in Scotland; but neither the place nor the time of his birth is well known; nor have we any memoirs of his life, except a letter from the Chevalier Ramsay, author of the Travels of Cyrus, in a letter to Father Castel, a Jesuit at Paris, and published in the Memoirs de Trevoux, p. 150, as follows: "True genius overcomes all the disadvantages of birth, fortune, and education; of which Mr. Stone is a rare example. Born a son of a gardener of the duke of Argyle, he arrived at eight years of age before he learnt to read. By chance a servant having taught young Stone the letters of the alphabet, there needed nothing more to discover and expand his genius. He applied himself to study, and he arrived at the knowledge of the most sublime geometry and analysis, without a master, without a conductor, without any other guide but pure genius.

"At 18 years of age he had made these considerable advances without being known, and without knowing himself the prodigies of his acquisitions. The duke of Argyle, who joined to his military talents a general knowledge of every science that adorns the mind of a man of his rank, walking one day in his garden, saw lying on the grass a Latin copy of Sir Isaac Newton's celebrated Principia. He called some one to him to take and carry it back to his library. Our young gardener told him that the book belonged to him. 'To you?' replied the duke. 'Do you understand geometry, Latin, Newton?' I know a little of them, replied the young man with an air of simplicity arising from a profound ignorance of his own knowledge and talents. The duke was surprised; and having a taste for the sciences, he entered into a conversation with the young mathematician: he asked him several questions, and was astonished at the force, the accuracy, and the candour of his answers. 'But how (said the duke) came you by the knowledge of all these things?' Stone replied, 'A servant taught me, ten years since, to read: Does one need to know any thing more than the 24 letters in order to learn everything else that one wishes? The duke's curiosity redoubled—he sat down upon a bank, and requested a detail of all his proceedings in becoming so learned.

"I first learned to read, said Stone: the masons were then at work upon your house: I went near them one day, and I saw that the architect used a rule, compasses, and that he made calculations. I inquired what might be the meaning and use of these things; and I was informed that there was a science called Arithmetic: I purchased a book of arithmetic, and I learned it.—I was told there was another science called Geometry: I bought the books, and I learnt geometry. By reading I found that there were good books in these two sciences in Latin: I bought a dictionary, and I learned Latin. I understood also that there were good books of the same kind in French: I bought a dictionary, and I learned French. And this, my lord, is what I have done: it seems to me that we may learn every thing when we know the 24 letters of the alphabet.'

"This account charmed the Duke. He drew this wonderful
wonderful genius out of his obscurity; and he provided
him with an employment which left him plenty of time
to apply himself to the sciences. He discovered in him
also the same genius for music, for painting, for archi-
tecture, for all the sciences which depend on calcula-
tions and proportions.

"I have seen Mr Stone. He is a man of great
simplicity. He is at present sensible of his own know-
ledge; but he is not pulled up with it. He is posses-
sed with a pure and disinterested love for the math-
ematics, though he is not solicitous to pass for a ma-
thematieian; vanity having no part in the great labour
he sustains to excel in that science. He despises for-
tune also; and he has solicited me twenty times to re-
quest the duke to give him less employment, which may
not be worth the half of that he now has, in order to
be more retired, and less taken off from his favourite
studies. He discovers sometimes, by methods of his
own, truths which others have discovered before him.
He is charmed to find on these occasions that he is not
a first inventor, and that others have made a greater
progress than he thought. Far from being a plagiarist,
he attributes ingenious solutions, which he gives to cer-
tain problems, to the hints he has found in others, al-
though the connection is but very distant," &c.

Mr Stone was author and translator of several useful
works; viz. 1. A New Mathematical Dictionary, in
1 vol. 8vo, first printed in 1726. 2. Fluxions, in 1
vol. 8vo, 1730. The Direct Method is a translation
from the French, of Hospital's Analyse des Infiniments
Petits; and the Inverse Method was supplied by Stone
himself. 3. The Elements of Euclid, in 2 vol. 8vo,
1731. A neat and useful edition of those Elements,
with an account of the life and writings of Euclid, and
a defence of his Elements against modern objectors.
Beside other smaller works. Stone was a fellow of
the Royal Society, and had inserted in the Philosophi-
cal Transactions (vol. xii. p. 218.), an "Account of
two species of lines of the 3d order, not mentioned by
Sir Isaac Newton or Mr Stirling."

STONE, Jerome, the son of a reputable seaman, was
born in the parish of Scoonie, in the county of Fife,
Newcastiel. His father being abroad when he was
but three years of age, and his mother, with her young
family, was left in very narrow circumstances. Jerome,
lke the rest of the children, having got the ordinary
school education, reading English, writing, and arith-
metic, betook himself to the business of a travelling
chapman. But the dealing in buckles, garters, and
such small articles, not suiting his superior genius, he
soon converted his little stock into books, and for some
years went through the country, and attended the fairs
as an itinerant bookseller. There is great reason to
believe that he engaged in this new species of traffic,
more with a view to the improvement of his mind than
for any pecuniary emolument. Formed by nature for
literature, he possessed a peculiar talent for acquiring
languages with amazing facility. Whether from a de-
sire to understand the Scriptures in their original lan-
guages, or from being informed that these languages
are the parents of many others, he began his philologi-
cal pursuits with the study of the Hebrew and Greek
tongues; and, by a wonderful effort of genius and ap-
plication, made himself so far master of these, without
any kind of assistance, as to be able to interpret the
Hebrew bible and Greek Testament into English ad
operturam libri. At this time he did not know one word
of Latin. Sensible that he could make no great pro-
gress in learning, without the knowledge of at least the
grammar of that language, he made application to the
parish schoolmaster for his assistance. Some time after-
wards, he was encouraged to prosecute his studies at the
university of St Andrew's. An unexampled proficiency
in every branch of literature recommended him to the
esteem of the professors; and an uncommon fund of
wit and pleasantry rendered him at the same time, the
favourite of all his fellow students, some of whom speak
of him to this day with an enthusiastic degree of admira-
tion and respect. About this period some very hu-
morous poetical pieces of his composition were published
in the Scots Magazine. Before he had finished his third
session, or term, at St Andrew's, on an application to
the college by the master of the school of Dunkeld for
an usher, Mr Stone was recommended as the best qua-
lified for that office; and about two or three years af-
after, the master being removed to Perth, Mr Stone,
by the favour of his Grace the Duke of Atholl, who had
conceived a high opinion of his abilities, was appointed
his successor.

When he first went to Dunkeld, he entertained but
an unfavourable opinion of the Gaelic language, which
he considered as nothing better than a barbarous inart-
iculate gibberish; but being bent on investigating the
origin and descent of the ancient Scots, he suffered not
his prejudices to make him neglect the study of their
primitive tongue. Having, with his usual assiduity and
success, mastered the grammatical difficulties which he
encountered, he set himself to discover something of the
ture genius and character of the language. He collect-
ed a number of ancient poems, the production of Irish
or Scottish bards, which, he said, were daring, inno-
cent, passionate, and bold. Some of these poems were
translated into English verse, which several persons
now alive have seen in manuscript, before Mr Mac-
pherson published any of his translations from Ossian.

He died while he was writing and preparing for the
press a treatise, intitled, "An Inquiry into the Origin,
Language and Language of the ancient Scots,
with Conjectures about the Primitive State of the Celtic
and other European Nations;" an idea which could not
have been conceived by an ordinary genius. In this
treatise he proves that the Scots drew their original, as
well as their language, from the ancient Gauls. Had
Mr Stone lived to finish this work, which discovers great
ingenuity, immense reading, and indefatigable industry,
it would have thrown light upon the dark and early pe-
riods of the Scottish history, as he opens a new and plain
path for leading us through the unexplored labyrinths
of antiquity. But a fever put an end to his life, his la-
bours, and his usefulness, in the year 1777, being then
only in the 30th year of his age. He left, in manus-
script, a much esteemed and well-known allegory, inti-
tled, "The Immortality of Authors," which has been
published and often reprinted since his death, and will
be a lasting monument of a lively fancy, sound judg-
ment, and correct taste. It was no small ornament of
this extraordinary character, that he paid a pious regard
to his aged mother, who survived him two years, and
received an annual pension from the Duchess of Atholl
as a testimony of respect to the memory of her son.

STONEHIVE,
STONEHIVE, or STONEHAVEN, a small town in the county of Kincardine, in Scotland, 15 miles south from Aberdeen. It was built in the time of Charles II. and stands at the foot of some high cliffs, in a small bay, with a rocky bottom, opening a little in one part; so that small vessels may find admission, but only at high water. A pier runs out from the harbour on the north side to secure them after their entrance. The town contains about 800 inhabitants. The manufactures are sail-cloths and oaksburghs, knit worsted and thread stockings.

STONES, in Natural History, have been defined bodies which are insipid, not ductile, nor inflammable, nor soluble in water. For a view of the classification of stones, and of their distribution, see Mineralogy and Geology.

Here we shall make a few observations on some speculative discussions relative to their natural history. As philosophers have perplexed themselves much about the origin and formation of the earth (a subject certainly far beyond the ken of the human intellect, at least if we believe that it was made by the almighty power of God, so they have also proposed theories to explain the origin of stones. When philosophers limit their inquiries within the boundaries of science, where they are led by the sober and safe conduct of observation and experiment, their conclusions may be solid and may be useful; but when, throwing experiment and observation aside, they rear a theory upon an airy nothing, or upon a single detached fact, their theories will vanish before the touch of true philosophy as a romantic palace before the rod of the enchanter. Sometimes from whim, or caprice, or vanity, they attempt to confound every thing; they wish to prove that the soul is mere matter, that plants are animals, and that fossils are plants, and thus would banish two substances, spirit and dead matter, entirely from the world; as if the Author of Nature were actuated by sordid views of parsimony in the works of creation, though we evidently see that a generous portion is left of the characteristic mark of these works. We leave the task of confounding the different classes of beings to those philosophers whose minds are too contracted to comprehend a great variety of being at one view, or who prefer novelty to everything else. We content ourselves with the old opinion, that the soul is a spiritual substance; that plants are plants, and that stones are stones.

We have been led into these remarks by finding that some philosophers say that stones are vegetables; that they grow and increase in size like a plant. This theory, we believe, was first offered to the world by M. Tournefort, in the year 1702, after returning from his travels in the east. It was founded on a curious fact. In surveying the labyrinth of Crete, he observed that the names which visitors had engraved upon the rock were not formed of hollow but of prominent letters like basso relievo.

He supposes that these letters were at first hollowed out by knives, that the hollows have since been filled up by the growth of the stone; and hence he concludes that stones vegetate. We wish we were fully assured of the fact that the letters were at first hollowed, before we attempt to account for their prominence. But even allowing the supposition to be true that they were at first hollow, we reply it is only a single fact, and that it is altogether unphilosophical to deduce a general system from a single fact.

In the second place, this prodigality of the characteristics is very improperly called vegetation, for it is not produced by a process in any respect like the vegetation of a plant. Vegetation supposes vessels containing fluids and growth by expansion; but who ever heard of vessels in a stone, of fluids moving in them, or of the different parts expanding and swelling like the branch or trunk of a tree? Even the fact which Tournefort mentions proves nothing. He does not pretend to say, that the rock itself is increasing, but only that a few small hollows are filled with new stone matter, which rise a little above the surrounding surface of the rock. This matter evidently has been once liquid, and at length has congealed in the channel into which it had run. But is not this easily explained by a common process, the formation of stalactites? When water charged with calcareous matter is exposed to the action of air, the water evaporates, and leaves the calcareous earth behind, which hardens and becomes like a stone.

Having thus examined the principal fact upon which M. Tournefort founds his theory, it is unnecessary to follow him minutely through the rest of his subject—He compares the accretion of matter in the labyrinth to the consolidation of a bone when broken, by a callus formed of the extravasated nutritious juice. This observation is thought to be confirmed, by finding that the projecting matter of the letters is whitish and the rock itself grayish. But it is easy to find comparisons. The difficulty, as Pope says, is to apply them. The resemblance between the filling up of the hollow of a stone, and the consolidation of a broken bone by a callus, we confess ourselves not philosophers enough to see.

Were we writing poetry in bad taste, perhaps it might appear. The circumstance, that the prominent matter of the letters is whitish, while the rock is grayish, we flatter ourselves strengthens our supposition that it consists of a deposition of calcareous matter. Upon the whole, we conclude, we hope logically, that no such theory as this, that stones are vegetables, can be drawn from the supposed fact respecting the labyrinth. We have to regret, that the account which we have seen of the subject is so imperfect, that we have not sufficient materials for a proper investigation. Tournefort has not even told us of what kind of stone or earth the accretion consists; yet this single information would probably have decided the question (a).

STONES

(a) To give a more distinct notion of Tournefort's theory, we shall subjoin his conclusions: From these observations (he says) it follows, that there are stones which grow in the quarries, and of consequence that are fed; that the same juice which nourishes them serves to rejoin their parts when broken; just as in the bones of animals, and the branches of trees, when kept up by bandages; and, in a word, that they vegetate. There is, then (he says), no room to doubt but that they are organized; or that they draw their nutritious juice from Vol. XIX. Part II.
STONES AND EARTHS, ANALYSIS OF.

At the close of our article Mineralogy, we referred to this place for an account of the method of examining the chemical constitution of earths and stones. In the article Ores, we have given a pretty full detail of the method of analysing that class of minerals. In this place we propose briefly to point out the most improved processes for the analysis of the other three classes of mineral bodies, viz. earths and stones, salts, and combustibles; to which we shall add some account of the method of examining soils.

But before proceeding to the immediate object of this treatise, it may be useful to make some observations on some preliminary processes connected with the subject under consideration.

In the first place, it is necessary that the mineral be examined be reduced to a fine powder. To effect this with very hard stones, they are made red hot, and in this state thrown into cold water. By the sudden change of temperature in the different parts of the stone, it cracks, and falls to pieces. If the pieces be not sufficiently small, the same process is to be repeated. The fragments are then to be reduced to smaller pieces in a polished steel mortar, and the cavity of this mortar ought to be cylindrical. A pestle of the same metal should be made to fit it exactly, that no part of the stone may escape during the operation of pounding. The stone being in this way reduced to powder, a determinate quantity is taken, 100 or 200 grains, for example, and this is to be reduced to as fine a powder as possible; or, as it is called, to an impalpable powder. This operation is most successfully performed in an agate mortar, with a pestle of the same mineral; a mortar of about four inches in diameter, and rather more than one inch deep, is found to answer the purpose very well. It is found most convenient to operate on small quantities only at a time; not more than five or six grains. When the powder feels soft, adheres, and appears under the pestle in the form of a cake, it is then as fine as possible. It is now to be accurately weighed, and it is usually found to have acquired some additional weight, arising from part of the mortar being worn off during the pounding. This additional weight must be attended to, and after the analysis is completed, a part of the substance of the mortar must be subtracted. In the case of an agate or flint mortar being used, the portion rubbed off, which increases the weight, may be regarded as pure siliceous earth.

The chemical vessels necessary for the analysis of minerals are crucibles for exposing the substances to heat, Preliminary glasses and shallow dishes for solutions and evaporations. The crucibles should be of platin a or pure silver, and of such a capacity as to hold from seven to eight cubic inches of water. The vessels in which the solutions, evaporations, and other processes are performed, should be of glass or porcelain; the glass vessels, as being more brittle, and therefore more apt to break, are found to be less economical than those of porcelain. Some chemists employ porcelain vessels which are in the form of sections of spheres, and are glazed both in the inside and outside, excepting part of the bottom, which comes into immediate contact with the fire. Wedgwood’s glazed vessels for evaporations, are found to answer very well; the glaze is thin, and the vessels are not very apt to crack; but it is supposed by some chemists, that it is occasionally acted on by strong acids. It is scarcely necessary to add, that an accurate balance is a necessary instrument in the hands of the analyst.

I. OF THE ANALYSIS OF EARTHS AND STONES.

The ingredients which have been discovered by means of analysis, in the composition of simple stones are silica, alumina, lime, magnesia, zirconia, and glucina, with some of the metallic oxides, as those of iron, copper, manganese, chromium, and nickel; but it never happens that the whole of these substances are found in combination; and indeed it is a rare circumstance to meet with more than four or five in the same stone. With a view of discovering the different substances which enter into the composition of stones, the following method is recommended.

Take 200 grains of the stone to be examined; in this case, the stone should be thoroughly cold, and the quantity of 200 grains will be sufficient. Let it be reduced to a fine powder, mixed with three times its weight of pure potash, and a small portion of water, and then subjected to heat in a crucible of silver. The heat must be applied slowly at first, and the matter is to be constantly stirred, that no part of it may be thrown out of the crucible by the swelling of the potash. The water being evaporated, the mixture is to be kept at a red heat for half an hour; and being removed from the furnace, some notion may be formed of the nature of the ingredients, by examining the contents; for, if the mixture be in a liquid state, the stone is chiefly composed of siliceous earth; if it be of the consistency of paste, and have an opaque appearance,
STONES, &c.

Preliminary, the other earths predominate; but if it remain in a powdery form, the aluminous earth is in greatest proportion. The oxides of different metals are indicated by the colour of the mass; when it is of a dark or brownish red, the metallic oxide is that of iron; a grass green colour denotes manganese; and yellowish green the oxide of chromium.

But there are some stones on which potash has a very feebble action, and in this case borax has been substituted for the alkalii. This is the method which was followed by Mr. Chenery in analysing aluminous stones. A hundred grains of sapphire in powder were mixed with 250 grains of calcined borax, and subjected to a strong heat in a crucible of platina for two hours. When the mass was cold, it exhibited the appearance of a greenish-blue glass, which adhered strongly to the crucible; but the whole being boiled for some hours in muriatic acid, it was completely dissolved; the earthy matter was then precipitated by means of sub-carbonate of ammonium, and the precipitate, after being well washed, was again dissolved in muriatic acid; and in this way the borax was separated. The remaining part of the analysis was nearly similar to that directed for other stones, excepting only that the alumina was separated from the potash by means of muriate of ammonia.

But to return to the examination and farther treatment of the mass in the silver crucible, which after being removed from the furnace, and wiped on the outside, is to be placed in a porcelain capsule; it is then filled with water, and this water is renewed occasionally, till the whole matter is separated from the crucible. By this means a part of the compound of the alkalii with the siliceous and aluminous earths, is dissolved, and with a sufficient quantity of water the whole may be dissolved. Muriatic acid is now to be added till the whole of the mass is brought to a state of solution. This, however, will not be the case, if the stone be composed chiefly of silica. On the first addition of the acid, a flakey precipitate is produced, because the acid unites with the alkalii, which held the mass in solution. An effervescence afterwards takes place, which arises from the decomposition of a portion of carbonate of potash, formed during the fusion; and the flakey precipitate is again dissolved, as well as the matter which remained in the form of powder at the bottom of the vessel. If the powder be silica and alumina, there is no effervescence; but if it contain lime, an effervescence is produced. The solution in the muriatic acid being formed, if it shall appear colourless, it may be inferred that it contains no metallic oxide, or at least a very small portion. An orange red colour shows that it contains iron, a purplish red indicates manganese, and a golden yellow, chromium.

The solution is now to be introduced into an evaporating dish of porcelain, and being covered with paper, is to be placed on a sand bath, and evaporated to dryness. Towards the end of the evaporation, the liquid assumes the form of a jelly, it must be constantly stirred with a rod of silver or porcelain, to permit the acid and water to pass off, and to allow the whole mass to be equally dried; for it is in this way that the silica and alumina are separated from each other. The matter being reduced to a dry powder, add to it a large quantity of pure water, expose it to a moderate heat, and pour it on a filter. This solution may be denominated A. Wash repeatedly the powder which remains preliminary upon the silver, till the water with which it is washed no longer precipitates silver from its solutions. The powder remaining is siliceous earth, which is first to be dried between folds of blotting paper, and then made red hot in a crucible of platina or silver; and when it is cold it is to be accurately weighed. If it be pure siliceous earth, it is in the form of a white powder, of a white colour, does not adhere to the fingers, and is insoluble in acids. If it be at all coloured, it shows that it contains some metallic oxide, and is a proof that the evaporation has been carried on with too great a heat. To separate the oxide, boil the silica with an acid, and then wash and dry it as before. This acid solution is to be added to the solution A, and the whole is to be evaporated to the quantity of an English pint; then add to it a solution of carbonate of potash, till the precipitation ceases; and it may be necessary to boil it a few moments, to allow the whole of the precipitate to fall to the bottom. The whole of the precipitate being collected at the bottom, the supernatant liquid is decanted off, and the water being put in its place, the precipitate and water are thrown on a filter; and when the water has run off, the filter with the precipitate upon it is placed on the folds of blotting paper. After the precipitate has acquired some degree of consistence, collect it carefully with an ivory knife, mix it with a solution of pure potash, and boil it in a capsule of porcelain. The potash dissolves the alumina or glucina, and the other substances remain in the form of a powder. This powder may be called B.

Add to the solution of potash as much acid as will saturate the potash, and also redissolve any precipitate which at first appeared; and then add carbonate of ammonia till the taste of it be perceptible in the liquid. The whole of the alumina is now precipitated in the form of white flakes, while the glucina remains dissolved, if a sufficient quantity of carbonate of ammonia had been employed. Filter the liquid; and the alumina remaining on the filter being washed and dried, and after being made red hot, and allowed to cool, is weighed. To prove its being alumina, dissolve it in sulphuric acid, and a sufficient quantity of sulphate or acetate of potash being added, the whole of it will be converted into alum crystals, if the earth employed be aluminous earth.

To separate the glucina, the liquid which passed through the filter is to be boiled for some time, and if the solution contain any of this earth it will be precipitated in the form of a light powder, which may be dried in the usual manner, and weighed. It is a fine, soft, light, tasteless powder, when in a state of purity; and the application of heat does not make it concrete, as happens to alumina.

We now return to the residuum B, in which may be expected lime, magnesia, and some of the metallic oxides. But if it be suspected that this residuum contains any yttria, it is to be treated with carbonate of ammonia, which dissolves the yttria, and leaves the other bodies untouched. The yttria being separated, the residuum B is to be dissolved in weak sulphuric acid, and the solution evaporated to dryness. Add a small quantity of water, which will dissolve the sulphate of magnesia, as well as the metallic sulphates; but the sulphate of lime remains undissolved, or if any part of it should dissolve,
STONES, &c. ANALYSIS OF.

Preliminary dissolve, it may be thrown down by adding a small portion of weak alcohol. After being made red hot in a crucible, it is to be weighed, and the time will amount to $\frac{1}{2}$ of the weight. The solution containing the remaining sulphates being diluted with a large portion of water, a small excess of acid is to be added, and then a saturated carbonate of potash. The magnetism and oxide of manganese remain dissolved, and the oxides of chromium, iron, and nickel, are precipitated. This precipitate may be termed C.

Add to the solution a solution of hydrosulphuret of potash, and the manganese in the state of a hydrosulphuret will be precipitated. Calcine the precipitate in contact with air, and weigh it. The addition of pure potash to the solution will precipitate the magnetism, which being washed, and subjected to a red heat, is also to be weighed. The residuum C is to be repeatedly boiled with nitric acid, and then mixed with pure potash; and, being heated, the liquid is to be decanted off. The precipitate thus obtained, consisting of the oxides of iron and nickel, is to be washed with pure water, and this water be added to the solution of the nitric acid and potash. The chromium, if any be present, is contained in that solution, and is in the form of an acid. Add to the solution muriatic acid in excess, and let the evaporation be continued till the liquor become of a green colour; then add a pure alkali, by which the chromium is precipitated in the state of oxide, which is to be dried in the usual way, and weighed. The precipitate containing the oxides of iron and nickel is to be dissolved in muriatic acid; ammonia is to be added in excess, when the oxide of iron precipitates, and being collected, washed, and dried, is to be weighed. By evaporating the solution, the oxide of nickel will be also precipitated, or the whole may be precipitated by the addition of hydrosulphuret of ammonia. This being treated in the same manner as the other substances, is also to be weighed.

The weight of the whole substances thus obtained being added together, and being compared with the weight of the matter originally taken up, if the two agree, or if the difference do not exceed three or four parts in 100, it may be inferred that the analysis is nearly correct; but a considerable loss of weight indicates some error, and requires the analysis to be carefully repeated. If the same loss of weight appear, it may be concluded that the stone contained some substance which is soluble in water, or has been driven off by the heat. To ascertain the last point, a portion of the stone is to be broken into small pieces, and exposed to a strong heat, in a porcelain retort. If it contain water, or any volatile substance, it will come over into the receiver, and by this means the nature and weight of the ingredients separated may be ascertained. If nothing come over into the receiver, or if what is obtained be not equal to the deficient weight, it may be inferred that the stone contains some matter which is soluble in water.

A fixed alkali has been not unfrequently found in simple stones; and to ascertain whether the mineral subjected to analysis contains any alkaline matter, different methods have been pursued. These methods we shall now describe. The stone being reduced to an impalpable powder, is cautiously heated repeatedly with sulphuric acid, and the mass is to be digested in water; and this solution being properly concentrated, is set aside for some days. The appearance of crystals of alum is a certain indication that the mineral contained potash; and the quantity of potash may be estimated at $\frac{1}{12}$ of the weight of those crystals; but if no crystals be obtained, the solution is to be evaporated to dryness, and the residuum exposed to a moderate red heat. Digest it afterwards in water, and add carbonate of ammonia, and filter; evaporate again to dryness, expose the residue to a heat of 700°, and redissolve it. The solution being properly concentrated, will give crystals of sulphate of soda or of potash, as the one or the other alkali is present. Potash may be discovered by adding to the solution of the salt, a solution of nitro-muriate of platinum somewhat concentrated. A yellow precipitate, which is muriate of platinum and potash, is thus obtained.

Klaproth's method for discovering fixed alkalies in minerals is the following. He takes four parts of nitrate of barytes to one of the mineral to be examined, and fuses them together in a porcelain crucible. A spongy mass of a light-blue colour was thus obtained, with the addition of diluted muriatic acid, was completely dissolved. The solution, which was of a yellow colour, was then mixed with a sufficient quantity of sulphuric acid, by which the barytes is precipitated, and the muriatic acid expelled. The liquid is next evaporated to dryness, and the mass being digested in water, is filtered, and the sulphate of barytes and silica remain on the filter. The clear solution is saturated with carbonate of ammonia, and filtered the second time; and all the earthy and metallic bodies being separated, the sulphates of fixed alkali and ammonia only remain in the solution, which being evaporated to dryness, the dry saline mass is introduced into a porcelain crucible, and subjected to such a degree of heat as is sufficient to drive off the sulphate of ammonia. The residuum is then dissolved in water, and crystallized; and thus a pure, fixed alkaline sulphate is obtained, which is again dissolved in water, and decomposed, by adding acetate of barytes. The solution is then filtered, and the liquid is evaporated to dryness; the mass thus obtained is the residue of a fixed alkali, which being exposed to a heat in a crucible, became of a reddish colour. The carbonaceous residuum is then to be dissolved in water, filtered, and crystallized, and the salt thus procured is a carbonate of a fixed alkali, the nature of which may be easily recognised by the means stated above.

Mr. Davy's method of detecting a fixed alkali in minerals, is different. One hundred grains of the stone is Nick in very fine powder are to be fused for half an hour at a strong red heat, in a crucible of platinum or silver, with 200 grains of boracic acid. An ounce and a half of nitric acid diluted with seven or eight times its quantity of water, is then digested upon the fused mass, till the decomposition of the whole is completed. Evaporate the fluid to about two ounces, or one ounce and a half; by this means the siliceous earth is separated, which being collected on a filter, is to be washed with distilled water, till the boric acid and the whole of the saline matter are separated. The fluid is then mixed with water that has passed through the filter, and evaporated to the quantity of half a pint, after which it is saturated with carbonate of ammonia, and boiled with an excess of this salt, till the whole of the substances capable of being
STONES, &c. ANALYSIS OF.

By this management, the siliceous earth separated in slimy, intumesced grains, and weighed, after ignition, 23 ½ grains.

F. The solution, thus freed from its silica, was now saturated with a boiling ley of mild alkali; and the precipitate was washed and dried in the air. This last weighed 114 grains, proving, upon every trial, to be jargonic earth. A fourth part of it, heated to redness, weighed 16 ½ grains; which make the whole amount to 66 grains.

G. The above six grains D, with the 23 ½ grains E, in the whole 20 ½ grains of siliceous earth, were ignited with a quadruple weight of vegetable alkali. When this mass had been again softened with water, it left a residue, which was extracted by nauriacic acid. From this muriatic solution, also, when saturated with potash, jargonic earth fell down, weighing four grains after ignition. Hence, subtracting these, the quantity of siliceous earth is reduced to 23 ½ grains.

One hundred parts of hyacinth, therefore, have been given

Jargonia - F 66 7 70

2. Of the Siliceous Genus.

A great proportion of the stones belonging to this genus are transparent, and have a vitreous appearance. They are so hard as to scratch glass, and, excepting the fluoric acid, they are not acted upon by acids. By fusion with alkalies they form glass; they also enter into fusion with boracic acid, and the acid of phosphorus. Stones composed chiefly of pure silicas, are transparent and colourless. When a mineral is presented for examination, even if it possess most of the properties which characterize stones belonging to this genus, some preliminary processes may be pursued to ascertain further its nature and component parts.

A. It is sometimes difficult to reduce siliceous stones to a fine powder. To facilitate this operation, a portion of the stone may be heated to redness, and in this state suddenly plunged into cold water. If by the first heating it is not sufficiently brittle, the operation may be repeated until the mineral can be reduced to a fine powder, as already directed.

B. One part of the stone in fine powder is now to be mixed with four or five parts of potash, dissolved in the same quantity of water. The mixture is introduced into a silver crucible, and evaporated to dryness, stirring it constantly with a silver rod, according to the directions given above. The mass being evaporated to dryness, the heat is to be gradually increased, till the crucible appears of a dull red heat, or till the mass enter into quiet fusion. In this state it is kept for an hour.

C. Remove the crucible from the fire before it is completely cold; soften the mass with water, by adding fresh.
STONES, &c.

fresh portions from time to time, till the whole is detached from the crucible, and then add 12 times its bulk of water to effect a solution. If the stone consisted chiefly of siliceous earth, the greater part of the mass will be dissolved.

D. Add muriatic acid till no further precipitate is effected, and without separating the precipitate, evaporate the whole to dryness.

E. Pour six times its bulk of muriatic acid, previously diluted with four parts of water, on the dry mass; boil the mixture for half an hour; let the insoluble part subside, and then collect it on a filter, and after being dried, subject it in a crucible to a red heat. This powder is the siliceous earth contained in the mineral.

But stones included under this genus contain very different proportions, not only of siliceous earth, but also of the other earths; and some of them even contain a far greater proportion of other earths than that which characterizes the genus under which they are arranged.

Analysis of Leucite.

The analysis of this mineral is particularly interesting, not only as Klaproth first detected in it, potash, which was supposed to belong exclusively to the vegetable kingdom, and hence called vegetable alkali, but also as it places the skill and address of that eminent chemist in its examination in a very conspicuous light. The process was conducted in the following manner.

Ignited alone upon charcoal, the leucite is completely insubstantial. It undergoes no manner of alteration, and its splinters lose nothing of their lustre.

A small fragment, put into fused borax, is for a long time moved about in it, before it dissolves, which it does by degrees; and the glass globule obtained is clear and light-brown.

By fusion with a neutral phosphate, the solution is still slower, and a colourless rufous glass pearl is produced.

One hundred grains of coarsely pounded leucite, exposed for an hour to a strong red heat, in a small porcelain pot, lost of weight only one-eighth of a grain, and even the violent heat of the porcelain furnace produced in the leucite only an inconsiderable change.

A. One hundred grains of leucite, reduced to an impalpable powder, being several times digested in muriatic acid, dissolved a considerable part. A siliceous residue of 54 grains remained after ignition.

B. The siliceous earth ignited with twice its weight of caustic alkali, softened again with water, covered with muriatic acid, added to excess of saturation, and, after sufficient digestion with this last, being collected on the filter, and heated to redness, was found to have lost little of its weight.

C. Prussiate of potash added to the muriatic solution produced a precipitate which indicated one-eighth of a grain of oxide of iron.

D. The solution by caustic ammonium being decomposed, and the precipitate being separated, the remaining liquor was tried with carbonate of soda, but no further change was effected.

E. The precipitate produced by means of pure ammonium D was first dried. It was next purified by digesting it with distilled vinegar, and afterwards neutralizing this acid by ammonia. It weighed 24 grains and a half, when edulcorated and ignited. Diluted sulphuric acid completely dissolved it to a limpid liquor, and when properly treated, the solution yielded only alum.

F. To obtain the earth, which possibly might have remained latent in the several washings, the whole were evaporated to dryness. After having re-dissolved the saline mass in water, the remaining portion of earth was collected, it amounted only to half a grain, and was siliceous earth.

There were therefore obtained,

|        | (A) | (F) | 54 | 4
|--------|-----|-----|----|---
| Silica |     |     | 54 | 54.5
| Alumina| (E) |     | 79 | 24.50
|        |     |     | 100|    

Loss: 21

The remarkable loss of more than one-fifth of the whole weight of the mineral under examination, excited suspicion that some error had crept into the analysis, and led to a repetition of the experiments, by varying the processes as follows.

A. One hundred grains of leucite in fine powder were ignited for half an hour, with double their weight of caustic potash. To the mass softened with water muriatic acid was added, just to the point of saturation, and the mixture being filtered, the remaining undissolved residuum was washed and dried.

B. The mineral thus prepared for decomposition, was then treated with muriatic acid, and kept for some time at a boiling heat. By this process a quantity of silica separated, which after being heated to redness weighed 54 grains and a half.

C. Oxalate of potash being added to the muriatic solution, concentrated by evaporation, produced no turbidity. The alumina was separated by the same means as in the former experiments, and its weight amounted to nearly the same. By other trials it did not appear to have any mixture of other earths, and no other earth could be obtained by evaporating the waters with which the powders had been washed.

Thus, after varying the experiments the same results were obtained, and the same loss still appeared. In the farther prosecution of this investigation, the following experiments were had recourse to.

A. Two hundred grains of leucite in fine powder were repeatedly digested with muriatic acid, and the siliceous earth collected on the filter, washed, and weighed after being red hot, amounted to 109 grains.

B. The muriatic solution was of a yellowish colour, and being reduced by evaporation in a sand heat to the consistence of honey, the surface appeared covered with a saline crust; and when completely cooled, the mass appeared like a thick clear oil, of a golden yellow colour, and full of crystals, some of which were of a cubic, and some of a tabular form. The yellow fluid was gently poured off, and the salt rinsed with small portions of alcohol. The solution diluted with alcohol was again evaporated, and the small portion of salt thus obtained
STONES, &c.

ANALYSIS OF.

The whole of the salt being dried, weighed 70 grains. This was dissolved in water, and some drops of a solution of ammonia being added, threw down some particles of alumina. The solution being crystallized in a warm place, yielded only cubic crystals, some of which were elongated to four-sided columns.

C. That part of the muriatic solution which shot into crystals being diluted with water, and decomposed in a boiling heat, by carbonate of soda, yielded a precipitate, which, after washing, drying, and ignition, amounted to 47½ grains of alumina earth. Three times its weight of concentrated sulphuric acid was added, and the mixture was evaporated nearly to dryness. The mass was again dissolved in water, and combined with solution of acetate of potash, which being crystallized, produced only alum.

D. The siliceous earth A was mixed with double its weight of potash, and subjected to a strong red heat for an hour. The mass was reduced to powder, and diluted with water. Muriatic acid was added in excess, and digested with it. The filtered muriatic solution being saturated with soda yielded 1½ grain of alumina earth, after which there remained of silica 107½ grains.

The 200 grains of leucite have thus afforded of

Here there was still a deficiency of 43.25 grains, to account for which the 70 grains of salt B must be examined. This examination was conducted in the following manner.

1. The taste and figure of the crystals were found to be the same with those of muriate of potash.
2. The solution produced no change in vegetable blues, or in reddened litmus paper.
3. When heated to redness, the salt made a crackling noise, and remained fixed in the fire.
4. Neither carbonate of soda nor caustic ammonia produced any turbidity in the solution.
5. Two parts of strong sulphuric acid were added to three of the salt, and the muriatic acid being driven off by heat, the mass was again dissolved in water, which afforded crystals of sulphate of potash.
6. The remaining portion of salt was dissolved in a small quantity of water, and to this was added a concentrated solution of crystallized acid of tartar. The acidulous tartrate of potash (cream of tartar) was thus immediately produced and precipitated in the form of sand. This was washed, dried, burnt in a silver crucible, and the coal obtained repeatedly washed with water. The solution being evaporated to dryness, after being examined by the proper tests, appeared to be a carbonate of potash, which being saturated with nitric acid, afforded nitrate of potash.

Thus it appears that the base of the 70 grains of salt consisted entirely of pure potash, which was neutralized by part of the muriatic acid employed in decomposing the mineral; and according to the proportion of base in muriate of potash, the 70 grains A contain 42.7 grains of alkali; and in this way the deficiency in the examination of the leucite is accounted for.

The result of the analysis is as follows.

Analysis of Pitchstone.

The pitchstone which is the subject of the following analysis, also conducted by Klapproth, is the transparent yellowish or olive green variety of that mineral from Meissen. It forms an example of soda, the other fixed alkali, forming a component part of stones.

A. 100 grains in coarse fragments were introduced into a covered crucible, and were subjected to a red heat for half an hour. When taken from the fire they appeared of a white gray mixed with a yellowish colour, and having a rough feel, with something of the appearance of glazing. They lost 8½ grains of weight.

B. In the heat of a porcelain furnace, the pitchstone was fused both in the clay and charcoal crucible, and was converted into a clear glass, full of small froth holes.

C. 100 grains of pitchstone in fine powder were treated with a solution of 200 grains of caustic soda, and being put into a silver crucible, were kept for half an hour in a pretty strong red heat. The mass was then softened with water; muriatic acid was added in excess; the solution was evaporated in a sand heat, nearly to dryness; water was again poured upon it, after which it was filtered, and 73 grains of siliceous earth were obtained.

D. Caustic soda was mixed in excess with the muriatic solution, and the whole was digested in a boiling heat, by which the precipitate formed at the beginning of the process was again dissolved; a brown residuum still remained, which being separated, the alkaline solution was neutralized, and precipitated with carbonate of soda. The precipitate, which was alumina, after being washed, dried, and heated to redness, amounted to 14½ grains. The whole of it yielded crystals of alum, with sulphuric acid and potash.

E. The residuum which remained undissolved by the caustic soda, D, was first dissolved in muriatic, and then united with sulphuric acid. Sulphate of lime was obtained, which was collected, and washed with diluted alcohol. By reducing the filtered fluid by evaporation to a smaller quantity, and combining it with sulphuric acid, another portion of sulphate of lime, which, added to the first, amounted to three grains, indicating 18 grains of pure lime.

F. The fluid was now freed from the calcareous earth; the iron which it contained was precipitated by carbonate of ammonia, which amounted to one grain. The remaining fluid was evaporated to dryness, and water being added to the saline residuum, fine minute flocks of oxide of manganese separated, but in no greater quantity than one-tenth of a grain.

G. 100 grains of pitchstone in powder were mixed with 300 grains of crystallized nitrate of barytes, and heated to redness in a porcelain vessel, till the salt was entirely...
entirely decomposed. The cold mass was softened with water, neutralized with muratic acid, and combined in such proportion with sulphuric acid, that the latter, after the evaporation of the mixture, and separation of the muratic acid by heat, was still in excess. The mass was washed with hot water; the residuum separated by filtration; and the clear fluid was mixed with carbonate of ammonia in excess. The precipitate thus obtained was collected on a filter, and the remaining fluid was evaporated to dryness, and the portion of sulphate of ammonia subjected to a moderate heat in a porcelain vessel, was driven off. A fixed salt remained, which appeared to be sulphate of soda. This was dissolved, and decomposed by acetate of barytes; the filtered solution was evaporated to dryness; the dry salt was heated to redness in a crucible of platinum. The saline residuum being redissolved, filtered, and again evaporated to dryness, yielded three grains of dry carbonate of soda, indicating 1 1/2 grain of pure soda. This being neutralized with nitric acid, gave crystals of nitrate of soda.

The 100 grains of the mineral thus examined consist of

3. ARGILLACEOUS GENUS.

As many of the stones included under this genus are composed of similar substances with those arranged in the former genus, it is obvious that the examination is to be conducted in the same way. We shall therefore give one example of the analysis of a stone belonging to this genus, and the example is that of basalt by Klaproth.

* * * 

Analysis of Basalt.

A. Small fragments of this stone were subjected to a strong red heat for 30 minutes; the loss of weight was two per cent. and the mass became of a lighter colour, and more readily yielded to the pestle.

B. Basalt exposed to the heat of a porcelain furnace in a common clay crucible, fused into a compact black brown glass, which in thin splinters was transparent. It also entered into thin fusion in a crucible of semi-indurated steatites; part of it run into the clefts produced in the steatites, and the rest was found crystallized in brown shining lamelasse, which on the surface were stratified, and cellularly concreted. In a charcoal crucible it was converted into a dull gray and finely porous mass, in which were inserted numerous grains of iron.

C. To ascertain whether this stone contained soda, 100 grains of basalt in fine powder were mixed with 400 grains of nitrate of barytes, and were at fist exposed in a large porcelain vessel to a moderate heat, and afterwards to a heat gradually raised to ignition. The mixture swelled up, and when the heat was increased, white fumes arose on uncovering the vessel, which led to a supposition that the soda was beginning to volatilize, the fire was then removed.

D. The porous mass, after cooling and being reduced to powder, was drenched with water, and treated with muratic acid. The whole entered into solution, and produced a clear yellow fluid. The solution was evaporated, and sulphuric acid was added gradually, till it was in excess. The sulphate of barytes was precipitated.

E. The saline mass by filtration was reduced to dryness, and water was added, the sediment separated, and appeared to consist of the sulphate of barytes, and the siliceous earth of the stone. The clear fluid was saturated with ammonia, and the precipitate, which was obtained being filtered off, the neutralized liquor was evaporated to dryness, and was exposed in a porcelain vessel to a moderately intense heat, till the whole sulphate of ammonia was driven off. The fixed portion remaining dissolved in water, and crystallized, appeared to be pure sulphate of soda. This was dissolved, decomposed by acetate of barytes; the precipitate, which was sulphate of barytes, was separated by the filter, and the clear fluid being evaporated to dryness, the dry acetate of soda was heated to redness in a crucible of platinum; and in this way 4 1/2 grains of dry carbonate of soda was obtained, which is equal to 2.6 grains of pure soda.

F. To separate the other ingredients, 100 grains of powdered basalt were ignited for two hours with 400 grains of carbonate of soda, in a crucible of porcelain; but with a degree of heat which did not produce fusion. It united into a yellowish, somewhat hard mass, which being reduced to powder, and softened with water, was neutralized with muratic acid. It was then a little supersaturated with nitric acid, and evaporated to dryness. The colour of the dry mass was saffron yellow. It was diffused in water, slightly acidulated with muratic acid, and after being digested for a short time it was filtered. The siliceous earth collected on the filter was exposed to a red heat, and being weighed, amounted to 44 1/2 grains.

G. The muratic solution being sufficiently diluted with water, was precipitated at the temperature of boiling water, by means of carbonate of soda. The precipitate being separated, was digested with a solution of caustic soda, and a dark brown residuum was separated by filtration. Muratic acid was added in a small excess to the alkaline fluid, and this was precipitated with carbonate of ammonia. The precipitate obtained after being washed and ignited, amounted to 16 1/2 grains. It yielded alum, when treated with sulphuric acid and potash, and was therefore aluminous earth.

H. The brown residuum G was dissolved in muriatic acid with particular attention to the precise point of saturation. Succinate of ammonia was added to the solution, to precipitate the iron; and the succinate of iron obtained, when perfectly washed and strongly heated in a covered crucible, afforded 25 grains of oxide of iron, which were attracted by the magnet.

I. The iron being separated, the fluid was treated at the temperature of boiling with carbonate of soda; a white precipitate was obtained, which was dissolved in nitric acid; and sulphuric acid being combined with the solution, threw down sulphate of lime. This was separated, and the remaining liquor being evaporated nearly
STONES, &c. ANALYSIS OF.

C. Prussiate of potash was added to the filtered solution and produced a blue precipitate, which being collected, washed, dried, and ignited with a little wax, was found, after cooling, to weigh seven grains. The whole of it was attracted by the magnet. The portion of iron belonging to the prussiate of potash being subtracted, left \( \frac{2}{3} \) grains of oxide of iron as a constituent of the mineral under examination.

D. Carbonate of potash being added to the solution freed from the iron, precipitated its earthy ingredient. This, after washing, and gentle ignition, weighed 192 grains. These were covered with a proportionate quantity of concentrated distilled vinegar, and being digested in a low heat, were thrown upon the filter. The earth remaining on the paper, which, after being dried and heated red hot, weighed 93 grains, was mixed with three times its weight of strong sulphuric acid, and the mixture being evaporated in a sand heat nearly to dryness, the dry mass was dissolved in water and filtered; 26 grains of siliceous earth were thus obtained.

E. In the sulphuric solution, there still remained 67 grains of earth, which being precipitated by an alkali, appeared to consist entirely of aluminous earth.

F. Ninety-nine grains of the first, 192 grains of the earthy precipitate, were taken up by the acetic acid, which being precipitated by carbonate of potash, and the earth obtained being tried by sulphuric acid, was found to be pure magnesia.

This analysis shows that the 480 grains of stearites, thus examined, afforded

5. CALCAREOUS GENUS.

The analysis of stones belonging to this genus must be varied according to the nature of the combination into which the lime has entered. With regard to the processes to be followed in the examination of calcareous stones, they are susceptible of a natural division into such as are soluble in muriatic or nitric acid with effervescence, and such as are scarce soluble in those acids, and do not effervesce. To the first belong all the stones called limestones, or carbonates of lime; and to the second belongs sulphate of lime, or gypsum.

Analysis of Carbonate of Lime.

Carbonate of lime, whether in the form of lime spar, or in a less pure state, in the form of limestone, is soluble with
ANALYSIS OF.

A. Let a determinate quantity of the stone be reduced to a fine powder. Digest it repeatedly with muriatic acid till no further action is produced upon it. Dilute the solution, throw it upon a filter, and, after drying, weigh the insoluble residuum.

B. Let the remaining solution be diluted with 24 times its bulk of water; add sulphuric acid diluted; a precipitate takes place if the stone contained any barytes, the amount of which, after being collected and dried, may be ascertained by weighing.

C. Add to the filtered solution, after the barytes has been separated, a solution of carbonate of soda, as long as any precipitate is formed. Collect this precipitate, and let it be so much dried that it may be easily removed from the filter.

D. Affuse the precipitate with sulphuric acid till all effervescence ceases.

E. Introduce the whole into a mixture of three parts of distilled water, and one of alcohol, in the proportion of eight parts of the mixture to the quantity of the substance previously dissolved in nitric acid. Let the whole be digested for some hours in the cold, filter the fluid, and dry the insoluble residuum and weigh it.

F. The remaining solution is next to be decomposed by a solution of carbonate of potash, and the precipitate being collected, is to be washed, dried, and weighed.

By this examination, if the stone is to be ranked with carbonate of lime, the weight of the insoluble part E, after subtracting from it one-third, must exceed the weight of the insoluble parts A and B.

Analysis of Sulphate of Lime.

As this is insoluble in nitric or muriatic acids, its analysis must be conducted in a different manner.

A. Let one part of the mineral, reduced to fine powder, be boiled with four times its weight of carbonate of potash in a sufficient quantity of water for two or three hours; as the fluid evaporates, water is to be added.

B. Introduce the insoluble mass obtained by the last process into a flask containing diluted nitric acid, and the whole being dissolved, let it be evaporated to dryness, and weighed.

C. Add to the dried mass more than its own weight of strong sulphuric acid; apply heat, and let it be gradually increased till fumes cease to rise, and let it be again weighed.

D. Let the insoluble part be digested in twice its weight of cold water; filter the fluid, collect the insoluble residuum, and dry it in a dull red heat. To ascertain the quantity of lime, subtract from the weight of the insoluble mass left (in C) 59 parts; what remains is equal to the quantity of lime.

The quantity of lime may also be ascertained by subjecting for some hours to a red heat, the insoluble mass B; for by this process it will be converted into quicklime.

Analysis of Fluorate of Lime.

In the examination of this mineral, a quantity of it may be reduced to powder, and moistened with sulphuric acid in a leaden or pewter vessel. The mixture being heated, fumes arise, to which a plate of glass being exposed, is soon corroded. In this way the fluoridic acid may be detected, and the quantity of base may be ascertained by decomposing the mineral by means of sulphuric acid, and afterwards analysing the sulphate of lime, as already directed.

Analysis of Phosphate of Lime.

The analysis of this mineral may be conducted in the following manner.

A. Let a determinate portion be digested in five times its quantity of nitric acid, and after the operation be repeated till the acid has no further action upon the residuum; decant the fluid, and then let it be diluted with water and filtered.

B. Add to the muriatic solution, liquid ammonia; collect the precipitate which is formed, and after being washed and dried, expose it to heat.

C. Add nitric acid to the precipitate till the whole is dissolved. Precipitate again by means of sulphuric acid; let the whole then be filtered, and the insoluble residuum be washed with so little water as possible.

D. Evaporate the filtered fluid to the consistency of syrup; the fluid thus obtained is phosphoric acid, if the stone examined have been phosphate of lime. The test of phosphoric acid is, that it precipitates lime water, and also forms precipitates with the solutions of sulphate of iron, and nitrate of mercury; but it does not precipitate the muriate or nitrate of barytes.

Analysis of Carbonate of Barytes.

A. Take a determinate quantity of the mineral, and dissolve it in diluted nitric acid; take a portion of the solution, and add to it a solution of sulphate of soda. If a precipitate take place, by adding a small quantity of the salt to the solution of the earth, diluted with 24 times its bulk of water, it may be inferred that the base of the mineral is barytes.

B. Let the nitric solution be evaporated to dryness, and exposed in a silver crucible to a white heat; the earth obtained is barytes, which is soluble in 20 times its weight of water; and after evaporation, crystallizes into long four-sided prisms.

Analysis of Sulphate of Barytes.

This mineral was analyzed by Klaproth in the following manner.

A. 200 grains were mixed with 500 grains of carbonate of potash, and were exposed for two hours to a red heat; the mass was reduced to powder, boiled with water, and the undissolved earth was collected on the filter.

B. To separate the siliceous earth, the fluid was neutralized by muriatic acid, and evaporated to dryness. The saline mass was redissolved in water, and the silica remaining after being ignited, weighed 18 grains.

C. The baryte earth, freed from the sulphuric acid B, was covered with water; muriatic acid was added; the whole was dissolved by digestion, except two grains of silica. The filtered solution was crystallized, and afforded muriate of barytes.

D. The crystals were redissolved in water, and sulphuric acid was added to the solution, while any precipitate appeared, and the regenerated sulphate of barytes being
STONES, &c.

being washed and dried, weighed 185 grains, but after
ignition, only 180 grains.

One hundred parts of this mineral are therefore com-
posed of

| Sulphate of barytes D | 90 |
| Silica B | 9 |
| C | 1 |

7. STRONTIAN GENUS.

Analysis of Carbonate of Strontian.

This mineral was analyzed by Klaproth, in the fol-
lowing manner.

A. 100 parts were dissolved in muriatic acid, diluted
with half its quantity of water. Thirty parts of carbo-
nic acid were driven off during the solution, which be-
ing evaporated, afforded crystals in the shape of needles;
and these crystals being dissolved in alcohol, communi-
cated to it the property of burning with a carmine red
flame. This is the test of strontian earth.

B. To ascertain whether the mineral examined con-
tained any barytes, three drops of a solution of one grain
of sulphate of potash in six ounces of water were added
to the muriatic solution; no appearance of precipitate
was observed till next day, and therefore it contained no
barytes, as in that case an immediate precipitate would
have taken place.

C. Carbonate of potash was then added to the muri-
atic solution; a decomposition took place; and the car-
bonate of strontian was precipitated. This being sub-
jected to a strong heat, the carbonic acid was driven off,
and the whole of the remaining earth being dissolved in
water, crystallized. After being dried, it weighed 69.5.

One hundred parts of this mineral therefore contain

| Pure earth | 69.5 |
| Carbonic acid | 30. |
| Water | 1.5 |

ANALYSIS OF.

produced a precipitate of 4/ grains of muriate of silver,
so that the quantity of common salt can only be estima-
ted at two grains. The pure nitre is thus reduced to
42/5 grains. Klaproth suspects that the neutral muriate
mixed with the native nitre, is rather a muriate of pot-
ash, than the muriate of soda.

C. The stony matters remaining amounted to 500
grains; muriatic acid was poured upon them, and pro-
duced great effervescence with pieces of limestone. One
hundred and eighty-six grains of white gypsum remain-
ed; and the sulphuric acid being separated from it, by
boiling with carbonate of potash, the carbonate of lime
remaining behind dissolved without residuum in nitric
acid.

D. The limestone taken up by the muriatic acid,
weighed 304 grains. Being further examined, it ap-
peared to be calcareous earth, slightly contaminated
with iron.

One hundred parts, therefore, of this salt contain

| Pure prismatic nitre B | 42.55 |
| Muriate of a neutral salt B | .20 |
| Sulphate of lime A B C | 25.45 |
| Carbonate of lime D | 30.4 |
| Loss | 1.4 |

100.00

III. COMBUSTIBLES.

Analysis of Coal.

The constituent parts of coal are carbone and bitumen,
with some earthy matters, and sometimes a small quan-
tity of metallic matter. The proportion of earthy mat-
ters contained in coal may be ascertained by weighing a
determinate quantity, and burning it. The nature of
the earths contained in the residuum may be discovered
by the processes already given.

To ascertain the proportion of charcoal and bitumen
contained in coal, we shall describe the method followed
by Mr. Kirwan.

It has been found that a certain proportion of carbone
or pure charcoal, detonated with nitre in the state of ig-
ition, decomposes a given proportion of that salt; and
it appears from the experiments of Lavoisier, that 13.27
parts of charcoal decompose 100 parts of nitre, while the
detonation is performed in close vessels; but in an open
crucible, a smaller proportion of charcoal is required, in
consequence of part of the nitre being decomposed by
the action of the air of the atmosphere. According to
Kirwan, about 10 parts of charcoal are sufficient to de-
compose 96 parts of nitre. Mr. Kirwan also found that
vegetable pitch and maltha did not produce any detona-
tion with nitre, but merely burnt on its surface; and
that the same quantity of charcoal was required for the
decomposition of the nitre, as if no bituminous substance
had been employed. Since, therefore, bitumen produces
no effect in decomposing nitre, Kirwan thought that the
proportion of charcoal, in any coal, might be ascertained
by detonation with nitre. In this way the proportion of
carbonaceous and earthy matter in any coal being dis-
covered, the proportion of bitumen which it contains
may be estimated by calculation.

In the experiments on the analysis of coal, Mr. Kirwan
employed a large crucible placed in a wind furnace, and
exposed to an equable heat. The coal was reduced to

small
STONES, &c. ANALYSIS OF.

In cases when the general nature of the soil of a field is to be ascertained, specimens of it should be taken from different pieces, two or three inches below the surface, and examined as to the similarity of their properties. It sometimes happens, that upon plains the whole of the upper stratum of the land is of the same kind, and in this case analysis will be sufficient; but in valleys, and near the beds of rivers, there are very great differences, and it now and then occurs, that one part of a field is calcareous, and another part siliceous; and in this case, and in analogous cases, the portions different from each other should be separately submitted to experiment.

Soils, when collected, if they cannot be immediately examined, should be preserved in phials quite filled with them, and closed with ground glass stoppers.

The quantity of soil most convenient for a perfect analysis is from two to four hundred grains. It should be collected in dry weather, and exposed to the atmosphere till it becomes dry to the touch.

The specific gravity of a soil, or the relation of its weight to that of water, may be ascertained by introducing into a phial, which will contain a known quantity of water, equal volumes of water and of soil; and this may be easily done by pouring in water till it is half full, and then adding the soil till the fluid rises to the mouth; the difference between the weight of the soil and that of the water will give the result. Thus, if the bottle contain 400 grains of water, and gains 200 grains when half filled with water and half with soil, the specific gravity of the soil will be two, that is, it will be twice as heavy as water; and if it gained 165 grains, its specific gravity would be 1.85, water being 1.000.

It is of importance that the specific gravity of a soil should be known, as it affords an indication of the quantity of animal and vegetable matter it contains; these substances being always most abundant in the lighter soils.

The other physical properties of soils should likewise be examined before the analysis is made, as they denote, to a certain extent, their composition, and serve as guides in directing the experiments. Thus siliceous soils are generally rough to the touch, and scratch glass when rubbed upon it; aluminoi soils adhere strongly to the tongue, and emit a strong earthy smell when breathed on; and calcareous soils are soft, and much less adhesive than aluminoi soils.

3. Soils, though as dry as they can be made by continued exposure to air, in all cases still contain a considerable quantity of water, which adheres with great obstinacy to the earths and animal and vegetable matter, and can only be driven off from them by a considerable degree of heat. The first process of analysis is, to free the soil from the given weight of the soil from as much of this water as possible, without, in other respects, affecting its composition; and this may be done by heating it for ten or twelve minutes over an Argand's lamp, in a cason of porcelain, to a temperature equal to 300 Fahrenheit; and in case a thermometer is not used, the proper degree may be easily ascertained, by keeping a piece of wood in contact with the bottom of the dish: as long as the colour of the wood remains unaltered, the heat is not too high; but when the wood begins to be charred, the process must be stopped. A small quantity of water will perhaps remain in the soil even after this operation, but
STONES, &c. ANALYSIS OF.

soils. but it always affords useful comparative results; and if a higher temperature were employed, the vegetable or animal matter would undergo decomposition, and in consequence the experiment be wholly unsatisfactory.

The loss of weight in the process should be carefully noted; and when in 400 grains of soil it reaches as high as 50, the soil may be considered as in the greatest degree absorbent, and retentive of water, and will generally be found to contain a large proportion of amorphous earth. When the loss is only from 20 to 10, the land may be considered as only slightly absorbent and retentive, and the silicious earth as most abundant.

4. None of the loose stones, gravel, or large vegetable fibres should be divided from the pure soil till after the water is drawn off; for these bodies are themselves often highly absorbent and retentive, and in consequence influence the fertility of the land. The next process, however, after that of heating, should be their separation, which may be easily accomplished by the sieve, after the soil has been gently bruised in a mortar. The weights of the vegetable fibres or wood, and of the gravel and stones, should be separately noted down, and the nature of the last ascertained: if calcareous, they will effervesce with acids; if silicious, they will be sufficiently hard to scratch glass; and if of the common amorphous class of stones, they will be soft, easily scratched with a knife, and incapable of effervescing with acids.

5. The greater number of soils, besides gravel and stones, contain larger or smaller proportions of sand of different degrees of fineness; and it is a necessary operation, the next in the process of analysis, to detach them from the parts in a state of more minute division, such as clay, loam, marl, and vegetable and animal matter. This may be effected in a way sufficiently accurate, by agitation of the soil in water. In this case, the coarse sand will generally separate in a minute, and the finer in two or three minutes; whilst the minutely divided animal or vegetable matter will remain in a state of mechanical suspension for a much longer time; so that, by pouring the water from the bottom of the vessel, after one, two, or three minutes, the sand will be principally separated from the other substances, which, with the water containing them, must be poured into a filter, and, after the water has passed through, collected, dried, and weighed. The sand must likewise be weighed, and their respective quantities noted down. The water of lixiviation must be preserved, as it will be found to contain the saline matter and the soluble animal or vegetable matters, if any exist in the soil.

6. By the process of washing and filtration, the soil is separated into two portions, the most important of which is generally the finely divided matter. A minute analysis of the sand is seldom or never necessary, and its nature may be detected in the same manner as that of the stones or gravel. It is always either silicious sand, or calcareous sand, or a mixture of both. If it consist wholly of carbonate of lime, it will be rapidly soluble in muriatic acid, with effervescence; but if it consist partly of this substance, and partly of silicious matter, the respective quantities may be ascertained by weighing the residue after the action of the acid, which must be applied till the mixture has acquired a sour taste, and has ceased to effervesce. This residue is the silicious part; it must be washed, dried, and heated strongly in a crucible: the difference between the weight of the whole, indicates the proportion of calcareous sand.

7. The finely divided matter of the soil is usually very compound in its nature; it sometimes contains all the alteration of the four primitive earths of soils, as well as animal and vegetable matter; and to ascertain the proportions of these with tolerable accuracy, is the most difficult part of the subject.

The first process to be performed, in this part of the examination, is the exposure of the fine matter of the soil to the action of the muriatic acid. This substance should be poured upon the earthy matter in an evaporating bason, in a quantity equal to twice the weight of the earthy matter; but diluted with double its volume of water. The mixture should be often stirred, and suffered to remain for an hour or an hour and a half before it is examined. If any carbonate of lime or of magnesia exist in the soil, they will have been dissolved in this time by the acid, which sometimes takes up likewise a little oxide of iron; but very seldom any alumina.

The fluid should be passed through a filter; the solid matter collected, washed with warm water, dried at a moderate heat, and weighed. Its loss will denote the quantity of solid matter taken up. The washings must be added to the solution; which, if not sour to the taste, must be made so by the addition of fresh acid, when a little solution of common prussiate of potash must be mixed with the whole. If a blue precipitate occurs, it denotes the presence of oxide of iron, and the solution of the prussiate must be dropped in till no further effect is produced. To ascertain its quantity, it must be collected in the same manner as other solid precipitates, and heated; the result is oxide of iron.

Into the fluid freed from oxide of iron, a solution of neutralized carbonate of potash must be poured till all effervescence ceases in it, and till its taste and smell indicate a considerable excess of alkaline salt.

The precipitate that falls down is carbonate of lime; it must be collected on the filter, and dried at a heat below that of redness.

The remaining fluid must be boiled for a quarter of an hour, when the magnesia, if any exist, will be precipitated from it, combined with carbonic acid, and its quantity is to be ascertained in the same manner as that of the carbonate of lime.

If any minute portion of alumina should, from peculiar circumstances, be dissolved by the acid, it will be found in the precipitate with the carbonate of lime, and it may be separated from it by boiling for a few minutes with soap lye, sufficient to cover the solid matter. This substance dissolves alumina, without acting upon carbonate of lime.

Should the finely divided soil be sufficiently calcereous to effervescce very strongly with acids, a very simple method may be adopted for ascertaining the quantity of carbonate of lime, and one sufficiently accurate in all common cases.

Carbonate of lime, in all its states, contains a determinate proportion of carbonic acid, i.e. about 45 per cent; so that when the quantity of this elastic fluid, given out by any soil during the solution of its calcareous matter in an acid, is known, either in weight or measure, the quantity of carbonate of lime may be easily discovered.

When
STONES, &c. ANALYSIS OF.

When the process by diminution of weight is employed, two parts of the acid and one part of the matter of the soil must be weighed in two separate bottles, and very slowly mixed together till the effervescence ceases; the difference between their weight before and after the experiment denotes the quantity of carbonic acid lost; for every four grains and a half of which, ten grains of carbonate of lime must be estimated.

The best method of collecting the carbonic acid, so as to discover its volume, is by the pneumatic apparatus, the construction and application of which are described at the end of this article. The estimation, for every ounce measure of carbonic acid, two grains of carbonate of lime.

8. After the fine matter of the soil has been acted upon by muriatic acid, the next process is to ascertain the quantity of finely divided insoluble animal and vegetable matter that it contains.

This may be done with sufficient precision, by heating it in strong ignition in a crucible over a common fire till no blackness remains in the mass. It should be often stirred with a metallic wire, so as to expose new surfaces continually to the air; the loss of weight that it undergoes denotes the quantity of the substance that it contains destructible by fire and air.

It is not possible to ascertain whether this substance is wholly animal or vegetable matter, or a mixture of both. When the smell emitted during the incineration is similar to that of burnt feathers, it is a certain indication of some animal matter; and a copious blue flame at the time of ignition almost always denotes a considerable proportion of vegetable matter. In cases when the experiment is needed to be very quickly performed, the destruction of the decomposable substances may be assisted by the agency of nitrate of ammonia, which, at the time of ignition, may be thrown gradually upon the heated mass, in the quantity of twenty grains for every hundred of residual oil. It affords the principle necessary to the combustion of the animal and vegetable matter, which it causes to be converted into elastic fluids; and it is itself at the same time decomposed and lost.

9. The substances remaining after the decomposition of the vegetable and animal matter, are generally minute particles of earthy matter containing usually alumina and silica with combined oxide of iron.

To separate these from each other, the solid matter should be boiled for two or three hours with sulphuric acid, diluted with four times its weight of water; the quantity of the acid should be regulated by the quantity of solid residuum to be acted on, allowing for every hundred grains two drachms or one hundred and twenty grains of acid.

The substance remaining after the action of the acid may be considered as siliceous; and it must be separated and its weight ascertained, after washing and drying in the usual manner.

The alumina and the oxide of iron, if they exist, are both dissolved by the sulphuric acid; they may be separated by carbonate of ammonia, added to excess; it throws down the alumina, and leaves the oxide of iron in solution; and this substance may be separated from the liquid by boiling.

Should any magnesia and lime have escaped solution in the muriatic acid, they will be found in the sulphuric acid; this, however, is scarcely ever the case; but the process for detecting them, and ascertaining their quantities, is the same in both instances.

10. The method of analysis by sulphuric acid is sufficiently precise for all usal experiments; but if very great accuracy be an object, dry carbonate of potash must be employed as the agent, and the residuum of the incinera- tion must be heated red for half an hour, with four times its weight of this substance, in a crucible of silver, or of well baked porcelain. The mass obtained must be dissolved in muriatic acid, and the solution evaporated till it is nearly solid; distilled water must then be added, by which the oxide of iron and all the earths, except silica, will be dissolved in combination as muriates.

The silex, after the usual process of lixiviation, must be heated red; the other substances may be separated in the same manner as from the muriatic and sulphuric solutions.

11. If any saline matter, or soluble vegetable or animal matter, be suspected in the soil, it will be found in the water of lixiviation used for separating the sand.

This water must be evaporated to dryness in an appropriate dish, at a heat below its boiling point.

If the solid matter obtained is of a brown colour and inflammable, it may be considered as partly vegetable extract. If its smell, when exposed to heat, be strong and fetid, it contains animal mucilaginous or gelatinous substance; if it be white and transparent, it may be considered as principally saline matter. Nitrate of potash (nitre), or nitrate of lime, is indicated in this saline matter, by its detonating with a burning coal. Sulphate of magnesia may be detected by its bitter taste; and sulphate of potash produces no alteration in solution of carbonate of ammonia, but precipitates solution of muriate of barytes.

12. Should sulphate or phosphate of lime be suspected in the entire soil, the detection of them requires a particular process upon it. A given weight of it, for instance four hundred grains, must be heated red for half (gypsum) and phosphate of lime in soils.

and charcoal. The mixture must be boiled for a quarter of an hour, in a half-pint of water, and the fluid collected through the filter, and exposed for some days to the atmosphere in an open vessel. If any soluble quantity of sulphate of lime (gypsum) existed in the soil, a white precipitate will gradually form in the fluid, and the weight of it will indicate the proportion.

Phosphate of lime, if any exist, may be separated from the soil after the process for gypsum. Muratic acid must be digested upon the soil, in quantity more than sufficient to saturate the soluble earths; the solution must be evaporated, and water poured upon the solid matter. This fluid will dissolve the compounds of earths with the muriatic acid, and leave the phosphate of lime untouched.

13. When the examination of a soil is completed, the products should be classified, and their quantities added together; and if they nearly equal the original quantity of soil, the analysis may be considered as accurate. It must however be noticed, that when phosphate or sulphate of lime is discovered by the independent process, a correction must be made for the general process, by subtracting a sum equal to their weight from the quantity of carbonate of lime obtained by precipitation from the muriatic acid.

In arranging the products, the form should be in the order...
STONES, &c. ANALYSIS OF.

In this instance the loss is supposed small; but in general, in actual experiments, it will be found much greater, in consequence of the difficulty of collecting the whole quantities of the different precipitates; and when it is within thirty for four hundred grains, there is no reason to suspect any want of due precision in the processes.

13. A very fertile corn soil from Ormiston in East Lothian afforded, in 100 parts, only 1 parts of mild calcareous earth; it contained 25 parts of siliceous sand; the finely divided clay amounted to 45 parts. It lost nine in decomposed animal and vegetable matter, and four in water, and afforded indications of a small quantity of phosphate of lime.

This soil was of a very fine texture, and contained very few stones or vegetable fibres. It is not unlikely that its fertility was in some measure connected with the phosphate; for this substance is found in wheat, oats, and barley, and may be a part of their food.

A soil from the low lands of Somersetshire, celebrated for producing excellent crops of wheat and beans without manure, was found to consist of one-ninth of sand, chiefly siliceous, and eight-ninths of calcareous marl tinged with iron, and containing about five parts in 100 of vegetable matter. No phosphate or sulphate of lime could be detected in it; so that its fertility must have depended principally upon its power of attracting principles of vegetable nourishment from water and the atmosphere.

Mr Tillet, in some experiments made on the composition of soils at Paris, found that a soil composed of three-eighths of clay, two-eighths of river sand, and three-eighths of the parings of limestone, was very proper for wheat.

14. In general, bulbous roots require a soil much more sandy and less absorbent than the grasses. A very good potato soil, from Varsel in Cornwall, afforded seven-eighths of siliceous sand; and its absorbent power was so small, that 100 parts lost only two by drying at 400 Fahrenheit.

Plants and trees, the roots of which are fibrous and hard, and capable of penetrating deep into the earth, will vegetate to advantage in almost all common soils which are moderately dry, and which do not contain a very great excess of vegetable matter.

The soil taken from a field at Sheffield-place in Sussex, remarkable for producing flourishing oaks, was found to consist of six parts of sand, and one part of clay and finely divided matter. And 100 parts of the entire soil, submitted to analysis, produced

15. From the great difference of the causes that influence the productivity of lands, it is obvious that, in the present state of science, no certain system can be devised for their improvement, independent of experiment: but there are few cases in which the labour of the analytical trials will not be amply repaid by the certainty with which they denote the best methods of amelioration, and this will particularly happen when the defect of composition is found in the proportions of the primitive earths.

In supplying animal or vegetable manure, a temporary food only is provided for plants, which is in all cases exhausted by means of a certain number of crops; but when a soil is rendered of the best possible constitution and texture, with regard to its earthy parts, its fertility may be considered as permanently established: it becomes capable of attracting a very large portion of vegetable nourishment from the atmosphere, and of producing its crops with comparatively little labour and expense.

Stones. 

Artificial Stone. See STUCCO.

Elastic Stone. Some marbles possess the property of elasticity, and hence come under the denomination of elastic stones. But the most remarkable stone of this nature is the elastic sandstone from Brazil. It is a miscellaneous sandstone in laminae not exceeding half an inch in thickness. Some siliceous stones also have the same property, or acquire it by being exposed to a certain degree of heat.

Philosopher's Stone. See PHILOSOPHER'S Stone.

Precious Stones. See Gem.

Rocking Stone, or Logan, a stone of a prodigious size, so exactly poised, that it would rock or shake with the smallest of these stones the ancients give us some account. Pliny says, that at Harpessa, a town of Asia, there was a rock of such a wonderful nature, that if touched with the finger it would shake, but could not be moved from its place with the whole force of the body. Ptolemy Hesboston mentions a gygonian stone near the ocean, which was agitated when struck by the stalk of an asphodel, but could not be removed by a great exertion of force. The word gygonius seems to be Celtic; for gutingog signifies motitana, the rocking-stone.

Many rocking stones are to be found in different parts of this island; some natural, others artificial, or placed in their position by human art. In the parish of St Leven, Cornwall, there is a promontory called Castle Trevyn. On the western side of the middle group, near the top, lies a very large stone, so evenly poised that any hand may move it from one side to another; yet it is so fixed on its base, that no lever nor any mechanical force can remove it from its present situation. It is called the Logon-stone, and is at such a height from the ground that no person can believe that it was raised to its present position by art. But there are other rocking stones, which are so shaped and so situated, that there can be no doubt but they were erected by human strength. Of this kind Borlase thinks the great Quoit or Karu-leau, in the parish of Tywidnec, to be. It is 39 feet in circumference, and four feet thick at a medium, and stands on a single pedestal. There is also a remarkable stone of the same kind in the island of St Agnes in Scilly. The under rock is 10 feet six inches high, 47 feet round the middle, and touches the ground with no more than half its base. The upper rock rests on one point only, and is so nicely balanced, that two or three men with a pole can move it. It is eight feet six inches high, and 47 in circumference. On the top there is a haxon hollowed out, three feet eleven inches in diameter at a medium, but wider at the rim, and three feet deep. From the globular shape of this upper stone, it is highly probable that it was rounded by human art, and perhaps even placed on its pedestal by human strength. In Sidney parish, near Helston, in Cornwall, stood the famous logan, or rocking stone, commonly Borlase, called Men Amber, q. d. Men au Bar, or the top stone. *chap. iv.
It was eleven feet by six, and four high, and so nicely poised on another stone, that a little child could move it, and all travellers who came this way desired to see it. But Shrubsole, Cromwell's governor of Pendennis, with much ado caused it to be undermined, to the great grief of the country. There are some marks of the tool on it, and, by its quadrangular shape, it was probably dedicated to Mercury.

That the rocking stones are monuments erected by the Druids cannot be doubted; but tradition has not informed us for what purpose they were intended. Mr Toland thinks that the Druids made the people believe that they alone could move them, and that by a miracle; and that by this pretended miracle they condemned or acquitted the accused, and brought criminals to confess what could not otherwise be extorted from them. How far this conjecture is right we shall leave to those who are deeply versed in the knowledge of antiquities to determine.

Sonorous Stone, a kind of stone remarkable for emitting an agreeable sound when struck, and much used in China for making musical instruments which they call king.

The various kinds of sonorous stones known in China differ considerably from one another in beauty, and in the strength and duration of their tone; and what is very surprising, is that this difference cannot be discovered either by the different degrees of their hardness, weight, or fineness of grain, or by any other qualities which might be supposed to determine it. Some stones are found remarkably hard, which are very sonorous; and others exceedingly soft, which have an excellent tone; some extremely heavy emit a very sweet sound; and there are others as light as pumice stone which have also an agreeable sound.

The chemists and naturalists of Europe have never yet attempted to discover, whether some of our stones may not have the same properties as the sonorous stones of the extremities of Asia. It however appears, that the Romans were formerly acquainted with a sonorous stone of the class of biang-che. Pliny says the Abbe du Bos, in his Reflections on Poetry and Painting, when speaking of curious stones) observes that the stone called cophonae, or brevon sound, is black; and that, according to the etymology of its name, it sends forth a sound much resembling that of brass when it is struck. The passage of Pliny is as follows: Chalcophanes niger est; sed cipha est in nitidum reddidit.

Some sonorous stones were at length sent into France, and
and the late Duke de Chaulnes examined them with particular attention. The following are some of his observations: "The Academy of Sciences, Mr Romé de Lisle, and several other learned mineralogists, when asked if they were acquainted with the black stone of which the Chinese king was made, for answer cited the passage of Pliny mentioned by Boetius de Boot, Linnæus, and in the Dictionary of Bomare, and added what Mr Anderson says in his Natural History of Iceland respecting a bluish kind of stone which is very sonorous. As the black stone of the Chinese becomes of a bluish colour when filed, it is probably of the same species. None of the rest who were consulted had ever seen it. The Chinese stone has a great resemblance at first sight to black marble, and like it is calcareous; but marble generally is not sonorous. It also externally resembles touchstone, which is a kind of basaltes, and the basaltes found near volcanoes; but these two stones are vitrifications."

The duke next endeavoured to procure some information from the stone-cutters. They all replied, that blue-coloured marble was very sonorous, and that they had seen large blocks of it which emitted a very strong sound; but the duke having ordered a king to be constructed of this kind of stone, it was found that it did not possess that property. By trying the black marble of Flanders, a piece was at length found which emitted an agreeable sound: it was cut into a king, which is almost as sonorous as those of China. All these observations give us reason to believe that the stones of which the king are formed are nothing else but a black kind of marble, the constituent parts of which are the same as those of the marble of Europe, but that some difference in their organization renders them more or less sonorous.

Swinestone (lapis silvis), or fesid stone, so called from its excessively fesid smell, is a calcareous stone impregnated with petroleum. See MINERALOGY INDEX.

Stone-Marrow, a variety of clay so called from its having the appearance of marrow.

STONEWARE, a species of pottery so called from its hardness. See DEBTE-WARE and PORCELAIN.

STONE in the Bladder. See MEDICINE, p. 400, and SURGERY INDEX.

Stone, in merchandise, denotes a certain weight for weighing commodities. A stone of beef at London is the quantity of eight pounds: in Herefordshire 12 pounds: in the North 16 pounds. A stone of glass is five pounds: of wax eight pounds. A stone of wool (according to the statute of 11 Hen. VII.) is to weigh 14 pounds: yet in some places it is more, in others less; as in Gloucestershire 15 pounds; in Herefordshire 12 pounds. Among horse-couriers a stone is the weight of 14 pounds.

The reason of the name is evident. Weights at first were generally made of stone. See Deut. xxv. 13, where the word סב, translated weight, properly signifies a stone.

STONE-CHATTER. See MOTACILLA, ORNITHOLOGY INDEX.

STONEHENGE, a celebrated monument of antiquity, stands in the middle of a flat area near the summit of a hill six miles distant from Salisbury. It is inclosed by a circular double bank and ditch near 30 feet broad, after crossing which we ascend 30 yards before we reach the work. The whole fabric consisted of two circles and two ovals. The outer circle is about 108 feet diameter, consisting when entire of 63 stones, 30 uprights and 30 imposts, of which remain only 24 uprights, 17 standing and 7 down, 34 feet asunder, and 8 imposts. Eleven uprights have their 5 imposts on them by the grand entrance. These stones are from 13 to 20 feet high. The lesser circle is somewhat more than 8 feet from the inside of the outer one, and consisted of 40 lesser stones (the highest 6 feet), of which only 19 remain, and only 12 standing: the walk between these two circles is 320 feet in circumference. The adyrum or cell is an oval formed of 10 stones (from 16 to 22 feet high), in pairs, with imposts, which Dr Stukeley calls trilithons, and above 30 feet high, rising in height as they go round, and each pair separate, and not connected as the outer pair; the highest 8 feet. Within these are 19 more smaller single stones, of which only 8 are standing. At the upper end of the adyrum is the altar, a large slab of blue coarse marble, 20 inches thick, 16 feet long, and 4 broad; pressed down by the weight of the vast stones that have fallen upon it. The whole number of stones, uprights, imposts, and altar, is exactly 140. The stones are far from being artificial, but were most probably brought from those called the Grey Weathers on Marlborough Down, 15 or 16 miles off; and if tried with a tool they appear of the same hardness, grain, and colour, generally reddish. The heads of oxen, deer, and other beasts, have been found on digging in and about Stonehenge; and human bones in the circumjacent barrows. There are three entrances from the plain to this structure, the most considerable of which is from the north-east, and at each of them were raised on the outside of the trench two huge stones with two smaller within parallel to them.

It has been long a dispute among the learned, by what nation, and for what purpose, these enormous stones were collected and arranged. The first account of this structure we meet with is in Geoffrey of Monmouth, who, in the reign of King Stephen, wrote the history of the Britons in Latin. He tells us, that it was erected by the counsel of Merlin the British enchanter, at the command of Aurelius Ambrosius the last British king, in memory of 460 Britons who were murdered by Hengist the Saxon. The next account is that of Polydore Virgil, who says that the Britons erected this as a sepulchral monument of Aurelius Ambrosius. Others suppose it to have been a sepulchral monument of Boadicea the famous British queen. Inigo Jones is of opinion, that it was a Roman temple; from a stone 16 feet long, and four broad, placed in an exact position to the eastward altar-fashion, Mr Charlton attributed it to the Danes, who were two years masters of Wiltshire. A tin tablet, on which were some unknown characters, supposed to be Punic, was dug up near it in the reign of Henry VIII. but is lost; probably that might have given some information respecting its founders. Its common name, Stonehenge, is Saxon, and signifies a "stone gallows," to which these stones, having transverse imposts, bear some resemblance. It is also called in Welsh chyr夏日, or "the giants dance."

Mr Grose thinks that Dr Stukeley has completely proved this structure to have been a British temple in which the Druids officiated. He supposes it to have been the metropolitan temple of Great Britain, and

Stonehenge.

STORK. See ARDEA, ORNITHOLOGY Index.

STOVE for heating apartments, greenhouses, hot-houses, fruit-walls, &c.

When treating of the mechanical properties of air, we explained in sufficient detail the manner in which the expansion produced in a mass of air by heat produces that motion up our chimneys which is called the draught of the chimney; and, in the article SMOKE, we considered the circumstances which tend to check, to promote, or to direct this current, so as to free us from the smoke and vitiated air which necessarily accompanies the consumption of the fuel. In PNEUMATICS we also attended to the manner in which our fires immediately operate in warming our apartments. At present, when about to describe a method of warming intrinsically different, we must pay some more attention to the distinguishing circumstance. Without pretending to explain the physical connection of heat and light, it may suffice to observe, that heat, as well as light, is communicated to distant bodies in an instant by radiation. A person passing hastily by the door of a glass-house feels the glow of heat in the very moment he sees the dazzling light of the furnace mouth, and it is interrupted by merely screening his face with his hand. In this way is an apartment partly warmed by an open fire; and we avoid the oppressive heat by sitting where the fire is not seen, or by interposing a screen. We are apt to connect this so strongly in the imagination with the light emitted by the fire, that we attribute the heat to the immediate action of the light. But this opinion is shown to be gratuitous by a curious experiment made before the Royal Society by Dr Hooke, and afterwards, with more care and accurate examination, by Mr Scheele. They found, that by bringing a plate of the most transparent glass briskly between the fire and one's face, the heat is immediately intercepted without any sensible diminution of the light. Scheele, by a very pretty investigation, discovered that the glass made the separation, and did it both in refraction and reflection; for he found, that when the light of the same fire was collected into a focus by means of a polished metal concave speculum, a thermometer placed there was instantly affected. But if we employ a glass speculum foiled in the usual manner with quicksilver, of the same diameter and focal distance, and of equally brilliant reflection, there is hardly any sensible heat produced in the focus, and the thermometer must remain there for a very long while before it is sensibly affected. When we repeated this curious experiment, we found, that after the glass has remained a long while in this position, whether transmitting or reflecting the light, it loses in a great measure its power of intercepting the heat. By varying this observation in many of its circumstances, we think ourselves entitled to conclude, that the glass absorbs the heat which it intercepts, and is very quickly heated by the absorption. While it rises in its own temperature, it intercepts the heat powerfully; but when it is, as it were, saturated, attracting no more than what it immediately imparts to the air in corporeal contact with it, the heat passes freely through along with the light. If the
the glass be held so near the fire that the surrounding air is very much heated, no sensible interruption of heat is perceived after the glass is thus saturated. We found the check more quickly sensible than the thermometer of the instantaneous radiation of the heat which accompanies the light, or is separated from it in this experiment. It is a very instructive experiment in the physiology of heat.

We cannot say how far this radiation of heat may extend, nor whether the accompaniment of light is absolutely necessary. The mathematician proceeds on the supposition that it extends as far as the radiation of light, and that, being also rectilinear, the density of the heat is proportional to that of the light. But these notions are somewhat gratuitous; and there are appearances which render them doubtful. When with a lens of an inch in diameter we form a focus on a piece of black unpolished marble of an inch diameter, the mathematician must allow that no more rays fall on the marble than if the lens were away: therefore the marble should be equally warmed in either case. But it is by no means so, as we have repeatedly found by exposing it during equal times, and then dropping it into water. The water which is heated by the marble on which the focus has been formed will be found to have acquired from it much more heat than from the other. The tops of lofty mountains which are never shaded by clouds, but enjoy perpetual sunshine and serenity, instead of being warmer than the valleys below, are covered with never-melting snow; and we have some grounds to suspect that the general influence of the sun upon the co-operation of the atmosphere, and to doubt whether there is any warmth at the moon, on which no atmosphere like ours can be observed. Perhaps the heat which cheers us, and fertilizes our earth, is chemically separated from our atmosphere by its elective attraction for the light of the sun. Our successors in the study of meteorology need not fear that the subject of their research will be soon deprived of scientific allusions. We know but little of it after all the progress we have made during this last century, and it still presents an ample field of discussion.

We said that the accompaniment of light is not demonstrably necessary. We are certain that heat may be imparted without any sensible light, in a manner which we can hardly suppose any thing but radiation. If a piece of very hot iron be placed a little without the principal focus of a metallic concave speculum, and a very sensible air-thermometer be placed in its conjugate focus, it will instantly show an elevation of temperature, although the iron is quite imperceptible to an eye which has even been a long while in the dark. No such rise of temperature is observed if the thermometer be placed a little to one side of the focus of the speculum; therefore the phenomenon is precisely similar to the radiation of light.

We are obliged therefore to acknowledge that the heat is radiated in this experiment in the same way that light is in the common optical experiments.

Although this is the most usual way that we in this country employ fuel for warming our apartments, it is by no means the only way in which the heat diffused from this fuel may be imparted to distant bodies. It is not even the most effectual method; it is diffused also by immediate communication to bodies in contact. The air in immediate contact with the burning fuel is heated and imparts some of its heat to the air lying beyond it, and this is partly shared with the air which is still farther off; and this diffusion, by conduction in contact, goes on till the remote air contiguous to the walls, floor, ceiling, the furniture, the company, all get a share of it in proportion to their attractions and their capacities. And as the air is thus continually supplied, and continually gives out heat, the walls, &c. become gradually warmer, and the room becomes comfortable and pleasant. But we apprehend that so great proportion of the heat actually acquired by the room is communicated in this way. This diffusion by contact is but slow, especially in air which is very dry; so slow indeed, that the air in the immediate neighbourhood of the fire is hurried up the chimney before it has time to impart any of the heat received in contact. We know that the time employed in diffusing itself in this way through stagnant air to any moderate distance is very considerable. We imagine therefore that the heat, communicated to our rooms by an open fire is chiefly by radiation, but in a way something different from what we mentioned before. We imagine, that as the piece of glass in Dr Hooke’s experiment absorbs the heat, so the whole mass of air which fills the room intercepts the radiated heat in every part of the room where the fire is seen, and is as it were saturated with it throughout, and ready to impart it to every body immersed in it. We cannot otherwise account for the equability of the heat in the different parts of the room. Mere radiation on the solid bodies would warm them in the inverse duplicate ratio of their distance from the fire; and diffusion by contact, if compatible with the rapid current up the chimney, would heat the room still more unequally. Recollect how slowly, and with what rapid diminution of intensity, the colour of blue vitiol is communicated to water even to a very small distance. But because all parts of the air of the room absorb radiated heat, what is saturated at a higher temperature, being nearer to the fire rises to the ceiling, spreads outwards along the ceiling, and has its place supplied by the air, which is thus pushed towards the fire from the places which are not directly illuminated.

Far different is the method of warming the room by a stove. Here the radiation, if any, is very feeble or scanty; and if a passage were allowed up the chimney for the warmed air, it would be quickly carried off. This is well known to the English who reside in the cold climates of St Petersburg, Archangel, &c. They love the exhilarating flutter of an open fire, and often have one in their parlour; but this, so far from warming the room during the extreme cold weather, obliges them to heat their stove more frequently, and even abstracts the heat from a whole suit of apartments. But all passage this way is shut up when we warm a room by stoves. The air immediately contiguous to the stove is heated by contact, and this heat is gradually, though slowly, diffused through the whole room. The diffusion would however be very slow indeed, were it not for the great expansibility of air by heat. But the air surrounding the stove quickly expands and rises to the ceiling, while the neighbouring air slides in to supply the place, and as in such a case the air which goes outwards aloft. Thus the whole air is soon mixed, and the room acquires almost an equal temperature throughout.
The warming by stoves must therefore be managed upon very different principles from those adopted in the employment of open fires. The general principle is, 1st, To employ the fuel in the most effectual manner for heating the external part of the stove, which is immediately efficient in warming the contiguous air; and, 2d, To keep in the room the air already warmed, at least as much as is consistent with wholesomeness and cleanliness.

The first purpose is accomplished by conducting the flue of the furnace round its external parts, or, in short, by making every part of the flue external. Of all forms, that of a long pipe, returned backwards and forwards, up and down (provided only that the place of its last discharge be considerably higher than its entry from the fire-place), would be the most effectual. We have seen a very small stove constructed in this way, the whole being inclosed in a handsome case of polished iron plate, pierced and cut into elegant foliage like the cock of a watch, so that the odd looking pipes were completely concealed. Though only three feet long, one foot thick, and six feet high, it warmed a very lofty room of 24 feet by 18, and consumed less than half the fuel of a stove of the more usual make, which did not so fully warm a smaller chamber.

It would occupy a volume to describe the immense variety of stoves which ingenuity or architectural taste has constructed. We shall content ourselves with giving a specimen of the two chief classes into which they may be distinguished.

The air of a room may be equally warmed, either by applying it to the surface of a small stove made very hot, or to the surface of a much larger stove more moderately heated. The first kind is chiefly used in Holland, Flanders, and the milder climates of Germany and Poland. The last are universally used in the frozen climates of Russia and Sweden. The first are generally made of cast-iron, and the last of brick-work covered with glazed tiles or stucco.

Plate DX.

Fig. 1. represents a small German stove fully sufficient for warming a room of 24 feet by 18. The base is about three feet broad and 14 inches deep, that is, from back to front, and six or seven feet high. The decoration is in the fashion of that country; but the operative structure of it will admit of any style of ornament. A, is the fire-place, and the wood or charred coal is laid on the bottom, which has no bars. Bars would admit the air too freely among the fuel, and would both consume it too fast and raise too great a heat. That no heat may be uselessly expended, the sole of the fire-place and the whole bottom of the stove is raised an inch or two above the floor of the room, and the air is therefore warmed by it in succession, and rises upwards. For the same reason the back of the stove is not in contact with the wall of the room, or of the niche in which it is placed. The fire-place is shut up by a door which fits closely to its case, and has a small wicket at the bottom, whose aperture is regulated by a sliding plate, so as to admit no more air than what suffices for slowly consuming the fuel. The flame and heated air rise to the top of the fire-place three or four inches above the arch or mantle piece, and get out laterally by two narrow passages B, B, immediately below the top-plate of the base. The current bends forward on each side, passes at C, C, under the partition plates which divide the two side chambers, and then rises upwards through the outer division of each, and passes through narrow slits D, D, in the top-plate, and thence along the two hollow piers E, E. The two lateral currents unite at the top of the arch, and go through the single passage F into the larger hollow behind the escutcheon G. From this place it either goes straight upwards into the vent in the wall by a pipe on the top of the stove, or it goes into the wall behind by a pipe inserted in the back of the stove. The propriety of this construction is very obvious. The current of hot air is applied to exterior parts of the stove everywhere except in the two side chambers of the base, where the partition-plates form one side of the canal. Even this might be avoided by making each of these side-chambers a detached hollow pillar. But this would greatly increase the trouble of construction and joining together, and is by no means necessary. The arch H has a graceful appearance, and affords a very warm situation for anything that requires it, such as a drink in a sick person's bed-chamber, &c. Persons of a certain class use this place for keeping a dish warm; nay, the lower part of the arch is frequently occupied by an inclosed chamber, where the heat rises high enough even for dressing victuals, as will be easily imagined when we reflect that the sole of it is the roof of the fire-place.

The stove now described is supplied with fuel and with air by the front door opening into the room. That there may be room for fuel, this middle part projects a few inches before the two side-chambers. These last, with the whole upper part of the stove, are not more than ten inches deep. The passages, therefore, from the fire-place are towards the back of it; so that if we have a mind to see the fire (which is always cheerful), the door may be thrown open, and there is no danger of the smoke coming out after the current has once warmed the upper part of the stove. When the stove is of such dimensions that the base is about two feet and a half or three feet high, the fire-place may be furnished with a small grate in the British style. If the door is so hung that it can not only be thrown back, but lifted off its hinges, we have a stove grate of the completest kind, fully adequate, in our mild climate, to warm a handsome apartment, even with an open fire; and when we hang on the door, and shut up the fire-place, a stove of the dimensions already given is almost too much for a large drawing room.

We have frequently remarked, that one side of these stoves grows much warmer than the other, and that it was difficult to prevent or remedy this; and we imagine that this is an unavoidable defect in all stoves with a double flue. It is scarcely possible to make the fire so equable in the fire-place, that one side shall not be a little warmer than the other, and a brisker current will then be produced in it. This must increase the consumption of the fuel on this side, which will increase the current, will heat this side still more, and go on continually till the fuel on this side is expended; after which the other side will obtain and increase the superiority. The flue is made double, that the fire-place may occupy the middle of the front; and it will be difficult to gain this point of symmetry with one flue. The inconvenience may, however, be corrected by damping valves placed in some part of the upright funnels E, E.
In the colder winters on the continent, it is thought necessary to increase the effect by making the fire-place open to the back of the stove. Its mouth or door communicates with or is joined to an opening of the same dimensions formed in the wall, and the door is on the other side in an antechamber or lobby. In Westphalia, and other places of Germany, the apartments are disposed round a spacious lobby, into which all their fire-places open, and are there supplied with fuel. By this construction it is plain that the air of the room, already warmed by the stove, is not carried off, and the room is more heated. But this method is very unfavourable to cheerfulness and health. The same air, confined, and repeatedly breathed and compounded with all the volatile emanations of the room, quickly loses that refreshing quality that is so desirable, and even so necessary for health. It is never renewed except by very partial admixtures when the room doors are thrown open, and becomes disagreeable to any person coming in from the open air; and in the houses of the less opulent becomes really offensive and nauseous.

Something of this is unavoidable in all rooms heated by stoves. Even in our apartments in this island, persons of delicate nerves are hurt by what they call the close air of a room; and it is long before the smell of dinner is quite removed from a dining-room, notwithstanding the copious current up the chimney. This must be incomparably more sensible in a room heated by a stove; and this inconvenience is peculiarily sensible with respect to the stove which we are considering at present, where we employ a small surface heated to a great degree.

Such stoves are seldom made of anything else than cast-iron. This (in those parts at least which are in immediate contact with the fuel) is in a state of continual calculation, and even throwing off scales. This indeed is not seen, because it is the bottom or sole of the fire-place which is so heated; but the effect on the air of the room is the same. The calculation of the iron is occasioned by the combination of pure vital air with the iron. This is abstracted from the general mass of atmospheric air in the room, of which it usually constitutes about two-fifths. By this abstraction the remainder becomes less fit for supporting animal life or flame, and may even become highly deleterious. In every degree the remainder becomes less refreshing, and grows dull and oppressive. This is always accompanied by a peculiar smell, which, though not disgusting, is unpleasant. It resembles the smell of burnt feathers, or more exactly the smell we feel if we rub violently for some time the palms of our hands together when perfectly dry.

For similar reasons these iron-stoves occasion a sickly smell, by burning every particle of dust which falls on the hot parts; and if they be wiped with a woolen cloth, or any cloth not perfectly free from every kind of greasy or oily matter, a smell is produced for a day or days afterwards; so that without the most scrupulous attention we suffer by our very cleanliness.

For such reasons we think that the stoves of brick-work covered with stucco or with glazed tiles are vastly preferable. These are much used in the genteeler houses in Flanders and Holland, where they are made in the most elegant forms, and decorated with beautiful sculpture or enamel; but it is plain that they cannot be so effectual, nor equally warm a room with the same expense of fuel. Earthen ware, especially when covered with porous stucco, is far inferior to metal in its power of conducting heat. If built of bricks, they must be vastly more bulky when the fire-place and flues are of the same dimensions. The most perfect way of constructing them would certainly be to make them of pottery, in parts exactly fitted to each other, and joined by a proper cement. This mode of constructing would admit of every elegance of form or richness of ornament, and would not be so bulky as those which are built of bricks. The great difficulty is to prevent their cracking by the heat. Different parts of the stove being of very different heats, they expand unequally, and there is no cement which can withstand this, especially when we recollect that the same heat which expands the baked earth causes the clay or cement, with which the parts of the stove are put together or covered, to contract. Accordingly those earthen ware stoves seldom stand a winter or two without cracking in some place or other, even when strengthened by iron hoops and cramps judiciously disposed within them. Even hooping them externally, which would be very unsightly, will not prevent this; for nothing can resist the expansion and contraction by heat and cold. When a crack happens in a stove, it is not only unsightly, but highly dangerous; because it may be so situated, that it will discharge into the room the air vitiated by the fire.

For these and other reasons, we can scarcely hope to make stoves of brick work or pottery which shall bear the necessary heat without cracking; and their use must therefore be confined to cases where very moderate heat is sufficient. We need not describe their construction. It is evident that it should be more simple than that of iron stoves; and we imagine that in the very few cases in which they are likely to be employed in this country, a single fire-place, and an arch over it, divided, if we please, by a partition or two of thin tile to lengthen the flue, will be quite enough. If the stove is made in whole or in part of potters ware, a base for the fire-place, with an urn, column, obelisk, or pyramid above it, for increasing the surface, will also be sufficient. The failure commonly happens at the joinings, where the different pieces of a different heat, and perhaps of a different baking, are apt to expand unequally, and by working on each other one of them must give way. Therefore, instead of making the joints close and using any cement, the upper piece should stand in a groove formed in the undermost, having a little powdered chalk or clay sprinkled over it, which will effectually prevent the passage of any air; and room being thus given for the unequal expansion, the joint remains entire. This may be considered as a general direction for all furnace-work, where it is in vain to attempt to hinder the mutual working of the parts.

We have seen stoves in small apartments at St Petersburg, which were made internally of potters ware, in a great variety of forms, and then covered with a thick coat of stucco, finished externally with the utmost elegance of ornament, and we were informed that they were very rarely subject to crack. They did not give much heat, on account of the very low conducting power of the porous stucco; but we imagine that they would be abundantly warm for a moderate room in this country.
When fitted up in these situations, and with these precautions, the brick or pottery stoves are incomparably more sweet and pleasant than the iron ones.

But in the intense colds of Russia and Sweden, or even for very large rooms in this kingdom, stoves of these small dimensions are not sufficiently powerful, and we must follow the practice of those countries where they are made of great size, and very moderately heated. It is needless to describe their external form, which may vary at pleasure. Their internal structure is the same in all, and is distinctly described in Pneumatics, No 364. We shall only enlarge a little on the peculiarities connected with the general principle of their construction.

The stove is intended as a sort of magazine, in which a great quantity of heat may be quickly accumulated, to be afterwards slowly communicated to the air of the room. The stove is therefore built extremely massive; and it is found that they are more powerful when coated with clay as well as can be made to hang together. We imagine the reason of this to be, that very wet clay, and more particularly stucco, must be exceedingly porous when dry, and therefore a very slow conductor of heat. Instead of sticking on the glazed tiles with no more clay or stucco than is sufficient to attach them, each tile has at its back a sort of box baked in one piece about two or three inches deep. It is represented in fig. 2. This is filled with mortar, and then stuck on the brick-work of the stove, which has a great number of iron pins or hooks driven into the joints, which may sink into this clay and keep it firmly attached when dry. This coating, with the massive brick-work, forms a great mass of matter to be heated by the fuel. The lowest chamber, which is the fire-place, is somewhat wider, and considerably thicker than the stories above, which are merely flues. When the fire-place is finished and about to be chocked over, a flat iron bar of small thickness is laid along the top of the side-wall on both sides, a set of finishing bricks being moulded on purpose with a notch to receive the iron bar. Cross bars are laid over these, one at each end, and a little between, having a bit turned down at the ends, which takes hold of the longitudinal bars, and keeps them from being thrust outwards either by the pressure of the arch or by the swelling in consequence of the heat. In fig. 3. A is the cross section of one of the long bars, and BC is part of one of the cross bars, and CD is the clench which confines the bar A. This precaution is chiefly necessary, because the contraction of the stove upwards obliterates the walls of the other stories to bear a little on the arch of the fire-place. The building above is kept together in like manner by other courses of iron bars at every second return of the flue. The top of the stove is finished by a pretty thick covering of brick-work. The last passage for the air at H (see Pneumatics, fig. 62.) has a ring lining its upper extremity, and projecting an inch or two above it. The flat round it is covered with sand. When we would stop this passage, a covered shape like a basin or cover for dishes at table is wheeled over it. The rim of this, resting on the sand, effectually prevents all air from coming through and getting up the vent. Access is had to this damper by a door which can be shut tight enough to prevent the heated air of the room from wasting itself up the vent. When the room is too warm, it may be very readily cooled by opening this door. The warm air rises up with great rapidity, and is replaced by cool air from without.

The management of the stove is as follows. About eight o'clock in the morning the pietchnick, or servant who has the charge of the stoves, takes off the cover, shuts the damper-door, and opens the fire-place door. He then puts in a handful of wood shavings or straw, and kindles it. This warms the stove and vent, and begins a current of air through it. He then lays a few chips on the sole of the fire-place, immediately within the door; and behind this he arranges the billets of birchwood with their ends inwards. Then he lays on more wood in the front, till he thinks there is enough. He sets fire to the chips, shuts the door and opens the small wicket at its bottom. The air blows the flame of the chips upon the billets behind them, and thus kindles them. They consume slowly, while the billets in front remain untouched by the fire. The servant, having made his first round of the rooms, returns to this stove, and opens the door above to admit air into the vent. This is to supply its draught, and thus to check the draught in the body of the stove, which is generally too strong at this time, and would consume the fuel too fast. By this time the billets in the front are burning, first at the bottom, and the rest in succession as they sink down on the embers and come opposite to the wicket. The room does not yet feel any effect from the fire, the heat of which has not yet reached its external surface; but in about half an hour this grows warm. The upper door is shut again, that no heat may now be wasted. The pietchnick by and by spreads the embers and ashes over the whole bottom of the fire-place with a rake, by which the bottom is greatly heated, and heats the air contiguous to it externally (for it stands on little pillars) very powerfully. He takes care to bring up to the top of the ashes every bit of wood or coal that is not yet consumed, that all may be completely expended. He does this as briskly as possible, that the room may not lose much warmed air by keeping open the fire-place door. At his last visit, when he observes no more glowing embers, he shuts the fire-place door and wicket, and puts the damper on the passage above, and shuts its door. — All this is over in about an hour and a half after kindling the fire. All current of air is now at an end within the stove, and it is now a great mass of brick-work, heated to a great degree within, but only about blood-warm externally. The heat gradually spreads outwards, and the external surface of the stove acquires its greatest heat about three o'clock in the afternoon; after which it gradually cools till next morning.

This heat seldom is so great that one cannot bear to touch the stove with his cheek, and to keep it there. In consequence of this it can burn none of the dust which unavoidably falls on the stove, and we are never troubled with the sickening smells that are usual when we employ the small cast-iron stoves much heated. The great expense of heat in a room arises from the glass windows. The pane is so thin that the external air keeps it continually cold, and thus the windows are continually robbing the air of the room of its heat. This expense of heat is reduced to less than one-third by double casements. The inner casement is about as much colder than the room as the outer casement is warmer.
warmer than the air of the fields; and we have the singular advantage of having no ice formed on the glasses. But to ensure this last advantage, the seams of the inner casement must be pasted with paper, and those of the outer casement must be left unpasted. If we do the contrary, we shall certainly have ice on the outer casement; the reason of which is easily seen.

We have been particular in our description of the management, because the reasons of some particulars are not very obvious, and the practice would not readily occur to us in this country; so that a person who, on the faith of our recommendation, should prefer one of these stoves to the German stove, whose management is simple and obvious, might be greatly disappointed. But by following this method, we are confident that the Russian stove will be found much superior both in warmth and agreeable air. The spreading out of the embers, and waiting till all is reduced to ashes before the doors are shut, is also absolutely necessary, and a neglect of it would expose us to eminent danger of suffocation by fixed air; and this is the only inconvenience of the Russian stove, from which the other stove is free. The fixed air has no smell; and the first indication of its presence is a slight giddiness and lassitude, which disposes us to sit down and to sleep. This would be fatal; and we must immediately open the upper passage and the fireplace door, so as to produce a strong current to carry the vitiated air of the room up the chimney. Throwing up the ashes, or at least opening all the doors, is proper on such an occasion.

If we burn pit-coal, either raw or charred, this precaution is still more necessary; because the cinder is not so easily or so soon completely consumed. This fuel will require a little difference in the management from wood fuel, but which is easily seen by any person of reflection. The safe way would be to rake out all half-burnt coal before shutting up the doors.

If we use raw pit-coal, great care is necessary to prevent the accumulation of soot in the upper part of the stove. It is an inaccessible place for the chimney-sweep; and if we attempt to burn it out, we run a great risk of splitting that part of the stove which is the most slightly constructed. It is advisable therefore to burn it away every day, by giving a brisk draught with an open door for five minutes. With wood or oak there is no danger.

It will not be improper in this place to give some instructions for the construction of stoves for warming several floors in a great manufactory, such as a cotton-mill, or a public library or museum.

In such situations we think cleanliness, wholesomeness, and sweetness of air, no less necessary than in the drawing room of a man of opulence. We therefore recommend the brick-stove in preference to the iron one; and though it would not be the best or most economical practice to heat it but once a day, and we should rather prefer the German practice of constant feeding, we still think it highly proper to limit the heat to a very moderate degree, and employ a large surface.

If the disposition of the rooms allows us the convenience of a thick party-wall, we would place the stove in the middle of this wall, in an arch which pierces through the wall. Immediately above this arch we would carry up a very wide chimney through the whole height. This chimney must have a passage opening into each floor on both sides, which may be very accurately shut up by a door. The stove being set up under the arch, it must have a pipe communicating with its flue, and rising up through this chimney. Could an earthen pipe be properly supported, and secured from splitting by hoops, we should prefer it for the reasons already given. But as this is perhaps expecting too much, we must admit the use of a cast iron pipe. This is the real chimney or flue of the stove, and must be of as great diameter as possible, that it may act, by an extensive surface, all the way up.

The stove stands under the arch in the wall; but the air that is warmed by its surface would escape on both sides, and would be expended in that single flue. To prevent this, the stove must be inclosed in a case: this may be of brick-work, at the distance of two or three inches from the stove all round. It must be well shut in above, and at the foundation must have a row of small holes to admit the air all around it. This air will then be warmed over the whole space between the stove and the case, pass up the chimney, and there receive additional heat from the flue-pipe which is in the middle. Great care must be taken that the fire-place door have no communication with the space between the stove and its case, but be inclosed in a metal frame, which comes through the case, and opens into the feeding-room. Thus all the air which goes up to the rooms will be pure and wholesome, provided we take care that every thing be kept clean and sweet about the air-holes below. Observe that those air-holes which are near the furnace door must be inclosed in a wooden trunk which takes in its air at some distance from this door; for since the current between the stove and case may be almost as great as the current within the stove (nay, when a puff of wind beats down the chimney, it may even exceed it), there is a risk of some vitiated air and smoke being drawn into the case.

If the stove cannot be placed in the arch of a party-wall, it may be set adjoining to a side or outer wall, and furnished with a case, a large chimney, and a flue-pipe, in the same manner. But in this case a great deal of heat is wasted on this outer wall, and carried off by the external air. In this situation we would recommend to line that part of the wall which is behind the stove (at two or three inches distance), and the whole of the chimney, with plaster or laths. These should be nailed on battens properly fastened on the wall, leaving a space of an inch between the laths and the wall. The plaster should be of the most spongy kind, having in it a quantity of clay in powder instead of the full proportion of sand. Horse-dung, washed with water and strained through coarse flannel, leaves a great portion of unassimilated vegetable fibre, which will mix very intimately in the plaster, and make it a substance very unfit for conducting heat. There is no danger of catching fire by this lining. We have seen a most tremendous fire rage for three hours, in contact with a partition of lath and plaster (on the plaster-side however), without discolouring the thin laths on the other side. We once saw a cottage chimney on fire, and burn till the soot was consumed. This chimney was nothing but a pipe of a foot wide, made of laths, and plastered on the inside and outside; and it passed through a thatched roof. We therefore recommend this in place of the brick-case for inclosing the stove. It should save heat; and as it might be
be made in pieces on detached frames, which could be joined by iron straps and hinges, any part of the stove could be laid open for repairs at pleasure.

We have no hesitation in saying that a stove constructed in this manner would be greatly superior in power to any we have seen, and would be free from many of their disgusting defects. We beg leave therefore to introduce here the description of one which was to have been erected in one of the churches of the city of Edinburgh.

Fig. 4. is a sketch of the plan of the church contained in the parallelogram AFED. P marks the place of the pulpit, and LMNO the front of the galleries. These are carried back to the side walls AB and DC. But at the end opposite to the pulpit they do not reach so far, but leave a space BFEC about 12 feet wide. Below the back of the galleries, on each side, there is a passage ABGH, KICD, separated from the seated part of the church by partitions which reach from the floor to the galleries, so that the space HGIK is completely shut in. The church is an ancient Gothic building, of a light and airy structure, having two rows of large windows above the arcades, and a spacious window in the east end above the pulpit. The congregation complain of a cold air, which they feel pouring down upon their heads. This is more particularly felt by those sitting in the fronts of the galleries. We imagine that this arises chiefly from the extensive surface of the upper row of windows, and of the cold stone-walls above, which robs the air of its heat as it glides up along the sides of the church. It becomes heavier by cooling, and in this state descends in the middle of the church.

The stove S is placed against the middle of the west wall at the distance of a few inches, and is completely inclosed in a case of lath and plaster. The vent, which is to carry off the smoke and burnt air, is conveyed up or along the wall, and through the roof or side-wall, but without any communication with the case. In like manner the fire-place door is open to the passage, without communicating with the case; and care is taken that the holes which admit the air into the case are so disposed that they shall run no risk of drawing in any air from the fire-place door.

From the top of this case proceed two trunks Q, R, each of which is two feet broad and six inches deep, coated within and without with the most spongy plaster that can be composed. For this purpose we should recommend a composition of powdered charcoal and as much clay and quicklime as will give it a very slight cohesion. We know that a piece of this may be held in the hand, without inconvenience, within an inch of where it is of a glowing red heat.—These trunks open into another trunk XVYZ, which ranges along the partition immediately under the galleries, and may be formed externally into a cornice, a little massive indeed, but not unsightly in a building of this style. This trunk is vaulted in the same manner. It has several openings a, a, &c. which have sliders that can be drawn aside by means of iron handles accessible from the outer passage.—At the extremities X and Z of this trunk are two perpendicular trunks which come up through the galleries, and are continued to a considerable height. At their junction with the horizontal trunk are two doors large enough to admit a lamp. Each perpendicular trunk has also a valve by which it can be completely stopped.

The stove is managed as follows: Early in the morning the superintendent shuts all the sliders, and sets a lamp (burning) in each of the trunks X and Z, and shuts the doors. He then puts on andkindles the fire in the stove, and manages it either in the Russian or German method. Perhaps the latter is preferable, as being liable to fewest accidents from mistake or neglect.

The lamps set in the lower ends of the upright trunks presently warm them, and produce a current of air upwards. This must be supplied by the horizontal trunk, which must take it from the case round the stove. Thus a current is begun in the direction we wish. By and by the air in the case acquires heat from the stove, and the current becomes extremely brisk. When the manager perceives this, he removes the lamps, shuts the valves, and opens the holes q, q, &c. beginning with the most remote, and proceeding slowly towards the stove from each extremity of the horizontal branches. The heated air now issues by these holes, glides along the ceiling below the galleries, and escapes, by rising up along the fronts of the galleries, and will be sensibly felt by those sitting there, coming on their faces with a gentle warmth. It will then rise (in great part) straight up, while some of it will glide backwards, to the comfort of those who sit behind.

The propriety of shutting the valves of the upright trunks is evident. If they were left open, no air would come out by the holes a, a, &c.; but, on the contrary, the air would go in at these holes to supply the current, and the stove be rendered useless. The air delivered by these holes will keep close to the ceiling, and will not, as we imagine, incommode those who sit below the galleries. But if it should be found to render these parts too warm, holes may be pierced through the ceiling, by which it will rise among the people above, and must be very comfortable. It will require the careful attention of some intelligent person to bring all this into a proper train at first, by finding the proper apertures of the different holes, so as to render the heat equable through the whole space. But this being once ascertainment the difficulty is over.

The air trunks must be very capacious, but may be contracted towards the extremities as their lateral discharges diminish; and the row of holes which admit the air to the case round the stove must be fully able to supply them.

It must be observed, that in this construction the ascensional force is but small. It is only the height of a short column of warm air from the ground to the galleries. At first indeed it is great, having the unlimited height of the perpendicular trunks at X and Z; but during the use of the stove it is reduced to nine or ten feet. It is necessary, therefore, that the stove be highly heated, perhaps considerably beyond the Russian practice, but yet inferior to the heat of the German iron stoves. But still we strongly recommend the brick or pottery stoves, on account of the wholesome sweetness of the air which they furnish: and we are certain that a stove of moderate dimensions, eight feet long, for instance, by eight feet high, will be sufficient for warming a church holding 1200 or 1500 people. If the stove could be placed lower, which in many situations is very practicable, its effect would be proportionally greater, because all depends on the rapidity of the current. When we are limited in height, we must extend the store.
composed of very different materials, has been lately erected in several of the churches in Edinburgh. This stove, which is formed entirely of cast iron, may be considered as a double stove, an outer case, and a furnace or inner stove. The fuel is burnt in the inner stove; and the smoke produced during the process of combustion, is carried off by a chimney, which passes through the top of the outer stove, and is conveyed to the outside of the building. The outer case includes not only the furnace or inner stove, but also a considerable space, occupied by the air of the atmosphere, which is freely admitted through a number of openings placed around it; and when any current of air is produced, it passes off from the space between the outer case and inner stove, and is conveyed by tubes through the body of the apartment. But we shall first describe the different parts of which the stove is composed, after which we shall be better able to understand its mode of operation.

Fig. 5. exhibits a perspective view of this stove. AB is the body, which is about three feet high, and of a circular form. BC is a square pedestal on which the stove is placed, and which contains the ash pit DD. The height of the pedestal is about a foot, and it is nearly insulated by resting on the spherical supports SS, also of cast iron. EEE are openings in front of the ash pit through which the air enters to support the combustion. These openings can be enlarged or diminished, or opened and shut at pleasure. FF is the door of the furnace through which the fuel is introduced. This door is attached to the inner furnace, and is double. It is one foot broad, and 11 inches high. CG is the chimney, which passes from the furnace within, through the outer case, and conveys the smoke out of the building. HHH are openings in the outer case, and are eight in number, through which the air enters, and being heated, is greatly rarified, and passes off through the funnel or pipe IIII. This pipe communicates only with the outer stove, and being shot at the end K, the air rushes out from the small tubes LL, inserted into the side of the pipe IIII, and thus mixes with the cold air of the church. The diameter of the outer case at the bottom is about two feet, and the diameter of the furnace within is about 16 inches.

Fig. 6. is a section of the stove. AB is the outer case, from which passes off the pipe or funnel CCC, by which the heated air is conveyed through the church. DD is the furnace in the inside, in which the fuel is burnt, and EEE is the chimney or funnel which conveys the smoke from the inner furnace out of the building. It passes through the outer stove AB at F.

Fig. 7. is a plan of this stove. AB is the pedestal on which it rests, and which contains the ash pit. CC is the outer case, and DD is the furnace within, in which are seen the transverse bars which support the fuel.

The length of the body of the church, in which two stoves of the form and dimensions now described are erected, is about 60 feet, and the breadth is about 45 feet. The tubes IIII are conveyed along the lower edge of the gallery, about half the length of the church. The fires are lighted up about four or five o’clock on the Sunday morning, during the earlier part of the cold season; but as the season advances, it is usual to light them up the night before. From this time till the congregation assemble for the afternoon service, the furnaces

5 A
are kept constantly supplied with fuel. By this management the air in the church is kept comfortably warm during the coldest season of the year.

These stoves, it appears to us, are susceptible of some improvement, both in their construction and in the places in which they are erected. With regard to the first circumstance, an external coating of plaster work, or of the same kind of materials as are used for coating the inside of chemical furnaces, would be of some use in preventing an unnecessary waste of heat, as well as the disagreeable smell which is sometimes complained of, and which is supposed to arise from the combustion of light bodies floating in the air and drawn by the current to the heated metal; and with regard to the last, viz. the places in which they are erected, it is perfectly obvious that they ought to be as completely insulated as possible, and particularly ought not to communicate with good conductors of heat. Some of the stoves erected in the churches of Edinburgh are faulty in this respect. But to the use of this stove there is a stronger objection. The air that is heated has circulated through the apartment, and has been respired and consequently vitiated. Hence some unpleasant effects have arisen from its use.

A stove erected by Mr. A. Kilpatrick, tinsmith in Edinburgh, is free from this serious objection. In his stoves the whole of the air heated is conveyed from the outside of the building. Stoves of this description answer well for heating large halls, staircases, and churches.

The following is the description of an improved stove by Mr. Field of Newman Street, London, in which, it is stated by the author, the various advantages of heating, boiling, steaming, evaporating, drying, ventilating, &c. are united, some of which shall detail in his own words.

"Fig. 8. represents a longitudinal section of the stove, showing the course of the air from its entrance into the flues of the stove at A, to its entrance into the upper chamber of the stove at B; and also the course of the smoke from the fire-place at C, till it escapes from the stove at D. E, E, are the doors or openings of the fire-place and ash-hole.

"Fig. 9. is a similar section at right angles with the above, exhibiting the course of the air through the chambers of the stove, from its entrance into the chamber N. at B to its entrance beneath the fire-place at F. This figure also shows sections of the flues, with the divisions through which the air and smoke pass separately, the smoke-flue in the centre, and the air-flues, on each side. G, G, are doors and openings through which the articles to be dried are introduced into the chambers.

"When the fire is lighted, and the doors of the chambers, ash-hole, and fire-place, closed, the air by which the fire is supplied enters at A, fig. 8. passes through the air-flues α, α, α, α, enters the upper chamber at B, traverses and descends through the chambers N., 2, 3; and arrives beneath the fire at F, fig. 9. Having supplied the fire with oxygen, it passes through the flue with the smoke, and escapes at D, heating in its protracted course the chambers and air-flues.

"As the cold air enters the stove at A, immediately above a plate forming the top of the fire-place, and pursues a similar route with the fire-flue, it enters the chambers very much heated and rarefied. Hence any moist substance placed in the chambers evaporates in consequence, not only of the heated flues circulating round them, but of a stream of warm rarefied air, which, while it continually raises evaporation, as continually bears away the exhaled moisture in its passage to the fire, thus imitating the gradual and efficacious plan of nature in drying by the sun and air. While these effects are taking place within the stove, part of the air which enters at A, fig. 8. and 9. passes through air-flues on the other side of the fire-flue, pursues a parallel course with the first, and gives out a current of warm air to the room at an aperture H. This effect may be obtained in a much higher degree, if the doors of the chambers and ash-hole are opened: should the hand or face be then brought near, they would be fanned with a stream of warm air, especially from the upper chamber.

"By means of this stove I have evaporated milk to dryness, without burning or discoloring it; and have dried cherries, plums, and other fruits, so as to imitate those which are received from abroad. I have repeatedly dried colours and the most delicate substances without the slightest injury, even though the operation proceeded quickly.

"The height of the stove is about five feet and a half; its diameter two feet and a half, and that of the flues four inches. The external part is constructed of brick, and the internal parts of thin Blyghton or fire-stone, except the top of the fire-place, which is a plate of cast iron. Were it to be wholly formed of iron, its effects would necessarily be more powerful.

"Fig. 10. represents an extension of the plan, in which stoves of this kind may be advantageously connected with one or more furnaces for chemical or other uses. The fire-place, brought out, either in front or on one side, by the present positions of its crown I, forms a reverberatory furnace, or will make a sand-bath by reversing it.

"The space occupied by the fire-place in fig. 8. may in this be converted into apartments for evaporating substances, or occasionally for cooling them by an opening at K to admit cold air, while the warm air of the stove is excluded by a register or door. The dotted lines show the manner in which a second furnace may be connected by an opening into the flue at L.

"In addition to the uses already pointed out, this stove would probably be found extremely serviceable in drying japanners goods, and consuming the noxious fumes and gas which arise from the oil and varnish used in this business.

"Since the stove is not limited to any certain dimensions, it might be adapted to the drying of malt and hops, perhaps of herbs, corn, and seeds generally. It might also be accommodated to the purpose of the sugar-bakers, connected with the great fires they employ for their boilers. It has been shown to be useful in the confectioners art, and probably it may be equally so in baking biscuits for the navy; nor less so in drying linen for the laundress, dyer, calico-printer, and bleacher. I have myself found it well accommodated for a chemical laboratory."
STOW, the name of a market-town in Gloucestershire in England, situated in W. Long. 1° 50'. N. Lat. 51° 54'. It is also the name of a fine seat of the marquis of Buckingham in Buckinghamshire. Here are the best gardens in England, adorned with busts, statues, obelisks, pavilions, and temples. It is two miles from the town of Buckingham.

STOW, John, the industrious historian, son of Thomas Stow merchant-taylor of St Michael's, Cornhill, in London, was born about the year 1525. Of the early part of his life we know very little, except that he was bred to his father's business, which in the year 1560 he relinquished, devoting himself entirely to the study of our ancient historians, chronicles, annals, charters, registers, and records. Of these he made a considerable collection, travelling for that purpose to different parts of the kingdom, and transcribing such manuscripts as he could not purchase. But this profession of an antiquary being attended with no present emolument, he was obliged for subsistence to return to his trade. It happened, however, that his talents and necessities were made known to Dr Parker archbishop of Canterbury; who being himself an antiquary, encouraged and enabled Mr Stow to prosecute his darling study. In those times of persecution, though Elizabeth was then upon the throne, honest John Stow did not escape danger. His collection of Popish records was deemed cause of suspicion. His younger brother Thomas preferred no less than 140 articles against him before the ecclesiastical commission; but the proof being insufficient, he was acquitted. In 1565 he first published his Summary of the Chronicles of England. About the year 1584 he began his Survey of London. In 1585 he was one of the two collectors for a great muster of Limestane ward; in the same year he petitioned the corporation of London to bestow on him the benefit of two freemen to enable him to publish his survey; and in 1589 he petitioned again for a pension. Whether he succeeded, is not known. He was principally concerned in the second edition of Holinshed's chronicle, published in 1587. He also corrected and twice augmented Chaucer's works, published in 1561 and in 1597. His survey of London was first published in 1598. To these laborious works he would have added his large Chronicle, or History of England; but he lived only to publish an abstract of it under the title of Flores Historiæ. The folio volume, which was printed after his death, with the title of Stow's Chronicle, was taken from his papers by Edmund Howes. Having thus spent his life and fortune in these laborious pursuits, he was at last obliged to solicit the charitable and well disposed for relief. For this purpose, King James I. granted him, in 1603, a brief, which was renewed in 1604, authorizing him to collect in churches the benefactions of his fellow-citizens. He died in April 1605, aged 80; and was buried in his parish church of St Andrew's Undershaft, where his widow erected a decent monument to his memory. John Stow was a most indefatigable antiquarian, a faithful historian, and an honest man.

STOWMARKET, a town of Suffolk, in England, situated in E. Long. 1° 6'. N. Lat. 52° 16'. It is a large handsome place, situated between the rivers Gipping and Orwell, and has the best cherries in England. It contained 2006 inhabitants in 1811.

STOWAGE, the general disposition of the several materials contained in a ship's hold, with regard to their figure, magnitude, or solidity.

In the stowage of different articles, as ballast, casks, cases, bales, and boxes, there are several general rules to be observed, according to the circumstances or qualities of those materials. The casks which contain any liquid are, according to the sea phrase, to be bung-up and bilge-free, i.e. closely wedged up in a horizontal position, and resting on their quarters: so that the bilges where they are thickest being entirely free all round, cannot rub against each other by the motion of the vessel. Dry goods, or such as may be damaged by the water, are to be carefully inclosed in casks, bales, cases, or wrappers; and wedged off from the bottom and sides of the ship, as well as from the bow, masts, and pumppwell. Due attention must likewise be had to their disposition with regard to each other, and to the trim and centre of gravity of the ship; so that the heaviest may always be nearest the keel, and the lightest gradually above them.

STRABISMUS, squinting. See Medicine Index. STRABO, a celebrated Greek geographer, philosopher, and historian, was born at Amasia, and was descended from a family settled at Gnossus in Crete. He was the disciple of Xenarchus, a Peripatetic philosopher, and at length attached himself to the Stoics. He contracted a strict friendship with Cornelius Gallus, governor of Egypt, and travelled into several countries to observe the situation of places, and the customs of nations. He flourished under Augustus, and died under Tiberius about the year 25, in a very advanced age. He composed several works, all of which are lost except his Geography in 17 books; which is justly esteemed very precious remains of antiquity. The two first books are employed in showing, that the study of geography is not only worthy of, but even necessary to, a philosopher; the third describes Spain; the fourth, Gaul and the Britannic isles; the fifth and sixth, Italy and the adjacent isles; the seventh, which is imperfect at the end, Germany, the countries of the Getæ and Illyriæ, Taurica Chersonesus, and Epirus; the eighth, ninth, and tenth, Greece with the neighbouring isles; the four following, Asia within Mount Taurus; the fifteenth and sixteenth, Asia without Taurus, India, Persia, Syria, Arabia; and the seventeenth, Egypt, Ethiopia, Carthage, and other places of Africa. Strabo's work was published with a Latin version by Xylander, and notes by Isaac Casaubon (or rather by Henry Scrimzer, from whom Casaubon chiefly stole them), at Paris, 1620, in folio. But the best edition is that of Amsterdam in 1707, in two volumes folio, by the learned Theodore Jansonius ab Almovenwegen, with the entire notes of Xylander, Casaubon, Meursius, Cluver, Holstenius, Salmasius, Bochart, Ez. Spanheim, Callarius, and others. To this edition is subjoined the Chrestomathia, or epitome of Strabo; which according to Mr Dodwell, who has written a very elaborate and learned dissertation about it, was made by some unknown person between the years of Christ 676 and 996. It has been found of some use,
not only in helping to correct the original, but in supplying in some measure the defect in the seventh book.

Dr. Dodwell's dissertation is prefixed to this edition.

STRADA, FAMIANUS, a very ingenuous and learned Jesuit, was born at Rome in the latter end of the 16th century, and taught rhetoric there, in a public manner, for fifteen years. He wrote several pieces upon the art of oratory, and published some orations with a view of illustrating by example what he had inculcated by precept. But his Prospusiones Academicae and his Historia de Belli Belgico are the works which raised his reputation, and have preserved his memory. His history of the war of Flanders was published at Rome; the first decad in 1640, the second in 1647; the whole extending from the death of Charles V. which happened in 1558, to the year 1592. It is written in good Latin, as all allow; but its merit in other respects has been variously determined. His Prospusiones Academicae shew great ingenuity, and a masterly skill in classical literature; that prolixion especially in which he introduces Lucan, Lucretius, Claudian, Ovid, Statius, and Virgil, each of them versifying according to his own strain. They have been often printed. We know not the year of Strada's birth or of his death.

STRAHAN, William, an eminent printer, was born at Edinburgh in the year 1715. His father, who had a small appointment in the customs, gave his son the education which every one of decent rank then received in a country where the avenues to learning were easy, and open to men of the most moderate circumstances. After having passed through the tuition of a grammar school, he was put apprentice to a printer; and when a very young man, removed to a wider sphere in that line of business, and went to follow his trade in London. Sober, diligent, and attentive, while his emoluments were for some time very scanty, he contrived to live rather within than beyond his income; and though he married early, and without such a provision as prudence might have looked for in the establishment of a family, he continued to thrive, and to better his circumstances. This he would often mention as an encouragement to early prudence; and used to say, that he never had a child born that Providence did not send some increase of income to provide for the increase of his household. With sufficient vigour of mind, he had that happy flow of animal spirits that is not easily discouraged by unpromising appearances.

His abilities in his profession, accompanied with perfect integrity and unabating diligence, enabled him, after the first difficulties were overcome, to advance with rapid success. And he was one of the most flourishing men of the trade, when, in the year 1740, he purchased a share of the patent for king's printer of Mr Eyre, with whom he maintained the most cordial intimacy during the rest of his life. Beside the emoluments arising from this appointment, as well as from a very extensive private business, he now drew largely from a field which required some degree of speculative sagacity to cultivate, as an account of the great literary property which he acquired by purchasing the copyright of the most celebrated authors of the time. In this his liberality kept pace with his prudence; and in some cases went perhaps further beyond it. Never had such rewards been given to the labours of literary men as now were received from him and his associates in those purchases of copy rights from authors.

Having now attained the first great object of business, wealth, Mr Strahan looked with a very allowable ambition on the stations of political rank and eminence. Politics had long occupied his active mind, which he had for many years pursued as his favourite amusement, by corresponding on that subject with some of the first characters of the age. Mr Strahan's queries to Dr Franklin in the year 1769, respecting the discontents of the Americans, published in the London Chronicle of 28th July 1778, show the just conception he entertained of the important consequences of that dispute, and his anxiety as a good subject to investigate, at that early period, the proper means by which their grievances might be removed, and a permanent harmony restored between the two countries. In the year 1775 he was elected a member of parliament for the borough of Malmsbury in Wiltshire, with a very illustrious colleague, the Hon. C. J. Fox; and in the succeeding parliament, for Wootton Bassett, in the same county. In this station, applying himself with that industry which was natural to him, he was a useful member, and attended the house with a scrupulous punctuality.

His talents for business acquired the consideration to which they were intitled, and were not unnoticed by the minister.

In his political connection he was constant to the friends to whom he had first been attached. He was a steady supporter of that party who were turned out of administration in spring 1784, and lost his seat in the house of commons by the dissolution of parliament with which that change was followed: a situation which he did not shew any desire to resume on the return of the new parliament; arising from a feeling of some decline in his health, which had rather suffered from the long sittings and late hours with which the political warfare in the preceding had been attended. Without any fixed disease, his strength visibly declined; and though his spirits survived his strength, yet the vigour and activity of his mind were considerably impaired. Both continued gradually to decline till his death, which happened on the 9th of July 1785 in the 71st year of his age.

Endued with much natural sagacity, and an attentive observation of life, he owed his rise to that station of opulence and respect which he attained, rather to his own talents and exertion, than to any accidental occurrence of favourable or fortunate circumstances. His mind was not uninform'd by letters; and from a habit of attention to style, he acquired a considerable portion of critical acuteness in the discernment of its beauties and defects. In one branch of writing he particularly excelled—the epistolary; in which he not only showed the precision and clearness of business, but possessed a neatness as well as a fluency of expression which few letter-writers have been known to surpass. Letter-writing was one of his favourite amusements; and among his correspondents were men of such eminence and talents as well repair'd his endeavours to entertain them. Among these, as before mentioned, was the justly celebrated Dr Franklin, originally a printer like Mr Strahan, whose friendship and correspondence, notwithstanding the difference of their sentiments in political matters, he
he continued to enjoy till his death. One of the latest letters which he received from his illustrious and venerable friend contained a humorous allegory of the state of politics in Britain, drawn from the profession of printing; of which, though the doctor had quitted the exercise, he had not forgotten the terms.

The judicious disposition which Mr Strahan made of his property, affords an evident proof of his good sense and propriety. After providing sufficiently for his widow and children, his principal study seems to have been to mitigate the affliction of those (and many there were) who would more immediately have felt his loss, by bequeathing them liberal annuities for their lives; and (recollecting that all of a profession are not equally provident) he left 1000L. to the Company of Stationers, the interest to be divided among infirm old printers.

As the virtuous connections of the life and the heart are always pleasing to trace,—of Mr Strahan it may briefly be said, that his capacity, diligence, and probity, raised him to the head of his profession. The good humour and obliging disposition which he owed to nature, he cultivated with care, and confirmed by habit. His sympathetic heart beat to the joy and sorrow of his friends. His advice was always ready to direct youth, and his pen open to relieve indigence. Living in times not the purest in the English annals, he escaped unsullied through the artifices of trade and the corruption of politics. In him a strong national sagacity, improved by an extensive knowledge of the world, served only to render respectable his unaffected simplicity of manners, and to make his Christian philanthropy more discerning and useful. The uninterrupted health and happiness which accompanied him for half a century in the capital, proves honesty to be the best policy, temperance the greatest luxury, and the essential duties of life its most agreeable amusement. In his elevated fortune, none of his former acquaintance ever accused him of neglect. He attained prosperity without envy, enjoyed wealth without pride, and dispensed bounty without ostentation.

STRAITS, in the military art, are strong plates of iron, six in number, fixed with large nails called straiknails, on the circumference of a cannon-wheel, over the joints of the fellows; both to strengthen the wheel, and to save the fellows from wearing on hard ways or streets.

STRAIN, a pain occasioned by the violent extension of some membraneous or tendinous part.

STRAIN, Stress, in Mechanics, are terms indiscriminately used to express the force which is excited in any part of a machine or structure of any kind tending to break it in that part. Thus every part of a rope is equally strained by the weight which it suspends. Every part of a pillar is equally strained by the load which it supports. A mill axle is equally twisted and strained in every part which lies between the part of the wheel actuated by the moving power and the part which is resisted by the work to be performed. Every part of a lever or joint is differently strained by a force acting on a distant part.

It is evident that we cannot make the structure fit for its purpose, unless the strength at every part be at least equal to the stress laid on, or the strain excited in that part. It is no less plain, that if we are ignorant of the principles which determine this strain, both in intensity and direction, in relation to the magnitude and the situation of its remote cause, the only security we have for success is to give to every part of the assemblage such solidity that we can leave no doubt of its sufficiency. But daily experience shows us that this vague security is in many cases uncertain, if we are thus ignorant. In all cases it is slovenly, unlike an artist, attended with useless expense, and in machines is attended with a loss of power which is wasted in changing the motions of a needless load of matter.

It must therefore greatly tend to the improvement of all professions occupied in the erection or employment of such structures, to have a distinct notion of the strains to which these parts are exposed. Frequently, may generally, these strains are not immediate, but arise from the action of forces on distant parts, by which the assemblage is strained, and there is a tendency to rupture in every part. This strain is induced on every part, and is there modified by fixed mechanical laws. These it is our business to learn; but our chief object in this investigation is to determine the strength of materials which it is necessary to oppose in every part to this strain; and how to oppose this strength in such a manner that it shall be exerted to the best advantage. The notions of strain and strength therefore hardly admit of separation; for it is even by means of the strength of the intermediate parts that the strain is propagated to, or excited in, the part under consideration. It is proper therefore to consider the whole together under the article Strength of Materials in mechanics.

STRAINING, is the clarification of a liquor, by passing it through a sieve or filter. The word is derived from the French, estraindre; which is formed from ex, "out of," and stringere, "to press."

STRAIT, a narrow channel or arm of the sea, shut up between lands on either side, and affording a passage out of one great sea into another.

There are three kinds of straits. 1. Such as join one ocean to another. Of this kind are the straits of Magellan and Le Maire. 2. Those which join the ocean to a gulf: the straits of Gibraltar and Babelmandel are of this kind, the Mediterranean and Red sea being only large gulfs. 3. Those which join one gulf to another; as the straits of Caffa, which join the Lake Mesopotamia to the Euxine or Black sea. The passage of straits is commonly dangerous, on account of the rapidity and opposite motion of currents. The most celebrated strait in the world is that of Gibraltar, which is about from 40 to 43 miles long, and from 15 to 94 broad, joining the Mediterranean sea with the Atlantic ocean. The straits of Magellan, discovered in 1520 by F. Magellan, were used some time as a passage out of the North into the South sea; but since the year 1616, that the strait of Le Maire has been discovered, the former has been deserted; both because of its length, which is full three hundred miles, and because the navigation thereof is very dangerous, from the waves of the North and South seas meeting in it and clashing. The strait at the entrance of the Baltic is called the Sound; that between England and France, Les pas de Calais, or the Channel. There are also the straits of Wezathe, of Jezo, of Anian, of Davis, and Hudson, &c.

STRAKES, or STRAIAK, in a ship, the uniform ranges of planks on the bottom and sides of a ship, or the continuation of planks joined to the ends of each other.
STRAKES, or Strakes, in mining, are frames of boards fixed on or in the ground, where they wash and dress the small ore in a little stream of water, hence called striked ore.

STRAUSUND, a strong and rich sea-port town of Germany, in Hither Pomerania, formerly an important trading-place. In 1678 it was forced to surrender to the elector of Brandenburg, after 1800 houses had been burnt to ashes in one night's time. The Swedes however recovered it, but lost it again in 1715. In 1720 it was rendered back to Sweden in a very poor condition.

In the year 1814, Stralsund, with the whole of Swedish Pomerania, was ceded to Prussia. It is almost surrounded by the sea and the lake Fransen, and has a harbour separated from the isle of Rugen by a narrow strait. It is 15 miles north-west of Grippenwald and 40 north-east of Gustrow. E. Long. 13. 28. N. Lat. 54. 17.

STRAMONIUM, a species of plant. See Datura.

BOTANY Index.

STRAND (Saxon), any shore or bank of a sea or great river. Hence the street in the west suburbs of London, which lay next the shore or bank of the Thames, was called the Strand. An immunity from custom, and all impositions upon goods or vessels by land or water, was usually expressed by *strand* or *stream*.

STRANGED (from the Saxon *stranded*), is when a ship is by tempest, or by ill steerage, run on ground, and so perishes. Where a vessel is stranded, justices of the peace, &c. shall command constables near the sea-coasts to call assistance for the preservation of the ship; and officers of men of war are to be aiding and assisting thereto.

STRANGE, Sir Robert, an eminent engraver, who carried the art to great perfection in this country, and was distinguished not only as an artist, but highly respected and beloved on account of his private virtues and domestic habits. Modest as he was ingenious, he used to say that the works of an artist should serve for his life and monument. His works no doubt will perpetuate his name whilst any taste for the fine arts remains.

Sir Robert Strange was born in the island of Pomona in Orkney, July the 14th 1721; and died at London July the 5th 1792. He was lineally descended from David Strange or Strang, a younger son of the family of the Stranges or Strauns of Balcasey, in the county of Fife, who settled in Orkney at the time of the Reformation. But as there were no males remaining of the elder branch of the Stranges of Balcasey, Sir Robert became the male representative of it, and was found by a legal investigation to have a right to the armorial bearings and every other mark of honour belonging to that ancient family.

He received his classical education at Kirkwall in Orkney, under the care of a learned, worthy, and much respected gentleman, Mr Murdoch Mackenzie, who has rendered infinite service to his country by the accurate surveys and charts he has given of the islands of Orkney, and of the British and Irish coasts.

Originally intended for the law, Mr Strange soon became tired of that profession, and perceived that his genius decisively led him to the arts of drawing and engraving. For this purpose he was introduced to the late Mr Richard Cooper at Edinburgh, the only person there who had then any taste in that line of the fine arts. He was bound with him as an apprentice for six years; during which time he made such progress in his new profession, that his friends entertained the highest expectation of his success; nor were they disappointed.

In the year 1747 he married Isabella, only daughter of William Lumsden, son of Bishop Lumsden; and soon after his marriage he went to France, where with the most ardent application he prosecuted his studies, chiefly at Paris, under the direction of the celebrated Le Bas, who engraved many excellent prints from the Dutch painters. It was from Le Bas he had the first hint of the use of the instrument commonly called the dry needle; but which he afterwards greatly improved by his own genius, and which has added such superior beauties to his engravings.

In the year 1751 Mr Strange removed with his family from Edinburgh and settled at London, where he engraved several fine historical prints, which justly acquired to him great reputation. At this period historical engraving had made little progress in Britain, and he may be properly considered as its father.

The admiration he always had for the works of the great Italian painters made him long desire to visit Italy, the seat of the fine arts; and the farther he advanced in life, he became the more persuaded that a journey to that country was essential to an artist who had the laudable ambition to excel in his profession. He therefore undertook this journey in the year 1760. In Italy he made many admirable drawings, several of which he afterwards engraved. These drawings are now in the possession of Lord Dundas.

Everywhere in Italy singular marks of attention were bestowed on Mr Strange; not only by great personages, but by the principal academies of the fine arts in that country. He was made a member of the academies of Rome, Florence, and Bologna, and professor in the royal academy at Parma.

To show the estimation in which his talents were held at Rome, we cannot but record the following anecdote. The ceiling of the room of the Vatican library, in which the collection of engravings is kept, is elegantly painted by Signor Rotafanelli. It represents the progress of engraving; and the portraits of the most eminent artists in that line are there introduced, among which is that of our artist. Under his arm he holds a portfolio, on which his name is inscribed. He is the only British artist on whom this honour has been conferred.

In France, where he resided many years at different periods, his talents likewise received every mark of attention that could be bestowed on a foreigner. He was made a member of the royal academy of painting at Paris.

His majesty King George III, ever attentive to the progress of the fine arts in Britain, and sensible of the advantages of which engraving particularly has been to

STRANGER, in Law, denotes a person who is not privy or party to an act. Thus a stranger to a judgment is he to whom a judgment does not belong; in which sense the word stands directly opposed to party or privy.

STRANGLES, in Farriery. See that article, No. 481.

STRANGURY, a suppression of urine. See Medicine Index.

STRAP, among surgeons, a sort of band used to stretch out limbs in the setting of broken or disjoined bones.

STRAP, in a ship, the rope which is spliced about any block, and made with an eye to fasten it anywhere on occasion.

STRAPS, in the manege. The straps of a saddle are small leather straps, nailed to the bows of the saddle, with which we make the girths fast to the saddle.

STRAPADO, or Strappado, a kind of military punishment, wherein the criminal's hands being tied behind him, he is hoisted up with a rope to the top of a long piece of wood, and let fall again almost to the ground; so that, by the weight of his body in the shock, his arms are dislocated. Sometimes he is to undergo three strapados or more.

STRASBURG, an ancient, large, handsome, and strong city of France, which contained 50,000 inhabitants in 1817. It contains about 200 streets, part of which are very narrow, and most of the houses are built after the ancient taste. However, there are a great number of handsome buildings, such as the hotel of the marshal of France, who is commander of the city; the hotel of the cardinal of Rouen, the bishop's palace, the Jesuits college, the royal hospital, the hotel of Hesse-Darmstadt, the arsenal, the town-house, and the cathedral. It has a wooden bridge over the Rhine, which is thought to be one of the finest in Europe, as likewise the cathedral church, whose tower is the handsomest in Germany, and the clock is greatly admired by all travelers. Some look upon it as one of the wonders of the world, and the steeple is allowed to be the highest in Europe. The clock not only shows the hours of the day, but the motion of the sun, moon, and stars. Among other things there is an angel, which turns an hour-
in England; though at present the living animals are not to be found except in the East and West Indies.

A Catalogue of Extraneous Fossils, showing where they were dug up; also their native Climates. Mostly selected from the curious Cabinet of Mr. Neilson, in King-street, Red-Lion Square.

Their Names, and Places where found. Native Climates.

Chambered Nautilus. Shelly island; Richmond in Surrey; Chinese Ocean, and other Parts of that great sea.

Teeth of Sharks. Shelly Island; Oxfordshire, Middlesex, Surrey, East and West Indies.

Sea-Tortoise, several kinds; the Hauksbill, Loggerhead, and West Indies.

Green species. Shelly Island; Mangrove Tree Oysters. West Indies.

Shelly Island; -

Coxcomb Tree Oysters. Oxfordshire, Gloucestershire, Dorsetshire, and Hampshire, -

East and West Indies.

Vertebré and Palates of the Ores. Shelly Island, and many other parts of England, -

Crocodile. Germany, Derbyshire, Nottinghamshire, Oxfordshire, and Yorkshire, -

Alligator's Teeth. Oxfordshire, Shelly Island, -

The Banded Buccinum. Oxfordshire, and the Alps, -

The Dipping-Snail, and Starfish. Shelly Island, -

Tail Buccinum. Shelly Island, -

Hordel Cliff, Hampshire, -

Nothing has more perplexed those who undertake to form theories of the earth than these appearances. Some have at once boldly asserted, from these and other phenomena, that the world is eternal. Others have had recourse to the universal deluge. Some, among whom is the Count de Buffon, endeavour to prove that the ocean and dry land are perpetually changing places; that for many ages the highest mountains have been covered with water, in consequence of which the marine animals just mentioned were generated in such vast quantities; that the waters will again cover these mountains, the habitable part of the earth become sea, and the sea became dry land as before, &c. Others have imagined that they might be occasioned by volcanoes, earthquakes, &c. which confused the different strata, and often intermix the productions of the sea with those of the dry land.

But for a view of the different strata so far as they are known, as well as for a view of some of the theories which have been proposed to account for the formation and changes of the earth, see Geology.

Mr. Forster has given an account of some of the strata of the South-sea islands, the substance of which may be seen in the following table.

South Georgia.

1. No soil, except in a few crevices of the rocks.
2. Ponderous slate, with some irony particles, in horizontal strata, perpendicularly intersected with veins of quartz.

Southern Isle of New Zealand.
1. Fine light black mould, in some places nine inches deep, but generally not so much.
2. An argillaceous substance, nearly related to the class of Talcums, turned into earth by the action of the air.
3. The same substance farther indurated, in oblique strata, generally dipping to the south.

Easter Island.
1. Reddish-brown dusty mould, looking as if it had been burnt.
2. Burnt rocks, resembling slags or dress and other volcanic matters.

Marquesas.
1. Clay mixed with mould.
2. An earthy argillaceous substance mixed with tareus and puzzolana.

Otahaui.

The shores are coral rock, extending from the reef encircling these islands to the very high water-mark. There begins the sand, formed in some places from small shells and rubbed pieces of coral; but in others the shores are covered with blackish sand, consisting of the former sort mixed with black, sometimes glittering, particles of mica, and here and there some particles of the refractory iron ores called in England Skim, the ferrum miscacellum of Linneus, and Kali, the motlybdenum spumasteg of the same author. The plains from the shores to the foot of the hills are covered with a very fine thick stratum of black mould, mixed with the above-mentioned sand, which the natives manure with shells. The first and lower range of hills are formed of a red ochreous earth, sometimes so intensely red, that the natives use it to paint their canoes and cloth. The higher hills consist of a hard, compact, and stiff clayey substance, hardening into stone when out of the reach of the sun and air. At the top of the valleys, along the banks of the rivers, are large masses of coarse granite stones of various mixtures; in one place are pillars of a gray, solid basaltes; and, in several others, fragments of black basaltes.

Friendly Islands and New Hebrides.
The same with the above.

Mallicollo.

Yellowish clay mixed with common sand.

Tanna, a Volcanic Island.
The chief strata here are clay mixed with luminous earth, interspersed with lumps of pure chalk. The strata of the clay are about six inches, deviating very little from the horizontal line.

New Caledonia and the adjacent Isles.
The shores consist of shell-sand, and particles of quartz; the soil in the plains a black mould mixed with this sand. The sides of the hills composed of a yellow ochreous clay, richly spangled with small particles of cat-silver, or a whitish kind of daze, the mica argentea of Linneus. The higher parts of the hills consist of a stone called by the German miners geustelstein, composed of quartz and great lumps of the above cat-silver. The latter is sometimes of an intensly red or orange colour, by means of an iron ochre.

"From the above account, says Mr Forster, it appears, I think, evidently, that all the high tropical isles of the South sea have been subject to the action of volcanoes. Pyritical and sulphureous substances, together with a few iron-stones, and some vestiges of copper, are no doubt found in several of them; but the mountains of New Caledonia are the most likely to contain the richest metallic veins; and the same opinion, I suspect, may be formed of the mountains in New Zealand."

In the city of Modena in Italy, and for some miles round that place, there is the most singular arrangement of strata perhaps in the whole world. From the surface of the ground to the depth of 14 feet, they meet with nothing but the ruins of an ancient city. Being come to that depth, they find paved streets, artificers' shops, floors of houses, and several pieces of inlaid work. After these ruins they find a very solid earth, which one would think had never been removed; but a little lower they find it black and marshy, and full of briars. Signior Ramazzini in one place found a heap of wheat entire at the depth of 24 feet; in another, he found filbert-trees with their nuts. At the depth of about 28 feet, they find a bed of chalk, about 11 feet deep, which cuts very easily; after this a bed of marshy earth of about two feet, mixed with rushes, leaves, and branches. After this bed comes another of chalk, nearly of the same thickness; and which ends at the depth of 42 feet. This is followed by another bed of marshy earth like the former; after which comes a new chalk-bed, but thinner, which also has a marshy bed underneath it. This ends at the depth of 63 feet; after which they find sand mingled with small gravel, and several marine shells. This stratum is usually about five feet deep, and underneath it is a vast reservoir of water. It is on account of this water that the soil is so frequently dug, and the strata so well known in this part of the world. After coming to the sandy bottom above mentioned, the workmen pierce the ground with a terebra or augre, when the water immediately springs up with great force, and fills the well to the brim. The flow is perpetual, and neither increases by rain, nor decreases by drought. Sometimes the augre meets with great trees, which give the workmen much trouble; they also sometimes see at the bottom of these wells great bones, coals, flints, and pieces of iron.

It has been ascertained by some, that the specific gravity of the strata constantly increased with the depth from the surface. But Dr Leigh, in his Natural History of Lancashire, speaking of the coal-pits, denies the strata to lie according to the laws of gravitation; observing, that the strata there are first a bed of marle, then free-stone, next iron-stone, then coal, or channel-mire, then some other strata, then coal again, &c.

This determined Mr Durham to make a nicer inquiry into the matter: accordingly, in 1712, he caused divers places to be bored, laying the several strata by themselves;
STRENGTH OF MATERIALS,

In Mechanics, is a subject of so much importance, that it cannot be otherwise. We have no means of instruction, except two very short and abstracted treatises of the late Mr. Emerson on the strength of materials. We do not recollect a performance in our language from which our artists can get information. Treatises written expressly on different branches of mechanical arts are totally silent on this, which is the basis and only principle of their performances. Who would imagine that Price’s British Carpenter, the work of the first reputation in this country, and of which the sole aim is to teach the carpenter to erect solid and durable structures, does not contain one proposition or one reason by which one form of a thing can be shown to be stronger or weaker than another? We doubt very much if one carpenter in an hundred can give a reason to convince his own mind that a joint is stronger when laid on its edge than when laid on its broad side. We speak in this strong manner in hopes of exciting some man of science to publish a system of instruction on this subject. The limits of our Work will not admit of a detail; but we think it necessary to point out the leading principles, and to give the traces of that systematic connection by which all the knowledge already possessed of this subject may be regulated by the strains to which they are exposed, and where repeated failures have been the only lessons.

In a nation so eminent as this for invention and ingenuity in all species of manufactures, and in particular so distinguished for its improvements in machinery of every kind, it is somewhat singular that no writer has treated it in the detail which its importance and difficulty demands. The man of science who visits our great manufactories is delighted with the ingenuity which he observes in every part, the innumerable inventions which come even from individual artisans, and the determined purpose of improvement and refinement which he sees in every workshop. Every cotton mill appears an academy of mechanical science; and mechanical invention is spreading from these fountains over the whole kingdom. But the philosopher is mortified to see this ardent spirit so cramped by ignorance of principle, and many of these original and brilliant thoughts obscured and clogged with needless and even hurtful additions, and a complication of machinery which checks improvement even by its appearance of ingenuity. There is nothing in which this want of scientific education, this ignorance of principle, is so frequently observed as in the injudicious proportion of the parts of machines and other mechanical structures; proportions and forms of parts in which the strength and position are nowise regulated by the strains to which they are exposed, and where repeated failures have been the only lessons.

In the British Carpenter, the work of the first reputation in this country, and of which the sole aim is to teach the carpenter to erect solid and durable structures, does not contain one proposition or one reason by which one form of a thing can be shown to be stronger or weaker than another? We doubt very much if one carpenter in an hundred can give a reason to convince his own mind that a joint is stronger when laid on its edge than when laid on its broad side. We speak in this strong manner in hopes of exciting some man of science to publish a system of instruction on this subject. The limits of our Work will not admit of a detail; but we think it necessary to point out the leading principles, and to give the traces of that systematic connection by which all the knowledge already possessed of this subject may be brought...
Strength of Materials.

The strength of materials arises immediately or ultimately from the cohesion of the parts of bodies. Our examination of this property of tangible matter has already been very partial and imperfect, and by no means enables us to apply mathematical calculations with precision and success. The various modifications of cohesion, in its different appearances of perfect softness, plasticity, ductility, elasticity, hardness, have a mighty influence on the strength of bodies, but are hardly susceptible of measurement. Their texture also, whether uniform like glass and ductile metals, crystallized or granulated like other metals and freestone, or fibrous like timber, is a circumstance of no little importance; yet even here, although we derive some advantage from remarking to which of these forms of aggregation a substance belongs, the aid is but small. All we can do in this want of general principles is to make experiments on every class of bodies. Accordingly philosophers have endeavoured to instruct the public in this particular. The Royal Society of London at its very first institution made many experiments at their meetings, as may be seen in the first registers of the Society. Several individuals have added their experiments. The most numerous collection in detail is by Muschenbroek, professor of natural philosophy at Leyden. Part of it was published by himself in his Essais de Physique, in two vols. 4to; but the full collection is to be found in his System of Natural Philosophy, published after his death by Lulofs, in three vols. 4to. This was translated from the Low Dutch into French by Sigaud de la Fond, and published at Paris in 1760, and is a prodigious collection of physical knowledge of all kinds, and may almost suffice for a library of natural philosophy. But this collection of experiments on the cohesion of bodies is not of that value which one expects. We presume that they were carefully made and faithfully narrated; but they were made on such small specimens, that the unavoidable natural inequalities of growth or texture produced irregularities in the results which bore too great a proportion to the whole quantities observed. We may make the same remark on the experiments of Couplet, Piot, De la Hire, Du Hamel, and others of the French academy. In short, if we except the experiments of Buffon on the strength of timber, made at the public expense on a large scale, there is nothing to be met with from which we can obtain absolute measures which may be employed with confidence; and there is nothing in the English language except a simple list by Emerson, which is merely a set of affirmations, without any narration of circumstances, to enable us to judge of the validity of his conclusions: but the character of Mr Emerson, as a man of knowledge and of integrity, gives even to these assertions a considerable value.

But to make use of any experiments, there must be employed some general principle by which we can generalize their results. They will otherwise be only narrations of detached facts. We must have some notion of the intermixture, by the intervention of which an external force applied to one part of a lever, joint, or pillar, occasions a strain on a distant part. This can be nothing but the cohesion between the parts. It is this connecting force which is brought into action, or, as we more shortly express it, excited. This action is modified in every part by the laws of mechanics. It is this action which is what we call the strength of that part, and its effect is the strain on the adjoining parts; and thus it is the same force, differently viewed, that constitutes both the strain and the strength. When we consider it in the light of a resistance to fracture, we call it strength.

We call every thing a force which we observe to be ever accompanied by a change of motion; or, more strictly speaking, we infer the presence and agency of a force wherever we observe the state of things in respect of motion different from what we know to be the result of the action of all the forces which we know to act on the body. Thus when we observe a rope prevent a body from falling, we infer a moving force inherent in the rope with as much confidence as when we observe it drag the body along the ground. The immediate action of this force is undoubtedly exerted between the immediately adjoining parts of the rope. The immediate effect is the keeping the particles of the rope together. They ought to separate by any external force drawing the ends of the rope contrarywise; and we ascribe their not doing so to a mechanical force really opposing this external force. When desired to give it a common name, we name it from what we conceive to be its effect, and therefore its characteristic, and we call it cohesion. This is merely a name for the fact; but it is not the same thing in all our denominations. We know nothing of the causes but in the effects; and our name for the cause is in fact the name of the effect, which is cohesion. We mean nothing else by gravitation or magnetism. What do we mean when we say that Newton understood thoroughly the nature of gravitation, of the force of gravitation; or that Franklin understood the nature of the electrical force? Nothing but this: Newton considered with patient sagacity the general facts of gravitation, and has described and classed them with the utmost precision. In like manner, we shall understand the nature of cohesion when we have discovered with equal generality the laws of cohesion, or general facts which are observed in the appearances, and when we have described and classed them with equal accuracy.

Let us therefore attend to the more simple and obvious phenomena of cohesion, and mark with care every circumstance of resemblance by which they may be classed. Let us receive these as the laws of cohesion, characteristic of its supposed cause, the force of cohesion. We cannot pretend to enter on this vast research. The modifications are innumerable: and it would require the penetration of more than Newton to detect the circumstance of similarity amidst millions of discriminating circumstances. Yet this is the only way of discovering which are the primary facts characteristic of the force, and which are the modifications. The study is immense, but it is by no means desperate; and we entertain great hopes that it will ere long be successfully prosecuted: but, in our particular predicament, we must content ourselves with selecting such general laws as seem to give the most immediate information of the circumstances that must be attended to by the mechanic in his constructions, that he may unite strength with simplicity, economy, and energy.

1. Then, it is a matter of fact that all bodies are in a certain
STRENGTH OF MATERIALS.

Strength of materials or bulk is changed by certain moderate compressions or distractions; it requires the continuance of the changing force to continue the body in this new state; and when the force is removed, the body recovers its original form.

We limit the assertion to certain moderate changes: For instance, take a lead wire of one-fifteenth of an inch in diameter and ten feet long; fix one end firmly to the ceiling, and let the wire hang perpendicular; affix to the lower end an index like the hand of a watch; on some stand immediately below let there be a circle divided into degrees, with its centre corresponding to the lower point of the wire: now turn this index twice round, and thus twist the wire. When the index is let go, it will turn backwards again, by the wire's untwisting itself, and make almost four revolutions before it stops; after which it twists and untwists many times, the index going backwards and forwards round the circle, diminishing however its arch of twist each time, till at last it settles precisely in its original position. This may be repeated for ever. Now, in this motion, every part of the wire partakes equally of the twist. The particles are stretched, require force to keep them in their state of extension, and recover completely their relative positions. These are all the characters of what the mechanician calls perfect elasticity. This is a quality quite familiar in many cases; as in glass, tempered steel, &c. but was thought incompetent to lead, which is generally considered as having little or no elasticity. But we make the assertion in the most general terms, with the limitation to moderate derangement of form. We have made the same experiment on a thread of pipe-clay, made by forcing soft clay through the small hole of a syringe by means of a screw; and we found it more elastic than the lead wire: for a thread of one-twentieth of an inch diameter and seven feet long allowed the index to make two turns, and yet completely recovered its first position.

2. But if we turn the index of the lead wire four times round, and let it go again, it untwists again in the same manner, but it makes little more than four turns back again; and after many oscillations it finally stops in a position almost two revolutions removed from its original position. It has now acquired a new arrangement of parts, and this new arrangement is permanent like the former; and, what is of particular moment, it is perfectly elastic. This change is familiarly known by the denomination of a set. The wire is said to have taken a set. When we attend minutely to the procedure of nature in this phenomenon, we find that the particles have as it were slid on each other, still cohering, and have taken a new position, in which their connecting forces are in equilibrium; and in this change of relative situation, it appears that the connecting forces which maintained the particles in their first situation were not in equilibrium in some position intermediate between that of the first and that of the last form. The force required for changing this first form augmented with the change, but only to a certain degree; and during this process the connecting forces always tended to the recovery of this first form. But after the change of mutual position has passed a certain magnitude, the union has been partly destroyed, and the particles have been brought into new situations; such, that the forces which now connect each with its neighbour tend, not to the recovery of the first arrangement, but to push them farther from it, into a new situation, to which they now verge, and require force to prevent them from acquiring. The wire is now in fact again perfectly elastic; that is, the forces which now connect the particles with their neighbours augment to a certain degree as the derangement from this new position augments. This is not reasoning from any theory. It is narrating facts, on which a theory is to be founded. What we have been just now saying is evidently a description of that sensible form of tangible matter which we call ductility. It has every gradation of variety, from the softness of butter to the firmness of gold. All these bodies have some elasticity; but we say they are not perfectly elastic, because they do not completely recover their original form when it has been greatly damaged. The whole gradation may be most distinctly observed in a piece of glass or hard sealing wax. In the ordinary form glass is perhaps the most completely elastic body that we know, and may be bent till just ready to snap, and yet completely recovers its first form, and takes no set whatever; but when heated to such a degree as just to be visible in the dark, it loses its brittleness, and becomes so tough that it cannot be broken by any blow; but it is no longer elastic, takes some set, and keeps it. When more heated, it becomes as plastic as clay; but in this state is remarkably distinguished from clay by a quality which we may call Viscidity, which is something like plasticity, of which clay and other bodies purely plastic exhibit no appearance. This is the joint operation of strong adhesion and softness. When a rod of perfectly soft glass is suddenly stretched a little, it does not at once take the shape which it acquires after some little time. It is owing to this, that in taking the impression of a seal, if we take off the seal while the wax is yet very hot, the sharpness of the impression is destroyed immediately. Each part drawing its neighbour, and each part yielding, the prominent parts are pulled down and blunted, and the sharp hollows are pulled upwards and also blunted. The seal must be kept on till all has become not only stiff but hard.

This Viscidity is to be observed in all plastic bodies which are homogeneous. It is not observed in clay, because it is not homogeneous, but consists of hard particles of argillaceous earth sticking together by their attraction for water. Something like it might be made of finely powdered glass and a clammy fluid such as turpentine. Viscidity has all degrees of softness till it degenerates toropy fluidity like that of olive oil. Perhaps something of it may be found even in the most perfect fluid that we are acquainted with, as we observed in the experiments for ascertaining specific gravity.

There is in a late volume of the Philosophical Transactions a narrative of experiments, by which it appears that the thread of the spider is an exception to our first general law, and that it is perfectly ductile. It is there asserted, that a long thread of gossamer, furnished with an index, takes any position whatever; and that though the index be turned round any number of times (even many hundreds), it has no tendency to recover its first form. The thread takes completely any set whatever. We have not had an opportunity of repeating this experiment, but we have distinctly observed a phenomenon totally inconsistent with it. If a fibre of gossamer about an inch long be held by the end horizontally, it bends downward
STRENGTH OF MATERIALS.

3. That whatever is the situation of the particles of a body with respect to each other, when in a quiescent state, they are kept in these situations by the balance of opposite forces. This cannot be refused, nor can we form to ourselves any other notion of the state of the particles of a body. Whether we suppose the ultimate particles to be of certain magnitudes and shapes, touching each other in single points of cohesion; or whether we (as Boscofich) consider them as at a distance from each other, and acting on each other by attractions and repulsions—we must acknowledge, in the first place, that the centres of the particles (by whose mutual distances we must estimate the distance of the particles) may and do vary their distances from each other. What else can we say when we observe a body increase in length, in breadth, and thickness, by heating it, or when we see it diminish in all these dimensions by an external compression? A particle, therefore, situated in the midst of many others, and remaining in that situation, must be conceived as maintained in it by the mutual balancing of all the forces which connect it with its neighbours. It is like a ball kept in its place by the opposite action of two springs. This illustration merits a more particular application. Suppose a number of elastic balls ranged on the table in the angles of equilateral triangles, and that each ball is connected with the six which lie around it by means of an elastic wire curled like a cork-screw; suppose such another stratum of balls above this, and parallel to it, and so placed that each ball of the upper stratum is perpendicularly over the centre of the equilateral triangle below, and let these be connected with the balls of the under stratum by similar spiral wires. Let there be a third and a fourth, and any number of such strata, all connected in the same manner. It is plain that this may extend to any size and fill any space. Now let the assemblage of balls be firmly contemplated by the imagination, and be supposed to shrink continually in all its dimensions, till the balls, and their distances from each other, and the connecting wires, all vanish from the sight as discrete individual objects. All this is very conceivable. It will now appear like a solid body, having length, breadth, and thickness; it may be compressed, and will again resume its dimensions; it may be stretched, and will again shrink; it will move away when struck; in short, it will not differ in its sensible appearance from a solid elastic body. Now when this body is in a state of compression, for instance, it is evident that any one of the balls is at rest, in consequence of the mutual balancing of the actions of all the spiral wires which connect it with those around it. It will greatly conduce to the full understanding of all that follows to recus to this illustration. The analogy or resemblance between the effects of this constitution of things and the effects of the corpuscular forces is very great; and wherever it obtains, we may safely draw conclusions from what we know would be the condition of a body of common tangible matter. We shall just give one instructive example, and then have done with this particular hypothetical body. We can suppose it of a long shape, resting on one point; we can suppose two weights A, B, suspended at the extremities, and the whole in equilibrium. We commonly express this state of things by saying that A and B are in equilibrium. This is very inaccurate. A is in fact in equilibrium with the united action of all the springs which connect the ball to which it is applied with.
STRENGTH OF MATERIALS.

Strength of the adjoining balls. These springs are brought into action, and each is in equilibrio with the joint action of all the rest. Thus through the whole extent of the hypothetical body, the springs are brought into action in a way and in a degree which mathematics can fully investigate. We need not do this; it is enough for our purpose that our imagination readily discovers that some springs are stretched, others are compressed, and that a pressure is excited on the middle point of support, and the support exerts a reaction which precisely balances it; and the other weight is, in like manner, in immediate equilibrio with the equivalent of the actions of all the springs which connect the last ball with its neighbours. Now take the analogous or resembling case, an oblong piece of solid matter, resting on a fulcrum, and loaded with two weights in equilibrio. For the actions of the connecting springs substitute the corporal forces, and the result will resemble that of the hypothesis.

Now as there is something that is at least analogous to a change of distance of the particles, and a concomitant change of the intensity of the connecting forces, we may express this in the same way that we are accustomed to do in similar cases. Let A and B (fig. 1) represent the centres of two particles of a coherent elastic body in their quiescent inactive state, and let us consider only the mechanical condition of B. The body may be stretched. In this case the distance AB of the particles may become AC. In this state there is something which makes it necessary to employ a force to keep the particles at this distance. C has a tendency towards A, or we may say that A attracts C. We may represent the magnitude of this tendency of C towards A, or this attraction of A, by a line Ċ perpendicular to AC. Again, the body may be compressed, and the distance AB may become AD. Something obliges us to employ force to continue this compression; and D tends from A, or A appears to repel D. The intensity of this tendency or repulsion may be represented by another perpendicular D to Ċ; and, to represent the different directions of these tendencies, or the different nature of these actions, we may set D on the opposite side of AB. It is in this manner that the Abbé Boscovich has represented the actions of corporal forces in his celebrated Theory of Natural Philosophy. Newton had said, that, as the great movements of the solar system were regulated by forces operating at a distance, and varying with the distance, so he strongly suspected (valde suspicor) that all the phenomena of cohesion, with all its modifications in the different sensible forms of aggregation, and in the phenomena of chemistry and physiology, resulted from the similar agency of forces varying with the distance of the particles. The learned Jesuit pursued this thought; and has shown, that if we suppose an ultimate atom of matter endowed with powers of attraction and repulsion, varying, both in kind and degree, with the distance, and if this force be the same in every atom, it may be regulated by such a relation to the distance from the neighbouring atom, that a collection of such may have all the sensible appearance of bodies in their different forms of solids, liquids, and vapours, elastic or unelastic, and endowed with all the properties which we perceive, by whose immediate operation the phenomena of motion by impulse, and all the phenomena of chemistry, and of animal and vegetable economy, may be produced. He shows, that notwithstanding a perfect sameness, and even a great simplicity in this atomic constitution, there will result from this union all that unaccountable variety of form and property which diversify and embellish the face of nature. We shall take the better opportunity of giving such an account of this celebrated work as it illustrates. We mention it presently, by the bye, as far as a general notion of it will be of some service on the present occasion. For this purpose, we just observe that Boscovich conceives a particle of any individual species of matter to consist of an unknown number of particles of simpler constitution; each of which particles, in their turn, is compounded of particles still more simply constituted, and so on through an unknown number of orders, till we arrive at the simplest possible constitution of a particle of tangible matter, susceptible of length, breadth, and thickness, and necessarily consisting of four atoms of matter. And he shows that the more complex we suppose the constitution of a particle, the more must the sensible qualities of the aggregate resemble the observed qualities of tangible bodies. In particular, he shows how a particle may be so constituted, that although it act on one other particle of the same kind through a considerable interval, the interposition of a third particle of the same kind may render it totally, or almost totally, inactive; and therefore an assemblage of such particles would form such a fluid as air. All these curious inferences are made with uncontrollable evidence; and the greatest encouragement is thus given to the mathematical philosopher to hope, that by cautious and patient proceeding in this way, we may gradually approach to a knowledge of the laws of cohesion, that will not shun a comparison even with the Principia of Newton. No step can be made in this investigation, but by observing with care, and generalizing with judgment, the phenomena, which are abundantly numerous, and much more at our command than those of the great and sensible motions of bodies. Following this plan, we observe,

4. It is matter of fact, that every body has some degree of compressibility and dilatability; and when the changes of dimension are so moderate that the body completely recovers its original dimensions on the cessation of the changing force, the extensions or compressions are sensibly proportional to the extending or compressing forces; and therefore the connecting forces are proportional to the distances of the particles from their quiescent, neutral, or inactive positions. This seems to have been first viewed as a law of nature by the penetrating eye of Dr Robert Hooke, one of the most eminent philosophers of the last century. He published a cipher, which he said contained the theory of springiness and of the motions of bodies by the action of springs. It was this, cœtis omnibus ius—When explained in his dissertation, published some years after, it was ut tenesic vic us. This is precisely the proposition just now asserted as a general fact, a law of nature. This dissertation is full of curious observations of facts in support of his assertion. In his application to the motion of bodies he gives his noble discovery of the balance spring of a watch, which is founded on this law. The spring, as it is more and more coiled up, or unwound, by the motion of the balance, acts on it with a force proportional to the distance of the balance from its quiescent position. The balance, therefore, is acted on by an accelerating force, which varies in the same manner as the force of gravity
STRENGTH OF MATERIALS.

Strength of gravity acting on a pendulum swinging in a cycloid. Its vibrations therefore must be performed in equal time, whether they are wide or narrow. In the same dissertation Hooke mentions all the facts which John Bernoulli afterwards added in support of Leibnitz's whimsical doctrine of the forces of bodies in motion, or the doctrine of the \textit{vires vivæ}; a doctrine which Hooke might justly have claimed as his own, had he not seen its futility.

Experiments made since the time of Hooke show that this law is strictly true in the extent to which we have limited it, viz. in all the changes of form which will be completely undone by the elasticity of the body. It is nearly true to a much greater extent. James Bernoulli, in his dissertation on the elastic curve, relates some experiments of his own, which seem to deviate considerably from it; but on close examination they do not. The finest experiments are those of Coulomb, published in some late volumes of the memoirs of the Academy of Paris. He suspended balls by wires, and observed their motions of oscillation, which he found accurately corresponding with this law.

This we shall find to be a very important fact in the doctrine of the strength of bodies, and we desire the reader to make it familiar to his mind. If we apply to this our manner of expressing these forces by perpendicular ordinates \( C, C, D \) (fig. 1.), we must take other situations \( E, F, \) of the particle \( B, \) and draw \( E, F, f; \) and we must have \( D d : E = B D : B F, \) or \( C : c \) \( = B C : B E. \) In such a supposition \( F d B, \) \( c \) \( = \) must be a straight line. But we shall have abundant evidence by and bye that this cannot be strictly true, and that the line \( B c \) which limits the ordinates expressing the attractive forces becomes converging towards the line \( A B, \) and that the part \( B d f \) is convex towards it. All that can be safely concluded from the experiments hitherto made is, that \textit{a certain extent} the forces, both attractive and repulsive, are \textit{sensibly} proportional to the dilatations and compressions.

5. It is universally observed, that when the dilatations have proceeded a certain length, a less addition of force is sufficient to increase the dilatation in the same degree. This is always observed when the body has been so far stretched that it takes a set, and does not completely recover its form. The like may be generally observed in compressions. Most persons will recollect, that in violently stretching an elastic cord, it becomes suddenly weaker, or more easily stretched. But these phenomena do not positively prove a diminution of the corpuscular force acting on one particle; it more probably arises from the disunion of some particles, whose action contributed to the whole or sensible effect. And in compressions we may suppose something of the same kind; for when we compress a body in one direction, it commonly bulges out in another; and in cases of very violent action some particles may be disunited, whose transverse action had formerly balanced \textit{part} of the compressing force. For the reader will see on reflection, that since the compression in one direction causes the body to bulge out in the transverse direction; and since this bulging out is in opposition to the transverse forces of attraction, it must employ some part of the compressing force. And the common appearances are in perfect uniformity with this conception of things. When we press a bit of dryish clay, it swells out and cracks transversely. When a pillar of wood is overloaded, it swells out, and small crevices appear in the direction of strength of the fibre. After this it will not bear half of the load.

The carpenters call \textit{crumbling} and a knowledge of the circumstances which modify it is of great importance, and enables us to understand some very paradoxical appearances, as will be shown by and bye.

This partial disuniting of particles formerly cohering is, we imagine, the chief reason why the total of the forces which really oppose an external strain does not increase in the proportion of the extensions and compressions. But sufficient evidence will also be given that the forces which would connect one particle with one other particle do not augment in the accurate proportion of the change of distance; that in extensions they increase more slowly, and in compressions more rapidly.

But there is another cause of this deviation perhaps \textit{ductility} equally effectual with the former. Most bodies manifest another degree of \textit{ductility}. Now what is this? The fact is, that the parts have taken a new arrangement, in which they again cohere. Therefore, in the passage to this new arrangement, the sensible forces, which are the joint result of many corpuscular forces, begin to respect this new arrangement instead of the former. This must change the simple law of corpuscular force, characteristic of the particular species of matter under examination. It does not require much reflection to convince us that the possible arrangements which the particles of a body may acquire, without appearing to change their nature, must be more numerous according as the particles are of a more complex constitution; and it is reasonable to suppose that the constitution even of the most simple kind of matter that we are acquainted with is exceedingly complex. Our microscopes show us animals so minute, that a heap of them must appear to the naked eye an uniform mass with a grain finer than that of the finest marble or razor hone; and yet each of these has not only limbs, but bones, muscular fibres, blood-vessels, fibres, and a blood consisting, in all probability, of globules organised and complex like our own. The imagination is here lost in wonder; and nothing is left but to adore inconceivable art and wisdom, and to exult in the thought that we are the only spectators of this beautiful scene who can derive pleasure from the view.

What is trodden under foot with indifference, even by the half-reasoning elephant, may be made by us the source of the purest and most unmixed pleasure. But let us proceed to observe.

6. That the forces which connect the particles of tangible bodies change by a change of distance, not only in degree, but also in kind. The particle \( B \) (fig. 1.) is attracted by \( A \) when in the situation \( C \) or \( E. \) It is repelled by it when at \( D \) or \( F. \) It is not affected by it when in the situation \( B. \) The reader is requested care fully to remark, that this is not an inference founded on the authority of our mathematical figure. The figure is an expression (to assist the imagination) of facts in nature. It requires no force to keep the particles of a body in their quiescent situations: but if they are separated by stretching the body, they endeavour (pardon the figurative expression) to come together again. If they are brought nearer by compression, they endeavour to recede. This endeavour is manifested by the necessity of employing force to maintain the extension or condensation; and we represent this by the different position of...
STRENGTH OF MATERIALS.

Strength of our lines. But this is not all: the particle B which is repelled by A when in the situation F or D, is neutral when at B, and is attracted when at C or E, may be placed at such a distance AG from A greater than AB that it shall be again repelled, or at such a distance, all that it shall again be attracted; and these alterations may be repeated again and again. This is curious and important, and requires something more than a bare assertion for its proof.

In the article Optics we mentioned the most curious and valuable observations of Sir Isaac Newton, by which it appears that light is thus alternately attracted and repelled. The rings of colour which appear between the object glasses of long telescopes showed, that in the small interval of $\frac{1}{300}$ of an inch, there are at least a hundred such changes observable, and that it is highly probable that these alternations extend to a much greater distance. At one of these distances the light actually converges towards the solid matter of the glass, which we express shortly, by saying that it is attracted by it, and that at the next distance it declines from the glass, or is repelled by it. The same thing is more simply inferred from the phenomena of light passing by the edges of knives and other opaque bodies. We refer the reader to the experiments themselves, the detail being too long for this place; and we request him to consider them minutely and attentively, and to form distinct notions of the inferences drawn from them. And we desire it to be remarked, that although Sir Isaac, in his discussion, always considers light as a set of corpuscles moving in free space, and obeying the actions of external forces like any other matter, the particular conclusion in which we are just now interested does not at all depend on this notion of the nature of light. Should we, with Des Cartes or Huygens, suppose light to be the undulation of an elastic medium, the conclusion will be the same. The undulations at certain distances are disturbed by forces directed towards the body, and at a greater distance, the disturbing forces tend from the body.

But the same alternations of attraction and repulsion may be observed between the particles of common matter. If we take a piece of very flat and well-polished glass, such as is made for the horizon glasses of a good Hadley's quadrant, and if we wrap it round a fibre of silk as it comes from the cocoon, taking care that the fibre nowhere cross another, and then press this pretty hard on such another piece of glass, it will lift it up and keep it suspended. The particles therefore of the one do most certainly attract those of the other, and this at a distance equal to the thickness of the silk fibre. This is nearly the limit; and it sometimes requires a considerable pressure to produce the effect. The pressure is effected only by compressing the silk fibre, and thus diminishing the distance between the glass plates. This adhesion cannot be attributed to the pressure of the atmosphere, because there is nothing to hinder the air from insinuating itself between the plates, since they are separated by the silk. Besides, the experiment succeeds equally well under the receiver of an air-pump. This most valuable experiment was first made by Huygens, who reported it to the Royal Society. It is narrated in the Philosophical Transactions, N° 86.

Here then is an attraction acting, like gravity, at a distance. But take away the silk fibre, and try to make the glasses touch each other, and we shall find a very great force necessary. By Newton's experiments it appears, that unless the prismatic colours begin to appear between the glasses, they are at least $\frac{1}{300}$ of an inch asunder or more. Now we know that a very considerable force is necessary for producing these colours, and that the more we press the glasses together the more rings of colours appear. It also appears from Newton's measures, that the difference of distance between the glasses where each of these colours appear is about the 80,000th part of an inch. We know farther, that when we have produced the last appearance of a greasy or pearly colour, and then augment the pressure, making it about a thousand pounds on the square inch, all colours vanish, and the two pieces of glass seem to make one transparent indistinguishable mass. They appear now to have no air between them, or to be in mathematical contact. But another fact shows this conclusion to be premature. The same circles of colours appear in the top of a soap bubble; and as it grows thinner at top, there appears an unreflecting spot in the middle. We have the greatest probability therefore that the perfect transparency in the middle of the two glasses does not arise from their being in contact, but because the thickness of air between them is too small in that place for the reflection of light. Nay, Newton expressly found no reflection where the thickness was thirds or more of the 30,000th part of an inch.

All this while the glasses are strongly repelling each other, for great pressure is necessary for continuing the appearance of those colours, and they vanish in succession as the pressure is diminished. This vanishing of the colours is a proof that the glasses are moving off from each other, or repelling each other. But we can put an end to this repulsion by very strong pressure, and at the same time sliding the glasses on each other. We do not pretend to account for this effect of the sliding motion; but the fact is, that by so doing, the glasses will cohere with very great force, so that we shall break them by any attempt to pull them asunder. It commonly happens (at least it did so with us), that in this sliding compression of two smooth flat plates of glass they scratch and mutually destroy each other's surface. It is also worth remarking, that different kinds of glass exhibit different properties in this respect. Flint glass will attract even though a silk fibre lies double between them, and they much more readily cohere by this sliding pressure. Here then are two distances at which the plates of glass attract each other; namely, when the silk fibre is interposed, and when they are forced together with this sliding motion. And in any intermediate situation they repel each other. We see the same thing in other solid bodies. Two pieces of lead made perfectly clean, may be made to cohere by grinding them together in the same manner. It is in this way that pretty ornaments of silver are united to iron. The piece is scraped clean, and a small bit of silver like a fish scale is laid on. Then the die which is to strike it into a flower or other ornament is then set on it, and we give it a smart blow, which forces the metals into contact as firm as if they were soldered together. It sometimes happens that the die adheres to the coin so that they cannot be separated: and it is found that this frequently happens, when the engraving is such, that the raised figure is not completely...
In this new state the particles are again in limits of strength of material, between attractive and repulsive forces, for water has been shown by the experiments of Canton and Zimmerman, to be elastic or compressible. It again expands by heat. It again absorbs a prodigious quantity of heat, and becomes elastic vapour; its particles repelling each other at all distancesyetobserved. The distance between the particles of one plate of glass and those of another which lies on it, and is carried by it, is a distance of repulsion; for the force which supports the upper piece is acting in opposition to its weight. This distance is less than that at which it would suspend it below it with a silk fibre interposed; for no prismatic colours appear between them when the silk fibre is interposed. But the distance at which glass attracts water is much less than this, for no colours appear when glass is wetted with water. This distance is less, and not greater, than the other; for when the glasses have water interposed between them instead of air, it is found, that when any particular colour appears, the thickness of the plate of water is to that of the plate of air which would produce the same colour nearly as 3 to 4. Now, if a piece of glass be wetted, and exhibit no colour, and another piece of glass be simply laid on it, no colour will appear; but if they are strongly pressed, the colours appear in the same manneras if the glasses had air between. Also, when glass is simply wetted, and the film of water is allowed to evaporate, when it is thus reduced to a proper thinness, the colours show themselves in great beauty.

These are a few of many thousand facts, by which it is unquestionably proved that the particles of matter connected by forces acting at a distance, varying with the distance, and alternately attractive and repulsive. If we represent these forces as we have already done in figure 1. by the ordinates $C_c, D_d, E_e, F_f$, &c. of a curve, it is evident that this curve must cross the axis at all those distances where the forces change from attractive to repulsive, and the curve must have branches alternately above and below the axis.

All these alternations of attraction and repulsion take place at small and insensible distances. At all sensible distances the particles are influenced by the attraction of gravitation; and therefore this part of the curve must be a hyperbola whose equation is $y = \frac{a}{x^2}$. What is the form of the curve corresponding to the smallest distance of the particles? that is, what is the mutual action between the particles just before their coming into absolute contact? Analogy should lead us to suppose it to be repulsion; for solidity is the last and simplest form of bodies with which we are acquainted.—Fluids are more compounded, containing fire as an essential ingredient. We should conclude that this ultimate repulsion is insuperable, for the hardest bodies are the most elastic. We are fully entitled to say, that this repelling force exceeds all that we have ever yet applied to overcome it; nay, there are good reasons for saying that this ultimate repulsion, by which the particles are kept from mathematical contact, is really insuperable in its own nature, and that it is impossible to produce mathematical contact.

We shall just mention one of these, which we consider as unanswerable. Suppose two atoms, or ultimate particles of matter, $A$ and $B$. Let $A$ be at rest, and $B$ move...
STRENGTH OF MATERIALS.

Strength of move up to it with the velocity z; and let us suppose that it comes into mathematical contact, and impels it (according to the common acceptation of the word).

Both move with the velocity i. This is granted by all to be the final result of the collision. Now the instant of time in which this communication happens is no part either of the duration of the solition motion of A, nor of the joint motion of A and B: It is the separation or boundary between them. It is at once the end of the first, and the beginning of the second, belonging equally to both. A was moving with the velocity z. The distinguishing circumstance therefore of its mechanical state is, that it has a determination (however incomprenensible) by which it would move for ever with the velocity z, if nothing changed it. This it has during the whole of its solition motion, and therefore in the last instant of this motion. In like manner, during the whole of the joint motion, and therefore in the first instant of this motion, the atom A has a determination by which it would move for ever with the velocity i. In one and the same instant; therefore, the atom A has two incompatible determinations. Whatever notion we can form of this state, which we call velocity, as a distinction of condition, the same impossibility of conception or the same absurdity occurs. Nor can it be avoided in any other way than by saying, that this change of A’s motion is brought about by insensible gradations; that is, that A and B influence each other precisely as they would do if a slender spring were interposed. The reader is desired to look at what we have said in the article PHYSICS, § 82.

The two magnets there spoken of are good representatives of two atoms endowed with mutual powers of repulsion; and the communication of motion is accomplished in both cases in precisely the same manner.

If, therefore, we shall ever be so fortunate as to discover the law of variation of that force which connects one ATOM of matter with another atom, and which is therefore characteristic of matter, and the ultimate source of all its sensible qualities; the curve whose ordinates represent the kind and the intensity of this atomic force will be something like that sketched in fig. 2. The first branch a B will have AK (perpendicular to the axis AH) for its asymptote, and the last branch l m o will be to all sense a hyperbola, having AO for its asymptote; and the ordinates l L, m M, &c. will be proportional to \(1, \frac{1}{1}, \frac{1}{1}, \frac{1}{1}\) &c. expressing the universal gravitation of matter. It will have many branches B b C, D d E, F / G, &c. expressing attractions, and alternate repulsive branches C c D, E e F, G g H, &c. All these will be contained within a distance AH, which does not exceed a very minute fraction of an inch.

The simplest particle which can be a constituent of a body having length, breadth, and thickness, must consist of four such atoms, all of which combine their influence on each atom of another such particle. It is evident that the curve which expresses the force that connect two such particles must be totally different from this original curve, this hyperbolic principle. Supposing the last known, our mathematical knowledge is quite able to discover the first; but when we proceed to compose a body of particles, each of which consists of four such particles, we may venture to say, that the compound force which connects them is almost beyond our search, and that the discovery of the primary force from an accurate knowledge of the corpuscular forces of this particular matter is absolutely out of our power.

All that we can learn is, the possibility, nay the certainty of an innumerable variety of external sensible forms and qualities, by which different kinds of matter will be distinguished, arising from the number, the order of composition, and the arrangement of the subordinate particles of which a particle of this or that kind of matter is composed. All these varieties will take place at those small and insensible distances which are between A and II, and may produce all that variety which we observe in the tangible or mechanical forms of bodies, such as elasticity, ductility, hardness, softness, fluidity, vapour, and all those unseen motions or actions which we observe in fusion and congelation, evaporation and condensation, solution and precipitation, crystallization, vegetable and animal assimilation and secession, &c. &c. while all bodies must be, in a certain degree, elastic, all must gravitate, and all must be incomprenensible.

This general and satisfactory resemblance between the appearance of tangible matter and the legitimate consequence of this general hypothetical property of an atom of matter, affords a considerable probability that such is the origin of all the phenomena. We earnestly recommend to our readers a careful perusal of Boscovich’s celebrated treatise. A careful perusal is necessary for seeing its value; and nothing will be got by a hasty look at it. The reader will be particularly pleased with the facility and evidence with which the ingenious author has deduced all the ordinary principles of mechanics, and with the explanation which he has given of fluidity, and his deduction from thence of the laws of hydrostatics. No part of the treatise is more valuable than the doctrine of the propagation of pressure through solid bodies. This, however, is but just touched on in the course of the investigation of the principles of mechanics. We shall borrow as much as will suffice for our present inquiry into the strength of materials; and we trust that our readers are not displeased with this general sketch of the doctrine (if it may be so called) of the cohesion of bodies. It is curious and important in itself, and is the foundation of all the knowledge we can acquire of bodies yet the present article. We are sorry to say that it is as a new subject of study, but it is a very promising one, and we by no means despair of seeing the whole of chemistry brought by its means within the pale of mechanical science. The great and distinguishing agent in chemistry is heat, or the cause of heat; and one of its most singular effects is the conversion of bodies into elastic vapour. We have the clearest evidence that this is brought about by mechanical forces: for it can be opposed or prevented by external pressure, a very familiar mechanical force. We may perhaps find another mechanical force which will prevent fusion.

HAVING now made our readers familiar with the mode of action in which cohesion operates in giving strength to solid bodies, we proceed to consider the strains to which this strength is opposed.

A piece of solid matter is exposed to four kinds of strains, pretty different in the manner of their operation, which

1. It may be torn asunder, as in the case of ropes, stretchers, king-posts, eye-beams, &c.

2.
STRENGTH OF MATERIALS.

2. It may be crushed, as in the case of pillars, posts, and truss beams.

3. It may be broken across, as happens to a joist or lever of any kind.

4. It may be wrenched or twisted, as in the case of the axle of a wheel, the nail of a press, &c.

I. IT MAY BE PULLED ASUNDER.

This is the simplest of all strains, and the others are indeed modifications of it. To this the force of cohesion is directly opposed, with very little modification of its action by any particular circumstances.

When a long cylindrical or prismatic body, such as a rod of wood or metal, or a rope, is drawn by one end, it must be resisted at the other, in order to bring its cohesion into action. When it is fastened at one end, we cannot conceive it any other way than as equally stretched in all its parts; for all our observations and experiments on natural bodies concur in showing us that the forces which connect their particles, in any way whatever, are equal and opposite. This is called the third law of motion; and we admit its universality, while we affirm that it is purely experimental (see PHYSICS). Yet we have met with dissertations by persons of eminent knowledge, where propositions are maintained inconsistent with this. During the dispute about the communication of motion, some of the ablest writers have said, that a spring compressed or stretched at the two ends was gradually less and less compressed or stretched from the extremities towards the middle: but the same writers acknowledged the universal equality of action and reaction, which is quite incompatible with this state of the spring. No such inequality of compression or dilatation has ever been observed; and a little reflection will show it to be impossible, in consistency with the equality of action and reaction.

Since all parts are thus equally stretched, it follows, that the strain in any transverse section is the same, as also in every point of that section. If therefore the body be supposed of a homogeneous texture, the cohesion of the parts is equal; and since every part is equally stretched, the particles are drawn to equal distances from their quiescent positions, and the forces which are thus excited, and now exerted in opposition to the straining force, are equal. This external force may be increased by degrees, which will gradually separate the parts of the body more and more from each other, and the connecting forces increase with this increase of distance, till at last the cohesion of some particles is overcome. This must be immediately followed by a rupture, because the remaining forces are now weaker than before.

It is the united force of cohesion, immediately before the disunion of the first particles, that we call the strength of the section. It may also be properly called its absolute strength, being exerted in the simplest form, and not modified by any relation to other circumstances.

If the external force has not produced any permanent change on the body, and it therefore recovers its former dimensions when the force is withdrawn, it is plain that this strain may be repeated as often as we please, and the body which withstands it once will always withstand it. It is evident that this should be attended to in all constructions, and that in all our investigations on this subject this should be kept strictly in view. When we treat of a piece of soft clay in this manner, and with this precaution, the force employed must be very small. If we exceed this, we produce a permanent change. The rod of clay is not indeed torn asunder; but it has become somewhat more slender: the number of particles in a cross section is now smaller; and therefore, although it will again, in this new form, suffer or allow an endless repetition of a certain strain without any further permanent change, this strain is smaller than the former.

Something of the same kind happens in all bodies which receive a stress by the strain to which they are exposed. All ductile bodies are of this kind. But there are many bodies which are not ductile. Such bodies break completely whenever they are stretched beyond the limit of their perfect elasticity. Bodies of a fibrous structure exhibit very great varieties in their cohesion.

In some the fibres have no lateral cohesion, as in the Great marble, case of a rope. The only way in which all the fibres can be made to unite their strength is, to twist them together. This causes them to bend each other so fast, that any one of them will break before it can be drawn out of the bundle. In other fibrous bodies, such as timber, the fibres are held together by some cement or gluten. This is seldom as strong as the fibre. Accordingly timber is much easier pulled asunder in a direction transverse to the fibres. There is, however, every possible variety in this particular.

In stretching and breaking fibrous bodies, the visible extension is frequently very considerable. This is not solely the increasing of the distance of the particles of the colouring fibre; the greatest part chiefly arises from drawing the crooked fibre straight. In this, too, there is great diversity; and it is accompanied with important differences in their power of withstanding a strain. In some woods, such as fir, the fibres on which the strength most depends are very straight. Such woods are commonly very elastic, do not take a set, and break abruptly when overstrained: others, such as oak and birch, have their resisting fibres very undulating and crooked, and stretch very sensibly by a strain. They are very liable to take a set, and they do not break so suddenly, but give warning by complaining, as the carpenters call it; that is, by giving visible signs of a rearrangement of texture. Hard bodies of an uniform glassy structure, or granulated like stones, are elastic through the whole extent of their cohesion, and take no set, but break at once when overloaded.

Notwithstanding the immense variety which nature exhibits in the structure and cohesion of bodies, there are certain general facts of which we may now avail ourselves with advantage. In particular, the absolute cohesion is proportional to the area of the section. This must be the case where the texture is perfectly uniform, as we have reason to think it is in stone or glass and the ductile metals. The cohesion of each particular being alike, the whole cohesion must be proportional to the number of the particles of cohesion, and that to the area of the section. The same must be admitted with respect to bodies of a granulated texture, where the granulation is regular and uniform. The same must be admitted of fibrous bodies, if we suppose their fibres equally strong, equally force.
STRENGTH OF MATERIALS.

Strength of dense, and similarly disposed through the whole section; and this we must either suppose, or must state the diversity, and measure the cohesion accordingly.

We may therefore assert, as a general proposition on this subject, that the absolute strength in any part of a body by which it resists being pulled asunder, or the force which must be employed to tear it asunder in that part, is proportional to the area of the section perpendicular to the extending force.

Therefore all cylindrical or prismatical rods are equally strong in every part, and will break alike in any part; and bodies which have unequal sections will always break in the slenderest part. The length of the cylinder or prism has no effect on the strength; and the vulgar notion, that it is easier to break a very long rope than a short one, is a very great mistake. Also the absolute strengths of bodies which have similar sections are proportional to the squares of their diameters or homologous sides of the section.

The weight of the body itself may be employed to strain it and to break it. It is evident, that a rope may be so long as to break by its own weight. When the rope is hanging perpendicularly, although it is equally strong in every part, it will break towards the upper end, because the strain on any part is the weight of all that is below it. Its relative strength in any part, or power of withstanding the strain which is actually laid on it, is inversely as the quantity below that part.

When the rope is stretched horizontally, as in towing a ship, the strain arising from its weight often bears a very sensible proportion to its whole strength.

Let AEB (fig. 3.) be any portion of such a rope, and AC, BC be tangents to the curve into which its gravity bends it. Complete the parallelogram ACBD.

It is well known that the curve is a catenaria, and that DC is perpendicular to the horizon; and that DC is to AC as the weight of the rope AEB to the strain at A.

In order that a suspended heavy body may be equally able in every part to carry its own weight, the section in that part must be proportional to the solid contents of all that is below it. Suppose it a conoidal spindle, formed by the revolution of the curve A a e (fig. 4.) round the axis CE. We must have $\Delta AZ = \alpha E B \times \alpha E b \times \alpha E e = A E B \times E a e$. This condition requires the logarithmic curve for A a e, of which C is the axis.

These are the chief general rules which can be safely deduced from our clearest notions of the cohesion of bodies.

In order to make any practical use of them, it is proper to have some measures of the cohesion of such bodies as are commonly employed in our mechanics, and other structures where they are exposed to this kind of strain. These must be deduced solely from experiment. Therefore they must be considered as no more than general values, or as the averages of many particular trials. The irregularities are very great, because none of the substances are constant in their texture and firmness. Metals differ apparently by a thousand circumstances unknown to us, according to their purity, to the heat with which they were melted, to the moulds in which they were cast, and the treatment they have afterwards received, strength of by forging, wire-drawing, tempering, &c.

It is a very curious and inexplicable fact, that by forging a metal, or by frequently drawing it through a smooth hole in a steel plate, its cohesion is greatly increased. This operation undoubtedly deranges the natural situation of the particles. They are squeezed closer together in one direction; but it is not in the direction in which they resist the fracture. In this direction they are rather separated to a greater distance. The general density, however, is augmented in all of them except lead, which grows rather rarer by wire-drawing; but its cohesion may be more than tripled by this operation. Gold, silver, and brass, have their cohesion nearly tripled; copper and iron have it more than doubled. In this operation they also grow much harder. It is proper to heat them to redness after drawing a little. This is called necking or annealing. It softens the metal again, and renders it susceptible of another drawing without the risk of cracking in the operation.

We do not pretend to give any explanation of all the remarkable and very important fact, which has something resembling it in woods and other fibrous bodies, as will be mentioned afterwards.

The varieties in the cohesion of stones and other minerals, and of vegetable and animal substances, are hardly susceptible of any description or classification.

We shall take for the measure of cohesion the number of pounds avoirdupois which are just sufficient to and tear asunder a rod or bundle of one inch square. From this it will be easy to compute the strength corresponding to any other dimension.

(a) This was an experiment by Muschenbroek, to examine the vulgar notion that iron forged from old horse-nails was stronger than all others, and shows its falsity.
STRENGTH OF MATERIALS.

It is very remarkable that almost all the mixtures of metals are more tenacious than the metals themselves. The change of tenacity depends much on the proportion of the ingredients, and the proportion which produces the most tenacious mixture is different in the different metals. We have selected the following from the experiments of Muschenbroek. The proportion of ingredients here selected is that which produces the greatest strength.

Two parts of gold with one of silver 28,000
Five parts of gold with one of copper 50,000
Five parts of silver with one of copper 48,500
Four parts of silver with one of tin 41,000
Six parts of copper with one of tin 41,000
Five parts of Japan copper with one of Bancan tin 37,000
Six parts of Chili copper with one of Malacca tin 60,000
Six parts of Swedish copper with one of Malacca tin 64,000
Brass consists of copper and zinc in an unknown proportion; its strength is 51,000
Three parts of block tin with one part of lead 10,200
Eight parts of block tin with one part of zinc 10,000
Four parts of Malacca tin with one part of regulus of antimony 12,000
Eight parts of lead with one of zinc 4,500
Four parts of tin with one of lead and one of zinc 13,000

These numbers are of considerable use in the arts. The mixtures of copper and tin are particularly interesting in the fabric of great guns. We see that, by mixing copper whose greatest strength does not exceed 37,000, with tin which does not exceed 6000, we produce a metal whose tenacity is almost double, at the same time that it is harder and more easily wrought. It is, however, more fusible, which is a great inconvenience. We also see that a very small addition of zinc almost doubles the tenacity of tin, and increases the lead of five times; and a small addition of lead doubles the tenacity of tin. These are economical mixtures. This is a very valuable information to the plumbers for augmenting the strength of water pipes.

By having recourse to these tables, the engineer can proportion the thickness of his pipes (of whatever metal) to the pressures to which they are exposed.

Woods.

We may premise to this part of the table the following general observations.

1. The wood immediately surrounding the pith or heart of the tree is the weakest, and its inferiority is so much more remarkable as the tree is older. In this assertion, however, we speak with some hesitation. Muschenbroek's detail of experiments is decidedly in the affirmative. Mr Buffon, on the other hand, says, that his experience has taught him that the heart of a sound tree is the strongest; but he gives no instances. We are certain, from many observations of our own, on very large oaks and firs, that the heart is much weaker than the exterior parts.

2. The wood next the bark, commonly called the strength of white or blea, is also weaker than the rest; and the wood gradually increases in strength as we recede from the centre to the blea.

3. The wood is stronger in the middle of the trunk than at the springing of the branches or at the root; and the wood of the branches is weaker than that of the trunk.

4. The wood of the north side of all trees which grow in our European climates is the weakest, and that of the south-east side is the strongest; and the difference is most remarkable in hedge-row trees, and such as grow singly. The heart of a tree is never in its centre, but always nearer to the north side, and the annual coats of wood are thinner on that side. In conformity with this, it is a general opinion of carpenters that timber is stronger whose annual plates are thicker. The trunks or air-vessels are weaker than the simple ligneous fibres. These air-vessels are the same in diameter and number of rows in trees of the same species, and they make the visible separation between the annual plates. Therefore when these are thicker, they contain a greater proportion of the simple ligneous fibres.

5. All woods are more tenacious while green, and lose very considerably by drying after the trees are felled.

The only author who has put it in our power to judge of the propriety of his experiments is Muschenbroek. He has described his method of trial minutely; and it seems unexceptionable. The woods were all formed into slips fit for his apparatus, and part of the slip was cut away to a parallelepiped of 1/44th of an inch square, and therefore 1/44th of a square inch in section. The absolute strengths of a square inch were as follows:

<table>

</tbody>
</table>

Mr Muschenbroek has given a very minute detail of the experiments on the ash and the walnut, stating the weights which were required to tear asunder slips taken from the four sides of the tree, and on each side, in a regular progression from the centre to the circumference. The number of this table corresponding to these two timbers may therefore be considered as the average of more than 50 trials made of each; and he says that all the others were made with the same care. We cannot therefore see any reason for not confiding in the results; yet they are considerably higher than those given by some other writers. Mr Pitot says, on the authority of his own experiments, and of those of Mr Parent, that 60 pounds will just tear asunder a square line of sound oak, and that it will bear 50 with safety. This gives 8640 for the utmost strength of a square inch, which is much inferior to Muschenbroek's valuation.

We
We may add to these,  
Ivory, - - - 16,270  
Bone, - - - 5,250  
Horn, - - - 8,750  
Whalebone, - - - 7,500  
Tooth of sea-calf, - - - 4,975  

The reader will surely observe, that these numbers express something more than the utmost cohesion; for the weights are such as will very quickly, that is, in a minute or two, tear the rods asunder. It may be said in general, that two thirds of these weights will sensibly impair the strength after a considerable while, and that one-half is the utmost that can remain suspended at them without risk for ever; and it this last allotment that the engineer should reckon upon in his constructions. There is, however, considerable difference in this respect. Woods of a very straight fibre, such as fir, will be less impaired by any load which is not sufficient to break them immediately. 

According to Mr Emerson, the load which may be safely suspended to an inch square is as follows:  
Iron, - - - 76,400  
Brass, - - - 35,600  
Hemp rope, - - - 19,600  
Ivory, - - - 13,700  
Oak, box, yew, plum-tree, - - - 7,850  
Elm, ash, beech, - - - 6,070  
Walnut, plum, - - - 5,360  
Red fir, holly, elder, plane, crab, - - - 5,000  
Cherry, hazel, - - - 4,760  
Alder, asp, birch, willow, - - - 4,390  
Lead, - - - 430  
Freestone, - - - 914  

He gives us a practical rule, that a cylinder whose diameter is 1 inches, loaded to one-fourth of its absolute strength, will carry as follows:  
Iron, - - - 135  
Good rope, - - - 22  
Oak, - - - 14  
Fir, - - - 9  

The rank which the different woods hold in this list of Mr Emerson's is very different from what we find in Muschenbroek's. But precise measures must not be expected in this matter. It is wonderful that in a matter of such unquestionable importance the public has not enabled some persons of judgment to make proper trials. They are beyond the abilities of private persons.

II. Bodies may be crushed.

It is of importance to know what will crush bodies. It is of equal, perhaps greater, importance to know the strain which may be laid on solid bodies without danger of crushing them. Pillars and posts of all kinds are exposed to this strain in its simplest form; and there are cases where the strain is enormous, viz. where it arises from the oblique position of the parts; as in the stuts, braces, and trusses, which occur very frequently in our great works.

It is therefore most desirable to have some general knowledge of the principle which determines the strength of bodies in opposition to this kind of strain. But unfortunately we are much more at a loss in this than in the last case. The mechanism of nature is much more complicated in the present case. It must be in some circuitous way that compression can have any tendency to tear asunder the parts of a solid body, and it is very difficult to trace the principles of it. We must suppose the particles insensibly hard and in contact, and disposed in lines which are in the direction of the external pressures, it does not appear how any pressure can disunite the particles; but this is a gratuitous supposition. There are infinite odds against this precise arrangement of the lines of particles; and the compressibility of all kinds of matter in some degree shows that the particles are in a situation equivalent to distance. This being the case, and the particles, with their intervals, or what is equivalent to intervals, being in situations that are oblique with respect to the pressures, must follow, that by squeezing them together in one direction, they are made to bulge out or separate in other directions. This may proceed so far that some may be thus pushed laterally beyond their limits of cohesion. The moment that this happens the resistance to compression is diminished, and the body will now be crushed together. We may form some notion of this by supposing a number of splinters, like small shot, sticking together by means of a cement. Compressing this in some particular direction causes the splinters to act among each other like so many wedges, each tending to penetrate through between the three which lie below it; and this is the simplest, and perhaps the only distinct, notion we can have of the matter. We have reason to think that the constitution of very homogeneous bodies, such as glass, is not very different from this. The particles are certainly arranged symmetrically in the angles of some regular solids. It is only such an arrangement that is consistent with transparency, and with the free passage of light in every direction.

If this be the constitution of bodies, it appears probable that the strength, or the resistance which they are capable of making to an attempt to crush them to pieces, or power of resistance to such a being similarly and equally acted on and resisted, the force, whole resistance must be as their number; that is, as the extent of the section.

Accordingly this principle is assumed by the few writers who have considered this subject; but we confess that it appears to us very doubtful. Suppose a number of brittle or friable balls lying on a table uniformly arranged, but not cohesion nor in contact, and that a board is laid over them and loaded with a weight; we have no hesitation in saying, that the weight necessary to crush the whole collection is proportional to their number or to the area of the section. But when they are in contact (and still more if they cohere), we imagine that the case is materially altered. Any individual ball is crushed only in consequence of its being bulged outwards in the direction perpendicular to the pressure employed. If this could be prevented by a hoop put round the ball like an equator, we cannot see how any force can crush it. Any thing therefore which makes this bulging outwards more difficult, makes a greater force necessary. Now this effect will be produced by the mere contact of the balls before the pressure is applied; for the central ball cannot swell outward laterally without pushing away the balls on all sides of it. This is prevented by the friction on the table and upper board.
STRENGTH OF MATERIALS.

To bend under the pressure, the case is greatly changed, because it is then exposed to a transverse strain; and this increases with the length of the pillar. But this will be considered with due attention under the next class of strains.

Several experiments have been made on this species of strength and strain. Mr. Petit says, that his experiments and those of Mr. Parent, show that the force necessary for crushing a body is nearly equal to that which will tear it asunder. He says that it requires something more than 60 pounds on every square line to crush a piece of sound oak. But the rule is by no means general: Glass, for instance, will carry a hundred times as much as oak in this way, that is, resting on it; but will not suspend above four or five times as much. Oak will suspend a great deal more than fir; but fir will carry twice as much as a pillar. Woods of a soft texture, although consisting of very tenacious fibres, are more easily crushed by their lead. This softness of texture is chiefly owing to their fibres not being straight but undulated, and there being considerable vacuities between them, so that they are easily bent laterally and crushed. When a post is overstrained by its load, it is observed to swell sensibly in diameter. Increasing the load causes longitudinal cracks or shivers to appear, and it presently gives way. This is called crippling.

In all cases where the fibres lie oblique to the strain the strength is greatly diminished, because the parts can then be made to slide on each other, when the cohesion of the cementing matter is overcome.

Muschelenbroek has given some experiments on this subject; but they are cases of long pillars, and therefore do not belong to this place. They will be considered afterwards.

The only experiments of which we have seen any detail (and it is useless to insert mere assertions) are those of Mr. Gauthier, in the 4th volume of Rozier's Journal de Physique. This engineer exposed to great pressures small rectangular parallelepipeds, cut from a great variety of stones, and noted the weights which crushed them. The following table exhibits the medium results of many trials on two very uniform kinds of freestone, one of them among the hardest and the other among the softest used in building.

to be ascertained only by experiment.
STRENGTH OF MATERIALS.

Little can be deduced from these experiments: The 1st and 3d, compared with the 5th and 6th, should furnish similar results; for the 1st and 4th are respectively half of the 3d and 6th: but the 3d is three times stronger (that is, a line of the 3d) than the first, whereas the 6th is only twice as strong as the 5th.

It is evident, however, that the strength increases much faster than the area of the section, and that a square line can carry more and more weight, according as it makes a part of a larger and larger section. In the series of experiments on the soft stone, the individual strength of a square line seems to increase nearly in the proportion of the section of which it makes a part.

Mr. Gauthy deduces, from the whole of his numerous experiments, that a pillar of hard stone of Givry, whose section is a square foot, will bear with perfect safety 664,000 pounds, and that its extreme strength is 871,000, and the smallest strength observed in any of his experiments was 490,000. The soft bed of Givry stone had for its smallest strength 187,000, for its greatest 311,000, and for its safe load 249,000. Good brick will carry with safety 320,000; chalk will carry only 9000. The boldest piece of architecture in this respect which he has seen is a pillar in the church of All-Saints at Angers. It is 24 feet long and 11 inches square, and is loaded with 56,000 pounds, which is not one-seventh of what is necessary for crushing it.

We may observe here by the way, that Mr. Gauthy's measure of the suspending strength of stone is vastly small in proportion to its power of supporting a load laid above it. He finds that a prism of the hard bed of Givry, of a foot section, is torn asunder by 4600 pounds; and if it be firmly fixed horizontally in a wall, it will be broken by a weight of 56,000 suspended a foot from the wall.

If it rest on two props at a foot distance, it will be broken by 206,000 laid on its middle. These experiments agree so ill with each other, that little use can be made of them. The subject is of great importance, and well deserves the attention of the patriotic philosopher.

A set of good experiments would be very valuable, because it is against this kind of strain that we must guard by judicious construction in the most delicate and difficult problems which come through the hands of the civil and military engineer. The construction of stone arches, and the construction of great wooden bridges, and particularly the construction of the frames of carpentry called centres in the erection of stone bridges, are the most difficult jobs that occur. In the centres on which the arches of the bridge of Orleans were built, some of the pieces of oak were carrying upwards of two tons on every square inch of their scantling. All who saw it said that it was not able to carry the fourth part of the intended load. But the engineer understood the principles of his art, and ran the risk; and the result completely justified his confidence; for the centre did not complain in any part, only it was found too supple; so that it went out of shape while the haunches only of the arch were laid on it. The engineer corrected this by loading it at the crown, and thus kept it completely in shape during the progress of the work.

In the Memoirs (old) of the Academy of Petersburg for 1778, there is a dissertation by Euler on this subject, but particularly limited to the strain on columns, in which the bending is taken into the account. Mr. Fuss has treated the same subject with relation to carpentry in a subsequent volume. But there is little in these papers besides a dry mathematical disquisition, proceeding on assumptions which (to speak favourably) are extremely gratuitous. The most important consequence of the compression is wholly overlooked, as we shall presently see. Our knowledge of the mechanism of cohesion is as yet far too imperfect to entitle us to a competent application of mathematics. Experiments should be multiplied.

The only way we can hope to make these experiments useful is to pay a careful attention to the manner in which the fracture is produced. By discovering the general resemblances in this particular, we advance a step in our power of introducing mathematical measurement. Thus, when a cubical piece of chalk is slowly crushed between the chaps of a vice, we see it uniformly split in a surface oblique to the pressure, and the two parts then slide along the surface of fracture. This should lead us to examine mathematically what relation there is between this surface of fracture and the necessary force; then we should endeavour to determine experimentally the position of this surface. Having discovered some general law or resemblance in this circumstance, we should try what mathematical hypothesis will agree with this. Having found one, we may then apply our simplest notions of cohesion, and compare the result of our computations with experiment. We are authorised to say, that a series of experiments has been made in this way, and that their results have been very uniform, and therefore satisfactory, and that they will soon be laid before the public as the foundations of successful practice in the construction of arches.

III. A BODY MAY BE BROKEN ACROSS.

The most usual, and the greatest strain, to which materials are exposed, is that which tends to break them transversely. It is seldom, however, that this is done in a manner perfectly simple; for when a beam projects horizontally from a wall, and a weight is suspended from it, its extremity, the beam is commonly broken near the transverse wall, and the intermediate part has performed the functions of a lever. Sometimes, though rarely, happens that the pin in the joint of a pair of pincers or scissors is cut through by the strain; and this is almost the only case of a simple transverse fracture. Being so rare, we may content ourselves with saying, that in this case the strength of the piece is proportional to the area of the section.

Experiments were made for discovering the resistances of bodies to this kind of strain in the following manner: Two iron bars were disposed horizontally at an uncertain distance, a third hung perpendicularly between them, being supported by a pin made of the substance to be examined. This pin was made of a prismatic form, so as to fit exactly the holes in the three bars, which were made very exact, and of the same size and shape. A scale was suspended at the lower end of the perpendicular bar, and loaded till it bore out that part of the pin which filled the middle hole. This weight was evidently the measure of the lateral cohesion of two sections. The side-bars were made to grasp the middle bar pretty strongly between them, that there might be no distance imposed between the opposite pressures. This would have combined the energy of a lever with the purely transverse pressure. For the same reason it was necessary.
STRENGTH OF MATERIALS.

Strength oratory that the internal parts of the holes should be no smaller than the edges. Great irregularities occurred in our first experiments from this cause, because the pins were somewhat tighter within than at the edges; but when this was corrected they were extremely regular. We employed three sets of holes, viz. a circle, a square (which was occasionally made a rectangle whose length was twice its breadth), and an equilateral triangle. We found in all our experiments the strength exactly proportional to the area of the section, and quite independent of its figure or position, and we found it considerably above the direct cohesion; that is, it took considerably more than twice the force to tear out this middle piece than to tear the pin asunder by a direct pull. A piece of fine freestone required 205 pounds to pull it directly asunder, and 575 to break it in this way. The difference was very constant in any one substance, but varied from four-thirds to six-thirds in different kinds of matter, being smallest in bodies of a fibrous texture. But indeed we could not make the trial on any bodies of considerable cohesion, because they required such forces as our apparatus could not support. Chalk, clay baked in the sun, baked sugar, brick, and freestone, were the strongest that we could examine.

But the more common case, where the energy of a lever intervenes, demands a minute examination.

Let DABC (fig. 5) be a vertical section of a prismatic solid (that is, of equal size throughout), projecting horizontally from a wall in which it is firmly fixed: and let a weight P be hung on it at B, or let any power P act at B in a direction perpendicular to AB. Suppose the body of insuperable strength in every part except in the vertical section DA, perpendicular to its length. It must break in this section only. Let the cohesion be uniform over the whole of this section; that is, let each of the adjoining particles of the two parts cohere with an equal force $f$.

There are two ways in which it may break. The part ABCD may simply slide down along the surface of fracture, provided that the power acting at B is equal to the accumulated force which is exerted by every particle of the section in the direction AD.

But suppose this effectually prevented by something that supports the point A. The action at P tends to make the body turn round A (or round a horizontal line passing through A at right angles to AB) as round a joint. This it cannot do without separating at the line DA. In this case the adjoining particles at D or at E will be separated horizontally. But their cohesion resists this separation. In order, therefore, that the fracture may happen, the energy or momentum of the power P, acting by means of the lever AB, must be superior to the accumulated energies of the particles. The energy of each depends not only on its cohesive force, but also on its situation; for the supposed insuperable firmness of the rest of the body makes it a lever turning round the fulcrum A, and the cohesion of each particle, such as D or E, acts by means of the arm DA or EA. The energy of each particle will therefore be had by multiplying the force exerted by it in the instant of fracture by the arm of the lever by which it acts.

Let us therefore first suppose, that in the instant of fracture every particle is exerting an equal force $f$. The energy of D will be $fx$ DA, and that of E will be $fx$ EA, and that of the whole will be the sum of all these products. Let the depth DA of the section be called $d$, the rectangle $fd$, and let any undetermined part of it EA be called $x$, and then the space occupied by any particle will be $x$.

The cohesion of this space may be represented by $f\times x$, and that of the whole by $f\times d$. The energy by which each element $x$ of the line DA, or $d$, resists the fracture, will be $fx\times d$, and the whole accumulated energies will be $fx\times d^2$, or $f\times d\times d\times d$. This we know to be $f\times d\times d$, or $f\times d\times d$.

It is the same therefore as if the cohesion $f\times d$ of the whole section had been acting at the point G, which is the middle of DA.

The reader who is not familiarly acquainted with this fluxionary calculus may arrive at the same conclusion in another way. Suppose the beam, instead of projecting horizontally from a wall, to be hanging from the ceiling, in which it is firmly fixed. Let us consider how the equal cohesion of every part operates in hindering the lower part from separating from the upper by opening round the joint A. The equal cohesion operates just as equal gravity would do, but in the opposite direction. Now we know, by the most elementary mechanics, that the effect of this will be the same as if the whole weight were concentrated in the centre of gravity G of the line DA, and that this point G is in the middle of DA.

Now the number of fibres being as the length $d$ of the line, and the cohesion of each fibre being $f$, the cohesion of the whole line is $f\times d\times d$. The accumulated energy therefore of the cohesion in the instant of fracture is $f\times d\times d$. Now this must be equal or just inferior to the energy of the power employed to break it. Let the length AB be called $l$; then $f\times l$ is the corresponding energy of the power. This gives us $f\times d\times d\times d\times l$ for the equation of equilibrium corresponding to the vertical section ADCB.

Suppose now that the fracture is not permitted at DA, but at another section $d$ more remote from B. The body being prismatic, all the vertical sections are equal; and therefore $f\times d\times d\times d\times l$ is the same as before. But the energy of the power is by this means increased, being now $f\times d\times d$, instead of $f\times l\times d$. Hence we see that when the prismatic body is not insuperably strong in all its parts, but equally strong throughout, it must break close at the wall, where the strain or energy of the power is greatest. We see, too, that a power which is just able to break it at the wall is unable to break it anywhere else; also an absolute cohesion $f\times d$, which can withstand the power $p$ in the section DA, will not withstand it in the section $d\times d$.

This teaches us to distinguish between absolute and relative strength. The relative strength of a section has a reference to the strain actually exerted on that section. This relative strength is properly measured by the power which is just able to balance or overcome it, when applied at its proper place. Now since we had $f\times d\times d\times l\times p$, we have $p=f\times d\times d\times l\times l$, or $f\times d\times l$, for the measure of the strength of the section DA, in relation to the power applied at B.

If the solid is a rectangular beam, whose breadth is $\delta$, it is plain that all the vertical sections are equal, and that AG or $\delta\times d$ is the same in all. Therefore the equa-
STRENGTH OF MATERIALS.

Strength of the equilibrium between the momentum of the external force and the accumulated momenta of cohesion will be \( p = \frac{f b d}{} \times \frac{d}{d} \).

The product \( d b \) evidently expresses the area of the sectional fracture, which we may call \( A \), and we may express the equilibrium thus, \( p = f s \times d \), and \( A : d = f s : p \).

Now \( f s \) is a proper expression of the absolute cohesion of the sectional fracture, and \( p \) is a proper measure of its strength in relation to a power applied at \( B \). We may therefore say, that twice the length of a rectangular beam is to the depth as the absolute cohesion to the relative strength.

Since the action of equal cohesion is similar to the action of equal gravity, it follows, that whatever is the figure of the section, the relative strength will be the same as if the absolute cohesion of all the fibres were acting at the centre of gravity of the section. Let \( g \) be the distance between the centre of gravity of the section and the axis of fracture, we shall have \( p = \frac{f}{} \times s \times g, \)

and \( l : g = f : s : p \). It will be very useful to recollect this analogy in words: "The length of a prismatic beam of any shape is to the height of the centre of gravity above the lower side, as the absolute cohesion to the strength relative to this length.

Because the relative strength of a rectangular beam is \( \frac{f b d}{} \times \frac{d}{d} \), it follows, that the relative strengths of different beams are proportional to the absolute cohesion of the particles, to the breadth, and to the square of the depth directly, and to the length inversely; also in prisms whose sections are similar, the strengths are as the cubes of the diameters.

Such are the more general results of the mechanism of this transverse strain, in the hypothesis that all the particles are exercising equal forces in the instant of fracture. We are indebted for this doctrine to the celebrated Galileo; and it was one of the first specimens of the application of mathematics to the science of nature.

We have not included in the preceding investigation that action of the external force by which the solid is drawn sideways, or tends to slide along the surface of fracture. We have supposed a particle \( E \) to be pulled only in the direction \( Ee \), perpendicular to the section of fracture, by the action of the crooked lever \( BAE \). But it is also pulled in the direction \( EA \); and its reaction is in some direction \( sE \), compounded of \( sf \), by which it resists being pulled outwards; and \( se \) by which it resists being pulled downwards. We are but imperfectly acquainted with the force \( se \), and only know that their accumulated sum is equal to the force \( p \); but in all important cases which occur in practice, it is unnecessary to attend to this force; because it is so small in comparison of the forces in the direction \( Ee \), as we easily conclude from the usual smallness of \( AD \) in comparison of \( AB \).

The hypothesis of equal cohesion, exerted by all the particles in the instant of fracture, is not conformable to nature: for we know, that when a force is applied transversely at \( B \), the beam is bent downwards, becoming convex on the upper side; that side is therefore on the stretch. The particles at \( D \) are further removed from each other than those at \( E \), and are therefore actually exerting greater cohesive forces. We cannot say with certainty and precision in what proportion each fibre is extended. It seems most probable that the extensions are proportional to the distances from \( A \). We shall suppose this to be really the case. Now recollect the general law which we formerly said was observed in all moderate extensions, viz., that the attractive forces exerted by the dilated particles were proportional to their dilatations. Suppose now that the beam is so much bent that the particles at \( D \) are exerting their utmost force, and that this fibre is just ready to break or actually breaks. It is plain that a total fracture must immediately ensue; because the force which was superior to the full cohesion of the particle at \( D \), and a certain portion of the cohesion of all the rest, will be more than superior to the full cohesion of the particle next within \( D \), and a smaller portion of the cohesion of the remainder.

Now let \( F \) represent, as before, the full force of the exterior fibre \( D \), which is exerted by it in the instant of its breaking, and then the force exerted at the same instant by the fibre \( E \) will be had by this analogy, \( AD : AE, \) or \( d : x = f \times \frac{s}{} : d \) and the force really exerted by the fibre \( E \) is \( f \times d \).

The force exerted by a fibre whose thickness is \( x \) is therefore \( f \times \frac{s}{} : d \); but this force resists the strain by acting by means of the lever \( EA \) or \( x \). Its energy or momentum is therefore \( f \times \frac{s}{} : d \), and the accumulated momenta of all the fibres in the line \( AE \) will be \( f \times \text{sum of} \times d \). This, when \( x \) is taken equal to \( d \), will express the momentum of the whole fibre in the line \( AD \). This, therefore, is \( f \times d \), or \( f \times d \), or \( f \times d \times d \). Now \( f \times d \) expresses the absolute cohesion of the whole line \( AD \).

The accumulated momenta is therefore the same as if the absolute cohesion of the whole line were exerted at one-third of \( AD \) from \( A \).

From these premises it follows that the equation expressing the equilibrium of the strain and cohesion is \( p \times \text{strength} = f \times d \times d \); and hence we deduce the analogy, "As the length is to the depth, so is the absolute cohesion to the relative strength."

This equation and this proportion will equally apply to rectangular beams whose breadth is \( b \); for we shall then have \( p = f \times b \times d \times d \).

We also see that the relative strength is proportional to the absolute cohesion of the particles, to the breadth, and to the square of the depth directly, and to the length inversely: for \( p \) is the measure of the force with which it is resisted, and \( p = f \times b \times d \times d \). In this respect therefore this hypothesis agrees with the Galilean; but it assigns to every beam a smaller proportion of the absolute cohesion of the sectional fracture, in the proportion of three to two. In the Galilean hypothesis this section has a momentum equal to one-half of its absolute strength, but in the other hypothesis it is only one-third. In beams of a different form the proportion may be different.

As this is a most important proposition, and the foundation
STRENGTH OF MATERIALS.

Thus suppose that the cohesion along the line AD only Strength of is considered. The whole cohesion will be represented by a triangle AD. D is represented by, and AD is d, and AD is x. Therefore AD d is \( \frac{x}{d} \). The centre of gravity of the triangle AD is in the intersection of a line drawn from A to the middle of D d with a line drawn from d to the middle of AD; and therefore the line O will make AO = \( \frac{x}{d} \) of AD. Therefore the actual moment of cohesion is \( \frac{x}{d} \times d \times \frac{x}{d} \), or equal to the absolute cohesion acting by means of the lever \( \frac{d}{d} \). If the section of fracture is a rectangle, as in a common joint, whose breadth a is \( \frac{d}{x} \), it is plain that all the vertical lines will be represented by triangles like AD d; and the whole actual cohesion will be represented by a wedge whose bases are vertical planes, and which is equal to half of the parallelepiped AD X D x a a, and will therefore be \( \frac{d}{d} \times d \times \frac{d}{d} \); and the distance AO of its centre of gravity from the horizontal line AD will be \( \frac{d}{d} \) of AD.

The momentum of cohesion of a joint will therefore be \( \frac{d}{d} \times d \times \frac{d}{d} \), or \( \frac{d}{d} \times d \times \frac{d}{d} \), as we have determined in the other way.

The beam represented in the figure is a triangular prism. The pyramid D a d d is \( \frac{x}{d} \) of the prism a a d a d. If we make s represent the surface of the triangle a a d, the pyramid is \( \frac{x}{d} \) of s. The distance AO of its centre of gravity from the horizontal line AD is \( \frac{x}{d} \) of AO, or \( \frac{x}{d} \). Therefore the momentum of actual cohesion is \( \frac{x}{d} \times \frac{x}{d} d \); that is, it is the same as if the full cohesion of all the fibres were accumulated at a point I whose distance from A is \( \frac{x}{d} \) of AD or d; or (if we may see its value in every point of view) it is \( \frac{x}{d} \) of the momentum of the full cohesion of all the fibres when accumulated at the point D, or acting at the distance d = AD.

This is a very convenient way of conceiving the moment of actual cohesion, by comparing it with the momentum of absolute cohesion applied at the distance AD from the axis of fracture. The momentum of the absolute cohesion applied at D is to the momentum of actual cohesion in the instant of fracture as AD to AO. Therefore the length of AI, or its proportion to AD, is a sort of index of the strength of the beam. We shall call it the INDEX, and express it by the symbol i.

Its value is easily obtained. The product of the absolute cohesion by AI must be equal to that of the actual cohesion by AO. Therefore say, "as the prismatic solid a a D d d d' is to the pyramidal solid a a D d, so is AO to AI." We are assisted in this determination by a very convenient circumstance. In this hypothesis of the actual cohesions being as the distances of the fibres from A, the point O is the centre of oscillation or percussion of the surface D a turning round the axis a o: for the momentum of cohesion of the line FF is FF X E = FF X EA, because FF is equal to EA. Now AO, by the nature of the centre of gravity, is equal to the sum of all these momenta divided by the pyramid a a D d; that is, by the sum of all the FF X F; that is, by the sum of all the FF X EA.

Therefore AO = \( \frac{\text{sum of FF X EA}}{\text{sum of FF X EA}} \), which is just the value of the distance of the centre of percussion of the triangle a D from A: (See Rotation). Moreover,
STRENGTH OF MATERIALS.

If \( G \) be the centre of gravity of the triangle \( a \Delta d \), we shall have \( DA = GA \) as the absolute cohesion to the sum of the cohesion actually exerted in the instant of fracture; for, by the nature of this centre of gravity, \( \frac{AG}{\text{sum of } FF \times EA} \), and the sum of \( FF \times FF \) is equal to the sum of \( FF \times EA \). But the sum of all the lines \( FF \) is the triangle \( a \Delta d \), and the sum of all \( FF \times EA \) is the sum of all the rectangles \( FF \times s \); that is, the pyramid \( d \Delta d a \). Therefore a prism whose base is the triangle \( a \Delta d \) and whose height is \( AG \) is equal to the pyramid, or will express the sum of the actual cohesion; and a prism, whose base is the same triangle, and whose height is \( DD \) or \( \Delta d \), expresses the absolute cohesion. Therefore \( DA \) is to \( GA \) as the absolute cohesion to the sum of the actual cohesions.

Therefore we have \( DA : GA = OA : IA \).

Therefore, whatever be the form of the beam, that is, whatever be the figure of its section, find the centre of oscillation \( O \), and the centre of gravity \( G \) of this section. Call their distances from the axis of fracture \( f \) and \( g \). Then \( AI \) or \( 2f \) and the momentum of cohesion is \( fs \times \frac{2f}{d^2} \), where \( s \) is the area of fracture.

This index is easily determined in all cases which generally occur in practice. In a rectangular beam, \( AI \) is \( \frac{1}{4} \) of \( AD \); in a cylinder (circular or elliptic) \( AI \) is \( \frac{\pi}{4} \) of \( AD \), &c. &c.

In this hypothesis, that the cohesion actually exerted by each fibre as its extension, and that the extensions of the fibres are as their distances from \( A \) (fig. 5.), it is plain that the forces exerted by the fibres \( D, E, \&c. \) will be represented by the ordinates \( DD \), \( EE \), \&c. to a straight line \( A \Delta d \). And we learn from the principles of rotation that the centre of percussion \( O \) is in the ordinate which passes through the centre of gravity of the triangle \( AD \), or (if we consider the whole section having breadth as well as depth) through the centre of gravity of the solid bounded by the planes \( DA \), \( DD \) and which we found that point \( O \) was the centre of effort of the cohesions actually exerted in the instant of fracture, and that \( I \) was the centre of an equal momentum, which would be produced if all the fibres were accumulated there and exerted their full cohesion.

This consideration enables us to determine, with equal facility and neatness, the strength of a beam in any hypothesis of forces. The above hypothesis was introduced with a cautious limitation to moderate strains, which produced no permanent change of form, or no sets as the action would: and this suffices for all purposes of practice, seeing that it would be improper to expose materials to more violent strains. But when we compare this theory with experiments in which the pieces are really broken, considerable deviations may be expected, because it is very probable that in the vicinity of rupture the forces are no longer proportional to the extensions.

That no doubt may remain as to the justness and completeness of the theory, we must show how the relative strength may be determined in any other hypothesis. Therefore suppose that it has been established by experiment on any kind of solid matter, that the forces actually exerted in the instant of fracture by the fibres at \( D, E, \&c. \) are as the ordinates \( DD \), \( EE \), \&c. of any curve line \( A \Delta d \). We are supposed to know the form of this curve, and that of the solid which is bounded by the vertical plane through \( AD \), and by the surface which passes through this curve and is perpendicular to the length of the beam. We know the place of the centre of gravity of this curve surface or solid, and can draw a line through it parallel to \( AB \), and cutting the surface of fracture in some point \( O \). This point is also the centre of effort of all the cohesions actually exerted; and the product of \( AO \) and of the solid which expresses the actual cohesions will give the momentum of cohesion equivalent to the former \( f \times \frac{2f}{d^2} \). Or we may find an index \( AI \), by making \( AI \) a fourth proportional to the full cohesion of the surface of fracture, to the accumulated actual cohesions, and to \( AO \); and then \( f \times \frac{2f}{d^2} \) will be the momentum of cohesion; and we shall still have \( I \) for the point in which all the fibres may be supposed to exert their full cohesion \( f \), and to produce a momentum of cohesion equal to the real momentum of the cohesions actually exerted, and the relative strength of the beam will still be \( f = \frac{fs}{d} \), or \( \frac{fs}{2f} \).

Thus, if the forces be as the squares of the extensions, (still supposed to be as the distances from \( A \)), the curve \( A \Delta d \) will be a common parabola, having \( AB \) for its axis and \( AD \) for the tangent at its vertex. The area \( AD \) will be \( \frac{1}{4} \) of \( AD \times DD \), and in the case of a rectangular beam, \( AO \) will be \( \frac{1}{3} \) of \( AD \), and \( AI \) will be \( \frac{1}{4} \) of \( AD \).

We may observe here in general, that if the forces actually exerted in the instant of fracture be as any power \( q \) of the distance from \( A \), the index \( AI \) will be \( AD = \frac{AD}{q+2} \) for a rectangular beam, and the momentum of cohesion will always be \( ceteris paribus \) (as the breadth and as the square of the depth) nay, this will be the case whenever the action of the fibres \( D \) and \( E \) is expressed by any similar functions of \( d \) and \( s \). This is evident to every reader acquainted with the fluxional calculus.

As far as we can judge from experience, no simple algebraic power of the distance will express the actual cohesions of the fibres. No curve which has either \( AD \) or \( AB \) for its tangent will suit. The observations which we made in the beginning show, that although the curve of fig. 2. must be sensibly straight in the vicinity of the points of intersection with the axis, in order to agree with our observations which show the moderate extensions to be as the extending forces, the curve must be concave towards the axis in all its attractive branches, because it cuts it again. Therefore the curve \( A \Delta d \) of fig. 5. must make a finite angle with \( AD \) or \( AB \), and it must, in all probability, be also concave towards \( AD \) in the neighbourhood of \( d \). It may however be convex in some part of the intermediate arch. We have made experiments on the extensions of different bodies, and find great diversities in this respect: But in all, the moderate extensions were as the forces, and this with great accuracy till the body took a set, and remained longer than formerly when the extending force was removed.

We must now remark, that this correction of the Galilean hypothesis of equal forces was suggested by the bending
bending which is observed in all bodies which are strained transversely. Because they are bent, the fibres on the convex side have been extended. We cannot say in what proportion this obtains in the different fibres. Our most distinct notions of the internal equilibrium between the particles render it highly probable that their extension is proportional to their distance from that fibre which retains its former dimensions. But by whatever law this is regulated, we see plainly that the motions of the stretched fibres must follow the proportions of some function of this distance, and that therefore the relative strength of a beam is in all cases susceptible of mathematical determination.

We also see an intimate connection between the strain and the curvature. This suggested to the celebrated James Bernouilli the problem of the Elastic Curve, i.e., the curve into which an extensible rigid body will be bent by a transverse strain. His solution in the Acta Lipsiae 1694 and 1695, is a very beautiful specimen of mathematical discussion; and we recommend it to the perusal of the curious reader. He will find it very peremptorily treated in the first volume of his works, published after his death, where the wide steps which he had taken in his investigation are explained so as to be easily comprehended. His nephew Daniel Bernouilli has given an elegant abridgment in the Petersburg Memoirs for 1729.

The problem is too intricate to be fully discussed in a work like ours; but it is also too intimately connected with our present subject to be entirely omitted. We must content ourselves with showing the leading mechanical properties of this curve, from which the mathematician may deduce all its geometrical properties.

When a bar of uniform depth and breadth, and of a given length, is bent into an arch of a circle, the extension of the outer fibres is proportional to the curvature; for, because the curves formed by the inner and outer sides of the beam are similar, the circumferences are as the radii, and the radius of the inner circle is to the difference of the radii as the length of the inner circumference is to the difference of the circumferences. The difference of the radii is the depth of the beam, the difference of the circumferences is the extension of the outer fibre, and the inner circumference is supposed to be the primitive length of the beam. Now the second and third quantities of the above analogy, viz., the depth and length of the beam, are constant quantities, as is also their product. Therefore the product of the inner radius and the extension of the outer fibre is also a constant quantity, and the whole extension of the outer fibre is inversely as the radius of curvature, or is directly as the curvature of the beam.

The mathematical reader will readily see, that into whatever curve the elastic bar is bent, the whole extension of the outer fibre is equal to the length of a similar curve, having the same proportion to the thickness of the beam that the length of the beam has to the radius of curvature.

Now let ABCD (fig. 7) be such a rod, of uniform breadth and thickness, firmly fixed in a vertical position, and bent into a curve AEFB by a weight W suspended at B, and of such magnitude that the extremity E has its tangent perpendicular to the action of the weight, or parallel to the horizon. Suppose too that the extensions are proportional to the extending forces. From any two points E and F draw the horizontal ordinates EG, FH. It is evident that the exterior fibres of the sections E e and F f are stretched by forces which are in the proportion of EG to FH (these being the long arms of the levers, and the equal thicknesses E e, F f being the short arms). Therefore (by the hypothesis) their extensions are in the same proportion. But because the extensions are proportional to some similar functions of the distance from the axes of fracture E and F, the extension of any fibre in the section E e is to the contemporaneous extension of the similarly situated fibre in the section F f, as the extension of the exterior fibre in the section E e is to the extension of the exterior fibre in the section F f: therefore the whole extension of E e is to the whole extension of F f as EG to FH, and EG is to FH as the curvature in E to the curvature in F.

Here let it be remarked, that this proportionality of the curvature to the extension of the fibres is not limited to the hypothesis of the proportionality of the extensions to the extending forces. It follows from the extension in the different sections being as some similar function of the distance from the axis of fracture; an assumption which cannot be refused.

This then is the fundamental property of the elastic curve, from which its equation, or relation between the abscissa and ordinate, may be deduced in the usual forms, and all its other geometrical properties. These are foreign to our purpose; and we shall notice only such properties as have an immediate relation to the strain and strength of the different parts of a flexible body, and which in particular serve to explain some difficulties in the valuable experiments of M. Buffon on the Strength of Beams.

We observe, in the first place, that the elastic curve is not a circle, but is gradually more incurvated as it recedes from the point of application B of the strain forces. At B it has no curvature; and if the bar were extended beyond B there would be no curvature there. In like manner, when a beam is supported at the ends and loaded in the middle, the curvature is greatest in the middle; but at the props, or beyond them, if the beam extend farther, there is no curvature. Therefore when a beam projecting 20 feet from a wall is bent to a certain curvature at the wall by a weight suspended at the end, and a beam of the same size projecting 20 feet is bent to the very same curvature at the wall by a greater weight at 10 feet distance, the figure and the mechanical state of the beam in the vicinity of the wall is different in these two cases, though the curvature at the very wall is the same in both. In the first case every part of the beam is incurvated; in the second, all beyond the 10 feet is without curvature. In the first experiment the curvature at the distance of five feet from the wall is three-fourths of the curvature at the wall; in the second, the curvature at the same place is but one-half of that at the wall. This must weaken the long beam in this whole interval of five feet, because the greater curvature is the result of a greater extension of the fibres.

In the next place, we may remark, that there is a certain determinate curvature for every beam which cannot be exceeded without breaking it; for there is a certain separation of two adjoining particles that poises an end to their cohesion. A fibre can therefore
STRENGTH OF MATERIALS.

The ultimate extension of the outer fibres must bear a certain determinate proportion to its length, and this proportion is the same with that of the thickness (or what we have hitherto called the depth) to the radius of ultimate curvature, which is therefore determinate.

A beam of uniform breadth and depth is therefore most incurved where the strain is greatest.

And when of uniform breadth and depth is most incurved where the strain is greatest.

A beam of uniform breadth and depth is therefore most incurved where the strain is greatest. But by changing its form, so as to make the strength of its different sections in the ratio of the strain, it is evident that the curvature may be the same throughout, or may be made to vary according to any law. This is a remark worthy of the attention of the watchmaker. The most delicate problem in practical mechanics is to taper the balance-spring of a watch that its wide and narrow vibrations may be isochronous. Hook's principle ut tensio sic vis is not sufficient when we take the inertia and motion of the spring itself into the account. The figure in which it bends and unbinds has also an influence. Our readers will take notice that the artist aims at an accuracy which will not admit an error of \( \frac{1}{10000} \), and that Harrison and Arnold have actually attained it in several instances. The taper of a spring is at present a nostrum in the hands of each artist, and he is careful not to impart his secret.

Again, since the depth of the beam is thus proportional to the radius of ultimate curvature, this ultimate or breaking curvature is inversely as the depth. It may be expressed by \( \frac{1}{d} \).

When a weight is hung on the end of a prismatic beam, the curvature is nearly as the weight and the length directly, and as the breadth and the cube of the depth inversely; for the strength is \( \frac{1}{d} \). Let us suppose that this produces the ultimate curvature \( \frac{1}{d} \).

Now let the beam be loaded with a smaller weight \( w \), and let the curvature produced be \( C \), we have this analogy \( \frac{1}{d} \) \( w \), \( C \), \( C = \frac{3}{d} \). It is evident that this is also true of a beam supported at the ends and loaded between the props; and we see how to determine the curvature in its different parts, whether arising from the load, or from its own weight, or from both.

When a beam is thus loaded at the end or middle, the loaded point is pulled down, and the space through which it is drawn may be called the deflection. This may be considered as the subtense of the angle of contact, or as the versed sine of the arch into which the beam is bent, and is therefore as the curvature when the length of the arches is given (the flexure being moderate), and as the square of the length of the arch when the curvature is given. The deflection therefore is as the curvature and as the square of the length of the arch jointly; that is, as \( \frac{1}{d} \times \frac{1}{d} \), or as \( \frac{1}{d} \).

The deflection from the primitive shape is therefore as the bending weight and the cube of the length directly, and as the breadth and cube of the depth inversely.

In beams just ready to break, the curvature is as the depth inversely, and the deflection is as the square of strength or the length divided by the depth; for the ultimate curvature at the breaking part is the same whatever is the length; and in this case the deflection is as the square of the length.

We have been the more particular in our consideration of this subject, because of the resulting theorems afford new terms resulting from the finest methods of examining the laws of corpuscular action, that is, for discovering the variation of the force of cohesion by a change of distance. It is true it is not the atomical law, or Hylarchic Principle as it may be called, which is thus made accessible, but the examination of the specific law of the particles of the substance or kind of matter under examination. But even this is a very great point; and coincidences in this respect among the different kinds of matter are of great moment. We may thus learn the nature of the corpuscular action of different substances, and perhaps approach to a discovery of the mechanism of chemical affinities. For that chemical actions are insensible cases of local motion is undeniable, and local motion is the province of mechanical discussion; and, we see that these hidden changes are produced by mechanical forces in many important cases, for we see them promoted or prevented by means purely mechanical. The conversion of bodies into elastic vapour by heat can at times be prevented by a sufficient external pressure. A strong solution of Glauber's salt will congeal in an instant by agitation, giving out its latent heat; and it will remain fluid for ever, and retain its latent heat in a close vessel which it completely fills. Even water will by such treatment freeze in an instant by agitation, or remain fluid for ever by confinement. We know that heat is produced or extricated by friction, that certain compounds of gold or silver with saline matters explode with irresistible violence by the smallest pressure or agitation. Such facts should rouse the mathematical philosopher, and incite him to follow out the conjectures of the illustrious Newton, encouraged by the ingenious attempts of Boscovich; and the proper beginning of this study is to attend to the laws of attraction and repulsion exerted by the particles of cohering bodies, discoverable by experiments made on their actual extensions and compressions. The experiments of simple extensions and compressions are quite insufficient, because the total stretching of a wire is so small a quantity, that the mistake of the 1000th part of an inch occasions an irregularity which deranges any progression so as to make it useless. But by the bending of bodies, a distortion of the 1000th of an inch may be easily magnified in the deflection of the spring ten thousand times. We know that the investigation is intricate and difficult, but not beyond the reach of our present mathematical attainments; and it will give very fine opportunities of employing all the address of analysis. In the 17th century and the beginning of the 18th this was a sufficient excitement to the first geniuses of Europe. The cycloid, the catenaria, the elastic curve, the velaria, the catastics, were reckoned an abundant recompense for much study; and James Bernoulli requested, as an honourable monument, that the logarithmic spiral might be inscribed on his tombstone. The reward for the study to which we now press to incite the mathematicians is the almost unlimited extension of natural science, important in every particular branch. To go no further than our present subject, a great deal of important practical knowledge...
STRENGTH OF MATERIALS.

Strength of the materials is derived from the single observation, that in the moderate extensions which happen before the parts are overstretched, the forces are nearly in the proportion of the extensions or separations of the particles. To return to our subject.

James Bernoulli, in his second dissertation on the elastic curve, calls in question this law, and accommodates his investigation to any hypothesis concerning the relation of the forces and extensions. He relates some experiments of lute strings where the relation was considerably different. Strings of three feet long, stretched by 2, 4, 6, 8, 10 lbs.

But this is a most exceptionable form of the experiment. The strings were twisted, and the mechanism of the extensions is here exceedingly complicated, combined with compressions and with transverse twists, &c. We made experiments on fine slips of the gum caoutchouc, and on the juice of the berries of the white bryony, of which a single grain will draw to a thread of two feet long, and again return into a perfectly round sphere. We measured the diameter of the thread by a microscope with a micrometer, and thus could tell in every state of extension the proportional number of particles in the sections. We found, that through the whole range in which the distance of the particles was changed in the proportion of 1 to 1, the extension did not sensibly deviate from the proportion of the forces. The same thing was observed in the caoutchouc as long as it perfectly recovered its first dimensions. And it is on the authority of these experiments that we presume to announce this as a law of nature.

Dr Robert Hooke was undoubtedly the first who attended to this subject, and assumed this as a law of nature. Mariotte indeed was the first who expressly used it for determining the strength of beams: this he did about the 1679, correcting the simple theory of Galileo. Leibnitz indeed, in his dissertation in the Acta Eruditorum 1684, de Resistenti Solidorum, introduces this consideration, and wishes to be considered as the discoverer; and he is always acknowledged as such by the Bernoullis and others who adhered to his peculiar doctrines. But Mariotte had published the doctrine in the most express terms long before; and Bulfinger, in the Comment. Petropol. 1729, completely vindicates his claim. But Hooke was unquestionably the discoverer of this law. It made the foundation of his theory of springs, announced to the Royal Society about the year 1661, and read in 1666. On this occasion he mentions many things on the strength of bodies as quite familiar to his thoughts, which are immediate deductions from this principle; and among these all the facts which John Bernoulli so vauntingly adduces in support of Leibnitz’s filial dogmas about the force of bodies in motion; a doctrine which Hooke might have claimed as his own, had he not perceived its frivolous inanity.

But even with this first correction of Mariotte, the mechanism of transverse strain is not fully nor justly explained. The force acting in the direction BP (fig. 5.), and bending the body ABCD, not only stretches the fibers on the side opposite to the axis of fracture, but compresses the side AB, which becomes concave by the strain. Indeed it cannot do the one without doing the other: For in order to stretch the fibres at D, there must be some fulcrum, some support, on which the virtual lever BAD may press, that it may tear asunder the stretched fibres. This fulcrum must sustain both the pressure arising from the cohesion of the distended fibres, and also the action of the external force, which immediately tends to cause the prominent part of the beam to slide along the section DA. Let BAD (fig. 5.) be considered as a crooked lever, of which A is the fulcrum. Let an external force be applied at B in the direction BP, and let a force equal to the accumulated cohesion of AB be applied at O in the direction opposite to AB, that is, perpendicular to AO; and let these two forces be supposed to balance each other by the intervention of the lever. In the first place, the force at O must be to the force at B as AB to AO: Therefore, if we make AK equal and opposite to AO, and AL equal and opposite to AB, the common principles of mechanics inform us that the fulcrum A is affected in the same manner as if the two forces AK and AL were immediately applied to it, the force AK being equal to the weight P, and AL equal to the accumulated cohesion actually exerted in the instant of fracture. The fulcrum is therefore really pressed in the direction AM, the diagonal of the parallelogram, and it must resist in the direction and with the force MA; and this power of resistance, this support, must be furnished by the repulsive forces exerted by those particles only which are in a state of actual compression. The force AK, which is equal to the external force P, must be resisted in the direction KA by the lateral cohesion of the whole particles between D and A (the particle D is not only drawn forward but downward). This prevents the part CDAB from sliding down along the section DA.

This is fully verified by experiment. If we attempt to break a long slip of cork, or any such very compressible, expansible body, we always observe it to bulge out on the concave side before it cracks on the other side. If it is a body of fibrous or foliated texture, it seldom fails splintering off on the concave side; and in many cases this splintering is very deep, even reaching half way through the piece. In hard and granulated bodies, such as a piece of freestone, chalk, dry clay, sugar, and the like, we generally see a considerable splinter or shiver fly off from the hollow side. If the fracture be slowly made by a force at B gradually augmented, the formation of the splinter is very distinctly seen. It forms a triangular piece like a16, which generally breaks in the middle. We doubt not but that attentive observation would show that the direction of the crack on each side of A is not very different from the direction AM and its correspondent on the other side. This is by no means a circumstance of idle curiosity, but intimately connected with the mechanism of cohesion.

Let us see what consequences result from this state of things, and the case respecting the strength of bodies. Let DAKC (fig. 8.) represent a vertical section of a prism of compressible materials, such as a piece of timber. Suppose the case, it loaded with a weight P hung at its extremity. Suppose it of such a constitution that all the fibers in AD are in a state of dilatation, while those in AA are in a state of compression. In the instant of fracture the particles at D and E are withheld by forces Dd, Ee, and the particles at A and E repel, resist, or support, with forces Aa, Aa.

Some lines, such as de Aa, will limit all these ordinate,
STRENGTH OF MATERIALS.

Six bars were cut ¼ through, and the cut filled with a wedge of hard wood stuck in with a little force: these broke with 532.

Six bars were cut half through, and the cut was filled in the same manner: they broke with 542.

Six bars were cut 3ths through: these broke with 530.

A batten cut 3ths through, and loaded till nearly broken, was unloaded, and the wedge taken out of the cut. A thicker wedge was put in tight, so as to make the batten straight again by filling up the space left by the compression of the wood: this batten broke with 577 pounds.

From this it is plain that more than 3ds of the thickness (perhaps nearly 4ths) contributed nothing to the strength.

The point A is the centre of fracture in this case; and in order to estimate the strength of the piece, we may suppose that the crooked lever virtually concerned in the strain is DAB. We must find the point I, which is the centre of effort of all the attractive forces, or that point where the full cohesion of AD may be applied, so as to have a momentum equal to the accumulated moments of all the variable forces. We must in like manner find the centres of effort i of the repulsive or supporting forces exerted by the fibres lying between A and D.

It is plain, and the remark is important, that this last centre of effort is the real fulcrum of the lever, although A is the point where there is neither extension nor contraction; for the lever is supported in the same manner as if the repulsions of the whole line AA were exerted at that point. Therefore let S represent the surface of fracture from A to D, and s represent the absolute cohesion of a fibre at D in the instant of fracture. We shall have $\frac{S}{s} \equiv \frac{I + i}{s} = p$, or $I + i = f \cdot S$; that is, the length AB is to the distance between the two centres of effort I and i, as the absolute cohesion of the section between A and D is to the relative strength of the section.

It would be perhaps more accurate to make AI and $i$ equal to the distances of A from the horizontal lines passing through the centres of gravity of the triangles $d$ AD and $d$ AA. It is only in this construction that the points I and i are the centres of real effort of the accumulated attractions and repulsions. But I and i determined as we have done, are the points where the full, equal, actions may be all applied, so as to produce the same moments. The final results are the same in both cases. The attentive and duly informed reader will see that Mr. Buflinger, in a very elaborate dissertation on the strength of beams in the Comment. Metropolitan. 1720, has committed several mistakes in his estimation of the actions of the fibres. We mention this because his reasonings are quoted and appealed to as authorities by Muschenbrock and other authors of note. The subject has been considered by many authors on the continent. We recommend to the reader's perusal the very minute discussions in the Memoirs of the Academy of Paris for 1702 by Varignon, the Memoirs for 1708 by Parent, and particularly that of Coulomb in the Mem. pour les Sciences Etrangères, tom. vii.

It is evident from what has been said above, that if $S$ and $s$ represent the surfaces of the sections above and below A, and if G and g are the distances of their centres of gravity from A, and O and o the distances of their centres...
STRENGTH OF MATERIALS.

The momentum of cohesion will be

\[ \text{strength of centres of oscillation, and } D \text{ and } d \text{ their whole depths,} \]

\[ \frac{3\cdot G\cdot O}{D} = \frac{f_b + \epsilon}{d} \]

\[ \approx p.1. \]

If (as is most likely) the forces are proportional to the extensions and compressions, the distances AI and A\(\Delta\), which are respectively \(\frac{G\cdot O}{D}\) and \(\frac{\epsilon}{d}\), respectively \(\approx \frac{1}{2} DA\) and \(\frac{1}{2} \Delta A\); and when taken together are \(\approx \frac{1}{2} D \Delta\). If, moreover, the extensions are equal to the compressions in the instant of fracture, and the body is a rectangular prism like a common joint or beam, then DA and \(\Delta A\) are also equal; and therefore the momentum of cohesion is \(\frac{1}{6} f\cdot b\cdot d\cdot \frac{1}{2} \cdot d = p.1.\) Hence we obtain this analogy, “Six times the length is to the depth as the absolute cohesion of the section is to its relative strength.”

This consequence further explained.

76

Thus we see that the compressibility of bodies has a very great influence on their power of withstanding a transverse strain. We see that in this most favourable supposition of equal dilatations and compressions, the strength is reduced to one half of the value of what it would have been had the body been incompressible. This is by no means obvious; for it does not readily appear how compressibility, which does not diminish the cohesion of a single fibre, should impair the strength of the whole. The reason, however, is sufficiently convincing when pointed out.

In the instant of fracture a smaller portion of the section is actually exerting cohesive forces, while a part of it is only serving as a fulcrum to the lever, by whose means the strain on the section is produced. We see too that this diminution of strength does not so much depend on the sensible compressibility, as on its proportion to the dilatability by equal forces. When this proportion is small, \(\Delta A\) is small in comparison of \(AD\), and a greater portion of the whole fibre is exerting attractive forces.

The experiments already mentioned, of Du Hamel de Monceau, on battens of willow, show that its compressibility is nearly equal to its dilatability. But the case is not very different in tempered steel. The famous Harrison, in the delicate experiments which he made while occupied in making his longitude watch, discovered that a rod of tempered steel was nearly as much diminished in its length as it was augmented by the same external force. But it is not by any means certain that this is the proportion of dilatation and compression which obtains in the very instant of fracture. We rather imagine that it is not. The forces are nearly as the dilatations till very near breaking; but we think that they diminish when the body is just going to break. But it seems certain that the forces which resist compression increase faster than the compressions, even before fracture. We know incontestably that the ultimate resistances to compression are insuperable by any force which we can employ. The repulsive forces therefore (in their whole extent) increase faster than the compressions, and are expressed by an asymptotic branch of the Boscovichian curve formerly explained. It is therefore probable, especially in the more simple substances, that they increase faster, even in such compressions as frequently obtain in the breaking of hard bodies. We are disposed to think that this is always the case in such bodies as do not fly off in splinters on the concave side; but this must be understood with the exception of the permanent changes of strength which may be made by compression, when the bodies are crippled by it. This always increases the compression itself, and causes the neutral point to shift still more towards \(D\). The effect of this is sometimes very great and fatal.

Experiment alone can help us to discover the proportion between the dilatability and compressibility of bodies. The strain now under consideration seems the best calculated for this research. Thus if we find that a piece of wood an inch square requires 12,000 pounds to tear it asunder by a direct pull, and that 250 pounds will break it transversely by acting 10 inches from the section of fracture, we must conclude that the neutral point \(\Delta\) is in the middle of the depth, and that the attractive and repulsive forces are equal. Any notions that we can form of the constitution of such fibrous bodies as timber, make us imagine that the sensible compressions, including what arises from the bending up of the compressed fibres, is much greater than the real corrupricular extensions. One may get a general conviction of this unexpected proposition by reflecting on what must happen during the fracture. An undulated fibre can only be drawn straight, and then the corrupcular extension begins; but it may be bent up by compression to any degree, the corrupcular compression being little affected all the while. This observation is very important; and though the forces of corrupcular repulsion may be almost insuperable by any compression that we can employ, a sensible compression may be produced by forces not enormous, sufficient to cripple the beam. Of this we shall see very important instances afterwards.

It deserves to be noticed, that although the relative strength of a prismatic solid is extremely different in the portions of three hypotheses now considered, yet the proportional strengths of different pieces follow the same ratio; namely, the direct ratio of the breadth, the direct ratio of the square of the depth, and the inverse ratio of the same re-length. In the first hypothesis (of equal forces) \(f_b \cdot d\), in the second (of attractive forces proportioned to the extensions) it was \(\frac{f_b \cdot d}{2} \); and in the third (equal attractions and repulsions proportional to the extensions and compressions) it was \(\frac{f_b \cdot d}{6} \), or more generally \(\frac{f_b \cdot d}{m \cdot l} \), where \(m\) expresses the unknown proportion between the attractions and repulsions corresponding to an equal extension and compression.

Hence we derive a piece of useful information, which The is confirmed by unexceptionable experience, that the strength of a piece depends greatly on its length, that a piece depends chiefly on that dimension which is in the direction of the strain—folly on its depth. A bar of timber of one inch in breadth and two inches in depth is four times as strong as a bar of only one inch deep, and it is twice as strong as a bar two inches broad and one deep; that is, a joist or lever is always strongest when laid on its edge.

There is therefore a choice in the manner in which the cohesion is opposed to the strain. The general aim in the manner in which the centre of effort is as far from the fulcrum or the neutral point as possible, so as to give the greatest energy or momentum to the cohesion. Thus if cohesion is a triangular bar projecting from a wall is loaded with a weight, the strain
STRENGTH OF MATERIALS.

Strength of weight at its extremity, it will bear thrice as much when one of the sides is uppermost as when it is undermost.

The bar of fig. 6 would be three times as strong if the side AB were uppermost and the edge DC undermost.

Hence it follows that the strongest joint that can be cut out of a round tree is not the one which has the greatest quantity of timber in it, but such that the product of its breadth by the square of its depth shall be the greatest possible. Let ABCD (fig. 9) be the section of this joint inscribed in the circle. AB being the breadth and AD the depth. Since it is a rectangular section, the diagonal BD is a diameter of the circle, and BAD is a right-angled triangle. Let BD be called \(a\), and BA be called \(x\); then AD is \(\sqrt{a^2 - x^2}\).

Now we must have \(AB \times AD\), or \(x \times a\), \(a^2 - x^2\), a maximum. Its fluxion \(d\frac{a^2 - x^2}{dx}\) must be made \(= 0\), or \(a^3 = 3a^2x\), or \(x = a^3\). If therefore we make \(DE = \frac{1}{3} DB\), and draw EC perpendicular to BD, it will cut the circumference in the point C, which determines the depth BC and the breadth CD.

Because BD : BC = CD : CE, we have the area of the section BC\(\times\)CD = BD\(\times\)CE. Therefore the different sections having the same diagonal BD are proportional to their heights CE. Therefore the section BCDA is less than the section BCDo, whose four sides are equal. The joint so shaped, therefore, is both stronger, lighter, and cheaper.

A hollow tube stronger than a solid rod containing the same quantity of matter is stronger than a solid rod containing the same quantity of matter. Let fig. 10, represent the section of a cylindric tube, of which AF and BE are the exterior and interior diameters, and C the centre. Draw BD perpendicular to BC, and join DC. Then, because \(\frac{BD}{CD} = CB\), BD is the radius of a circle containing the same quantity of matter with the ring. If we estimate the strength by the first hypothesis, it is evident that the strength of the tube will be to that of the solid cylinder, whose radius is BD, as \(\frac{BD^4 \times AC}{BD^4 \times BD}\); that is, as AC to BD : for BD\(\times\)expresses the cohesion of the ring of the circle, and AC and BD are equal to distances of the centres of effort (the same with the centres of gravity) of the ring and circle from the axis of the fracture.

The proportion of these strengths will be different in the other hypotheses, and is not easily expressed by a general formula; but in both it is still more in favour of the ring or hollow tube.

The following very simple solution will be readily understood by the intelligent reader. Let O be the centre of oscillation of the exterior circle, \(\omega\) the centre of oscillation of the inner circle, and \(\omega\) the centre of oscillation of the ring included between them. Let M be the quantity of surface of the exterior circle, \(m\) that of the inner circle, and \(\mu\) that of the ring.

We have \(Fw = \frac{mF_0 - mF_0}{\mu} = 5 FC + EC\)

and the strength of the ring \(= \frac{f\mu \times Fw}{2}\), and the strength of the same quantity of matter in the form of a solid cylinder is \(f\mu \times \frac{1}{2} BD\); so that the strength of the ring is to that of the solid rod of equal weight as \(Fw\) to \(\frac{1}{2} BD\), or nearly as FC to BD. This will easily appear by recollecting that FO is \(= \frac{m \times FC}{2}\) (see Rotation), and that the momentum of cohesion is \(f\mu \times FC\) Ca \(= \frac{m \times FC}{2}\) for the inner circle, &c.

Emerson has given a very inaccurate approximation to this value in his Mechanics, 410.

This property of hollow tubes is accompanied also with greater stiffness; and the superiority in strength and stiffness is so much the greater the surrounding shell is thinner in proportion to its diameter.

Here we see the admirable wisdom of the Author of the nature in forming the bones of animal limbs hollow, wisdom in forming the office of levers, and thus opposed to very great transverse strains. By this form they become incomparably stronger and stiffer, and give more room for the insertion of muscles, while they are lighter and therefore more agile; and the same Wisdom has made use of this hollow for other valuable purposes of the animal economy. In like manner the quills in the wings of birds acquire by their thinness the very great strength which is necessary, while they are so light as to give sufficient buoyancy to the animal in the rare medium in which it must live and fly about. The stalks of many plants, such as all the grasses, and many reeds, are in like manner hollow, and thus possess an extraordinary strength. Our best engineers now begin to imitate nature by making many parts of their machines hollow, such as their axles of cast iron, &c. ; and the ingenious Mr. Ramsden now makes the axles and framings of his great astronomical instruments in the same manner.

In the supposition of homogeneous texture, it is plain that the fracture happens as soon as the particles at D are separated beyond their utmost limit of cohesion. This is a determined quantity, and the piece bends till this degree of extension is produced in the outermost fibre. It follows, that the smaller we suppose the distance between A and D, the greater will be the curvature which the beam will acquire before it breaks. Greater depth therefore makes a beam not only stronger but also stiffer. But if the parallel fibres can slide on each other, both the strength and the stiffness will be diminished. Therefore if, instead of one beam DAKC (fig. 3) we suppose two, DABC and AAKB, not cohering, each of them will bend, and the extension of the fibres AB of the upper beam will not hinder the compression of the adjoining fibres AB of the upper beam may the two together therefore not be more than twice formed. How a compound beam may be prevented, if it were possible to unite the two beams all along the beam AB, so that the one shall not slide on the other. This may be done in small works, by gluing them together with a cement as strong as the natural lateral cohesion of the fibres. If this cannot be done (as it cannot in large works), the sliding is prevented by joggling the beams together; that is, by cutting down several rectangular notches in the upper side of the lower beam, and making similar notches in
STRENGTH OF MATERIALS.

Strength of in the under side of the upper beam, and filling up the square spaces with pieces of very hard wood firmly driven in, as represented in fig. 11. Some employ iron bolts by way of joggles. But when the joggles is much harder than the wood into which it is driven, it is very apt to work loose, by widening the hole into which it is lodged. The same thing is sometimes done by scarfing the one upon the other, as represented in fig. 12; but this wastes more timber, and is not so strong, because the mutual hooks which this method form on each beam are very apt to tear each other up. By one or other of these methods, or something similar, may a compound beam be formed, of any depth, which will be almost as stiff and strong as an entire piece.

On the other hand, we may combine strength with pliability, by composing our beam of several thin planks laid on each other, till they make a proper depth, and leaving them at full liberty to slide on each other. It is in this manner that coach-springs are formed, as is represented in fig. 13. In this assemblage there must be no joggles nor bolts of any kind put through the planks or plates; for this would hinder their mutual sliding. They must be kept together by straps which surround them, or by something equivalent.

The preceding observations show the propriety of some maxims of construction, which the artists have derived from long experience. Thus, if a mortise is to be cut out of a piece which is exposed to a cross strain, it should be cut out from that side which becomes concave by the strain, as in fig. 14, but by no means as in fig. 15.

If a piece is to be strengthened by the addition of another, the added piece must be joined to the side which grows convex by the strain, as in fig. 16 and 17.

Before we go any farther, it will be convenient to recall the reader’s attention to the analogy between the strain on a beam projecting from a wall and loaded at the extremity, and a beam supported at both ends and loaded in some intermediate point. It is sufficient on this occasion to read attentively what is delivered in the article Roof, No. 19.—We learn there that the strain on the middle point C (fig. 17, of the present article) of a rectangular beam AB, supported on props at A and B, is the same as if the part CA projected from a wall, and were loaded with the half of the weight W suspended at A. The momentum of the strain is therefore

\[ \frac{1}{4} W \times \frac{1}{4} AB = W \times \frac{1}{4} AB = p \frac{1}{4} \text{ or } \frac{p}{4}. \]

The momentum of cohesion must be equal to this in every hypothesis.

Having now considered in sufficient detail the circumstances which affect the strength of any section of a solid body that is strained transversely, it is necessary to take notice of some of the chief modifications of the strain itself. We shall consider only those that occur most frequently in our constructions.

The strain depends on the external force, and also on the lever by which it acts.

It is evidently of importance, that since the strain is exerted in any section by means of the cohesion of the parts intervening between the section under consideration and the point of application of the external force, the body must be able in all these intervening parts to propagate or excite the strain in the remote sections. In every part it must be able to resist the strain excited in strength of that part. It should therefore be equally strong; and it is useless to have any part stronger, because the piece will nevertheless break where it is not stronger throughout; and it is useless to make it stronger (relatively to its strain) in any part, for it will nevertheless equally fail in the part that is too weak.

Suppose then, in the first place, that the strain arises from a weight suspended at one extremity, while the other end is firmly fixed in a wall. Supposing also the cross sections to be all rectangular, there are several ways of shaping the beam so that it shall be equally strong throughout. Thus it may be equally deep in every part, the upper and under surfaces being horizontal planes. The condition will be fulfilled by making all the horizontal sections triangles, as in fig. 18. The two sides are vertical planes meeting in an edge at the extremity L. For the equation expressing the balance of strain and strength is \[ p = \frac{1}{b} f a. \] Therefore since \[ a = \frac{l}{l+h}, \] and \( b \) (the breadth AD of any section ABCD) must be proportional to \( f \) (or \( AL \)), which it evidently is.

Or, if the beam be of uniform breadth, we must have \( d^2 \) everywhere proportional to \( f \). This will be obtained by making the depths the ordinates of a common parabola, of which \( L \) is the vertex and the length is the axis. The upper or under side may be a straight line, as in fig. 19, or the middle line may be straight, and fig. 19.

Then both upper and under surfaces will be curved. It is almost indifferent what is the shape of the upper and under surfaces, provided the distances between them in every part be as the ordinates of a common parabola.

Or, if the sections are all similar, such as circles, squares, or any other similar polygons, we must have \( d^2 \) or \( b^2 \) proportional to \( f \), and the depths or breadths must be as the ordinates of a cubical parabola.

It is evident that these are also the proper forms for a lever moveable round a fulcrum, and acted on by a force at the extremity. The force comes in the place of the weight suspended in the case already considered; and such levers always are connected with another arm, we readily see that both arms should be fashioned in the same manner. Thus in fig. 18, the piece of timber may be supposed a kind of steel-yard, moveable round a horizontal axis OP, in the front of the wall, and having the two weights P and \( \in \) in equilibrio. The strain occasioned by each at the section in which the axis OP is placed must be the same, and each arm OL and O\( \in \) must be equally strong in all its parts. The longitudinal sections of each arm must be a triangle, a common parabola, or a cubic parabola, according to the conditions previously given.

And, moreover, all these forms are equally strong: For any one of them is equally strong in all its parts, and they are all supposed to have the same section at the front of the wall or at the fulcrum. They are not, however, equally stiff. The first, represented in fig. 18, will bend least upon the whole, and the one formed by the cubic parabola will bend most. But their curvature at the very fulcrum will be the same in all.

It is also plain, that if the lever is of the second or third kind, that is, having the fulcrum at one extremity, it must still be of the same shape; for in abstract mechanics it is indifferent which of the three points is considered as the axis of motion. In every lever the
STRENGTH OF MATERIALS.

The external straining force may be distributed over the beam. To make a beam in such circumstances equally strong in all its parts, the shape must be considerably different from the former.

Thus suppose the beam to project from a wall. If it be of equal breadth throughout, its sides being vertical planes parallel to each other and to the length, the vertical section in the direction of its length must be a triangle instead of a common parabola; for the weight uniformly distributed over the part lying beyond any section, is as the length beyond that section: and since it may all be conceived as collected at its centre of gravity, which is the middle of that length, the lever by which this load acts or strains the section is also proportional to the same length. The strain on the section (or momentum of the load) is as the square of that length. The section must have strength in the same proportion. Its strength being as the breadth and the square of the depth, and the breadth being constant, the square of the depth of any section must be as the square of its distance from the end, and the depth must be as that distance; and therefore the longitudinal vertical section must be a triangle.

But if all the transverse sections are circles, squares, or any other similar figures, the strength of every section, or the cube of the diameter, must be as the square of the length beyond that section, or the square of its distance from the end; and the sides of the beam must be a semicircular parabola.

If the upper and under surfaces are horizontal planes, it is evident that the breadth must be as the square of the distance from the end, and the horizontal sections may be formed by arcs of the common parabola, having the length for their tangent at the vertex.

By recurring to the analogy so often quoted between a projecting beam and a joint, we may determine the proper form of joints which are uniformly loaded through their whole length.

This is a frequent and important case, being the office of joints, rafters, &c.; and there are some circumstances which must be particularly noticed, because they are not so obvious, and have been misunderstood. When a beam AB (fig. 22.) is supported at the ends, and a weight is laid on any point P, a strain is excited in every part of the beam. The load on P causes the beam to press on A and B, and the props react with forces equal and opposite to these pressures. The load at P is to the pressures at A and B as AB to PB and PA, and the pressure at A is to that at B as PB to PA; the beam therefore is in the same state, with respect to strain in every part of it, as if it were resting on a prop at P, and were loaded at the ends with weights equal to the two pressures on the props: and observe, these pressures are such as will balance each other, being inversely as their distances from P. Let P represent the weight or load at P. The pressure on the prop P must be \( P \times \frac{PA}{AB} \). This is therefore the reaction of the prop B, and is the weight which we may suppose suspended at B, when we conceive the beam resting on a prop at P, and carrying the balancing weights at A and B.

The strain occasioned at any other point C, by the load P at P, is the same with the strain at C, by the weight \( P \times \frac{PA}{AB} \) hanging at B, when the beam rests on P, in the manner now supposed; and it is the same if the beam, instead of being balanced on a prop at P, had its part AP fixed in a wall. This is evident. Now we have shown at length that the strain at C, by the weight \( P \times \frac{PA}{AB} \) hanging at B, is \( P \times \frac{PA}{AB} \times BC \). We desire it to be particularly remarked that the pressure at A has no influence on the strain at C, arising from the action of any load between A and C; for it is indifferent how the part AP of the projecting beam PB is supported. The weight at A just performs the same office with the wall in which we suppose the beam to be fixed.

We are thus particular, because we have seen even persons not accustomed to discussions of this kind puzzled in their conceptions of this strain.

Now let the load P be laid on some point p between C and B. The same reasoning shows us that the point is (with respect to strain) in the same state as if the beam were fixed in a wall, embracing the part p B, and a weight \( P \times \frac{pB}{AB} \) were hung on at A, and the strain at C is \( P \times \frac{pB}{AB} \times AC \).

In general, therefore, the strain, on any point C, arising from a load P laid on another point P, is proportional to the rectangle of the distances of P and C from the ends nearest to each. It is \( P \times \frac{PA \times CB}{AB} \), or \( P \times \frac{pB \times CA}{AB} \), according as the load lies between C and A or between C and B.

Cor. 1. The strains which a load on any point P occasions on the points C, c, lying on the same side of P, are as the distances of these points from the end B. In like manner the strains on E and e are as EA and e A.

Cor. 2. The strain which a load occasions in the part on which it rests is as the rectangle of the parts on each side. Thus the strain occasioned at C by a load is to that at D by the same load as AC \( \times \) CB to AD \( \times \) DB. It is therefore greatest in the middle.

Let us now consider the strain on any point C arising from a load uniformly distributed along the beam. Let \( AP \) be represented by \( x \), and \( Pp \) by \( x \), and the whole weight on the beam by a. Then

The weight on \( Pp \) is \( = \frac{\alpha}{AB} \).
STRENGTH OF MATERIALS.

II. If the beam is necessarily loaded at some given strength of point C, and we would have the beam equally able in materials, all its parts to resist the strain arising from the weight at C, we must make the strength of every transverse section between C and either end as its distance from that end. Therefore,

1. If the sides are parallel vertical planes, we must make CD: EF = AC : AE.

2. If the sections are similar, then CD: EF = AC : AE.

3. If the upper and under surfaces are parallel, then, breadth at C : breadth at E = AC : AE.

The same principles enable us to determine the strain and strength of square or circular plates, of different extent, but equal thickness. This may be comprehended in this general proposition.

Similar plates of equal thickness supported all round will carry the same absolute weight, uniformly distributed, or resting on similar points, whatever is their extent, but.

Suppose two similar oblong plates of equal thickness, and let their lengths and breadths be L, l, and B, b determined.

Let their strength or momentum of cohesion be Cc, c from the and the strains from the weights W, w, be S, s.

Suppose the plates supported at the ends only, and resisting fracture transversely. The strains, being as the weights and lengths, are as WL and wL; but their cohesion are as the breadths; and since they are of equal relative strength, we have Wl = wL = b, and Wl = wL = w/L and L = wB : Wb : b since they are of similar shapes L = wB : B : b, and therefore w = W.

The same reasoning holds again when they are also supported along the sides, and therefore holds when they are supported all round (in which case the strength is doubled).

And if the plates are of any other figure, such as circles or ellipses, we need only conceive similar rectangles inscribed in them. These are supported all round by the continuity of the plates, and therefore will sustain equal weights; and the same may be said of the segments which lie without them, because the strengths of any similar segments are equal, their lengths being as their breadths.

Therefore the thickness of the bottoms of vessels holding heavy liquors or grins should be as their diameters, and as the square root of their depths jointly.

Also the weight which a square plate will bear is to that which a bar of the same matter and thickness will bear as twice the length of the bar to its breadth.

There is yet another modification of the strain which the condition of the strain tends to break a body transversely, which is of very frequent occurrence, and in some cases must be very carefully attended to; viz. the strain arising from its own weight.

When a beam projects from a wall, every section is strained by the weight of all that projects beyond it. This may be considered as all collected at its centre of gravity. Therefore the strain on any section is in the joint ratio of the weight of what projects beyond it, and the distance of its centre of gravity from the section.

The determination of this strain and of the strength necessary for withstanding it must be more complicated than the former, because the form of the piece which results from this adjustment of strain and strength influences.
STRENGTH OF MATERIALS.

The general principle must evidently be, that the strength or moment of cohesion of every section must be as the product of the weight beyond it multiplied by the distance of its centre of gravity. For example:

Suppose the beam DLA (fig. 21.) to project from the wall, and that its sides are parallel vertical planes, so that the depth is the only variable dimension. Let \( LB = x \) and \( BZ = y \). The element \( b \) c \( C \) is \( -y \) \( x \). Let \( G \) be the centre of gravity of the part lying without \( B \) b, and \( g \) be its distance from the extremity \( L \). Then \( x - y \) is the arm of the lever by which the strain, in the section \( Bb \). Let \( Bb \) or \( Fy \) be as some power \( m \) of \( LB \); that is, let \( y = x^m \). Then the contents of \( LB b \) is \( \frac{x^{m+1}}{m+1} \). The momentum of gravity round a horizontal axis at \( L \) is \( y x = x^{m+1} x \), and the whole momentum round the axis is \( \frac{x^{m+2}}{m+2} \). The distance of the centre of gravity from \( L \) is had by dividing this momentum by the whole weight, which is \( \frac{x^{m+1}}{m+1} \). The quotient \( g \) is \( \frac{x^{m+1}}{m+1} \). And the distance of the centre of gravity from the section \( Bb \) is \( x - \frac{x^{m+1}}{m+1} = x \frac{m+2}{m+2} = \frac{x}{m+2} \). Therefore the strain on the section \( Bb \) is had by multiplying \( \frac{x^{m+1}}{m+2} \) by \( \frac{x}{m+1} \). The product is \( \frac{x^{2m+1}}{m+2} \). This must be as the square of the depth, or as \( y^2 \). But \( y \) is as \( x^m \), and \( y^2 \) as \( x^{2m} \). Therefore we have \( m+2 = 2m \), and \( m = 2 \); that is, the depth must be as the square of the distance of the extremity, and the curve \( LDA \) is a parabola touching the horizontal line in \( L \).

It is easy to see that a conoid formed by the rotation of this figure round \( DL \) will also be equally able in every section to bear its own weight.

We need not prosecute this farther. When the figure of the piece is given, there is no difficulty in finding the strain; and the circumstance of equal strength to resist this strain is chiefly a matter of curiosity.

It is evident, from what has already been said, that a projecting beam becomes less able to bear its own weight, as it projects farther. Whatever may be the strength of the section \( DA \), the length may be such that it will break by its own weight. If we suppose two beams \( A \) and \( B \) of the same substance and similar shapes, that is, having their lengths and diameters in the same proportion; and further suppose that the shorter can just bear its own weight; then the longer beam will not be able to do the same. For the strengths of the sections are as the cubes of the diameters, while the strains are as the biquadrates of the diameters; because the weights are as the cubes, and the levers by which these weights act in producing the strain are as the lengths or as the diameters.

These considerations show us, that in all cases where strain is affected by the weight of the parts of the machine or structure of any kind, the smaller bodies are more able to withstand it than the greater; and that the strength of materials, so as to be bound to nature to the size of machines constructed of any given materials. Even when the weight of the parts of the machine is not taken into the small account, we cannot enlarge them in the same proportion does more in all their parts. Thus a steam-engine cannot be doubled able to in all its parts, so as to be still efficient. The pressure which the strain on the piston is quadrupled. If the lift of the pump be also doubled in height while it is doubled in diameter, by the load will be increased eight times, and will therefore exceed the power. The depth of lift therefore, must remain unchanging; and in this case the machine will be of the same relative strength as before, independent of its own weight. For the beam being doubled in all its dimensions, its momentum of cohesion is eight times greater, which is again a balance for a quadruple load acting by a double lever. But if we now consider the increase of the weight of the machine itself, which must be supported, and which must be put in motion by the intervention of its cohesion, we see that the large machine is weaker and less efficient than the small one.

There is a similar limit set by nature to the size of plants and animals formed of the same matter. The cohesion of an herb could not support it if it were increased to the size of a tree, nor could an oak support itself if 40 or 50 times bigger, nor could an animal of the make of a long-legged spider be increased to the size of a man; the articulations of its legs could not support it.

Hence may be understood the prodigious superiority of the small animals both in strength and agility. Even small animals are remarkable for strength and agility. A man by falling twice his own height may break his firmest bones. A mouse may fall 20 times its height without injury; and even the tender mite or wood-louse may fall unhurt from the top of a steeple. But their greatest superiority is in respect of nimbleness and agility. A flea can leap above 500 times its own length, while the strength of the human muscles could not raise the trunk from the ground on limbs of the same construction.

The angular motions of small animals (in which consists their nimbleness or agility) must be greater than those of large animals, supposing the force of the muscular fibre to be the same in both. For supposing them similar, the number of equal fibres will be as the square of their linear dimensions; and the levers by which they act are as their linear dimensions. The energy therefore of the moving force is as the cube of these dimensions. But the momentum of inertia, or \( \int p \cdot r^2 \), is as the 4th power:

Therefore the angular velocity of the greater animals is smaller. The number of strokes which a fly makes with its wings in a second is astonishingly great; yet, being voluntary, they are the effects of its agility.

We have hitherto confined our attention to the simplest form in which this transverse strain can be produced. This was quite sufficient for showing us the mechanism of nature by which the strain is resisted; and a very slight attention is sufficient for enabling us to reduce to this every other way in which the strain can be produced. We shall not take up the reader's time with the application of the same principles to other cases of this strain, but refer him to what has been said in the article ROOPS. In that article we have shown the analogy between the strain on the section of a beam projecting from a wall and loaded at the extremity, and the strain...
STRENGTH OF MATERIALS.

Fig. 21.

Strain on the same section of a beam simply resting on supports at the ends, and loaded at some intermediate point or points. The strain on the middle C of a beam AB (fig. 22.) so supported, arising from a weight laid on there, is the same with the strain which half that weight hanging at B would produce on the same length C if the other end of the beam were fixed in a wall. If therefore 1000 pounds hung on the end of a beam projecting 10 feet from a wall just break it at the wall, it will require 4000 pounds on its middle to break the same beam resting on two props 10 feet asunder.

We have also shown in that article the additional strength which will be given to this beam by extending both ends beyond the props, and there framing it firmly into other pillars or supports. We can hardly add any thing to what has been said in that article, except a few observations on the effects of the obliquity of the external force. We have hitherto supposed it to act in the direction BP (fig. 8.) perpendicular to the length of the beam. Suppose it to act in the direction BP’, oblique to BA. In the article Roof we supposed the strain to be the same as if the force p acted at the distance AB’, but still perpendicular to AB: so it is. But the strength of the section AA is not the same in both cases; for by the obliquity of the action the piece DCKA is pressed to the other. We are not sufficiently acquainted with the corpuscular forces to say precisely what will be the effect of the pressure arising from this obliquity; but we can clearly see, in general, that the point A, which in the instant of fracture is neither stretched nor compressed, must now be farther up, or nearer to D; and therefore the number of particles which are in tension and the number of particles which are in compression is smaller, and therefore the strength is diminished. Therefore, when we endeavour to proportion the strength of a beam to the strain arising from an external force acting obliquely, we make too liberal allowance by increasing this external force in the ratio of AB to AB. We acknowledge our inability to assign the proper correction. But this circumstance is of very great influence. In many machines, and many framings of carpentry, this oblique action of the straining force is unavoidable; and the most enormous strains to which materials are exposed are generally of this kind.

In the frames set up for carrying the ringstones of arches, it is hardly possible to avoid them: for although the judicious engineer disposes his beams so as to sustain only pressures in the direction of their lengths, tending either to crush them or to tear them asunder, it frequently happens that, by the settling of the work, the pieces come to check and bear on each other transversely, tending to break each other across. This we have remarked upon in the article Roof, with respect to a truss by Mr Price (see Roof, No. 49, 41, 45). Now when a cross strain is thus combined with an enormous pressure in the direction of the length of the beam, it is in the utmost danger of snapping suddenly across. This is one great cause of the carrying away of masts. They are compressed in the direction of their length by the united force of the shrouds, and in this state the transverse motion of the wind soon completes the fracture.

When considering the compressing strains to which materials are exposed, we deferred the discussion of the strain on columns, observing that it was not, in the cases which usually occur, a simple compression, but was combined with a transverse strain, arising from the bending of the column. When the column ACB (fig. 23.) rests on the ground at B, and loaded at top with a weight A, acting in the vertical direction AB, is bent into a curve ACB, so that the tangent at C is perpendicular to the horizon, its condition somewhat resembles that of a beam firmly fixed between B and C, and strongly pulled by the end A, so as to bend it between C and A. Although we cannot conceive how a force acting on a straight column AB in the direction AB can bend it, we may suppose that the force acted first in the horizontal direction A b till it was bent to this degree, and that the rope was then gradually removed from the direction A b to the direction AB, increasing the force as much as is necessary for preserving the same quantity of flexure.

The first author (we believe) who considered this important subject with scrupulous attention was the celebrated Euler, who published in the Berlin Memoirs for 1757 his Theory of the Strength of Columns. The general proposition established by this theory is, that columns, the strength of prismatical columns is in the direct quadruplicate ratio of their diameters, and the inverse duplicate ratio of their lengths. He prosecuted this subject in the Petersburgh Commentaries for 1778, confirming his former theory. We do not find that any other author has bestowed much attention on it, all seeming to acquiesce in the determinations of Euler, and to consider the subject as of very great difficulty, requiring the application of the most refined mathematics. Muschenbroek has compared the theory with experiment; but the comparison has been very unsatisfactory, the difference from the theory being so enormous as to afford no argument for its justness. But the experiments do not contradict it, for they are so anomalous as to afford no conclusion or general rule whatever.

To say the truth, the theory can be considered in another light than as a specimen of ingenious and very artful algebraic analysis. Euler was unquestionably the first analyst in Europe for resource and address. He knew this, and enjoyed his superiority, and without scruple admitted any physical assumptions which gave him an opportunity of displaying his skill. The inconsistency of his assumptions with the known laws of mechanism gave him no concern; and when his algebraic processes led him to any conclusion which would make his readers stare, being contrary to all our usual notions, he frankly owned the paradox, but went on in his analysis, saying, "Sed analysi magicus fideendum." Mr Robins has given some very visible instances of this confidence in his analysis, or rather of his confidence in the indolent submission of his readers. Nay, so fond was he of this kind of amusement, that after having published an untenable Theory of Light and Colours, he published several Memoirs, explaining the aberration of the heavenly bodies, and deducing some very wonderful consequences, fully confirmed by experience, from the Newtonian principles, which were opposite and totally inconsistent with his own theory, merely because the Newtonian theory gave him "occasionem analyzis promovere." We are thus severe in our observations, because his theory of the strength of columns is one of the strongest instances of this wanton kind of proceeding, and because his followers in the Academy of St Peterburgh, such as Mr Fuss, Lexill, and others, adopt his conclusions, and merely echo his words. Since the death of Daniel Bernoulli,
STRENGTH OF MATERIALS.

Euler considers the column ACB as in a condition precisely similar to that of an elastic rod bent into the curve by a cord AB connecting its extremities. In this case, there is no mistake. But he then draws CD perpendicular to AB, and considers the strain on the section C as equal to the momentum or mechanical energy of the weight A acting in the direction DB upon the lever CD, movable round the fulcrum C, and tending to tear asunder the particles which cohere along the section C. This is the same principle (as Euler admits) employed by James Bernoulli in his investigation of the elastic curve ACB. Euler considers the strain on the section C as the same with what it would sustain if the same power acted in the horizontal direction EF on a point E as far removed from C as the point D is. We reasoned in the same manner (as has been observed) in the article ROofs, where the obliquity of action was inconsiderable. But in the present case, this substitution leads to the greatest mistakes, and has rendered the whole of this theory false and useless. It would be just if the column were of materials which are incompressible. But it is evident, by what has been said above that by the compression of the parts the real fulcrum of the lever shifts away from the point C, so much more the more as the compression is greater. In the great compressions of loaded columns, and the almost unmeasurable compressions of the truss beams in the centres of bridges, and other cases of chief importance, the fulcrum is shifted far over towards C, so that very few fibres resist the fracture by their cohesion; and these few have a very feeble energy or momentum, on account of the short arm of the lever by which they act. This is a most important consideration in carpentry, yet makes no element of Euler's theory. The consequence of this is, that a very small degree of curvature is sufficient to cause the column or strutt to snap in an instant, as is well known to every experienced carpenter. The experiment by Muschenbroek, which Euler makes use of in order to obtain a measure of strength in a particular instance, from which he might deduce all others by his theorem, is an incontestable proof of this. The force which broke the column is not the twentieth part of what is necessary for breaking it by acting at E in the direction EF. Euler takes no notice of this immense discrepancy, because it must have caused him to abandon the speculation with which he was then amusing himself.

This theory false and useless.

The limits of this work do not afford room to enter minutely upon the refutation of this theory; but we can easily show its uselessness, by its total inconsistency with common observation. It results legitimately from this theory, that if CD have no magnitude, the weight A can have no momentum, and the column cannot be broken. — True, it cannot be broken in this way, snapped by a transverse fracture, if it do not bend; but we know very well that it can be crushed or crumbled, and we see this material frequently happen. This circumstance or event does not enter into Euler's investigation, and therefore the theory is imperfect at least and useless. Had this crumbling been introduced in the form of a physical assumption, every topic of reasoning employed in the process must have been laid aside, as the intelligent reader will easily see. But the theory is not only imperfect, but false. The ordinary reader will be convinced of this by another legitimate consequence of it. Fig. 24. is the same as in Euler's Mechanics, with fig. 106. of Emerson's Mechanics, where this subject is treated on Euler's principles, and represents a crooked piece of matter resting on the ground at F, and loaded at A with a weight acting in the vertical direction AF. It results from Euler's theory that the strains at B, D, E, &c. are as &c. BC, DI, EK, &c. Therefore the strains at G and H are nothing; and this is asserted by Emerson and Euler as a serious truth; and the piece may be thinned ad infinitum in these two places, or, even cut through, without any diminution of its strength. The absurdity of this assertion strikes at first hearing. Euler asserts the same thing with respect to a point of contrary flexure. Farther discussion is (we apprehend) needless.

This theory must therefore be given up. Yet Euler's dissertations on the Petersburgh Commentaries deserve a perusal, both as very ingenious specimens of a peculiar analysis, and because they contain maxims of practice which are important. Although they give an erroneous measure of the comparative strength of columns, they show the immense importance of preventing all bendings, and point out with accuracy where the tendencies to bend are greatest, and how this may be prevented by very small forces, and what a prodigious accession of force this gives the column. There is a valuable paper in the same volume by Fuss on the Strains on framed Carpentry, which may also be read with advantage.

It will now be asked, what shall be substituted in place of this erroneous theory? what is the true proportion of the strength of columns? We acknowledge our inability to give a satisfactory answer. Such can be obtained only by previous knowledge of the laws which control the theory cannot be substituted in place by the knowledge of the absolute compressions producible by a given force; and by a knowledge of the degree of that derangement of parts which is termed crippling. These circumstances are but imperfectly known to us, and there lies before us a wide field of experimental inquiry. Fortunately the force requisite for crippling a beam is prodigious, and a very small lateral support is sufficient to prevent that bending which puts the beam in imminent danger. A judicious engineer will always employ transverse bridle, as they are called, to stay the middle of long beams, which are employed as pillars, struts, or truss beams, and are exposed, by their position, to enormous pressures in the direction of their lengths. Such stays may be observed, disposed with great judgment and economy, in the centres employed by Mr. Perronet in the erection of his great stone arches. He was obliged to correct this omission made by his ingenious predecessor in the beautiful centres of the bridge of Orleans, which we have no hesitation in affirming to be the finest piece of carpentry in the world.
STRENGTH OF MATERIALS.

Experiments 1st and 5th show the strength nearly in the inverse proportion of the lengths, but with a sensible deficiency in the longer pieces.

Experiments 5th and 7th show the strengths proportional to the breadths and the square of the depth.

Experiments 1st and 7th show the same thing, compounded with the inverse proportion of the length: the deficiency relative to the length is not so remarkable here.

Experiments 1st and 2d, and experiments 5th and 6th, show the increase of strength, by fastening the ends, to be in the proportion of 2 to 3. The theory gives the proportion of 2 to 4. But a difference in the manner of fixing may produce this deviation from the theory, which only supposed them to be held down at places beyond the props, as when a joist is held in the walls, and also rests on two pillars between the walls. (See what is said on this subject in the article ROOF, § 19.)

The chief source of irregularity in such experiments is the fibrous, or rather plated texture of timber. It consists of annual additions, whose cohesion with each other is vastly weaker than that of their own fibres. Let Fig. 25. represent the section of a tree, and ABCD, Fig. 29. a b c d the section of two battens that are to be cut out of it for experiment, and let AD and a d be the depths, and DC, d c the breadths. The batten ABCD will be the strongest, for the same reason that an assemblage of planks set edgewise will form a stronger joist than planks laid above each other like the plates of a coach-spring. M. Buffon found by many trials that the strength of ABCD was to that of a b c d (in oak) nearly as 8 to 7. The authors of the different experiments were not careful that their battens had their plates all disposed similarly with respect to the strain. But even with this precaution they would not have afforded sure grounds of computation for large works; for great beams occupy much, if not the whole, of the section of the tree; and from this it has happened that their strength is less than in proportion to that of a small lath or batten. In short, we can trust no experiments but such as have been made on large beams. These must be very rare, for they are most expensive and laborious, and exceed the abilities of most of those who are disposed to study this matter.

But we are not wholly without such authority. M. Buffon and M. Du Hamel, two of the first philosophers and mechanicians of the age, were directed by government to make experiments on this subject, and were supplied with ample funds and apparatus. The relation of their experiments is to be found in the Memoirs of the French Academy for 1740, 1741, 1742, 1768; as also in Du Hamel’s valuable performances sur l’Exploitation des Arbres, et sur la Conservation et le Transport de Bois. We earnestly recommend these dissertations to the perusal of our readers, as containing much useful information relative to the strength of timber, and the best methods of employing it. We shall here give an abstract of M. Buffon’s experiments.
STRENGTH OF MATERIALS.

Mr. Buffon's experiments on bars of sound oak.

He relates a great number which he had prosecuted during two years on small battens. He found that the odds of a single layer, or part of a layer, more or less, or even a different disposition of them, had such influence that he was obliged to abandon this method, and to have recourse to the largest beams that he was able to break. The following table exhibits one series of experiments on bars of sound oak, clear of knots, and four inches square. This is a specimen of all the rest.

Column 1st is the length of the bar in clear feet between the supports.

Column 2d is the weight of the bar (the 2d day after it was felled) in pounds. Two bars were tried of each length. Each of the first three pairs consisted of two cuts of the same tree. The one next the root was always found the heaviest, stiffest, and strongest. Indeed M. Buffon says that this was invariably true, that the heaviest was always the strongest; and he recommends it as a certain (or sure) rule for the choice of timber. He finds that this is always the case when the timber has grown vigorously, forming very thick annual layers. But he also observes that this is only during the advances of the tree to maturity; for the strength of the different circles approaches gradually to equality during the tree's healthy growth, and then it decays in those parts in a contrary order. Our tool-makers assert the same thing with respect to beech: yet a contrary opinion is very prevalent; and wood with a fine, that is, a small grain, is frequently preferred. Perhaps no person has ever made the trial with such minuteness as M. Buffon, and we think that much deference is due to his opinion.

Column 3d is the number of pounds necessary for breaking the tree in the course of a few minutes.

Column 4th is the inches which it bent down before breaking.

Column 5th is the time at which it broke.

M. Buffon had found by numerous trials that oak timber lost much of its strength in the course of drying or seasoning; and therefore, in order to secure uniformity, his trees were all felled in the same season of the year, were squared the day after, and tried the third day. Trying them in this green state, gave him an opportunity of observing a very curious and unaccountable phenomenon. When the weights were laid briskly on nearly sufficient to break the log, a very sensible smoke was observed to issue from the two ends with a sharp hissing noise. This continued all the while the tree was bending and cracking. This shows that the log is affected or strained through its whole length; indeed this must be inferred from its bending through its whole length. It also shows us the great effects of the compression. It is a pity M. Buffon did not take notice whether this smoke issued from the upper or compressed half of the section only, or whether it came from the whole.

We must now make some observations on these experiments, in order to compare them with the theory which we have endeavoured to establish.

M. Buffon considers the experiments with the 5-inch bars as the standard of comparison, having both extended these to greater lengths, and having tried more pieces of each length.

Our theory determines the relative strength of bars of the same section to be inversely as their lengths. But (if we except the five experiments in the first column) we find a very great deviation from this rule. Thus the 5-inch bar of 28 feet long should have half the strength of that of 14 feet, or 2670; whereas it is but 1775. The bar of 14 feet should have half the strength of that of 7 feet, or 5762; whereas it is but 5300. In like manner, the fourth of 1525 is 2881; but the real strength of the 28 feet bar is 1775. We have added a column A, which exhibits the strength which each of the 5-inch bars ought to have by the theory. This deviation is most distinctly seen in fig. 26, where BK is the scale of lengths, B being at the point 7 of the scale and K at 28. The ordinate CB is 11525, and the other ordinates DE, GK, &c. are respectively 7 CB.

The lines DF, GH, &c. are made = 4350, 1775, &c. expressing the strengths given by experiment. The 10 feet bar and the 24 feet bar are remarkably anomalous. But all are deficient, and the defect has an evident progression from the first to the last. The same thing may be shown of the other columns, and even of the first, though
STRENGTH OF MATERIALS.

...though it is very small in that column. It may also be observed in the experiments of Belidor, and in all that we have seen. We cannot doubt therefore of its being a law of nature, depending on the true principles of cohesion, and the laws of mechanics.

But it is very puzzling, and we cannot pretend to give a satisfactory explanation of the difficulty. The only effect which we can conceive the length of a beam to have, is to increase the strain at the section of fracture by employing the intervening beam as a lever. But we do not distinctly see what change this can produce in the mode of the fibres in this section, so as either to change their cohesion or the place of their centre of effort: yet something of this kind must happen.

We see indeed some circumstances which must contribute to make a smaller weight sufficient, in Mr Buffon's experiments, to break a long beam, than in the exact inverse proportion of its length.

In the first place, the weight of the beam itself augments the strain as much as if half of it were added in the form of a weight. Mr Buffon has given the weights of every beam on which he made experiments, which is nearly 74 pounds per cubic foot. But they are very much too small to account for the deviation from the theory. The half weights of the 5-inch beams of 7.14, and 28 feet length are only 45, 92, and 182 pounds; which makes the real strains in the experiments 11560, 5390, and 1936; which are far from having the proportions of 4, 2, and 1.

Buffon says that healthy trees are universally strongest at the root end; therefore, when we use a longer beam, its middle point, where it is broken in the experiment, is in a weaker part of the tree. But the trials of the 4-inch beams show that the difference from this cause is almost insensible.

The length must have some mechanical influence which the theory we have adopted has not yet explained. It may not however be inadequate to the task. The very ingenious investigation of the elastic curve by James Bernoulli and other celebrated mathematicians is perhaps as refined an application of mathematical analysis as we know. Yet in this investigation it was necessary, in order to avoid almost insuperable difficulties, to take the simplest possible case, viz. where the stress is exceedingly small in comparison with the length. If the thickness be considerable, the quantities neglected in the calculus are too great to permit the conclusion to be accurate, or very nearly so. Without being able to define the form into which an elastic body of considerable thickness will be bent, we can say with confidence, that in an extreme case, where the compression in the concave side is very great, the curvature differs considerably from the Bernoullian curve. But as our investigation is incomplete and very long, we do not offer it to the reader. The following table of considerations will, we apprehend, render it highly probable that the relative strength of beams decreases faster than in the inverse ratio of their length. The curious observation by Mr Buffon, of the vapour which issued with a hissing noise from the ends of a beam of green oak, while it was breaking by the load on its middle, shows that the whole length of the piece was affected: indeed it must be, since it is bent throughout. We have shown above, that a certain definite curvature of a beam of a given form is always accompanied by rupture. Now suppose the beam A of 10 feet long, and the beam B of 20 feet long, strength of bent to the same degree, at the place of their fixture in the wall; the weight which hangs on A is nearly double that which must hang on B. The form of any portion, suppose 5 feet, of these two beams, immediately adjoining to the wall, is considerably different. At the distance of 5 feet the curvature of A is 5 of its curvature at the wall. The curvature of B in the corresponding point is 4 of the same curvature at the wall. Through the whole of the intermediate 5 feet, therefore, the curvature of B is greater than that of A. This must make it weaker throughout. It must occasion the fibres to slide more on each other (that it may acquire this greater curvature), and thus affect their lateral union; and therefore those which are stronger will not assist their weaker neighbours. To this we must add, that in the shorter beams the force with which the fibres are pressed laterally on each other is double. This must impede the mutual sliding of the fibres which we mentioned a little ago; and, this lateral compression may change the law of longitudinal cohesion (as will readily appear to the reader who is acquainted with Boscovich's doctrines), and increase the strength of the very surface of fracture, in the same way (however inexplicable) as it does in metals when they are hammered or drawn into wire.

The reader must judge how far these remarks are worthy of his attention. The engineer will carefully keep in mind the important fact, that a beam of quadruple length, instead of having 4th of the strength, has only about 4th; and the philosopher should endeavour to discover the cause of this diminution, that he may give the artist a more accurate rule of computation.

Our ignorance of the law by which the cohesion of the particles changes by a change of distance, hinders us from discovering the precise relation between the curvature and the momentum of cohesion; and all we can do is to multiply experiments, upon which we may establish some empirical rules for calculating the strength of solids, and the momentums of cohesion. Those from which we must reason at present are too few and too anomalous to be the foundation of such an empirical formula. We may, however, observe, that Mr Buffon's experiments gave us considerable assistance in this particular: For if to each of the numbers of the column for the 5-inch beams, corrected by adding half the weight of the beam, we add the constant number 1245, we shall have a set of numbers which are very nearly reciprocals of the lengths. Let 1245 be called c, and let the weight which is known by experiment to be necessary for breaking the 5-inch beam of the length a be called P. We shall have \( P + c \times a = p \). Thus the weight necessary for breaking the 7 foot bar is 11560. This added to 1245, and the sum multiplied by 7, gives 89635. Let \( l \) be 18; then \( 89635 = 1245 \times \frac{3725}{18} = p \), which differs not more than \( \frac{1}{48} \)th from what experiment gives us. This rule holds equally well in all the other lengths except the 10 and 24 feet beams, which are very anomalous. Such a formula is abundantly exact for practice, and will answer through a much greater variety of length, though it cannot be admitted as a true one; because, in a certain very great length, the strength will be nothing. For other sizes
STRENGTH OF MATERIALS.

The constant number must change in the proportion of
Materials. 

The next comparison which we have to make with
the theory is the relation between the strength and the
square of the depth of the section. This is made by
comparing with each other the numbers in any horizontal
line of the table. In making this comparison we
find the numbers of the five-inch bars uniformly greater
than the rest. We imagine that there is something pecu-
lar to these bars: They are in general heavier than
in the proportion of their section, but not so much so as
to account for all their superiority. We imagine that
this set of experiments, intended as a standard for the
rest, has been made at one time, and that the season has
had a considerable influence. The fact however, is that
if this column be kept out, or uniformly diminished
about one-sixteenth in their strength, the different sizes
will deviate very little from the ratio of the square of
the depth, as determined by theory. There is however
a small deficiency in the bigger beams.

We have been thus anxious in the examination of
these experiments, because they are the only ones which
have been related in sufficient detail, and made on a
proper scale for giving us data from which we can de-
duce confidential maxims for practice. They are so
troublesome and expensive that we have little hopes of
seeing their number greatly increased; yet surely our
navy board would do an unspeakable service to the pub-
ic by appropriating a fund for such experiments under
the management of some man of science.

There remains another comparison which is of chief
importance, namely, the proportion between the abso-
late cohesion and the relative strength. It may
be guessed, from the very nature of the thing, that this
must be very uncertain. Experiments on the absolute
strength must be confined to very small pieces, by reason
of the very great forces which are required for tearing
them asunder. The values therefore deduced from them
must be subject to great inequalities. Unfortunately we
have not as yet any experiments; all that we have
to depend on is two passages of Muschenbroek's Essois
de Physique; in one of which he says, that a piece of
sound oak $\frac{4}{5}$ths of an inch square is torn asunder by
1150 pounds; and in the other, that an oak plank 12
inches broad and one thick will just support 189163
pounds. These give for the cohesion of an inch square
15,755 and 15,763 pounds. Bouguer, in his Traité du
Navire, says that it is very well known that a rod of
sound oak one-fourth of an inch square will be torn
asunder by 1000 pounds. This gives 16000 for the
cohesion of a square inch. We shall take this as a
round number, easily used in our computations. Let us
compare this with M. Buffon's trials of beams four
inches square.

The absolute cohesion of this section is 16,000 $\times$ 16
= 256,000. Did every fibre exert its whole force in
the instant of fracture, the momentum of cohesion would
be the same as if it had all acted at the centre of gravity
of the section at 2 inches from the axis of fracture, and
is therefore 51,200. The 4-inch beam, 7 feet long,
was broken by 5312 pounds hung on its middle.
The half of this, or 2656 pounds, would have broken it, if
suspended at its extremity, projecting 35 feet, or 42
inches from a wall. The momentum of this strain is
therefore 2656 $\times$ 42, = 111,552. Now this is in equi-
lbrary with the actual momentum of cohesion, which is
therefore 111,550, instead of 51,200. The strength is
therefore diminished in the proportion of 51,200 to
111,550, or very nearly of 4.5 to 1.

As we are quite uncertain as to the place of the cen-
tre of effort, it is needless to consider the full cohesion
as acting at the centre of gravity, and producing the
momentum 51,200; and we may convert the whole into
a simple multiplier $m$ of the length, and say, as $m$ times
the length is to the depth, so is the absolute cohesion of
the section to the relative strength. Therefore let the abso-
olute cohesion of a square inch be called $f$, the breadth $b$,
the depth $d$, and the length $l$ (all in inches), the relative
strength, or the external force $p$, which balances it, is
$f b d^2$; or in round numbers $f b d^2 = \frac{9}{18}$; for $m = 2 \times 4.59$.

This great diminution of strength cannot be wholly
accounted for by the inequality of the cohesive forces
exerted in the instant of fracture; for in this case we
know that the centre of effort is at $\frac{2}{3}$ of the height in a
rectangular section (because the forces really exerted are
as the extensions of the fibres). The relative strength
would be $\frac{f b d^2}{3 l}$, and $p$ would have been 8127 instead
of 2656.

We must ascribe this diminution (which is three times
greater than that produced by the inequality of the co-
hesive forces) to the compression of the under part of
the beam; and we must endeavour to explain in what
manner this compression produces an effect which seems
so little explicable by such means.

As we have repeatedly observed, it is a matter of
nearly universal experience that the forces actually ex-
certed by the particles of bodies, when stretched or com-
pressed, are very nearly in the proportion of the distan-
tes to which the particles are drawn from their natural
positions. Now, although we are certain that, in
enormous compressions, the forces increase faster than in this
proportion, this makes no sensible change in the present
question, because the body is broken before the com-
pressions have gone so far; nay, we imagine, that the
compressed parts are crippled in most cases even before
the extended parts are torn asunder. Muschenbroek as-
serts this with great confidence with respect to oak, on
the authority of his own experiments. He says, that al-
though oak will suspend half as much again as fir, it will
not support, as a pillar, two-thirds of the load which
fir will support in that form.

We imagine therefore that the mechanism in the
present case is nearly as follows:

Let the beam $D C K \Delta$ (fig. 27) be loaded at its ex-
tremity with the weight $P$, acting in the direction $K P$
perpendicular to $DC$. Let $D \Delta$ be the section of frac-
ture. Let $D A$ be about one-third of $D \Delta$. $A$ will be
the particle or fibre which is neither extended nor com-
pressed. Make $A D = D z = D A$. The triangles
$D A, A z$, will represent the accumulated attracting
and repelling forces. Make $A D = \frac{x}{2}$ and $A z = \frac{x}{2} A$.
The point $I$ will be that to which the full co-
hesion $D d$ or $f$ of the particles in $A D$ must be applied,
so as to produce the same momentum which the variable
forces at $I$, $D$, &c. really produce at their several
points of application. In like manner, $i$ is the circle of sem-
lar effort of the repulsive forces excited by the compres-
sion
STRENGTH OF MATERIALS.

It is most convenient to measure the breadth and depth of a beam in inches, and its length in feet. Since then, a beam four inches square and seven feet between the supports is broken by 5312 pounds, we must conclude that a batten one inch square and one foot between practical supports will be broken by 581 pounds. Then the rule may be for the strength of any other beam of oak, or the weight which will just break it when hung on its middle, is \( 581 \times b^2 \) from Mr. Buffon’s experiments.

But we have seen that there is a very considerable deviation from the inverse proportion of the lengths, and we must endeavour to accommodate our rule to this deviation. We found, that by adding 1245 to each of the ordinates or numbers in the column of the five-inch bars, we had a set of numbers very nearly reciprocal of the lengths; and if we make a similar addition to the other columns in the proportion of the cubes of the sizes, we have nearly the same result. The greatest error (except in the case of experiments which are very irregular) does not exceed \( \frac{3}{10} \)th of the whole. Therefore, for a radical number, add to the 5312 the number 640, which is to 1245 very nearly as 4 to 5. This gives 5952. The 64th of this is 93, which corresponds to a bar of one inch square and seven feet long. Therefore 93 \( \times \frac{7}{8} \) will be the reciprocal corresponding to a bar of one foot. This is 651. Take from this the present empirical correction, which is \( \frac{b^4}{40} \) or 10, and there remains 641 for the strength of the bar. This gives us the general rule \( p = 651 \times \frac{b^2}{7} - 10 \times b^3 \).

Example. Required the weight necessary to break an oak beam eight inches square and 20 feet between the props, \( p = 651 \times \frac{8^2}{20} - 10 \times 8 \times 8^3 \). This is 11545, whereas the experiment gives 11487. The error is very small indeed. The rule is most deficient in comparison with the five inch bars, which we have already said appear stronger than the rest.

The following process is easily remembered by such as are not algebraists.

Multiply the breadth in inches twice by the depth, and call this product \( f \). Multiply \( f \) by 651, and divide by the length in feet. From the quotient take 10 times \( f \). The remainder is the number of pounds which will break the beam.

We are not sufficiently sensible of our principles to be confident that the correction 10 \( f \) should be in the proportion of the section, although we think it most probable. It is quite empirical, founded on Buffon’s experiments. Therefore the safe way of using this rule is to suppose the beam square, by increasing or diminishing its breadth till equal to the depth. Then find the strength by this rule, and diminish or increase it for the change which has been made in its breadth. Thus, there can be no doubt that the strength of the beam given as an example is double of that of a beam of the same depth and half the breadth.

The reader cannot but observe that all this calculation relates to the very greatest weight which a beam will bear for a very few minutes. Mr. Buffon uniformly found that two thirds of this weight sensibly impaired its strength, and frequently broke at the end of two or
STRENGTH OF MATERIALS.

Strength of materials. One-half of this weight brought the beam to a certain bend, which did not increase after the first minute or two, and may be borne by the beam for any length of time. But the beam contracted a bend, of which it did not recover any considerable portion. One-third seemed to have no permanent effect on the beam; but it recovered its rectilinear shape completely, even after having been loaded several months, provided that the timber was seasoned when first loaded; that is to say, one-third of the weight which would quickly break a seasoned beam, or one-fourth of what would break one just felled, may lie on it forever without giving the beam a set.

We have no detail of experiments on the strength of other kinds of timber: only Mr. Buffon says, that fir has about 5/32ths of the strength of oak; Mr. Parent makes it 5/32ths; Emerson, 5/32ths, &c.

We have been thus minute in our examination of the mechanism of this transverse strain, because it is the greatest to which the parts of our machines are exposed. We wish to impress on the minds of artists the necessity of avoiding this as much as possible. They are improving in this respect, as may be seen by comparing the centres on which stone arches of great span are now turned with those of former times. They were formerly a load of mere joists resting on a multitude of posts, which obstructed the navigation, and were frequently losing their shape by some of the posts sinking into the ground. Now they are more generally trusses, where the beams abut on each other, and are relieved from transverse strains. But many performances of eminent artists are still very injudiciously exposed to cross strains. We may instance one which is considered as a fine work, viz. the bridge at Walton on Thames. Here every beam of the great arch is a joist, and it hangs together by framing. The finest piece of carpentry that we have seen is the centre employed in turning the arches of the bridge at Orleans, described by Perronet. In the whole there is not one cross strain. The beam, too, of Hornblower's steam-engine, described in that article, is very scientifically constructed.

IV. The last species of strain which we are to examine is that produced by twisting. This takes place in all axles which connect the working parts of machines. Although we cannot pretend to have a very distinct conception of that modification of the cohesion of a body by which it resists this kind of strain, we can have no doubt that, when all the particles act alike, the resistance must be proportional to the number of particles. For we suppose the two parts ABCD, ABFE (fig. 28.), of the body EFCDE to be of insuperable strength, but cohesion more weakly in the common surface AB, and that one part ABCD is pushed laterally in the direction AB, there can be no doubt that it will yield only there, and that the resistance will be proportional to the surface.

In like manner, we can conceive a thin cylindrical tube, of which KAH (fig. 29.) is the section, as cohesion more weakly in that section than anywhere else. Suppose it to be grasped in both hands, and the two parts twisted round the axis in opposite directions, as we would twist the two joints of a flute, it is plain that it will first fail in this section, which is the circumference of a circle, and the particles of the two parts which are contiguous to this circumference will be drawn from each other laterally. The total resistance will be as the strength of the number of equally resisting particles, that is, as the circumference (for the tube being supposed very thin, there can be no sensible difference between the dilatation of the external and internal particles). We can now suppose another tube within this, and a third within the second, and so on till we reach the centre. If the particles of each ring exerted the same force (by suffering the same dilatation in the direction of the circumference), the resistance of each ring of the section would be as its circumference and its breadth (supposed indefinitely small), and the whole resistance would be as the surface; and this would represent the resistance of a solid cylinder. But when a cylinder is twisted in this manner by an external force applied to its circumference, the external parts will suffer a greater circular extension than the internal; and it appears that this extension (like the extension of a beam strained transversely) will be proportional to the distance of the particles from the axis. We cannot say that this is demonstrable, but we can assign no proportion that is more probable. This being the case, the forces simultaneously exerted by each particle will be as its distance from the axis. Therefore the whole force exerted by each ring will be as the square of its radius, and the accumulated force actually exerted will be as the cube of the radius; that is, the accumulated force exerted by the whole cylinder, whose radius is CA, is to the accumulated force exerted at the same time by the part whose radius is CE, as CA² to CE².

The whole cohesion now exerted is just two-thirds of what it would be if all the particles were exerting the same attractive forces which are just now exerted by the particles in the external circumference. This is plain to any person in the least familiar with the fluxionary calculus. But such as are not may easily see it in this way.

Let the rectangle AC ab be set upright on the surface of the circle along the line CA, and revolve round the axis CC. It will generate a cylinder whose height is CC or AA, and having the circle KAH for its base. If the diagonal CA be supposed also to revolve, it is plain that the triangle CCA will generate a cone of the same height, and having for its base the circle described by the revolution of CA, and the point C for its apex. The cylindrical surface generated by AA will express the whole cohesion exerted by the circumference AHK, and the cylindrical surface generated by EE will express the cohesion exerted by the circumference ELM, and the solid generated by the rectangle CA ab will represent the cohesion exerted by the whole circle AHK, and the cylinder generated by the rectangle AC ab will represent the cohesion exerted by the same surface if each particle had suffered the extension AA.

Now it is plain, in the first place, that the solid generated by the triangle CE is to that generated by AC as CE² to CA². In the next place, the solid generated by AC is two-thirds of the cylinder, because the cone generated by CA is one-third of it.

We may now suppose the cylinder twisted till the particles in the external circumference lose their cohesion. There can be no doubt that it will now be wrenched asunder, all the inner circles yielding in succession. Thus we obtain one useful information, viz. that a body of homogeneous texture resists a simple twist with two-thirds of the force with which it resists an attempt to force one part laterally from the other, or with one-third part
STRENGTH OF MATERIALS.

With what force a body of a homogeneous texture resists a simple twist.

When two cylinders AHK and BNO are wrenched asunder, we must conclude that the external particles of each are just put beyond their limits of cohesion, are equally extended, and are exerting equal forces. Hence it follows, that in the instant of fracture the sum total of the forces actually exerted are as the squares of the diameters.

For drawing the diagonal CE, it is plain that CE = AA expresses the distension of the circumference ELM, and that the solid generated by the triangle CEE expresses the cohesion exerted by the surface of the circle ELM, when the particles in the circumference suffer the extension E equal to AA. Now the solids generated by CA and CE being respectively two-thirds of the corresponding cylinders, are as the squares of the diameters.

Having thus ascertained the real strength of the section, and its relation to its absolute lateral strength, let us examine its strength relative to the external force employed to break it. This examination is very simple in the case under consideration. The straining force must act by some lever, and the cohesion must oppose it by acting on some other lever. The centre of the section may be the neutral point, whose position is not disturbed.

Let F be the force exerted laterally by an exterior particle. Let a be the radius of the cylinder, and x the indeterminate distance of any circumference, and x the indefinitely small interval between the concentric arches; that is, let x be the breadth of a ring and x its radius. The forces being as the extensions, and the extensions as the distances from the axis, the cohesion actually exerted at any part of any ring will be \( f \cdot \frac{x^2}{a} \). The force exerted by the whole ring (being as the circumference or as the radius) will be \( f \cdot \frac{x^2}{a} \). The momentum of cohesion of a ring, being as the force multiplied by its lever, will be \( f \cdot \frac{x^2}{a} \). The accumulated momentum will be the sum or fluent of \( f \cdot \frac{x^2}{a} \); that is, when \( x = a \), it will be \( \frac{1}{4} f a^2 \).

Hence we learn that the strength of an axle, by which it resists being wrenched asunder by a force acting at a given distance from the axis, is as the cube of its diameter.

But farther, \( \frac{1}{4} f a^2 \) is \( = f a^2 \times \frac{1}{4} a \). Now \( f a^2 \) represents the full lateral cohesion of the section. The momentum therefore is the same as if the full lateral cohesion were accumulated at a point distant from the axis by one-fourth of the radius or one-eighth of the diameter of the cylinder.

Therefore let F be the number of pounds which measures the lateral cohesion of a circular inch, d the diameter of the cylinder in inches, and l the length of the lever by which the straining force \( p \) is supposed to act, strength of materials.

We shall have \( F \times \frac{1}{4} d^2 = \frac{p}{l} \), and \( F \frac{d^2}{8} = \frac{p}{l} \).

We see in general that the strength of an axle, by which it resists being wrenched asunder by twisting, is as the cube of its diameter.

We see also that the internal parts are not acting so powerfully as the external. If a hole be bored out of the axle of half its diameter, the strength is diminished only one-eighth, while the quantity of matter is diminished one-fourth. Therefore hollow axles are stronger than solid ones containing the same quantity of matter. Thus let the diameter be 5 and that of the hollow 4; then the diameter of another solid cylinder having the same quantity of matter with the tube is 3. The strength of the solid cylinder of the diameter 5 may be expressed by \( 5^3 = 125 \); of the tube \( 4^3 = 64 \); therefore the strength of the tube is \( 64 \times \frac{1}{6} = 61 \). But the strength of the solid axle of the same quantity of matter and diameter 3 is \( 3^3 = 27 \), which is not half that of the tube.

Engineers, therefore, have of late introduced this improvement in their machines, and the axles of cast iron are all made hollow when their size will admit it. They have the additional advantage of being much stiffer, and of affording much better fixture for the flanges, which are used for connecting them with the wheels or levers by which they are turned and strained. The superiority of strength of hollow tubes over solid cylinders is much greater in this kind of strain than in the former or transverse. In this last case the strength of the tube would be that of the solid cylinder of equal weight as 61 to 32 and a half nearly.

The apparatus which we mentioned on a former occasion for trying the lateral strength of a square inch of solid matter, enabled us to try this theory of twist with all desirable accuracy. The bar which hung down from the pin in the former trials was now placed in a horizontal position, and loaded with a weight at the extremity. Thus it acted as a powerful lever, and enabled us to wrench asunder specimens of the strongest materials. We found the results perfectly conformable to the theory, in as far as it determined the proportional ratio of the resistance to twisting to the simple lateral resistance considerably different; but we found the ratio of the resistance to twisting to the simple lateral resistance considerably different; and it was some time before we discovered the cause.

We had here taken the simplest view that is possible of the action of cohesion in resisting a twist. It is frequently exerted in a very different way. When, for instance, an iron axle is joined to a wooden one by being driven into one end of it, the extensions of the different circles of particles are in a very different proportion. A little consideration will show that the particles in immediate contact with the iron axe are in a state of violent extension; so are the particles of the exterior surface of the wooden part, and the intermediate parts are less strained. It is almost impossible to assign the exact proportion of the cohesive forces exerted in the different parts. Numberless cases can be pointed out where parts of the axle are in a state of compression, and where it is still more difficult to determine the state of the other particles. We must content ourselves with the deductions made from this simple case, which is fortunately the most common. In the experiments just now mentioned.
STRENGTH OF MATERIALS.

It is otherwise if it be of a fibrous texture like timber; the fibres are bent before breaking, being twisted into spirals like a cork screw. The length of the axle has somewhat of the influence of a lever in this case, and it is easier wrenched asunder if long. Accordingly we have found it so; but we have not been able to reduce this influence to calculation.

Our readers are requested to accept of these endea-vours to communicate information on this important and difficult subject. We are duly sensible of their imperfection, but flatter ourselves that we have in many instances pointed out the method which must be pursued for improving our knowledge on this subject; and we have given the English reader a more copious list of experiments on the strength of materials than he will meet with in our language. Many useful deductions might be made from these premises respecting the manner of disposing and combining the strength of materials in our structures. The best forms of joints, mortises, tenons, scarpas; the rules for jogging, tabling, faying, fishing, &c. practised in the delicate art of mast-making, are all founded on this doctrine: but the discussion of these would be equivalent to writing a complete treatise of carpentry. We hope that this will be executed by some intelligent mechanician, for there is nothing in our language on this subject but what is almost contemptible; yet there is no mechanic art that is more susceptible of scientific treatment. Such a treatise, if well executed, could not fail of being well received by the public in this age of mechanical improvement.

STRENGTHENERS, or CORROBORANTS, such medicines as are supposed to add to the firmness of the solids. See MATERIA MEDICA INDEX.

STRETCHING, in Navigation, is generally understood to imply the progression of a ship under a great surface of sail, when close hauled. The difference between this term and steaming, consists apparently in the quantity of sail; which in the latter may be very moderate; but stretching generally signifies excess; as, we saw the enemy at daybreak stretching to the southward under a crowd of sail, &c. Falcóner.

STRETTO, in Italian music, is sometimes used to signify that the measure is to be short and concise, and consequently quick. In this sense it stands opposed to LARGO.

STRIATED LEAF, among botanists, one that has a number of longitudinal furrows on its surface.

STRIKE, a measure of capacity, containing four bushels. Also an instrument used in measuring corn.

STRIX, the Owl; a genus of birds belonging to the order of accipitres. See ORNITHOLOGY INDEX.

The bubo, or great eared owl inhabits inaccessible rocks and desert places, and preys on hares and feathered game. Its appearance in cities was deemed an unlucky omen; Rome itself once underwent a lustration because one of them strayed into the capitol. The ancients had them in the utmost abhorrence; and thought them, like the screech-owls, the messengers of death. Pliny styles it bubo funebris, and noctis monstrum.
STROMBOLI, the most northern of the Lipari islands. It is a volcano, which constantly discharges much fire and smoke. It rises in a conical form above the surface of the sea. On the east side it has three or four little craters ranged near each other, not at the summit, but on the declivity, nearly at two-thirds of its height. But as the surface of the volcano is very rugged and intersected with hollow ways, it may be naturally concluded, that at the time of some great eruption, the summit and a part of this side fell in, in must have happened also at Vesuvius; consequently, the common chimney is at this day on the declivity, although always in the centre of the whole base. It is inhabited notwithstanding its fires; but care is taken to avoid the proximity of the crater, which is yet much to be feared. “I was assured (says M. de Luc) by an Englishman, who, like me, had the curiosity to visit these isles, that the fine weather having invited him and his company to land at Stromboli, they ascended a volcano, whose craters at that time threw out nothing; but that while they were attentively viewing them, unapprehensive of any danger, they were suddenly saluted by such a furious discharge, as to be obliged to retreat with precipitation, and not without one of the company being wounded by a piece of scoria.” Of all the volcanoes recorded in history, Stromboli seems to be the only one that burns without ceasing. Etna and Vesuvius often remain quiet for many months, and even years, without the least appearance of fire; but Stromboli is ever at work, and for ages past has been looked upon as the great lighthouse of those seas. E. Long. 15. 23. N. Lat. 38° 50'.

STROMBUS, a genus of shell-fish. See CONCHOLOGLY Index.

STRONGOLI, a town of the kingdom of Naples, with a bishop’s see. It is situated on a rugged mountain, is about three miles from the sea, and seven north from St. Severino. It is supposed to be the ancient Pteleia, which made a conspicuous figure in the second Punic war by its obstinate resistance against Hannibal. Near its walls Marcellus the rival of Hannibal was slain in a skirmish. E. Long. 17. 26. N. Lat. 39° 20'.

STRONTITIES, or STRONTIAN EARTH, so called from having been discovered at Strontian in Argyllshire in Scotland. See CHEMISTRY Index.

STROPE, in ancient poetry, a certain number of verses, including a perfect sense, and making the first part of an ode. See POETRY, No. 130.

STRUMÆ, scrofulous tumours arising on the neck and throat, constituting what is commonly called the king’s evil. See MEDICINE Index.

STRUMPFIA, a genus of plants belonging to the class Syngenesia. See BOTANY Index.

STRUTHIO, a genus of birds belonging to the order of Grallae. See ORNITHOLOGY Index.

STRUTHIOLA, a genus of plants belonging to the class of Tetrandria. See BOTANY Index.

STRYCHNOS, a genus of plants belonging to the class Pentandria, and in the natural system ranging under the 28th order, Lurideæ. See BOTANY Index.

STRYMON, in Ancient Geography, formerly Coroneia; a river constituting the ancient limits of Macedonia and Thrace; rising in Mount Scornburius (Aristotle). Authors differ as to the modern name of this river.

STRYPE, John, was descended from a German family, born at London, and educated at Cambridge. He was vicar of Low Leyton in Essex, and distinguished himself by his compilations of Lives and Memoirs; in which
which, as Dr Birch remarks, his fidelity and industry
will always give a value to his writings, however desti-
tute they may be of the graces of style. He died in
1737, after having enjoyed his vicarage near 68 years.

Stuart, Dr Gilbert, was born at Edinburgh
in the year 1742. His father Mr George Stuart was
professor of humanity in the university, and a man of
considerable eminence for his classical taste and litera-
ture. For these accomplishments he was probably in-
debted in no small degree to his relation the celebrated
Ruddiman, with whom both he and his son conversed fami-
larily, though they afterwards united to injure his fame.

Gilbert having finished his classical and philosophical
studies in the grammar-school and university, applied
himself to jurisprudence, without following, or probably
intending to follow, the profession of the law. For that
profession he has been represented as unqualified by in-
dolence; by a passion which at a very early period of
life he displayed for general literature; or by boundless
dissipation:—and all these circumstances may have con-
tributed to make him relinquish pursuits in which he
could hope to succeed only by patient perseverance and
strict decorum of manners. That he did not waste his
youth in idleness, is, however, evident from an Histori-
cal Dissertation concerning the Antiquity of the British
Constitution, which he published before he had completed
his twenty-second year, and which had so much merit as
to induce the university of Edinburgh to confer upon the
author, though so young a man, the degree of L.L.D.

After a studious interval of some years, he produced
a valuable work, under the title of A View of Society in
Europe, in its Progress from Rudeness to Refinement;
or, Inquiries concerning the History of Laws, Govern-
ment, and Manners. He had read and meditated with
patience on the most important monuments of the mid-
gle ages; and in this volume (which speedily reached a
second edition) he aimed chiefly at the praise of original-
ity and invention, and discovered an industry that is sel-
dom connected with ability and discernment. About
the time of the publication of the first edition of this
performance, having turned his thoughts to an academ-
ical life, he asked for the professorship of public law in
the university of Edinburgh. According to his own
account he had been promised that place by the min-
ister, but had the mortification to see the professorship
bestowed on another, and all his hopes blasted by the in-
fluence of Dr Robertson, whom he represented as under
obligations to him.

To the writer of this article, who was a stranger to
these rival candidates for historical fame, this part of
the story seems very incredible; as it is not easy to
conceive how it ever could be in the power of Dr
Stuart to render to the learned Principal any essential
service. It was believed indeed by many, who ob-
erved that the illiberal jealousy not unfrequent in
the world of letters, was probably the source of this
opposition; which entirely broke the intimacy of two
persons who, before that time, were understood to
be on the most friendly footing with each other. In-
gratitude, however, is as likely to have been the vice of
Dr Stuart as of Dr Robertson; for we have been told
by a writer, who, at least in one instance, has com-
pletely proved what he affirms, that such was Gilbert
Stuart's laxity of principle as a man, that he considered
ingratitude as one of the most venial sins; such was his
conceit as a writer, that he regarded no one's merits but
his own; such were his disappointments, both as a writer
and a man, that he allowed his peevishness to sour into
malice, and indulged his malevolence till it settled in
corruption.

Soon after this disappointment, Dr Stuart went to
London, where he became from 1768 to 1774 one of the
writers of the Monthly Review. In 1772 Dr Adam,
rector of the high-school at Edinburgh, published a Lat-
in Grammar, which he intended as an improvement of
the famous Ruddiman's. Stuart attacked him in a pamph-
let under the name of Bushby, and treated him with
much severity. In doing this, he was probably actuated
more by some personal dislike of Dr Adam than by re-
gard for the memory of his learned relation; for on
other occasions he showed sufficiently that he had no re-
gard to Ruddiman's honour as a grammarian, editor, or
critic.

In 1774 he returned to his native city, and began the
Edinburgh Magazine and Review, in which he discussed
the liberty and constitution of England, and distinguished
himself by an inquiry into the character of John Knox
the reformer, whose principles he reproved in the severest terms. About this time he revised and published
Soon after he turned his thoughts to the history of Scot-
land, and published Observations concerning its Public
Law and Constitutional History; in which he examined
with a critical care the preliminary book to Dr Robert-
son's History. His next work was The History of the
Reformation; a book which deserves praise for the easy
dignity of the narrative, and for strict impartiality. His
last great work, The History of Scotland from the Estab-
lishment of the Reformation to the Death of Queen
Mary, which appeared in 1782, has been very gene-
really read and admired. His purpose was to vindicate
the character of the injured queen, and expose the
weakness of the arguments by which Dr Robertson had
endeavoured to prove her guilty; but though the style
of this work is his own, it contains very little matter
which was not furnished by Goodall and Tytler; and it
is with the arms which these two writers put into his
hands that Dr Stuart attacked his great antagonist.

In 1782 he once more visited London, and engaged in
the Political Herald and English Review; but the
jaundice and dyspepsy increasing on him, he returned by
sea to his native country, where he died in the house of
his father on the 13th of August 1786.

In his person Dr Stuart was about the middle size and
justly proportioned. His countenance was modest and
expressive, sometimes glowing with sentiments of friend-
ship, of which he was truly susceptible, and at others
daring that satire and indignation at folly and vice which
appear in some of his writings. He was a boon com-
panion; and, with a constitution that might have stood
the shock of ages, he fell a premature martyr to intem-
perance. His talents were certainly great, and his writ-
ings are useful; but he seems to have been influenced
more by passion than prejudice, and in his character
there was not much to be imitated.

STUCCO, in building, a composition of white mar-
ble pulverised, and mixed with plaster of lime; and the
whole being sifted and wrought up with water, is to be
used like common plaster: this is called by Pliny mar-
moratum opus, and albarium opus.
A patent was granted to Mr. B. Higgins for inventing a new kind of stucco, or water cement, more firm and durable than any heretofore. Its composition, as extracted from the specification signed by himself, is as follows: "Drift-sand, or quarry (A) sand, which consists chiefly of hard quartzose, flat-faced grains with sharp angles; which is the freest, or may be most easily freed by washing, from clay, salts, and calcareous, gypseous, or other grains less hard and durable than quartz; which contains the smallest quantity of pyrites or heavy metallic matter inseparable by washing; and which suffers the smallest diminution of its bulk in washing in the following manner—is to be preferred before any other.

And where a coarse and a fine sand of this kind, and corresponding in the size of their grains with the coarse and fine sands hereafter described, cannot be easily procured, let such sand of the foregoing quality be chosen as may be sorted and cleansed in the following manner:

Let the sand be sifted in streaming clear water, through a sieve which shall give passage to all such grains as do not exceed one-sixteenth of an inch in diameter; and let the stream of water and the sifting be regulated so that all the sand, which is much finer than the Lynn-sand commonly used in the London glass-houses, together with clay and every other matter particularly lighter than sand, may be washed away with the stream, whilst the purer and coarser sand, which passes through the sieve, subsides in a convenient receptacle; and whilst the coarse rubbish and rubble remain on the sieve to be rejected.

Let the sand which thus subsides in the receptacle, be washed in clean streaming water through a finer sieve, so as to be further cleansed and sorted into two parcels; a coarser, which will remain in the sieve which is to give passage to such grains of sand only as are less than one-thirtieth of an inch in diameter, and which is to be saved apart under the name of coarse-sand; and a finer, which will pass through the sieve and subside in the water, and which is to be saved apart under the name of fine sand.—Let the coarse and the fine sand be dried separately, either in the sun or on a clean iron-plate, set on a convenient surface, in the manner of a sand-heap (B).

"Let lime be chosen (C) which is stone-lime, which heats the most in slaking, and slakes the quickest when duly watered; which is the freshest made and closest kept; which dissolves in distilled vinegar with the least effervescence, and leaves the smallest residue insoluble, and in this residue the smallest quantity of clay, gyspum or martial matter.

"Let the lime chosen according to these important rules be put in a brass-wired sieve to the quantity of 14 pounds. Let the sieve be finer than either of the foregoing; the finer, the better it will be: let the lime be slaked (D) by plunging it in a butt filled with soft water, and raising it out quickly and suffering it to heat and fume, and by repeating this plunging and raising alternately, and agitating the lime, until it be made to pass through the sieve into the water; and let the part of the lime which does not easily pass through the sieve be rejected: and let fresh portions of the lime be thus used, until as many (E) ounces of lime have passed through the sieve as there are quarts of water in the butt. Let the water thus impregnated stand in the butt closely covered (F) until it becomes clear; and through wooden (G) cocks placed at different heights in the butt, let the clear liquor be drawn off as fast (H) and

(A) "This is commonly called pit-sand.

(B) "The sand ought to be stirred up continually until it is dried, and is then to be taken off; for otherwise the evaporation will be very slow, and the sand which lies next the iron-plate, by being overheated, will be discoloured.

(C) "The preference given to stone-lime is founded on the present practice in the burning of lime, and on the closer texture of it, which prevents it from being so soon injured by exposure to the air as the more spongy chalk-lime is; not on the popular notion that stone-lime has something in it whereby it excels the best chalk in the cementing properties. The gyspum contained in lime-stone remains unaltered, or very little altered, in the lime, after the burning; but it is not to be expected that clay or martial matter should be found in their native state in well-burned lime; for they concrete or vitrify with a part of the calcareous earth, and constitute the hard grains or lumps which remain undissolved in weak acids, or are separable from the slaked lime by sifting it immediately through a sieve.

(D) "This method of impregnating the water with lime is not the only one which may be adopted. It is, however, preferred before others, because the water clears the sooner in consequence of its being warmed by the slaking lime; and the gyspous part of the lime does not diffuse itself in the water so freely in this way as it does when the lime is slaked to fine powder in the common method, and is then blended with the water; for the gyspous part of the lime slakes at first into grains rather than into fine powder, and will remain on the sieve after the pure lime has passed through, long enough to admit of the intended separation; but when the lime is otherwise slaked, the gyspous grains have time to slake to a finer powder, and passing through the sieve, dissolve in the water along with the lime. I have imagined that other advantages attended this method of preparing the lime-water, but I cannot yet speak of them with precision.

(E) "If the water contains no more acidulous gas than is usually found in river or rain water, a fourth part of this quantity of lime, or less, will be sufficient.

(F) "The calcareous crust which forms on the surface of the water ought not to be broken, for it assists in excluding the air, and preventing the absorption of acidulous gas whereby the lime-water is spoiled.

(G) "Brass cocks are apt to colour a part of the liquor.

(H) "Lime-water cannot be kept many days unimpaired, in any vessels that are not perfectly air-tight. If the liquor be drawn off before it clears, it will contain whiting, which is injurious; and if it be not instantly used
I call the cementing liquor (f). The freer the water is from saline matter, the better will be the cementing liquor made with it.

Let 56 pounds of the asforesaid chosen lime be slaked, by gradually sprinkling on it, and especially on the unslaked pieces, the cementing liquor, in a close (k) clean place. Let the slaked part be immediately (l) sifted through the last-mentioned fine brass-wire sieve: Let the lime which passes be used instantly, or kept in air-tight vessels, and let the part of the lime which does not pass through the sieve be rejected (m).

This finer richer part of the lime which passes through the sieve I call purified lime.

Let bone-ash be prepared in the usual manner, by grinding the whitest burnt bones, but let it be sifted, to be much finer than the bone-ash commonly sold for making copals.

The most eligible materials for making my cement being thus prepared, take 36 pounds of the coarse sand and 42 pounds of the fine sand; mix them on a large plank of hard wood placed horizontally; then spread the sand so that it may stand to the height of six inches, with a flat surface on the plank; wet it with the cementing liquor; and let any superficial quantity of the liquor, which the sand in the condition described cannot retain, flow away off the plank. To the wettest sand add 14 pounds of the putrefied lime in several successive portions, mixing and beating them up together in the mean time with the instruments generally used in making fine mortar: then add 14 pounds of the bone-ash in successive portions, mixing and beating all together. The quicker and the more perfectly these materials are mixed and beaten together, and the sooner the cement thus formed is used, the better (n) it will be. I call this water-cement coarse-grained, which is to be applied in building, pointing, plastering, stuccoing, or other work, as mortar and stucco now are; with this difference chiefly, that as this cement is shorter than mortar or common stucco, and dries sooner, it ought to be worked expeditiously in all cases; and in stuccoing, it ought to be laid on by sliding the trowel upwards on it; that the materials used along with this cement in building, or the ground on which it is to be laid in stuccoing, ought to be well wetted with the cementing liquor in the instant of laying on the cement; and that the cementing liquor is to be used when it is necessary to moisten the cement, or when a liquid is required to facilitate the floating of the cement.

When such cement is required to be of a finer texture, take 58 pounds of the fine sand, wet it with the cementing liquor, and mix it with the purified lime and the bone-ash in the quantities and in the manner above described; with this difference only, that 15 pounds of lime, or (o) thereof, are to be used instead of 14 pounds, if the greater part of the sand be as fine as Lynn-sand. This I call water-cement fine-grained. It is to be used in giving the last coating, or the finish to any work intended to imitate the finer grained stones or stucco. But it may be applied to all the uses of the water-cement coarse-grained, and in the same manner.

When for any of the foregoing purposes of pointing, building, &c. such a cement is required much cheaper and coarser grained, then much coarser clean sand than the foregoing coarse sand, or well-washed fine rubble, is to be provided. Of this coarse sand or rubble, take 56 pounds, of the foregoing coarse sand 28 pounds, and of the fine sand 14 pounds; and after mixing these, and wetting them with the cementing liquor in the foregoing manner, add 14 pounds, or somewhat less, of the (p) purified lime, and then 14 pounds or somewhat less

used after it is drawn liquid from the butt into open vessels, it will grow turbid again, and deposit the lime changed to whiting by the gas absorbed from the air. The calcareous matter which subsides in the butt resembles whiting the more nearly as the lime has been more sparingly employed; in the contrary circumstances, it approaches to the nature of lime; and in the intermediate state, it is fit for the common composition of the plasterers for inside stucco.

(1) At the time of writing this specification, I preferred this term before that of lime water, on grounds which I had not sufficiently examined.

(k) The vapor which arises in the slaking of lime contributes greatly to the slaking of these pieces which lie in its way; and an unnecessary waste of the liquor is prevented, by applying it to the lime heaped in a pit or in a vessel, which may restrain the issue of the vapor, and direct it through the mass. If more of the liquor be used than is necessary to slake the lime, it will create error in weighing the slaked powder, and will prevent a part of it from passing freely through the sieve. The liquid is therefore to be used sparingly, and the lime which has escaped its action is to be sprinkled apart with fresh liquor.

(l) When the aggregation of the lump of lime is thus broken, it is impaired much sooner that it is in the former state, because the air more freely pervades it.

(m) Because it consists of heterogenous matter or of ill-burnt lime; which last will slake and pass through the sieve, if the lime be not immediately sifted after the slaking, agreeable to the text.

(n) These proportions are intended for a cement made with sharp sand, for incrustation in exposed situations, where it is necessary to guard against the effects of hot weather and rain. In general, half this quantity of bone-ashes will be found sufficient; and although the incrustation in this latter case will not harden deeply so soon, it will be ultimately stronger, provided the weather be favourable.

(o) The injuries which lime and mortar sustain by exposure to the air, before the cement is finally placed in a quiescent state, are great; and therefore our cement is the worse for being long beaten, but the better as it is quickly beaten until the mixture is effected, and no longer.

(p) The quantity of bone-ashes is not to be increased with that of the lime; but it is to be lessened as the exposure and purposes of the work will admit.

(q) Because less lime is necessary, as the sand is coarser.
of the bone-ash, mixing them together in the manner already described. When my cement is required to be white, white sand, white lime, and the whitest bone-ash are to be chosen. Gray sand, and gray bone-ash formed of half-burnt bones, are to be chosen to make the cement gray; and any other colour of the cement is obtained, either by choosing coloured sand, or by the admixture of the necessary quantity of coloured tale in powder, or of coloured, vitreous, or metallic powders, or other durable colouring ingredients commonly used in paint.

To the end that such a water-cement as I have described may be made as useful as it is possible in all circumstances; and that no person may imagine that my claim and right under these letters-patent may be eluded by diverse variations, which may be made in the foregoing process without producing any notable defect in the cement; and to the end that the principles of this art, as well as the art itself, of making my cement, may be gathered from this specification and perpetuated to the public; I shall add the following observations:

This my water-cement, whether the coarse or fine-grained, is applicable in forming artificial stone, by making alternate layers of the cement and of flint, hard stone, or brick, in moulds of the figure of the intended stone, and by exposing the masses so formed to the open (q) air to harden.

When such cement is required for water (a) fences, two-thirds of the prescribed quantity of bone-ashes are to be omitted; and in the place thereof an equal measure of powdered terras is to be used; and if the sand employed be not of the coarsest sort, more terras must be added, so that the terras shall be by weight one-sixth part of the weight of the sand.

When such a cement is required of the finest grain (s) or in a fluid form, so that it may be applied with a brush, flint powder, or the powder of any quartzite or hard earthy substance, may be used in the place of sand; but in a quantity smaller, as the flint or other powder is finer; so that the flint-powder, or other such powder, shall not be more than six times the weight of the lime, nor less than four times its weight. The greater the quantity of lime within these limits, the more will the cement be liable to crack by quick drying, and vice versa.

Where such sand as I prefer cannot be conveniently procured, or where the sand can be conveniently washed and sorted, that sand which most resembles the mixture of coarse and fine sand above prescribed, may be used as I have directed, provided due attention is paid to the quantity of the lime, which is to be greater (t) as the quantity is finer, and vice versa.

Where sand cannot be easily procured, any durable stony body, or baked earth grossly powdered (u), and sorted nearly to the sizes above prescribed for sand, may be used in the place of sand, measure for measure, but not weight for weight, unless such gross powder be as heavy specifically as sand.

Sand may be cleansed from every softer, lighter, and less durable matter, and from that part of the sand which is too fine, by various methods preferable (x), in certain circumstances, to which I have described.

Water may be found naturally free from fixable gas, seleine, or clay; such water may, without any notable inconvenience, be used in the place of the cementing liquor; and water approaching this state will not require so much lime as I have ordered to make the cementing liquor; and a cementing liquor sufficiently useful may be made by various methods of mixing lime and water in the described proportions, or nearly so.

When stone-lime cannot be procured, chalk-lime, or shell-lime, which best resembles stone-lime, in the characters above written of lime, may be used in the manner

---

(a) "But they must not be exposed to the rain until they are almost as strong as fresh Portland stone; and even then they ought to be sheltered from it as much as the circumstances will admit. These stones may be made very hard and beautiful, with a small expence of bone-ash, by soaking them, after they have dried thoroughly and hardened, in the lime liquor, and repeating this process twice or thrice, at distant intervals of time. The like effect was experienced in incrustations.

(b) "In my experiments, mortar made with terras-powder, in the usual method, does not appear to form so strong a cement for water-fences as that made, according to the specification, with coarse sand; and I see no more reason for avoiding the use of sand in terras-mortar, than there would be for rejecting stone from the embankment. The bone-ashes meant in the place are the dark gray or black sort. I am not yet fully satisfied about the operation of them in this instance.

(c) "The qualities and uses of such fine calcareous cement are recommended chiefly for the purpose of smoothing and finishing the stronger crustaceous works, or for washing walls to a lively and uniform colour. For this last intention, the mixture must be as thin as new cream, and laid on briskly with a brush, in dry weather; and a thick and durable coat is to be made by repeated washing; but is not to be attempted by using a thicker liquor; for the coat made with this last is apt to scale, whilst the former endures the weather much longer than any other thin calcareous covering that has been applied in this way. Fine yellow-ochre is the cheapest colouring ingredient for such wash, when it is required to imitate Bath-stone, or the warm-white stones.

(d) "If sea-sand be well washed in fresh water, it is as good as any other round sand.

(e) "The cement made with these and the proper quantities of purified lime and lime-water, are inferior to the best, as the grains of these powders are more perishable and brittle than those of sand. They will not therefore be employed, unless for the sake of evasion, or for want of sand: in this latter case, the finer powder ought to be washed away.

(f) "This and the next paragraph is inserted with a view to evasions, as well as to suggest the easier and cheaper methods which may be adopted in certain circumstances, by artists who understand the principles which I endeavour to teach.
manner described, except that fourteen pounds and a
half of chalk-lime will be required in the place of four-
teen pounds of stone-lime. The proportion of lime which
I have prescribed above may be increased without incon-
venience, when the cement or stucco is to be applied
where it is not liable to dry quickly; and in the con-
trary circumstance, this proportion may be diminished;
and the defect of lime in quantity or quality may be
very advantageously supplied (γ), by causing a consi-
derable quantity of the cementing liquor to soak into
the work, in successive portions, and at distant intervals
of time, so that the calcareous matter of the cementing
liquor, and the matter attracted from the open air, may
fill and strengthen the work.

"The powder of almost every well-dried or burnt ani-
mal substance may be used instead of bone-ash; and sev-
eral earthly powders, especially the micaceous and the
metallic; and the elixited ashes of divers vegetables whose
earth will not burn to lime; and the ashes of mineral
fuel, which are of the calcareous kind, but will not
burn to lime, will answer the end of bone-ash in some
degree.

"The quantity of bone-ash described may be lessened
without injuring the cement, in those circumstances espe-
cially which admit the quantity of lime to be lessened,
and in those wherein the cement is not liable to dry
quickly. And the art of remediuyng the defects of lime
may be advantageously practised to supply the deficiency
of bone-ash, especially in building, and in making arti-
ficial stone with this cement."

STUD, in the manage, a collection of breeding horses
and mares.

STUDDING-SAILS, certain light sails extended, in
moderate and steady breezes, beyond the skirts of the
principal sails, where they appear as wings upon the
yard-arms.

STUFF, in commerce, a generic name for all kinds
of fabrics of gold, silver, silk, wool, hair, cotton, or
thread, manufactured on the loom; of which number
are velvets, brocades, moheirs, satins, taffetas, cloths,
serges, &c.

STUKELY, DR WILLIAM, a celebrated antiq-
uiarian, descended from an ancient family in Lincolnshire,
was born at Holbeech in 1687, and educated in Bemst
college, Cambridge. While an under graduate, he often
indulged a strong propensity to drawing and designing;
but made physic his principal study, and first began to
practise at Boston in his native country. In 1717 he
removed to London, where, on the recommendation of
Dr Mead, he was soon after elected a fellow of the
Royal Society; he was one of the first who revived that
of the antiquarians in 1718, and was their secretary for
many years during his residence in town. In 1729 he took
holy orders by the encouragement of Archbishop Wake;
and was soon after presented by Lord-chancellor King
with the living of All-Saints in Stamford. In 1741 he
became one of the founders of the Egyptian society,
which brought him acquainted with the benevolent duke
of Montague, one of the members; who prevailed on
him to leave Stamford, and presented him to the living

of St George the Martyr, Queen Square. He died of a
stroke of the palsy in 1765. In his medical capacity,
his Dissertation on the Spleen was well received; and
his Itinerarium Curiosum, the first fruit of his juvenile
excursions, was a good specimen of what was to be ex-
pected from his riper age. His great learning, and pro-
found researches into the dark remains of antiquity,
enabled him to publish many elaborate and curious
works: his friends used to call him the arch-druid of
his age. His discourses, intitled Paleographia Sacra,
on the vegetable creation, bespeak him a botanist, phi-
losopher, and divine.

STUM, in the wine-trade, denotes the unfermented
juice of the grape after it has been several times racked
off and separated from its sediment. The casks are for
this purpose well matched or fumigated with brimstone
every time, to prevent the liquor from fermenting, as it
would otherwise readily do, and become wine. See
MUST.

STUPIDITY. The Greek word μουρος cor-
responds most with our English word stupidity or foolis-
whes, when used to express that state of mind in which
the intellects are defective. The immediate causes are
said to be, a deficiency of vital heat, or a defect in the
brain. Stupid children sometimes become sprightly
youths; but if stupidity continues to the age of puber-
ty, it is hardly ever removed. If stupidity follows up
on a violent passion, an injury done to the head, or oth-
er evident cause, and if it continues long, it becomes in-
curable. But the stupidity which consists in a loss of
memory, and succeeds a lethargy, spontaneously ceases
when the lethargy is cured.

STUPOR, a numbness in any part of the body, wheth-
er occasioned by ligatures obstructing the blood's mo-
tion, by the palsy, or the like.

STUPPA, or STUPE, in Medicine, is a piece of cloth
dipped in some proper liquor, and applied to an affected
part.

STURDY, a distemper to which cattle are subject,
called also the turning evil. See FARRIER INDEX.

STURGEON. See ACCIPENSER, ICHTHYOLOGY
Index.

STURMIUS, JOHN, a learned philologer and rhet-
orician, was born at Sileia in Eisel near Cologne in
1507. He studied at first in his native country with the
sons of Count de Manderscheid, whose receiver his fa-
ther was. He afterwards pursued his study at Liege in
the college of St Jerome, and then went to Louvain in
1524. Five years he spent there, three in learning and
two in teaching. He set up a printing-press with Rodger
Resceus professor of the Greek tongue, and printed sev-
eral Greek authors. He went to Paris in 1529, where
he was highly esteemed, and read public lectures on the
Greek and Latin writers, and on logic. He married
there, and kept a great number of boarders: but as he
liked what were called the new opinions, he was more
than once in danger; and this undoubtedly was the rea-
son why he removed to Strasburg in 1537, in order to
take possession of the place offered him by the magi-
strates. The year following he opened a school, which
became

(γ) "This practice is noticed, as the remedy which may be used for the defects arising from evasive mea-
sures, and as the method of giving spongy incrustations containing bone-ashus the greatest degree of hardness."
became famous, and by his means obtained of Maximilian II. the title of an university in 1566. He was very well skilled in polite literature, wrote Latin with great purity, and was a good teacher. His talents were not confined to the school; for he was frequently in the company of the great men of Germany and foreign countries, and discharged these employments with great honour and diligence. He showed extreme charity to the refugees on account of religion: He not only laboured to assist them by his advice and recommendations; but he even impoverished himself for them. He died in his 82d year, after he had been for some time blind. He published many books; the principal of which are, 1. Partitiones Dialecticae. 2. De Educatione Principium. 3. De Nobilitate Anglicana. 4. Linguae Latinae resolutae Ratio. 5. Excellent Notes on Aristotle’s and Hermogenes’s Rhetoric, &c.

He ought not to be confounded with John Sturmius, a native of Mechlin, and physician and professor of mathematics at Louvain, who also wrote several works.

STURNUS, the Starling; a genus of birds belonging to the order of passerines. See Ornithology Index.

STYLE, or Stythe, in the eye. See Crithe.

STYLE, a word of various significations, originally deduced from stylos, a kind of bodkin wherein the ancients wrote on plates of lead, or on wax, &c. and which is still used to write on ivory-leaves and paper prepared for that purpose, &c.

Style, in dialling, denotes the gnomon or cock of a dial raised on the plane thereof to project a shadow.

STYLE, in Botany. See Botany.

Style, in language, is the peculiar manner in which a man expresses his conceptions. It is a picture of the ideas which rise in his mind, and of the order in which they are there produced.

The qualities of a good style may be ranked under two heads: perspicuity and ornament. It will readily be admitted, that perspicuity ought to be essentially connected with every kind of writing; and to attain it, attention must be paid, first to single words and phrases, and then to the construction of sentences. When considered with respect to words and phrases, it requires these three qualities; purity, propriety, and precision. When considered with regard to sentences, it requires a clear arrangement of the words and unity in the sense; to which, if strength and harmony be added, the style will become ornamented.

One of the most important directions to be observed by him who wishes to form a good style, is to acquire clear and precise ideas on the subject concerning which he is to write or speak. To this must be added frequency of composition, and an acquaintance with the style of the best authors. A servile imitation, however, of any author is carefully to be avoided; for he who copies, can hardly avoid copying faults as well as beauties. A style cannot be proper unless it be adapted to the subject, and likewise to the capacity of our hearers, if we are to speak in public. A simple, clear, and unadorned style, such as that of Swift, is fittest for intricate disquisition; a style elegant as Addison’s, or impetuous like Johnson’s, is most proper for fixing the attention on truths, which, though known, are too much neglected. We must not be inattentive to the ornaments of style, if we wish that our labours should be read and admired:

but he is a contemptible writer, who looks not beyond the dress of language, who lays not the chief stress upon his matter, and who does not regard ornament as a secondary and inferior recommendation. For further observations on the different kinds of style, see Oratory, Metaphysics, &c.

Style, in Jurisprudence, the particular form or manner of proceeding in each court of jurisdiction, agreeable to the rules and orders established therein: thus we say, the style of the court of Rome, of chancery, of parliament, of the Privy-council, &c.

Style, in Music, denotes a peculiar manner of singing, playing, or composing: being properly the manner that each person has of playing, singing, or teaching; which is very different both in respect of different geniuses, or countries, nations, and of the different matters, places, times, subjects, passions, expressions, &c. Thus we say, the style of Palestrina, of Lully, of Corelli, of Handel, &c.; the style of the Italians, French, Spaniards, &c.

Old Style, the Julian method of computing time, as the New Style is the Gregorian method of computation. See Kalendar.

STYLFORUS CHORDATUS, a genus of fishes belonging to the order of apodes. See Ichthyology Index, and Transactions of the Linnaean Society, vol. i.

STYLET, a small dangerous kind of poniard which may be concealed in the hand, chiefly used in treacherous assassinations. The blade is usually triangular, and so small that the wound it makes is almost imperceptible.

STYLITES, Pillar Saints, in ecclesiastical history, an appellation given to a kind of solitary, who stood motionless upon the tops of pillars, raised for this exercise of their patience, and remained there for several years, amidst the admiration and applause of the stupid populace. Of these we find several mentioned in ancient writers, and even as low as the twelfth century, when they were totally suppressed.

The founder of the order was St Simeon Stylites, a famous anchorit in the fifth century, who first took up his abode on a column six cubits high; then on a second of twelve cubits, a third of twenty-two, a fourth of thirty-six, and on another of forty cubits, where he thus passed thirty-seven years of his life. The tops of these columns were only three feet in diameter, and were defended by a rail that reached almost to the girde, somewhat resembling a pulpit. There was nothing lying down in it. The faquires, or devout people of the East, imitate this extraordinary kind of life to this day.

STYLOCERALOIDES, Stylo-Glossus, Stylo-Hypoides, Stylo-Pharyngans, STYLOIDIES, STYLOSANTHES, a genus of plants belonging to the diadelphus class, and in the natural method ranking under the 32d order, Papilionaceae. See Botany Index.

STYPTIC, in Pharmacy, a medicine which by its astrigency stops hemorrhages, &c. See Materia Medica Index.

STYRAX, the Storax-Tree, a genus of plants belonging to the class decandria, and in the natural system ranging.
STYX, in *Fabulous History*, a celebrated river of hell, round which it flows nine times. The gods held the waters of the Styx in such veneration, that to swear by them was reckoned an oath altogether inviolable. If any of the gods had perjured themselves, Jupiter obliged them to drink the waters of the Styx, which lushed them for one whole year into a senseless stupidity, for the nine following years they were deprived of the ambrosia and the nectar of the gods, and after the expiration of the years of their punishment, they were restored to the assembly of the deities, and to all their original privileges. It is said that this veneration was shown to the Styx, because it received its name from the nymph Styx, who with her three daughters assisted Jupiter in his war against the Titans.

STYX was a river which it was necessary for departed shades to pass before they could enter the infernal regions; and it was the office of Charon to ferry them over in a boat which was kept for that purpose. The ghosts of those who had not been honourable with the rites of sepulture were obliged to wander an hundred years before Charon could admit them into his boat to convey them before the judges of Hades. What could have given rise to this fable of Charon and his boat, it is not very material to inquire. Mythological writers have said, that the Greeks learned it from the Egyptians, which is indeed probable enough; that the Egyptians framed both this, and some other fables relating to the dead, from certain customs peculiar to their country; that in particular there was, not far from Memphis, a famous burying-place, to which the dead bodies were conveyed in a boat across the lake Acherusia; and that Charon was a boatman who had long officiated in that service. The learned Dr Blackwell says, in his life of Homer, that, in the old Egyptian language, *Charon* signified "ferryman."

SUABIA, a circle of Germany, bounded on the north by the circle of Franconia and that of the Lower Rhine; on the west by the circle of the Lower Rhine and Alsace; on the south by Switzerland; and on the east by the circle of Bavaria. Of all the circles of the empire, Suabia is the most divided; it contains four ecclesiastical and thirteen lay principalities, nineteen independent priories and abbeys, twenty-six earldoms and lordships, and thirty-one free cities. The prime directors of the circle, as they are termed, were formerly the bishop of Constance and the duke of Wirtemberg. But this circle has suffered similar changes with neighbouring states.

The mixture of the various forms of government and religious sects; the oppression exercised by the great on the poor; the game constantly played by the emperor, who possesses many pieces of detached country in Suabia, which depend not on the circle, and can, in consequence of his privileges as archduke of Austria, extend his possessions in it by various ways; are circumstances (says Baron Riesbeck) which give the cultivation of the country, and the character of the inhabitants, a most extraordinary cast. In several of the post towns where you stop, you see the highest degree of cultivation in the midst of the most savage wildness; a great degree of knowledge and polish of manners, mixed with the grossest ignorance and superstition; traces of liberty, under the deepest oppression; national pride, together with the contempt and neglect of the native country; in short, all the social qualities in striking contrast and opposition to each other. Those parts of Suabia which belong to the great potentates, such as Wirtemberg, Austria, and Baden, are certainly the most improved. The whole of Suabia may comprehend about nine hundred German square miles, and two millions of people. More than half of these are subjects of the three above-mentioned princes, though they are not proprietors of near one half of the lands.

SUARES, Francis, a Jesuit, who was born in Granada in Spain, in January 1548. He was a professor of theology at Alcalá, Salamanca, Rome, and Coimbra in Portugal. He died at Lisbon in 1617 with the greatest resignation; "I never thought (said he) that it was so easy to die." His memory was astonishing, he could repeat the whole of his voluminous works by heart. His writings fill 22 folio volumes, and are mostly on theological and moral subjects. His *Treatise of Laws* has been reprinted in this country. His Defence of the Catholic Faith against the Errors of England was written at the request of Pope Paul V. This book was publicly burnt at London by order of James I. When Suarez heard it, he is said to have exclaimed, "O that I too could seal with my blood the truths which I have defended with my pen."

SUBAH, the general name of the viceroyships, or greater governments, into which the Mogul empire was divided, consisting of several provinces. The jurisdiction of a subahdar, the same as subahshah, subsidaries, or nizamat.

SUBAHDAR, the viceroy, lord-lieutenant, or governor, holding a subah; the same as nabob or nazim.

Also the black commander of a company of sepoys.

SUBALTERN, a subordinate officer, or one who discharges his post under the command and subject to the direction of another; such are lieutenants, sublieutenants, cornets, and ensigns, who serve under the captain.

SUBLAVIAN, in *Anatomy*, is applied to any thing under the armpit or shoulder, whether artery, nerve, vein, or muscle.

SUBDEACON, an inferior minister, who anciently attended at the altar, prepared the sacred vessels, delivered them to the deacons in time of divine service, attended the doors of the church during communion-service, went on the bishop's embassies with his letters or messages to foreign churches, and was invested with the first of the holy orders. They were so subordinate to the superior rulers of the church, that, by a canon of the council of Leodicea, they were forbidden to sit in the presence of a deacon without his leave. According to the canons, a person must be twenty-two years of age to be promoted to the order of subdeacon. See DEACON.

SUBDOMINANT, in *Music*, a name given by M. Rameau to the fourth note of the tone, which of consequence is the same interval from the tonic when descending as the dominant in rising. This denomination arises from the affinity which this author finds by inversion between the minor mode of the subdominant and the major mode of the tonic.

SUBDUPLICATE, when any number or quantity is contained in another twice. Thus 3 is said to be subduplicate of 6, as 6 is duplicate of 3. See RATIO.
SUBDUPLICATE RATIO of any two quantities, is the ratio of their square roots.

SUBER, the specific name of the Cork-tree. See Quercus, Botany Index.

SUBJECT, a person under the rule and dominion of a sovereign prince or state.

SUBJECT is also used for the matter of an art or science, or that which it considers, or whereon it is employed: thus the human body is the subject of medicine.

SUBINFEUDATION, was where the inferior lords, in imitation of their superiors, began to carve out and grant to others minuter estates than their own, to be held of themselves; and were so proceeding downwards in infinitum, till the superior lords observed, that by this method of subinfeudation they lost all their feudal profits, of wardships, marriages, and escheats, which fell into the hands of these mesne or middle lords, who were the immediate superiors of the terre-tenant, or him who occupied the land. This occasioned the stat. of Westm. 3. or quia emptores, 18 Edw. I. to be made; which directs, that upon all sales or feoffments of lands, the feu-fie shall hold the same, not of his immediate feoffor, but of the chief lord of the fee of whom such feoffor himself held it. And from hence it is held, that all manors existing at this day must have existed by immemorial prescription; or at least ever since the 18 Edw. I., when the statute of quia emptores was made.

SUBITO, in the Italian music, is used to signify that a thing is to be performed quickly and hastily; thus we meet with voli subito, turn over the leaf quickly.

SUBJUNCTIVE, in Grammar. See Grammar.

SUBLIMATE, a chemical preparation, consisting of quicksilver united with muriatic acid. See Mercury, Chemistry Index.

SUBLIMATION, in Chemistry, the condensing and collecting, in a solid form, by means of vessels aptly constructed, the fumes of bodies raised from them by the application of a proper heat.

SUBLIME, or Sublimity. See the article Grandeur and Sublimity.

SUBLINGUAL ARTERY. See Anatomy.

SUBLINGUAL Glands, in Anatomy, two glands under the tongue, placed one on each side thereof.

SUBMULTIPLE, in Geometry, &c. A submultiple number, or quantity, is that which is contained a certain number of times in another, and which, therefore, repeated a certain number of times, becomes exactly equal thereto. Thus 3 is a submultiple of 21 in which sense a submultiple coincides with an aliquot part.

SUBMULTIPLE Ratio, is that between the quantity contained and the quantity containing. Thus the ratio of 3 to 21 is submultiple. In both cases submultiple is the reverse of multiple: 21, e. gr. being a multiple of 3, and the ratio of 21 to 3 a multiple ratio.

SUBORDINARIES. See Heraldry, Chap. III. Sect. II.

SUBORDINATION, a relative term, expressing an inferiority between one person and another.

SUBORATION, in Law, a secret, underhand, preparing, instructing, or bringing in a false witness; and from hence suboration of perjury is the preparing or corrupt alluring to perjury. The punishment for this crime was formerly death, then banishment or cutting out the tongue, afterwards forfeitures of goods; and it is now a fine and imprisonment, and never more to be received as evidence. The statute 2 Geo. II. c. 25, superadded a power for the court to order the offender to be sent to the house of correction for a term not exceeding seven years, or be transported for the same period.

SUBPOENA, in Law, a writ whereby common persons are called into chancery, in such cases where the common law hath provided an ordinary remedy; and the name of it proceeds from the words therein, which charge the party called to appear at the day and place affirmed, sub poena centum librarum, &c. The subpoena is the leading process in the courts of equity; and by statute, when a bill is filed against any person, process of subpoena shall be taken out to oblige the defendant to appear and answer the bill, &c.

SUBPOENA ad testificandum, a writ or process to bring in witnesses to give their testimony. If a witness on being served with this process does not appear, the court will issue an attachment against him; or a party, plaintiff or defendant, injured by his non-attendance, may maintain an action against the witness. See Blackst. Com. vol. viii. p. 309.

SUBPOENA, in Equity, a process in equity, calling on a defendant to appear and answer to the complainant's bill. See statute 5th Geo. II. c. 25, which enacts, that where the party cannot be found to be served with a subpoena, and absconds (as is believed) to avoid being served, a day shall be appointed him to appear to the bill of the plaintiff; which is to be inserted in the London Gazette, read in the parish church where the defendant last lived, and fixed up at the Royal Exchange: and if the defendant doth not appear upon that day, the bill shall be taken pro confesso.

SUBREPTIOUS, a term applied to a letter, licence, patent, or other act, fraudulently obtained of a superior, by concealing some truth which, had it been known, would have prevented the concession or grant.

SUBROGATION, or Surrogation, in the civil law, the act of substituting a person in the place, and intitling him to the rights, of another. In its general sense, subrogation implies a succession of any kind, whether of a person to a person, or of a thing to a thing.

There are two kinds of subrogation: the one conventional, the other legal. Conventional subrogation is a contract whereby a creditor transfers his debt, with all appurtenances thereof, to the profit of a third person. Legal subrogation is that which the law makes in favour of a person who discharges an antecedent creditor; in which case there is a legal translation of all rights of the ancient creditor to the person of the new one.

SUBSCRIPTION, in general, signifies the signature put at the bottom of a letter, writing, or instrument.

In commerce, it is used for the share or interest which particular persons take in a public stock or a trading company, by writing their names, and the shares they require, in the backs or register thereof.

Subscription to articles of faith is required of the clergy of every established church, and of some churches not established. Whether such subscription serves any good purpose, in a religious or theological view, is a very doubtful question. It may be necessary in an establishment, as a test of loyalty to the prince; and of attachment to the constitution, civil and ecclesiastical, but it cannot
produce uniformity of opinion. As all language is more or less ambiguous, it becomes difficult, if not impossible, to determine in what sense the words of long established creeds are to be interpreted; and we believe that the clergy of the churches of England and Scotland seldom consider themselves as fettered by the Thirty-nine Articles, or the Confession of Faith, when composing instructions either for their respective parishes or for the public at large. See INDEPENDENTS.

Subscription, in the commerce of books, signifies an engagement to take a certain number of copies of a book, intended to be printed, and a reciprocal obligation of the bookseller or publisher, to deliver the said copies, on certain terms. These subscriptions, which had their rise in England about the middle of the 17th century, were lately very frequent in France and Holland, and are now very common among ourselves.

SUBSEQUENT, something that comes after another, particularly with regard to the order of time.

SUBSIDY, in Law, signifies an aid or tax granted to the king by parliament, for the necessary occasions of the kingdom; and is to be levied on every subject of ability, according to the rate or value of his lands or goods: but this word, in some of our statutes, is confounded with that of customs. See TAX.

SUBSTANCE, the subjects to which we suppose qualities belong. Thus gold is the substance to which the qualities of ductility, yellowness, density, &c. belong. See METAPHYSICS, No. 145.

SUBSTANTIAL, in the schools, something belonging to the nature of substance.

SUBSTANTIVE, in Grammar. See GRAMMAR.

SUBSTITUTE, a person who officiates for another in his absence.

SUBSTITUTION, in the Civil Law, a disposition of a testament, whereby the testator substitutes one heir for another, who has only the usufruct, and not the property of the thing, left him.

SUBTRACTION, or SUBTRACTION, in Arithmetic, the second rule, or rather operation, in arithmetic, whereby we deduct a less number from a greater, to learn their precise difference. See ARITHMETIC and ALGEBRA.

SUBTANGENT of a curve, the line that determines the intersection of a tangent with the axis; or that determines the point wherein the tangent cuts the axis prolonged.

SUBTENSE, formed from SUB “under,” and TENSOR “I stretch,” in Geometry, a right line which is opposite to an angle, and drawn between the two extremities of the arc which measures that angle.

SUBTERRANEAN, whatever is under ground; thus naturalists speak of subterraneous fires, subterraneous damps, &c.

SUBTERRANEOUS CAVERNS. See QUARRIES.

SUBTILE, in Physics, an appellation given to whatever is extremely small, fine, and delicate; such as the animal spirits, the effluvia of odorous bodies, &c. are supposed to be.

SUBULARIA, ROUGH-LEAVED ALYSTON, or AULwort, a genus of plants belonging to the class tetrady- namia, and in the natural order ranging under the 39th order Sibiwoideae. See Botany Index.

SUBULATED, something shaped like an awl.
SUCCESSION

Suckling

union will form a constitution, in theory the most beautiful of any, in practice the most approved, and, we trust, in duration the most permanent.

In France the succession to the monarchy was limited to heirs male (see Salic); but in Navarre the crown was inherited by the heir of line, whether male or female. The case stands thus: Philip the fourth, king of France, surnamed the Fair, in the year 1285 espoused Jane queen of Navarre in her own right; and as king consort of this latter kingdom added the title of Navarre to his former one of France. Louis X., son and heir of Philip and Jane (surnamed Hutin or the Buxterous), succeeded to both crowns. By Margaret his first wife, who had been crowned queen of Navarre, he left one daughter, Joan or Jane. His second wife Clementina was pregnant at the time of his decease, and was delivered of a posthumous son, whom most of the French annalists recognize as John I. of France, though he lived no longer than three weeks. On his death the kingdom of France passed to Philip V. surnamed the Long, and that of Navarre (to which the Salic law could not by any construction extend) to Joanna the only child and heir of Louis and Margaret. From Joanna, in lineal succession, the kingdom of Navarre passed to Jane d'Albret, mother of Henry IV. of France, and wife of Anthony of Vendome, who as king consort wore the crown of Navarre. On the accession of Henry to the kingdom of France, the two monarchies were united, and the four succeeding princes assumed the joint title.

Succinic acid, an acid extracted from amber by sublimation in a gentle heat, and which rises in a concrete form into the neck of the subliming vessel. See Chemistry Index.

Succinum, amber, in Mineralogy, a species of bitumen classed under the inflammable substances. See Mineralogy Index.

Succory, see Cichorium, Botany Index.

Succoth, in Ancient Geography, a town which lay between the brook Jabbock and the river Jordan, where Jacob fixed his tents. There was another Succoth, where the Israelites first encamped after their departure from Rameses towards the Red sea. Succoth signifies tents.

Succubus, a term used by some writers for a demon who assumes the shape of a woman, and as such lies with a man; in which sense it stands opposed to incubus, which was a daemon in form of a man, that lies with a woman. But the truth is, the succubus is only a species of the nightmare. See Medicine, No. 329.

Succula, in Mechanics, an axis or cylinder, with staves in it to move it round; but without any tympanum or peritrochium.

Succulent Plants, among botanists, such whose leaves are thick and full of juice.

Sucker, see Cyclopetrus, Ichthyology Index.

Suckers, in Gardening, the same with Offsets.

Sucking-Fish, see Echeneis, Ichthyology Index.

Suckling, Sir John, an English poet and dramatic writer, was the son of Sir John Suckling, comptroller of the household to King Charles I. and born at Witham in Essex in 1613. He discovered an uncommon propensity to the acquiring of languages, insomuch that he is reported to have spoken Latin at five years of age, and to have written it at nine. When he grew up, he travelled; but seems to have affected nothing more than the character of a courtier and fine gentleman; which he so far attained, that he was allowed to have the peculiar happiness of making every thing he did become him. In his travels he made a campaign under the great Gustavus Adolphus; and his loyalty, if not his valour, appeared in the beginning of our civil wars; for, after his return to England, he raised a troop of horse for the king's service entirely at his own charge; and mounted them so completely and richly, that they were said to have cost him 12,000l. This troop, with Sir John at its head, behaved so ill in the engagement with the Scots, upon the English borders, in 1639, as to occasion the famous lampoon composed by Sir John Mennis; "Sir John he got him an ambling nag," &c. This ballad, which was set to a brisk tune, was much sung by the parliamentarians, and continues to be sung to this day. This disastrous expedition, and the ridicule that attended it, was supposed to have hastened his death; being seized by a fever, of which he died, at 28 years of age. He was a sprightly wit, and an easy versifier, but no great poet. His works, consisting of a few poems, letters, and plays, have nevertheless gone through several editions.

Suction, the act of sucking or drawing up a fluid, as air, water, milk, or the like, by means of the mouth and lungs; or, in a similar manner, by artificial means. See Pneumatics and Hydrodynamics.

Sudatory, a name given by the ancient Romans to their hot or sweating rooms; sometimes also called Laconic.

Sudorific, an appellation given to any medicine that causes or promotes sweat.

Suessiones, a branch of the Remi, a people of Gallia Belgica, (Pliny;) called sometimes Suessones, in the lower age Sueci; situated between the Remi to the east, the Nervii to the north, the Veromandui to the west, and the Medes to the south, in the tract now called le Soissons.—Suessiones, Suessones, and Suessonum, the name of their city in the lower age; thought to have been formerly called Noviodunum (Cesar;) now called Soissons.

Suet, Sebum, or Sebren, in Anatomy, the solid fat found in several animals, as sheep, oxen, &c. but not in the human species. See the article Fat.—It is of the sebum that tallow is made.

Suetonius Tranquillus, Caius, a famous Latin historian, was born at Rome, and became secretary to the emperor Adrian, about the 118th year of the Christian era; but that post was taken from him three years after, when several persons fell under that prince's displeasure for not showing the empress Sabina all the respect she deserved. During his disgrace he composed many works, which are lost. Those now extant are his History of the XII first Emperors, and a part of his treatise of the Illustrious Grammarians and Historicians. Pliny the Younger was his intimate friend, and persuaded him to publish his books. His History of the XII Roman Emperors has been much commended by most of our polite scholars. He represents, in a continued series of curious and interesting particulars, without any digressions or reflections, the actions of the emperors, without omitting their vices, which he expresses with all
tions, and with the same freedom mentions 
the deiformity, and with the same freedom mentions 
good qualities of the very same persons; but the 
horrid dissoluteness and obscene actions he relates of Il-
erius, Caligula, Nero, &c. have made some say, that 
hewrote the lives of the emperors with the same licen-
tiousness with which they lived. The edition of this 
history procured by Greavius at Utrecht in 1672, with 
the excellent Commentaries of Torrentius and Casaubon, 
and the notes of some other learned critics, is much es-
4to, with notes.

SUEVI, the Catti or Chattis of Caesar (Strabo.), placed 
on the Rhine: the reason of Caesar’s calling them thus 
does not appear, though considerably distant from the 
proper Suevi or Alemani.

SUEVI, (Tacitus), a common name of the people si-
tuated between the Elbe and the Vistula, distinguished 
otherwise by particular names; as in Ptolemy, Suevi 
Angoli, Suevi Scenones.

SUEVUS, in Ancient Geography, a river of Ger-
many, thought to be the same with the Vistula or Oder, 
emptying itself at three mouths into the Baltic, the mid-
dlemost of which is called Scione or Swene; which last 
comes nearer the name Suevus.

SUEZ, a small sea-port town, situated near the nor-
thern extremity of the Red sea, and about 30 hours jour-
ney east from Cairo. The country around it is a sandy 
plain, without the smallest spot of verdure. The only 
water which can be drunk is brought from El-Naba, or 
the spring, at the distance of three hours’ journey; and 
it is so brackish, that without a mixture of rum, it is 
insupportable to Europeans. The town itself is a collec-
tion of miserable ruins, the khans being the only solid 
buildings; yet from March till June, the season when 
the Jidda and Yambo fleet arrives, the town becomes 
crowded; but after its departure nobody remains ex-
cept the governor, who is a Mamlouk, 12 or 14 per-
sons who form his household, and the garrison. The 
fortress is a defenceless heap of ruins, which the Arabs 
consider as a citadel, because it contains six brass four-
pounders, and two Greek gunners, who turn their heads 
aside when they fire. The harbour is a wretched quay, 
where the smallest boats are unable to reach the shore, 
except at the highest tides. There, however, the mer-
chandise is embarked, to convey it over the banks of 
sand to the vessels which anchor in the road. This road, 
s Situated a league from the town, is separated from it by 
from a shore which is level dry at low water; it has no works 
for its defence, so that the vessels which M. Volney tells 
us he has seen there, to the number of 28 at a time, 
might be attacked without opposition; for the ships 
themselves are incapable of resistance, none having any 
other artillery than four rusty swivels.

Suez has always been, notwithstanding its local disad-
antages, a place of great trade, on account of its geo-
ographical situation. It was by the gulf of Suez that the 
commodities of India were formerly conveyed to Eu-
rope, till the discovery of the passage by the Cape of 
Good Hope converted that trade into a new channel. 
As the isthmus of Suez, which separates the Red sea 
from the Mediterranean, is not more than 57 miles, it 
has been frequently proposed to join these two seas to-
gether by a canal. As there are no mountains nor re-
markable inequalities of surface, this plan would at first 
view appear easy to be executed. But though the dif-
ference of levels would not prevent a junction, the great 
difficulty arises from the nature of the corresponding 
coasts of the Mediterranean and the Red sea, which are 
of a low and sandy soil, where the waters form lakes, 
shoals, and morasses, so that vessels cannot approach 
within a considerable distance. It will therefore be 
found scarcely possible to dig a permanent canal amid 
these shifting sands: not to mention, that the shore is 
destitute of harbours, which must be entirely the work 
of art. The country besides has not a drop of fresh wa-
ter, and, to supply the inhabitants, it must be brought as 
far as from the Nile.

The best and only method therefore of effecting this 
junction, is that which has been already successfully 
practised at different times; which is, by making the 
river itself the medium of communication, for which 
the ground is perfectly well calculated; for Mount Mokat-
tum suddenly terminating in the latitude of Cairo, forms 
only a low and semicircular mound, round which is a 
continued plain from the banks of the Nile as far as the 
point of the Red sea. The ancients, who early under-
stood the advantage to be derived from this situation, 
adopted the idea of joining the two seas by a canal con-
ected with the river. Strabo* observes, that this was 
first executed under Sesostris, who reigned about the 
time of the Trojan war; and this work was so consid-
erable as to occasion it to be remarked, “that it was 100 
cubits (or 170 feet) wide, and deep enough for large 
vessels.” After the Greeks conquered the country, it 
was restored by the Ptolemies, and again renewed by 
Trajan. In short, even the Arabs themselves followed 
these examples. “In the time of Omar Ibn-el-Kattab 
(says the historian El Makin), the cities of Mecca, and 
Medina suffering from famine, the caliph ordered Amr 
governor of Egypt to cut a canal from the Nile to Kol-
zoum, that the contributions of corn and barley ap-
pointed for Arabia might be conveyed that way.”

This canal is the same which runs at present to Cairo, 
and loses itself in the country to the north-east of Ber-
ket-el-Hadjj, or the Lake of the Pilgrims.

The place on the west coast of the gulf of Suez, 
where the children of Israel are supposed to have en-
tered it, is called Badea, about six miles to the north 
of Cape Korondel, on the other side of the gulf, as we 
are informed in a letter from the ingenious Edward Wort-
ley Montague, F. R. S. to Dr. Watson, containing an 
account of his journey from Cairo to the Written Moun-
tains in the desert of Sinai. Opposite to Badea is a 
strong current which sets to the opposite shore, about 
south-east, with a whirlpool called Birque Pharase, the 
well or pool of Pharaseh, being the place where his host 
is said to have been destroyed. We are told by the 
same gentleman, that the Egyptian shore from Suez to 
Badea is so rocky and steep, that there was no entering 
upon the gulf but at one of these two places.

The British nation, we believe, never attempted to 
carry on commerce with any of the ports of the Red sea 
beside Jidda, till, on the suggestion of Mr. Bruce, in 
1776, some British merchants at Bengal equipped two 
or three vessels for Suez, laden with piece-goods of Ben-
gal and coast manufactures. The command of the ves-
sels was committed to Captain Greig, a meritorious sea-
man; and the management of the goods was entrusted to 
Mr. Straw, a gentleman distinguished for his mercant-
tile knowledge. The sale turned out to advantage; but 
such
such great expenses were incurred in making presents to the bey of Cairo and Suez, as to consume the whole
profits gained by the sale of the cargo. The great pur-
pose of the expedition was, however, accomplished, as
a firm was obtained from the government of Cairo
to trade by the way of Suez. In consequence of this, three
ships went to Suez the following year, and as many in
1778. The opening of this trade alarmed the jealousy
of the East India Company; they applied to our gov-
ernment, and orders were given to relinquish this pro-
mising commerce. These orders reached Egypt sooner
than Bengal, and the consequence was fatal to the un-
fortunate adventurers who visited Suez that year (1779).
By a plan concerted between the boys, a large body of
Bedouin Arabs attacked the caravan passing from Suez
to Cairo with goods valued at 12 lacks of rupees.
The goods were plundered, the Europeans were stripped
and left naked in the desert, exposed to the burning rays
of the sun, without a drop of water to quench their thirst,
or food to support life. Most of them died, and some
of their bodies were afterwards found mangled and dis-
figured by wolves. We have been favoured with a par-
ticular account of the sufferings of our countrymen by a
correspondent, which, we are sorry, we have not room
to insert. Those who wish to obtain a more full ac-
count may consult the Annual Register for 1781 or
1782.

SUFFETULA, in Ancient Geography, a town of
Africa, in the dominions of Carthage; probably so cal-
ced from Suffetes, the title of the magistrates of that
city. It is now called Spaltia, in the kingdom of Tunis,
and has many elegant remains of antiquity. There are
three temples in a great measure entire; one of them
of the Composite order, the other two Corinthian. "A
beautiful and perfect capital of the Composite order
(says Mr Bruce), the only perfect one that now exists,
is designed in all its parts in a very large size; and with
the detail of the rest of the ruin, is a precious monu-
ment of what that order was, now in the collection of
the king." The town itself (he says) is situated in the
most beautiful spot in Barbary, surrounded by great
numbers of juniper-trees, and watered by a pleasant
stream, which sinks under the earth at that place,
without appearing any more.

SUFFOCATION, the privation of the function of
respiration or breathing. See the articles DROWNING,
HANGING, &c.

SUFFOLK, a county of England. Its name is
contrasted from Southfolk, so called from its situation in
regard to Norfolk. It is bounded on the west by Cam-
bridge-shire; on the south by Essex, from which it is
parted by the river Stour; on the east by the German
ocean; and on the north by Norfolk, separated from it
by the lesser Ouse and the Waveney. From west to
east it is 52 miles in length, about 20 at a medium in
breadth, and 196 in circumference. It contains 22
hundreds, 29 market-towns, 575 parishes; and in 1811
the number of houses was 37,581, and of inhabitants
234,211. The whole is divided into two parts, viz. the
Liberty of St Edmund, and the Geldable; the former
of which contains the west parts of the county, and the
other the east; and there is a grand jury for each at
the assizes. The air is reckoned as wholesome and plea-
 sant as any in the kingdom; nor is it otherwise upon
the sea coast, which is free from salt marshes. The soil,
extcept to the west and upon the sea-coast, is very rich,
being a compound of clay and marl. Towards the sea
there are large heaths and tracts of sand; but these
produce hemp, rye, and peas, and feed great flocks of
sheep. About Newmarket the soil is much the same;
but in high Suffolk or the woodlands, besides wood,
there are very rich pastures, where abundance of cattle
are fed. In other parts of the county, as about Bury,
there is plenty of corn. As this county is noted for the
richness of its pastures, so is it for butter and cheese,
especially the former, which is said to be remarkably
good; so that being packed up in flaxens, it is sold for
all uses both by sea and land, and conveyed to many
parts of England, especially to London. The inland
parts of the county are well supplied with wood for fuel,
and those upon the sea-coast with coals from Newcastle.
The manufactures of the county are chiefly woollen and
linen cloth. It lies in the diocese of Norwich, has two
archdeacons, viz. of Sedbury and Suffolk; gives title of
earl to a branch of the Howards; sends two members
to parliament for the county, and two for each of the
following places, Ipswich, Dunwich, Orford, Albor-
rough, Sudbury, Eye, and St Edmond's-Bury. The
county is extremely well watered by the following ri-
vers, viz. the Lesser Ouse, the Waveney, the Blithe,
the Deben, the Orwell, the Gipping, and the Stour. See
SUFFOLK, SUPPLEMENT.

SUFFRAGAN, an appellation given to simple bi-
ishops with regard to archbishops, upon whom they depend,
and to whom appeals lie from the bishops courts.

Suffragan is likewise the appellation given to a bi-
shop, who is occasionally appointed to reside in a town
or village, and assist the diocesan.

SUFFRAGE, denotes a vote given in an assembly,
where something is deliberated on, or where a person is
elected to an office or benefice.

SUFFRUTEX, among botanists, denotes an under-
shrub, or the lowest kind of woody plants, as lavender.
SUGAR, a solid sweet substance obtained from the
juice of the sugar-cane; or, according to chemists, an
essential salt, capable of crystallization, of a sweet and
agreeable flavour, and contained in a greater or less
quantity in almost every species of vegetables, but most
abundant in the sugar-cane.

As the sugar-cane is the principal production of the
value of West Indies, and the great source of their riches; as sugar,
is so important in a commercial view, from the employ-
ment which it gives to seamen, and the wealth which it
opens for merchants; and besides now is become a ne-
necessary of life—it may justly be esteemed one of the most
valuable plants in the world. The quantity consumed
in Europe is estimated at nine millions sterling, and the
demand would probably be greater if it could be sold at
a reduced price. Since sugar then is reckoned so pre-
cious a commodity, it must be an object of desire to all
persons of curiosity and research, to obtain some general
knowledge of the history and nature of the plant by
which it is produced, as well as to understand the pro-
cess by which the juice is extracted and refined. We
will therefore first inquire in what countries it origi-
nally flourished, and when it was brought into general
use, and became an article of commerce.

From the few remains of the Grecian and Roman au-
tors which have survived the ravages of time, we can
find no proofs that the juice of the sugar-cane was known

at
That the sugar-cane is an indigenous plant in some parts of the East Indies, we have the strongest reason to believe; for Thunberg found it in Japan, and has accordingly mentioned it as a native of that country in his *Flora Japonica*, published in 1784. Osbeck also found it in China in 1751. It may indeed have been transplanted from some other country; but as it does not appear from history that the inhabitants of Japan or China ever carried on any commerce with remote nations, it could only be conveyed from some neighbouring country. Marco Polo, a noble Venetian, who travelled into the East about the year 1250, found sugar in abundance in Bengal. Vasco de Gama, who doubled the Cape of Good Hope in 1497, relates, that a considerable trade in sugar was then carried on in the kingdom of Calicut. On the authority of Dioscorides and Pliny, too, we should be disposed to admit, that it is a native of Arabia, did we not find, on consulting Niebuhr's Travels, that that botanist has omitted it when enumerating the most valuable plants of that country. If it be a spontaneous production of Arabia, it must still flourish in its native soil. Mr Bruce found it in Upper Egypt. If we may believe the relation of Giovan Lioni, a considerable trade was carried on in sugar in Nubia in 1500: it abounded also at Thebes, on the Nile, and in the northern parts of Africa, about the same period.

There is reason to believe that the sugar-cane was introduced into Europe during the crusades; expeditions which, however romantic in their plan, and unsuccessful in their execution, were certainly productive of many advantages to the nations of Europe. Albertus Aeguisius, a monkish writer, observes, that the Christian soldiers in the Holy Land frequently derived refreshment and support during a scarcity of provisions by sucking the canes. This plant flourished also in the Morea, and in the islands of Rhodes and Malta; from which it was transported into Sicily. The date of this transaction is not easy to ascertain; but we are sure that sugar was cultivated in that island previous to the year 1266; for Lattau the Jesuit, who wrote a history of the Portuguese discoveries, mentions a donation made that year to the monastery of St Benett, by William the second, King of Sicily, of a mill for grinding sugar-canes, with all its rights, members, and appurtenances.

From Sicily, where the sugar-cane still flourishes on the sides of Mount Hybla, it was conveyed to Spain, Madeira, the Canary and Cape de Verd islands, soon after they were discovered in the 15th century.

An opinion has prevailed, that the sugar-cane is not a native of the western continent, or its adjacent islands by some the West Indies, but was conveyed thither by the Spanish or Portuguese soon after the discovery of America by Columbus. From the testimony of Peter Martyr, in the third book of his first decade, composed during Columbus's second voyage, which commenced in 1493 and ended in 1495, it appears, that the sugar-cane was known at that time in Hispaniola. It may be said, that it was brought thither by Columbus; but for this assertion we have found no direct evidence; and though we had

(A) For a more minute account of the history of sugar in the early and middle ages, a paper of the Manchester Transactions, in vol. iv. by Dr Falconer, may be consulted.
had direct evidence, this would not prove that the sugar-
cane was not an indigenous plant of the West Indies.

There are authors of learning, who, after investigating
this subject with attention, do not hesitate to maintain,
that it is a native both of the islands and of the con-

P. Labat has supported this opinion with much ap-
pearance of truth; and, in particular, he appeals to
the testimony of Thomas Gage, an Englishman, who
visited New Spain in 1625. Gage enumerates sugar-
canes among the provisions with which the Charaives
of Guadaloupe supplied his ship. "Now (says Labat) it
is a fact that the Spaniards had never cultivated an inch
of ground in the smaller Antilles. Their ships com-
monly touched at those islands indeed for wood and wa-
ter; and they leftswine in the view of supplying with
fresh provisions such of their countrymen as might call
there in future; but it would be absurd in the highest
degree to suppose, that they would plant sugar-canes,
and at the same time put hopes ashore to destroy them.

"Neither had the Spaniards any motive for bestow-
ing this plant on islands which they considered as of
no kind of importance, except for the purpose that has been
mentioned; and to suppose that the Charaives might
have cultivated, after their departure, a production of
which they knew nothing, betrays a total ignorance of
the Indian disposition and character.

§
From testi-
mony.

"But (continues Labat) we have surer testimony,
and such as proves, beyond all contradiction, that the
sugar-cane is the natural production of America. For,
besides the evidence of Francis Ximenes, who, in a
Treatise on American Plants, printed at Mexico, asserts,
that the sugar-cane grows without cultivation, and to
an extraordinary size, on the banks of the river Plate,
we are assured by Jean de Lery, a Protestant minister,
who was chaplain in 1576 to the Dutch garrison in the
fort of Coligny, on the river Janciao, that he himself
found sugar-canes in great abundance in many places on
the banks of that river, and in situations never visited by
the Portuguese. Father Hennepen and other voyagers
bear testimony in like manner to the growth of the cane
near the mouth of the Mississippi; and Jean de Laet to
its spontaneous production in the island of St Venant.
It is not for the plant itself, therefore, but for the secret
of making sugar from it, that the West Indies are in-
depted to the Spaniards and Portuguese; and these to
the nations of the east."

Such is the reasoning of Labat, which the learned
Lafitau has pronounced incontrovertible; and it is
greatly strengthened by recent discoveries, the sugar-
cane having been found in many of the islands of the

Pacific ocean by our late illustrious navigator Captain
Cook.

The sugar-cane, or saccharum officinarum of botanists,
is a jointed reed, commonly measuring (the flag part not
included) from three feet and a half to seven feet in
height, but sometimes rising to 12 feet. When ripe it
is of a fine straw colour inclining to yellow, producing
leaves or blades, the edges of which are finely and
sharply serrated, and terminating in an arrow decorated
with a panicle. The joints in one stalk are from 40 to
60 in number, and the stalks rising from one root are
sometimes very numerous. The young shoot ascends
from the earth like the point of an arrow; the shaft of
which soon breaks, and the two first leaves, which had
been inclosed within a quadruple sheath of seminale
leaves, rise to a considerable height (a).

As the cane is a rank succulent plant, it must require
a strong deep soil to bring it to perfection, perhaps in
favourable deed no soil can be too rich for this purpose. The soil to its
growth which experience has found to be most favourable to the
cultivation of it in the West Indies is the dark gray
loam of St Christopher's, which is so light and porous as
to be penetrable by the slightest application of the hoe.
The under stratum is gravel from 8 to 12 inches deep.
Canes planted in particular spots in this island have been
known to yield 8000 pounds of Muscovado sugar from
a single acre. The average produce of the island for a
series of years has been 16,000 hogsheads of 16 cwt.
which is one half only of the whole cane-land, or 8200
acres. When annually cut, it gives nearly two hogs-
heads of 16 cwt. per acre for the whole of the land in
ripe canes.

Next to the ashy loam of St Christopher's is the soil
which in Jamaica is called brick-mould; not as reser-
bling a brick in colour, but as containing such a due
mixture of clay and sand as is supposed to render it well
adapted for the use of the kiln. It is a deep, warm, and
mellow, hazel earth, easily worked; and though its sur-
fice soon grows dry after rain, the under stratum retains
a considerable degree of moisture in the driest weather;
with this advantage too, that even in the wettest season
it seldom requires trenching. Plant-canep, by which is
meant canes of the first growth, have been known in
very fine seasons to yield two tons and a half of sugar
per acre. After this may be reckoned the black mould
of several varieties. The best is the deep black earth of
Edward's
Barbadoes, Antigua, and some other of the windward History of
islands; but there is a species of this mould in Jamaica
that is but little, if any thing inferior to it, which
abounds with limestone and flint on a substratum of
soapy marle. Black mould on clay is more common;

(a) "A field of canes, when standing, in the month of November, when it is in arrow or full blossom (says
Mr Beckford in his descriptive Account of the Island of Jamaica), is one of the most beautiful productions that
the pen or pencil can possibly describe. It in common rises from three to eight feet or more in height; a dif-
fERENCE OF GROWTH that very strongly marks the difference of soil or the varieties of culture. It is when ripe of a
bright and golden yellow; and where obvious to the sun, is in many parts very beautifully streaked with red.
the top is of a darkish green; but the more dry it becomes, from either an excess of ripeness or a continuance of
drought, of a russet yellow, with long and narrow leaves depending; from the centre of which shoots up an ar-
row like a silver wand from two to six feet in height; and from the summit of which grows out a plume of white
feathers, which are delicately fringed with a lilac dye; and indeed is, in its appearance, not much unlike the
tuft that adorns this particular and elegant tree.
Sugar. [ 800 ] Sugar.

but as the mould is generally shallow, and the clay stiff and retentive of water, this last sort of land requires great labour, both in ploughing and trenching, to render it profitable. When manured and properly pulverized, it becomes very productive. It is unnecessary to attempt a minute description of all the other soils which are found in these islands. There is, however, a peculiar sort of land on the north side of Jamaica, chiefly in the parish of Trelawney, that cannot be passed over unnoticed, not only on account of its scarcity but its value; few soils producing finer sugars, or such as answer so well in the pan; an expression signifying a greater return of refined sugar than common. The land alluded to is generally of a red colour; the shades of which, however, vary considerably from a deep chocolate to a rich scarlet; in some places it approaches to a bright yellow, but it is everywhere remarkable, when first turned up, for a glossy or shining surface, and if wetted stains the fingers like paint.

Proper season for planting it.

As in every climate there is a season more favourable for vegetation than others, it is of great importance that plants for seed be committed to the ground at the commencement of this season. As the cane requires a great deal of moisture to bring it to maturity, the properest season for planting it is in the months of September and October, when the autumnal rains commence, that it may be sufficiently luxuriant to shade the ground before the dry weather sets in. Thus the root is kept moist, and the crop is ripe for the mill in the beginning of the ensuing year. Canes planted in the month of November, or later in the season, lose the advantage of the autumnal rains; and it often happens that dry weather in the beginning of the ensuing year retards their vegetation until the vernal or May rains set in, when they sprout both at the roots and the joints; so that by the time they are cut the field is loaded with unripe suckers instead of sugar-canes. A January plant, however, commonly turns out well; but canes planted very late in the spring, though they have the benefit of the May rains, seldom answer expectation; for they generally come in unseasonably, and throw the ensuing crops out of regular rotation. They are therefore frequently cut before they are ripe; or if the autumnal season sets in early, are cut in wet weather, which has probably occasioned them to spring aflush; in either case the effect is the same: The juice is unconcentrated, and all the sap being in motion, the root is deprived of its natural nourishment, to the great injury of the ratoon. The chief objection to a fall plant is this, that the canes become rank and top-heavy, at a period when violent rains and high winds are expected, and are therefore frequently lodged before they are fit to be cut.

Method of planting

The sugar cane is propagated by the top-shoots, which are cut from the tops of the old canes. The usual method of planting in the West Indies is this: The quantity of land intended to be planted, being cleared of weeds and other incumbrances, is first divided into several plots of certain dimensions, commonly from 15 to 25 acres each; the spaces between each plot or division are left wide enough for roads, for the convenience of carting, and are called intervals. Each plot is then subdivided, by means of a line and wooden pegs, into small squares of about three feet and a half. Sometimes indeed the squares are a foot larger; but this circumstance makes but little difference. The negroes are then placed in a row in the first line, one to a square, and directed to dig out with their hoes the several squares, commonly to the depth of five or six inches. The mould which is dug up being formed into a bank at the lower side, the excavation or cane-hole seldom exceeds 15 inches in width at the bottom, and two feet and a half at the top. The negroes then fall back to the next line, and proceed as before. Thus the several squares between each line are formed into a trench of much the same dimensions with that which is made by the plough. An able negro will dig from 100 to 120 of these holes for his day's work of ten hours; but if the land has been previously ploughed and lain fallow, the same negro will dig nearly double the number in the same time (c).

The cane-holes or trench being now completed, whether by the plough or by the hoe, and the cuttings selected for planting, which are commonly the tops of the canes that have been ground for sugar (each cutting containing five or six gems), two of them are sufficient for a cane hole of the dimensions described. These, being placed longitudinally in the bottom of the hole, are covered with mould about two inches deep; the rest of the bank being intended for future use. In 12 or 14 days the young sprouts begin to appear; and as soon as they rise a few inches above the ground, they are, as it is called, being cleared; the cane-holes in order to be, carelessly cleared of weeds, and furnished with an addition of mould from the banks. This is usually performed by the hand. At the end of four or five months the banks are wholly levelled, and the spaces between the rows carefully hoe-ploughed. Frequent cleanings, while the canes are young, are indeed so essentially necessary, that no other merit in an overseer can compensate for the want of attention in this particular. A careful manager will remove at the same time all the lateral shoots or suckers that spring up after the canes begin to joint, as they seldom come to maturity, and draw nourishment from the original plants.

In the cultivation of other lands, in Jamaica, especially (says Mr. Edwards, the elegant historian of the West Indies, whose superior excellence has induced us frequently to refer to him in the course of this article), the plough has been introduced of late years, and in some few cases to great advantage; but it is not every soil or situation that will admit the use of the plough; some lands being much too stony, and others too steep; and I am sorry I have occasion to remark, that a practice

(c) As the negroes work at this business very unequally, according to their different degrees of bodily strength, it is sometimes the practice to put two negroes to a single square; but if the land has not had the previous assistance of the plough, it commonly requires the labour of 50 able negroes for 13 days to hole 20 acres. In Jamaica, some gentlemen, to ease their own slaves, have this laborious part of the planting business performed by job work. The usual price for holling and planting is 6l. currency per acre (equal to £l. 7s. sterling). The cost of falling and clearing heavy wood-land is commonly as much more.
Sugar commonly prevails in Jamaica, on properties where this auxiliary is used, which would exhaust the finest lands in the world. It is that of ploughing, then cross-ploughing, round-riding, and harrowing the same lands from year to year, or at least every other year, without affording manure: accordingly it is found that this method is utterly destructive of the ratoon or second growth, and altogether ruinous. It is indeed astonishing that any planter of common reading or observation should be passive under so pernicious a system. Some gentlemen, however, of late manage better: their practice is to break up stiff and clayey land, by one or two ploughings, early in the spring, and give it a summer's fallow. In the autumn following, being then mellow and more easily worked, it is hoed and planted by manual labour after the old method, which has been already described.

But in truth, the only advantageous system of ploughing in the West Indies is to confine it to the simple operation of holing, which may certainly be performed with much greater facility and dispatch by the plough than by the hoe; and the relief which, in the case of stiff and dry soils, is thus given to the negroes, exceeds all estimation, in the mind of a humane and provident owner. On this subject I speak from practical knowledge. At a plantation of my own, the greatest part of the land which is usually planted is neatly and sufficiently laid into cane-holes, by the labour of one able man, three boys, and eight oxen, with the common single-wheeled plough. The ploughshare indeed is somewhat wider than usual; but this is the only difference, and the method of ploughing is the simplest possible. By returning the plough back along the furrow, the turf is alternately thrown to the right and to the left, forming a trench seven inches deep, about two feet and a half wide at the top, and one foot wide at the bottom. A space of 18 or 20 inches is left between each trench, on which the mould being thrown by the share, the banks are properly formed, and the holing is complete. Thus the land is not exhausted by being too much exposed to the sun; and in this manner a field of 20 acres is hoed with one plough, and with great ease, in 13 days. The plants are afterwards placed in the trench as in the common method, where manual labour alone is employed.

In most parts of the West Indies it is usual to hole and plant a certain proportion of the cane-land, commonly one-third, in annual rotation. Canes of the first year's growth are called plant canes, as has been already observed. The sprouts that spring from the roots of the canes that have been previously cut for sugar are called ratoons; the first yearly returns from their roots are called first ratoons; the second year's growth second ratoons.

Mr Edwards informs us, that the manure generally used is a compost formed, 1st, Of the vegetable ashes drawn from the fires of the boiling and still houses. 2dly, Feculent discharges from the still house, mixed up with rubbish of buildings, white-lime, &c. 3dly, Refuse, or field-trash (i.e.), the decayed leaves and stems of the canes; so called in contradistinction to cane-trash, reserved for fuel. 4thly, Dung, obtained from the horse and mule stables, and from moveable pens, or small inclosures made by posts and rails, occasionally shifted upon the lands intended to be planted, and into which the cattle are turned at night. 5thly, Good mould, collected from gullies and other waste places, and thrown into the cattle-pens.

The sugar-cane is liable to be destroyed by monkeys, rats, and insects. The upland plantations suffer greatly from monkeys; these creatures, which now abound in the mountainous parts of St Christopher's, were first brought thither by the French, when they possessed half that island; they come down from the rocks in silent parties by night, and having posted sentinels to give the alarm if anything approaches, they destroy incredible quantities of the cane, by their gambols as well as their greediness. It is in vain to set traps for these creatures, however baited; and the only way to protect the plantation, and destroy them, is to set a numerous watch, well armed with fowling-pieces, and furnished with dogs. The negroes will perform this service cheerfully, for they are very fond of monkeys as food. The celebrated Father Labat says, they are very delicious, but the History of white inhabitants of St Kitt's never eat them.

The low-land plantations suffer as much by rats as those on the mountains do from monkeys; but the rats are no more than the monkeys, are natives of the place; they came with the shipping from Europe, and breed in the ground under loose rocks and bushes: the field negroes eat them greedily, and they are sold by petty sold in the markets at Jamaica. To free the plantations from these vermin, the breed of wild cats should be encouraged, and snakes suffered to multiply un molested; they may also be poisoned with arsenic, and the rapped root of the casave made into pellets, and plentifully scattered over the grounds. This practice, however, is dangerous; for as the rats when thus poisoned become exceeding thirsty, they run in dews to the neighbouring streams which they poison as they drink, and the cattle grazing on the banks of these polluted waters have frequently perished by drinking after them: It is safer therefore to make the pellets of flour, kneaded with the juice of the nightshade, the scent of which will drive them away though they will not eat it. There is an East Indian animal called mangoece, which bears a natural antipathy to rats; if this animal was introduced into our sugar islands, it would probably extirpate the whole race of these noxious vermin. The formica cromatic of Linneus, the carnivorous ant, which is called the raffle's ant, would soon clear a sugar plantation of rats.

The sugar-cane is also subject to a disease which no astounding can obviate, and for which human wisdom has no sects. Hitherto in vain attempted to find a remedy. This disease is called the blast, and is occasioned by a species of ophis. When this happens, the fine, broad, green blades become sickly, dry, and withered; soon after they appear stained and spots; and if these spots are carefully examined, they will be found to contain innumerable eggs of an insect like a bug, which are soon quickened, and cover the plants with the vermin: the juice of the canes thus affected becomes sour, and no future shoot issues from the joints. Ants also concur with the bugs to spoil the plantation, and against these evils it is hard to find a remedy.

The crops of sugar-canes do not ripen precisely at the same period in all the colonies. In the Brazilian, Spanish, and Dutch settlements, they begin in January, and continue till October. This method does not imply any fixed season for the maturity of the sugar-cane. The

Sugar.

The English cut their canes in March and April; but they are not induced to do this on account of their ripeness. The drought that prevails in their islands renders the rains which fall in September necessary to their planting; and as the canes are 18 months in growing, this period always brings them to the precise point of maturity (p. 125).

"The time of crop in the sugar islands (says Mr. Edwards) is the season of gladness and festivity to man and beast. So palatable, salutary, and nourishing, is the juice of the cane, that every individual of the animal creation, drinking freely of it, derives health and vigour from its use. The meagre and sickly among the negroes exhibit a surprising alteration in a few weeks after the mill is set in action. The labouring horses, oxen, and mules, though almost constantly at work during this season, yet, being indulged with plenty of the green tops of this noble plant, and some of the scumblings from the boiling-house, improve more than at any other period of the year. Even the pigs and poultry fatten on the refuse. In short, on a well-regulated plantation, under a humane and benevolent director, there is such an appearance during crop-time of plenty and busy cheerfulness, as to soften, in a great measure, the hardships of slavery, and induce a spectator to hope, when the miseries of life are represented as insupportable, that they are sometimes exaggerated through the medium of fancy."

The canes when cut are sent to the mill.

The plants being cut, the branches at the top are given to the cattle for food; the top-shoot, which is full of eyes, is preserved for planting. The canes are cut into pieces about a yard long, tied up in bundles, and carried in carts to the mill, where they are bruised, and the juice is extracted from them. The mill consists principally of three upright iron-plated rollers or cylinders, from 30 to 40 inches in length, and from 20 to 25 inches in diameter; and the middle one, to which the moving power is applied, turns the other two by means of cogs. Between these rollers, the canes (being previously cut short, and tied into bundles) are twice compressed; for having passed through the first and second rollers, they are turned round the middle one by a circular piece of frame-work or screen, called in Jamaica the Dumb-returner, and forced back through the second and third; an operation which squeezes them completely dry, and sometimes even reduces them to powder. The cane juice is received in a leaden bed, and thence conveyed into a vessel called the receiver. The refuse, or macerated rind of the cane (which is called cane-trash, in contradistinction to field-trash), serves for fuel to boil the liquor.

The juice as it flows from the mill, taken at a me. The juice medium, contains eight parts of pure water, one part of extracted sugar, and one part consisting of coarse oil and mucilaginous gum, with a portion of essential oil.

As this juice has a strong disposition to fermentation, it must be boiled as soon as possible. There are some for purely water-mills that will grind with great ease canes sufficient for 30 hogsheads of sugar in a week. It is necessary to have boiling vessels, or clarifiers, that will correspond in dimensions to the quantity of juice flowing from the receiver. These clarifiers are commonly three in number, and are sometimes capable of containing 1000 gallons each; but it is more usual to see them of 300 or 400 gallons each. Besides the clarifiers which are used for the first boiling, there are generally four copper boilers. The clarifiers are placed in the middle or at one end of the boiling-house. If at one end, the boiler called the teache is placed at the other, and several boilers (generally three) are ranged between them. The teache is ordinarily from 70 to 100 gallons, and the boilers between the clarifiers and teache diminish in size from the first to the last. Where the clarifiers are in the middle, there is usually a set of three boilers on each side, which constitute in effect a double boiling-house. On very large estates this arrangement is found useful and necessary. The objection to so great a number is the expense of fuel; to obviate which, in some degree, the three boilers on each side of the clarifiers are commonly hung to one fire.

The juice runs from the receiver along a wooden gut: The clarifier lined with lead into the boiling-house, where it is received into one of the clarifiers. When the clarifier is filled, a fire is lighted, and a quantity of Bristol quick-lime in powder, which is called temper, is poured into the vessel. The use of the lime is to unite with the superabundant acid, which, for the success of the process, it is necessary to get rid of. The quantity sufficient to separate the acid must vary according to the strength of the quicklime and the quality of the liquor. Some planters allow a pint of lime to every 100 gallons of liquor; but Mr. Edwards thinks that a little more than half the quantity is a better medium proportion, and even then, that it ought to be dissolved in boiling water, that as little of it as possible may be precipitated. The heat is suffered gradually to increase till it approaches within a few degrees of the heat of boiling water, that the impurities

(d) The account given in the text concerning the time when the sugar canes are collected, we have taken from the Abbe Raynal's History of the Trade and Settlements of the East and West Indies; but Mr. Cazaud observes, that in February, March, and April, all the canes, whatever be their age, are as ripe as the nature of the soil ever allows them to be. He says farther, that the dryness of the weather, and not the age of the canes, which increases from January to April, is the cause that in January 400 gallons of juice commonly yield 48 gallons of sugar and molasses, one with another; in February from 56 to 64; in March from 64 to 72; in April sometimes 80; after which period the sugar ferments, and even burns, when the refiner is not very expert at his business.
SUG [ 803 ]

Sugar.

purities may be thoroughly separated. But if the liquor were suffered to boil with violence, the impurities would again incorporate with it. It is known to be sufficiently heated when the scum begins to rise in blisters, which break into white froth, and appear generally in about 40 minutes. The fire is then suddenly extinguished by means of a damper, which excludes the external air, and the liquor is allowed to remain about an hour undisturbed, during which period the impurities are collected at the surface. The juice is then drained off either by a syphon or a cock; the scum, being of a tenacious gummy nature, does not flow out with the liquor, but remains behind in the clarifier. The liquid juice is conveyed from the clarifier by a gutter into the evaporating boiler, commonly termed the grand copper; and if it has been obtained from good canes it generally appears transparent.

In the evaporating boiler, which should be large enough to receive the contents of the clarifier, the liquor is allowed to boil; and as the scum rises it is taken off. The scumming and evaporation are continued till the liquor becomes finer and thicker, and so far diminished in bulk that it may be easily contained in the second copper. When put into the second copper, it is nearly of the colour of Madeira wine; the boiling and scumming are continued, and if the impurities be considerable, a quantity of lime-water is added. This process is carried on till the liquor be sufficiently diminished in quantity to be contained in the third copper. After being purified a second time, it is put into the fourth copper, which is called the teaca, where it is boiled and evaporated till it is judged sufficiently pure to be removed from the fire. In judging of the purity of the liquor, many of the negroes (says Mr Edwards) guess solely by the eye (which by long habit they do with great accuracy), judging by the appearance of the grain on the back of the ladle: but the practice most in use is to judge by what is called the touch; i.e. taking up with the thumb a small portion of the hot liquor from the ladle; and, as the heat diminishes, drawing with the fore-finger the liquid into a thread. This thread will suddenly break, and shrink from the thumb to the suspended finger, in different lengths, according as the liquor is more or less boiled. The proper boiling height for strong muscovado sugar is generally determined by a thread of a quarter of an inch long. It is evident, that certainty in this experiment can be attained only by long habit, and that no verbal precepts will furnish any degree of skill in a matter depending wholly on constant practice.

The juice being thus purified by passing through the clarifier and four coppeers, it is poured into coolers, which are usually six in number. The removal from the teaca to the cooler is called striking. The cooler is a shallow wooden vessel seven feet long, from five to six wide, about 11 inches deep, and capable of containing a hogshead of sugar. As the liquor cools, the sugar grains, that is, collects into an irregular mass of imperfect crystals, separating itself from the melasses. It is then removed from the cooler, and conveyed to the curing house, where the melasses drain from it. For receiving them there is a large cistern, the sloping sides of which are lined with boards. Directly above the cistern a frame of joint-work without boarding is placed, on which empty hogsheads without heads are ranged.

The bottoms of these hogsheads are pierced with 8 or 10 holes, in each of which the stalk of a plantain leaf is fixed to project six or eight inches below the joints, and rise a little above the top of the hogshead. The hogshead being filled with the contents of the cooler, consisting of sugar and melasses, the melasses being liquid, drain through the sponggy stalk, and drop into the cistern. After the melasses are drained off, the sugar crystals become pretty dry and fair, and is then called muscovado or raw sugar.

We have described the process for extracting sugar, which is generally adopted in the British West India islands, according to the latest improvements; and have been anxious to present it to our readers in the simplest and most perspicuous form, that it might be intelligible to every person; and have therefore avoided to mention the observations and proposed amendments of those who have written on this subject. Had we done so, we should have swelled the present article to too great a size, without accomplishing the purpose which we have in view; for our intention is not to instruct the planters, but to give a distinct account of the most approved methods which the planters have generally adopted. But though we judge it useless to trouble our readers with all the little varieties in the process which different persons employ, we flatter ourselves it will not be disagreeable to learn by what methods the French make their sugar purer and whiter than ours. A quantity of Method of purification from these is put into conical pans or earthen pots, called by the French formes, having small perforations at the apex, which is kept closed. Each cone, reversed on its apex, is supported in another earthen vessel. The syrup is stirred together, and then left to crystallize. At the end of 15 or 16 hours, the hole in the point of each cone is opened, that the impure syrup may run out. The base of the sugar leaves is then taken out, and white pulverized sugar substituted in its stead; which being well pressed down, the whole is covered with clay moistened with water. This water filters through the mass, carrying the syrup with it which was mixed with the sugar, but which by this management flows into a pot substituted in the place of the first. This second fluid is called fine syrup. Care is taken to moisten and keep the clay to a proper degree of softness as it becomes dry. The sugar loves are afterwards taken out, and dried in a stove for eight or ten days; after which they are pulverized, packed and exported to Europe, where they are still farther purified. The reason assigned why this process is not universally adopted in the British sugar islands is this, that the water which dilutes and carries away the melasses dissolves and carries with it so much of the sugar, that the difference in quality does not pay for the difference in quantity. The French planters probably think otherwise, upwards of 400 of the plantations of St Domingo having the necessary apparatus for claying and actually carrying on the system.

The art of refining sugar was first made known to the Europeans by a Venetian, who is said to have received refining sugar 100,000 crowns for the invention. This discovery was in part introduced by a method made before the new world was explored; but whether Venetian, it was an invention of the person who first communicated it, or whether it was conveyed from China, where it had been known for a considerable time before, cannot now perhaps be accurately ascertained. We find no mention
mention made of the refining of sugar in Britain till the year 1659, though it probably was practised several years before. For in the Portuguese island of St. Thomas in 1624 there were 74 sugar ingenios, each having upwards of 200 slaves. The quantity of raw sugar imported into England in 1757 amounted to 1,493,995 cwt.; the quantity imported into Scotland in the same year was 117,285 cwt.; the whole quantity imported into Great Britain in 1787 was 1,026,741 cwt.

The sugar which undergoes the operation of refining in Europe is either raw sugar, sometimes called muscovado, or cassonado, which is raw sugar in a purer state. The raw sugar generally contains a certain quantity of melasses as well as earthy and feculent substances. The cassonado, by the operation of heating, is freed from its melasses. As the intention of refining these sugars is to give them a higher degree of whiteness and solidity, it is necessary for them to undergo other processes. The first of these is called clarification. It consists in dissolving the sugar in a certain proportion of lime-water, adding to a proper quantity of bullock’s blood, and leaving it to heat in order to remove the impurities which still remain. The heat is increased very gradually till it approach that of boiling water. By the assistance of the heat, the animal matter which was thrown in coagulates, at the same time that it attracts all the solid feculent and earthy matter, and raises it to the surface in the appearance of a thick foam of a brownish colour. As the feculences are never entirely removed by a first process, a second is necessary. The solution is therefore cooled to a certain degree by adding some water; then a fresh quantity of blood, but less considerable than at first, is poured in. The fire is renewed, and care is taken to increase the heat gently as before. The animal substance seizes on the impurities which remain, collects them on the surface, and they are then skimmed off. The same operation is repeated a third and even a fourth time, but no addition is made to the liquor except water. If the different processes have been properly conducted, the solution will be freed from every impurity, and appear perfectly clear. It is then conveyed by a pipe into an oblong basket about 16 inches deep, lined with a woollen cloth, and after filtering through this cloth, it is received in a cistern or copper which is placed below.

The solution being thus clarified, it undergoes a second general operation called evaporation. Fire is applied to the copper into which the solution was received, and the liquid is boiled till it has acquired the proper degree of consistency. A judgment is formed of this by taking up a small portion of the liquid and drawing it into a thread. When, after this trial, it is found sufficiently viscous, the fire is extinguished, and the liquid is poured into coolers. It is then stirred violently by an instrument called an ear, from the resemblance it bears to the ear of a boat. This is done in order to diminish the viscosity, and promote what is called the granulation, that is, the forming of it into grains or imperfect crystals. When the liquid is properly mixed and cooled, it is then poured into moulds of the form of a sugar loaf. These moulds are ranged in rows. The small ends, which are lowest, are placed in pots; and they have each of them apertures stopped up with linen for filtering the syrup, which runs from the moulds into the pots. The liquor is then taken out slowly in ladlefuls from the coolers, and poured into the moulds. When the moulds are filled, and the contents still in a fluid state, it is necessary to stir them, that no part may adhere to the moulds, and that the small crystals which are just formed may be equally diffused through the whole mass. When the sugar is completely crystallized, the linen is taken away from the apertures in the syrup is moulds, and the syrup, or that part which did not crystallize, descends into the pots in which the moulds are placed. After this purgation the moulds are removed and fixed in other pots, and a stratum of fine white clay diluted with water is laid on the upper part of the loaf. The water descending through the sugar by its own weight, mixes with the syrup which still remains in the body of the loaf, and washes it away. When the clay dries, it is taken off, and another covering of moist clay put in its place; and if it be not then sufficiently washed, a third covering of clay is applied. After the loaves have stood some days in the moulds, and have acquired a considerable degree of firmness and solidity, they are taken out, and carried to a stove, where they are gradually heated to the 50th of Beament (64° of Fahrenheit), in order to dissipate any moisture which may be still confined in them. After remaining in the stove eight days, they are taken out; and after cutting off all discoloring specks, and the head if still wet, they are wrapped in blue paper, and are ready for sale. The several syrups collected during the different parts of the process, treated in the same manner which we have just described, afford sugars of inferior quality; and the last portion, which no longer affords any sugar, is sold by the name of melasses.

The beauty of refined sugar, when formed into loaves, in what consists in whiteness, joined to a smallness of grain; in the beauty being dry, hard, and somewhat transparent. The process which we have described above refers to sugar once refined; but some more labour is necessary to produce double refined sugar. The principal difference in the operation is this, the latter is clarified by white of eggs instead of blood, and fresh water in place of lime-water.

Sugar-candy is the true essence of the cane formed into large crystals by a slow process. When the syrup candy is well clarified, it is boiled a little, but not so much as is done for the proof mentioned in the process for making common sugar. It is then placed in old moulds, having their lower ends stopped with linen, and crossed at little distances with small twigs to retain the sugar as it crystallizes. The moulds are then laid in a cool place. In proportion as the syrup cools, crystals are formed. In about nine or ten days the moulds are carried to the stove, and placed in a pot; but the linen is not removed entirely, so that the syrup falls slowly in drops. When the syrup has dropped away, and the crystals of the sugar-candy are become dry, the moulds are taken from the stove and broken in pieces, to disengage the sugar, which adheres strongly to the sides of the mould. If the syrup has been coloured with cochineal, the crystals take a slight tint of red; if indigo has been mixed, they assume a bluish colour. If it be desired to have the candy perfumed, the essence of flowers or amber may be dropped into the moulds along with the syrup.

Having now given some account of the method usually employed for refining sugar, it will not be improper.

Sugar is soluble in water, and in a small degree in alcohol. When united with a small portion of water, it becomes fusible; from which quality the art of preserving is indebted for many of its preparations. It is phosphoric and combustible; when exposed to fire emitting a blue flame if the combustion be slow, and a white flame if the combustion be rapid. By distillation it produces a quantity of phlegm, acid, oil, gas, and charcoal. Bergman, in treating sugar with the nitrous acid, obtained a new acid, now known by the name of the oxalic acid; but he has omitted to mention the principles of which sugar is composed. Lavoisier, however, has supplied this omission; and after many experiments has assigned three principles in sugar, hydrogen, oxygen, and carbon. If the juice expressed from the sugar cane be left to itself it passes into the acetic fermentation; and during the decomposition of the sugar, which is continued for three or four months, a great quantity of glutinous matter is separated. This matter when distilled gives off a portion of ammonium. If the juice be exposed to the spirituous fermentation, a wine is obtained analogous to cyder. If this wine, after being kept in bottles a year, be distilled, we obtain a portion of eau de vie.

The uses to which sugar is applied are indeed numerous and important: it can be made so solid as in the art of preserving to receive the most agreeable colours and the greatest variety of forms. It can be made so fluid as to mix with any soluble substance. It preserves the juice and substance of fruits in all countries and in all seasons. It affords a delicious seasoning to many kinds of food. It is useful in pharmacy, for it unites with medicines, and removes their disagreeable flavour: it is the basis of all syrups. M. Macquer has shown in a very satisfactory manner how useful sugar would be if employed in fermenting wines. Sugar has also been found a remedy for the scurvy, and a valuable article of food in cases of necessity. M. Humbert de Lenners, first surgeon to the late Duke of Orleans, published the following statement in the Gazette de Sante, which confirms this assertion. A vessel laden with sugar bound from the West Indies was becalmed in its passage for several days, during which the stock of provisions was exhausted. Some of the crew were dying of the scurvy, and the rest were threatened with a still more terrible death. In this emergency recourse was had to the sugar. The consequence was, the symptoms of the scurvy went off, the crew found it a wholesome and substantial aliment, and returned in good health to France.

Sugar (says Dr Rush) affords the greatest quantity of nourishment in a given quantity of matter of any substance in nature; of course it may be preserved in less room in our houses, and may be consumed in less time than more bulky and less nourishing aliment. It has this peculiar advantage over most kinds of aliment, that it is not liable to have its nutritional qualities affected by time or the weather; hence it is preferred by the Indians in their excursions from home. They mix a certain quantity of maple sugar, with an equal quantity of Indian corn, dried and powdered, in its milky state. This mixture is packed in little baskets, which are frequently wetted in travelling, without injuring the sugar. A few spoonfuls of it mixed with half a pint of spring water afford them a pleasant and strengthening meal. From the degrees of strength and nourishment which are conveyed into animal bodies by a small bulk of sugar, it might probably be given to horses with great advantage, when they are used in places or under circumstances which make it difficult or expensive to support them with more bulky or weighty aliment. A pound of sugar with grass or hay has supported the strength and spirits of a horse during a whole day's labour in one of the West India islands. A larger quantity given alone has fattened horses and cattle, during the war before last in Hispaniola, for a period of several months, in which the exportation of sugar, and the importation of grain, were prevented by the want of ships.

The plentiful use of sugar in diet is one of the best preventives that has ever been discovered of the diseases least and which are produced by worms. Nature seems to have a deep-seated implanted a love for this aliment in all children, as if it were an purpose to defend them from those diseases. Dr Rush knew a gentleman in Philadelphia, who early adopted this opinion, and who, by indulging a large family of children in the use of sugar, has preserved them all from the diseases usually occasioned by worms.

Sir John Pringle has remarked, that the plague and plague never been known in any country where sugar commonly against poses a material part of the diet of the inhabitants. Dr the plague and other malignant fivers of all kinds have been lessened by this diet. It is poss ible to keep as few as possible of any species from being so often affected by them.

In the numerous and frequent disorders of the breast, which occur in all countries where the body is exposed to a variable temperature of weather, sugar affords the basis of many agreeable remedies. It is useful in weakesses, and acrid defluxions upon other parts of the body. Many facts may be adduced in favour of this assertion. Dr Rush mentions only one, which, from the venerable name of the person whose case furnished it, cannot fail of commanding attention and credit. Upon the inquiring of Dr Franklin, at the request of a friend of mine (says our respectable author), about a year before he died, whether he had found any relief from the pain of the stone, from the blackberry jam, of which he took large quantities, he told me that he had, but that he believed the medicinal part of the jam resided wholly in the sugar; and as a reason for thinking so, he added, that he often found the same relief by taking about half a pint of a syrup, prepared by boiling a little brown sugar in water, just before he went to bed, that he did from a dose of opium. It has been supposed by some of the early physicians of our country, that the sugar obtained from the maple-tree is more medicinal than that obtained from the West India sugar-cane; but this opinion I believe is without foundation. It is preferable in its qualities to the West India sugar only from its superior cleanliness.

Cases may occur in which sugar may be required in medicine, or in diet, by persons who refuse to be benefited, even indirectly by the labour of slaves. In such cases the innocent maple sugar will always be preferred. It has been said, that sugar injures the teeth; but this opinion to the notion now has so few advocates, that it does not deserve a serious refutation.
SUG [ 806 ]

In the account which we have given above of the method of cultivating and manufacturing sugar, we have had in our eye the plantations in the West Indies, where slaves alone are employed; but we feel a peculiar pleasure in having it in our power to add a short description of the method used in the East Indies, because their sugar is manufactured by free men, on a plan which is much more economical than what is followed in the West Indies. The account which we mean to give is an extract from the report of the committee of Privy-council for trade on the subject of the African slave-trade, drawn up by Mr Botham. We shall give it in the author's own words.

"Having been for two years in the English and French West India islands, and since conducted sugar estates in the East Indies; before the abolition of the slave-trade was agitated in parliament, it may be desirable to know that sugar of a superior quality and inferior price is produced in our islands than in the East Indies; that the culture of the cane, the manufacture of the sugar and arrack, is, with these material advantages, carried on by free people. Chir, Bengal, the coast of Malabar, all produce quantities of sugar and spirits; but as the most considerable growth of the cane is carried on near Batavia, I shall explain the improved manner in which sugar estates are there conducted. The proprietor of the estate is generally a wealthy Dutchman, who has erected on it substantial mills, boiling and curing houses. He rents this estate to a Chinese, who resides on it as a superintendent; and this renter (supposing the estate to consist of 300 or more acres) relets it to free men in parcels of 50 or 60 on these conditions: 'That they shall plant it in canes, and receive so much per peck of 133 lbs. of every peck of sugar that the canes shall produce.'

When crop time comes on, the superintendent collects a sufficient number of persons from the adjacent towns or villages, and takes off his crop as follows. To any set of tradesmen who bring their carts and buffaloes he agrees to give such a price per peck to cut all his crop of canes, carry them to the mill and grind them. A second to boil them per peck. A third to clay them and basket them for market per peck. So that by this method of conducting a sugar estate the renter knows to a certainty what the produce of it will cost him per peck. He has not any permanent or unnecessary expense; for when the crop is taken off, the taskmen return to their several pursuits in the towns and villages they came from; and there only remain the cane planters who are preparing the next year's crop. This, like all other complex arts, by being divided into several branches, renders the labour cheaper and the work more perfectly done.

Only clayed sugars are made at Batavia; these are in quality equal to the best sort from the West Indies, and are sold so low from the sugar estates as eighteen shillings sterling per peck of 133 lbs. This is not the selling price to the trader at Batavia, as the government there is arbitrary, and sugar subject to duties imposed at will. The Shabander exacts a dollar per peck on all sugar exported. The price of common labour is from gd. to 10d. per day. By the method of carrying on the sugar estates, the taskmen gain considerably more than this, not only from working extraordinary hours, but from being considered artists in their several branches. They do not make spirits on the sugar estates. The molasses is sent for sale to Batavia, where one distillery may purchase the produce of an hundred estates. Here is a vast saving and reduction of the price of spirits; not as in the West Indies, a distillery, for each estate; many centre in one, and arrack is sold at Batavia from 21 to 25 rixdollars per leauger of 160 gallons; say 8d. per gallon."

The Sugar Maple, (the Acer saccharinum of Linneus), as well as the sugar-cane, produces a great quantity of sugar. This tree grows in great numbers in the western counties of all the middle states of the American union. Those which grow in New York and Pennsylvania yield the sugar in a greater quantity than those which grow on the waters of the Ohio. These trees are generally found mixed with the beech, hemlock, white and white ash, the cucumber tree, linden, aspen, buter nut, and wild cherry trees. They sometimes appear in groves covering five or six acres in a body, but they are more commonly interspersed with some or all of the forest trees which have been mentioned. From 30 to 50 trees are generally found upon an acre of ground. They grow on all the good soils, and frequently in stony ground. Springs of the purest water abound in their neighbourhood. They are, cal Society, when fully grown, as tall as the white and dark oaks, vol. iii. and from two to three feet in diameter. They put forth a beautiful white blossom in the spring before they show a single leaf. The colour of the blossom distinguishes them from the acer rubrum, or the common maple, which affords a blossom of a red colour. The wood of the sugar maple-tree is extremely inflammable, and is preferred upon that account by hunters and surveyors for fire-wood. Its small branches are so much impregnated with sugar as to afford support to the cattle, horses, and sheep of the first settlers, during the winter, before they are able to cultivate forage for that purpose. Its ashes afford a great quantity of potash, exceeded by few, or perhaps by none, of the trees that grow in the woods of the United States. The tree is supposed to arrive at its full growth in the woods in twenty years.

It is not injured by tapping; on the contrary, the tree often is tapped, the more syrup is obtained from it. In this respect it follows a law of animal secretion. A single tree had not only survived, but flourished after forty-two tappings in the same number of years. The obtained effects from a yearly discharge of sap from the tree, in increasing and increasing the sap, are demonstrated from the superior excellence of those trees which have been perforated in an hundred places, by a small wood-pecker which feeds upon the sap. The trees, after having been wounded in this way, distil the remains of their juice on the ground, and afterwards acquire a black colour. The sap of these trees is much sweeter to the taste than that which is obtained from trees which have not been previously wounded, and it affords more sugar.

From twenty-three gallons and one quart of sap, produced in twenty-four hours from only two of these dark-coloured trees, Arthur Noble, Esq. of the state of New York, obtained four pounds and thirteen ounces of good-grained sugar.

A tree of an ordinary size yields in a good season from twenty to thirty gallons of sap, from which are made from five to six pounds of sugar. To this there are sometimes
times remarkable exceptions. Samuel Lowe, Esq. a justice of peace in Montgomery county, in the state of New York, informed Arthur Noble, Esq. that he had made twenty pounds and one ounce of sugar between the 14th and 23d of April, in the year 1789, from a single tree that had been tapped for several successive years before. [49]

From the influence which culture has upon forest and garden, it has been supposed, that by transplanting the sugar maple-tree into a garden, or by destroying such other trees as shelter it from the rays of the sun, the quantity of the sap might be increased, and its quality much improved. A farmer in Northampton county, in the state of Pennsylvania, planted a number of these trees above twenty years ago in his meadow, from three gallons of the sap of which he obtains every year a pound of sugar. It was observed formerly, that it required five or six gallons of the sap of the trees which grow in the woods to produce the same quantity of sugar.

The sap distills from the wood of the tree. Trees which have been cut down in the winter for the support of the domestic animals of the new settlers, yield a considerable quantity of sap as soon as their trunks and limbs feel the rays of the sun in the spring of the year. It is in consequence of the sap of these trees being equally diffused through every part of them, that they live three years after they are girdled, that is, after a circular incision is made through the bark into the substance of the tree, for the purpose of destroying it. It is remarkable that grass thrives better under this tree in a meadow, than in situations exposed to the constant action of the sun. The season for tapping the trees is in February, March, and April, according to the weather which occurs in these months.

Warm days and frosty nights are most favourable to a plentiful discharge of sap. The quantity obtained in a day from a tree is from five gallons to a pint, according to the greater or less heat of the air. Mr. Lowe informed Arthur Noble, Esq. that he obtained near three and twenty gallons of sap in one day (April 17, 1789) from the single tree which was before mentioned. Such instances of a profusion of sap in single trees are however not very common.

There is always a suspension of the discharge of sap in the night if a frost succeed a warm day. The perspiration in the tree is made with an axe or an auger. The latter is preferred from experience of its advantages. The auger is introduced about three quarters of an inch, and in an ascending direction (that the sap may not be frozen in a slow current in the mornings or evenings), and is afterwards deepened gradually to the extent of two inches. A spout is introduced about half an inch into the hole made by this auger, and projects from three to twelve inches from the tree. The spout is generally made of the sumach or elder, which usually grows in the neighbourhood of the sugar trees. The tree is first tapped on the south side; when the discharge of its sap begins to lessen, an opening is made on the north side, from which an increased discharge takes place. The sap flows from four to six weeks, according to the temperature of the weather. Troughs large enough to contain three or four gallons, made of white pine, or white ash, or of dried water ash, aspen, linden, poplar, or common maple, are placed under the spout to receive the sap, which is carried every day to a large receiver, made of either of the trees before mentioned. From this receiver it is conveyed, after being strained, to the boiler.

We understand that there are three modes of reducing the sap to sugar by evaporation, by freezing, and by boiling; of which the latter is most general, as being the most expeditious. We are farther assured, that the profit of the maple tree is not confined to its sugar. It affords most agreeable melasses, and an excellent vinegar. The sap which is suitable for these purposes is obtained after the sap which affords the sugar has ceased to flow, so that the manufactories of these different products of the maple tree, by succeeding, do not interfere with each other. The melasses may be made to compose the basis of a pleasant summer beer. The sap of the maple is moreover capable of affording a spirit; but we hope this precious juice will never be prostituted to this ignoble purpose. Should the use of sugar in diet become more general in this country (says Dr. Rush) it may tend to lessen the inclination or supposed necessity for spirits, for I have observed a relish for sugar in diet to be seldom accompanied by a love for strong drink.

There are several other vegetables in our own country which afford sugar; as beet-roots, skirrets, pars- cled, leeks, potatoes, celery, red cabbage stalks, the young many other shoots of Indian wheat. The sugar is most readily obtained from these, by making a tincture of the subject in rectified spirit of wine; which, when saturated by heat, will deposit the sugar upon standing in the cold.

Sugar of Milk. See MILK, CHEMISTRY INDEX. Acid of Sugar. See CHEMISTRY INDEX.

SUGILLATION, in Medicine, an extravasation of blood in the coats of the eye, which at first appears of a reddish colour, and afterwards livid or black. If the disorder is great, bleeding and purging are proper, as are also discontinuities.
