Suicide.

SUICIDE, the crime of self-murder, or the person who commits it.

We have often wished to see a history of crimes drawn up by a man of ability and research. In this history we would propose that the author should describe the crimes peculiar to different nations in the different stages of society, and the changes which they undergo in the progress of civilization. After having arranged the historical facts, he might, by comparing them with the religion and the knowledge of the people, deduce some important general conclusions, which would lead to a discovery of the cause of crimes, and of the remedy most proper to be applied. Some crimes are peculiar to certain stages of society, some to certain nations, &c.

1 Suicide among the Jews.

Suicide is one of those crimes which we are led to believe not common among savage nations. The first instances recorded of it in the Jewish history are those of Saul and Ahitophel; for we do not think the death of Samson a pro, 'r example. We have not reason to suppose that it became common among the Jews till their wars with the Romans, when multitudes slaughtered themselves that they might not fail alive into the hands of their enemies. But at this period the Jews were a most desperate and abandoned race of men, had corrupted the religion of their fathers, and rejected that pure system which their promised Messiah came to Jerusalem to announce.

2 Among the Greeks.

When it became remarkable among the Greeks, we have not been able to discover; but it was forbidden by Pythagoras, as we learn from Athenæus, by Socrates and Aristotle, and by the Theban and Athenian laws. In the earliest ages of the Roman republic it was seldom committed; but when luxury and the Epicurean and Stoical philosophy had corrupted the simplicity and virtue of the Roman character; then they began to seek shelter in suicide from their misfortunes or the effects of their own vices.

3 The Bramins and Gentoos.

The religious principles of the bramins of India led them to admire suicide on particular occasions as honourable. Accustomed to abstinence, mortification, and the contempt of death, they considered it as a mark of weakness of mind to submit to the infirmities of old age. We are informed that the modern Gentoos, who still in most things conform to the customs of their ancestors, when old and infirm, are frequently brought to the banks of rivers, particularly to those of the Ganges, that they may die in its sacred streams, which they believe can wash away the guilt of their sins. But the maxims of the bramins, which have encouraged this practice, we are assured by Mr Holwell, are a corruption of the doctrines of the Shastah, which positively forbid suicide under the severest punishment. The practice which religion or affection has established among the Gentoos, for women at the death of their husbands to burn themselves alive on the funeral pile, we do not think ought to be considered as suicide, as we are not anxious to extend the meaning of the word; for were we to extend it thus far, it would be as proper to apply it to those who choose rather to die in battle than make their escape at the expence of their honour. Thus we should condemn as suicides the brave Spartans who died at Thermopylæ in defence of their country; we should also be obliged to apply the same disgraceful epithet to all those well-meaning but weak-minded Christians in this island, who in the last century chose rather to die as martyrs than comply with commands which were not morally wrong. According to the Gentoo laws, "it is proper for a woman after her husband's death to burn herself in the fire with his corpse. Every woman who thus burns shall remain in paradise with her husband three crore and fifty lacks of years. If she cannot, she must in that case preserve an inviolable chastity. If she remain chaste, she goes to paradise; and if she do not preserve her chastity, she goes to hell."

Sullivan's Phil. Rhap. vol. ii. Holwell's Interesting Events, &c. vol. i.

4 Among the Americans.

A custom similar to this prevailed among many nations on the continent of America. When a chief died, a certain number of his wives, of his favourites, and of his slaves, were put to death, and interred together with him, that he might appear with the same dignity in his future station, and be waited upon by the same attendants. This persuasion is so deeply rooted, that many of their retainers offer themselves as victims; and the same custom prevails in many of the negro nations in Africa.

Robertson's America.

5 The Japanese, and

If we can belive the historians of Japan, voluntary death is common in that empire. The devotees of the idol Amida drown themselves in his presence, attended by their relations and friends, and several of the priests, who all consider the devoted person as a saint who is gone to everlasting happiness. Such being the supposed honours appropriated to a voluntary death, it is not surprising that the Japanese anxiously cherish a contempt of life. Accordingly it is a part of the education of their children "to repeat poems in which the virtues of their

Raynal's Hist. of the East and West Indies, vol. i.

ancestors are celebrated, an utter contempt of life is inculcated, and suicide is set up as the most heroic of actions."

6
Scythians,

A notion seems also to have prevailed among the ancient Scythian tribes, that it was pusillanimous and ignoble for a man whose strength was wasted with disease or infirmity, so as to be useless to the community, to continue to live. It was reckoned an heroic action voluntarily to seek that death which he had not the good fortune to meet in the field of battle. Perversion of moral feeling does not spring up, we hope, spontaneously in any nation, but is produced by some peculiarities of situation. A wandering people like the Scythians, who roamed about from place to place, might often find it impossible to attend the sick, or to supply from their precarious store the wants of the aged and infirm. The aged and infirm themselves, no longer able to support the character of warriors, would find themselves unhappy. In this way the practice of putting to death such persons as were useless to the community might originate, and afterwards be inculcated as honourable; but he who put an end to his infirmities by his own hand, obtained a character still more illustrious.

7
and Scandinavians.

The tribes of Scandinavia, which worshipped Odin the "father of slaughter," were taught, that dying in the field of battle was the most glorious event that could befal them. This was a maxim suited to a warlike nation. In order to establish it more firmly in the mind, all were excluded from Odin's feast of heroes who died a natural death. In Asgardia stood the hall of Odin; where, seated on a throne, he received the souls of his departed heroes. This place was called *Valhalla*, signifying "the hall of those who died by violence." Natural death being thus deemed inglorious, and punished with exclusion from Valhalla the paradise of Odin, he who could not enjoy death in the field of battle was led to seek it by his own hands when sickness or old age began to assail him. In such a nation suicide must have been very common.

8
It prevailed much in the decline of the Roman empire.

As suicide prevailed much in the decline of the Roman empire, when luxury, licentiousness, profligacy, and false philosophy, pervaded the world, so it continued to prevail even after Christianity was established. The Romans, when they became converts to Christianity, did not renounce their ancient prejudices and false opinions, but blended them with the new religion which they embraced. The Gothic nations also, who subverted the Roman empire, while they received the Christian religion, adhered to many of their former opinions and manners. Among other criminal practices which were retained by the Romans and their conquerors, that of suicide was one; but the principles from which it proceeded were explained, so as to appear more agreeable to the new system which they had espoused. It was committed, either to secure from the danger of apostasy, to procure the honour of martyrdom, or to preserve the crown of virginity.

9
Too common in modern times, but not more so in England than in other countries.

When we descend to modern times, we lament to find so many instances of suicide among the most polished nations, who have the best opportunities of knowing the atrocity of that unnatural crime. The English have long been reproached by foreigners for the frequent commission of it; and the "gloomy month of November" has been stigmatized as the season when it is most common. But this disgraceful imputation, we think, may be justly attributed, not to the greater frequency of the crime in England than in other places, but to the custom of publishing in the newspapers every instance of suicide which is known. Mr Moore, who lately published a full inquiry into this subject, was at great pains to obtain accurate information concerning the perpetration of this crime in different countries. Mercier, who wrote in 1782, says, that the annual number of suicides in Paris was then about 150. He does not tell us how he came by the information; but we have the authority of the Abbe Fontana for asserting, that more persons put an end to their lives in Paris than in London. The Abbe had this information from the lieutenant of the police. Mr Moore was informed by one of the principal magistrates of Geneva, that in that city, which contains about 25,000 inhabitants, the average number of suicides is about *eight*. The average number of suicides, from what cause soever, for the last 28 years, has been 32 each year for London, Southwark, and Westminster. In Edinburgh, which contains 80,000 inhabitants, we are convinced the average number of suicides does not exceed *four*. Mr Moore found, from the accounts with which he was favoured by the several coroners of the county of Kent, that for the last 18 years the number has been upwards of 32 each year. Kent is supposed to contain 200,000 inhabitants, and London 800,000. It is easy therefore to see, that in the metropolis many instances of suicide must occur which are never the subject of legal inquiry, and consequently never made known to the world. Whereas in the country towns and villages of Kent it is scarcely possible to conceal such an action as self-murder from the knowledge of the whole neighbourhood. The calculation therefore respecting Kent we may receive as true, while we must increase the average number in London very considerably. Mr Moore computes the average number of suicides in England every year at a thousand; but the principles on which he founds this opinion are so imperfect and vague, that we do not think it can be depended on as coming near the truth.

Mercier's Tableau de Paris.

10
The number of suicides in Paris, London, Geneva, &c. according to the best accounts.

11
In what rank and situation suicide is most common.

It might lead to some interesting conclusions to compare together, not only the number of suicides in different countries, but also the rank and principles, the sex and age, of those unhappy persons by whom it has been committed. Mercier says, that at Paris it was the lower ranks who were most commonly guilty of it; that it was mostly committed in garrets or hired lodgings; and that it proceeded from poverty and oppression. A great many, he says, wrote letters to the magistrates before their death. Mr Moore's correspondent from Geneva informed him, that from the year 1777 to 1787 more than 100 suicides were committed in Geneva; that two-thirds of these unfortunate persons were men; that few of the clerical order have been known to commit it; and that it is not so much the end of an immoral, irreligious, dissipated life, as the effect of melancholy and poverty. By the information obtained from the coroners of Kent, it appears, that of the 32, three-fourths have destroyed themselves by hanging; that the proportion of males to females has been about two-thirds of the former; that no one season of the year is more distinguished for this crime than another; and that suicide is upon the increase. Our accounts respecting the city of London are very imperfect; but we think ourselves intitled to conclude, that suicide is more common among the great and wealthy

Moore's Full Inquiry into the Causes of Suicide.

Suicide.

wealthy than among the lower ranks, and that it is usually the effect of gaming and dissipation.

12 Physical causes to which it has been ascribed in Britain.

Those who have inquired into the causes of suicide in Britain have enumerated many physical as well as moral causes. They have ascribed it to the variableness of our climate, to the great use of animal food, to strong spirituous liquors, to tea, and to the sulphureous exhalations of the pit coal used as fuel, which are said to produce a depression of spirits and nervous affections. Of our climate, we have no cause to complain, nor have we any reason to impute any of our vices to its influence. There are many climates much more unfavourable where suicide is scarcely known. That an excessive quantity of gross animal food, or of strong liquors, or of tea, will powerfully affect the human constitution, we will not deny: but before we consider these as causes, it must first be determined, whether those who are guilty of self-murder be much addicted to them; and if they are, whether there be not other causes much more violent in their nature which have operated on their minds; for we ought not rashly to attribute vicious effects to any of those things which seem to have been created on purpose for the comfort or convenience of man. We are rather surprised to find that coal is mentioned even as a distant cause of suicide; for it is one of the blessings of our island; and a good coal fire we have always found rather conducive to good spirits than injurious to them.

13 And moral causes.

Among the moral causes which are supposed to cooperate in producing suicide in Britain, the freedom of our constitution and laws is reckoned one. That rational liberty should have any tendency to encourage crimes of any kind, a Christian philosopher can never allow; for such an opinion is totally discountenanced by enlightened views of nature. Mercier has ascribed the frequency of suicide in Paris to the oppression of the late government. Now it appears somewhat extraordinary, that suicide in one country should be occasioned by liberty, and in another by the want of it. One of these opinions must be false, and it is surely not difficult to distinguish which.

14 Not owing always to insanity.

Humanity would in most cases dispose us to conclude, that suicide is the effect of insanity, were there not so many instances of cool deliberate self-murder. That suicide is an unnatural crime, which none but a madman would commit, compassion indeed may suppose; but the murder of a wife, a father, or a child, are also unnatural; yet compassion does not teach us in all cases to ascribe such a crime to madness. Passion may often arise to such a height of outrage as to be scarcely distinguishable from madness in its symptoms and its effects; yet we always make a distinction between that madness which arises from disease and that which is owing to a violent perturbation of mind. If a person be capable of managing his wordly affairs, of making a will, and of disposing of his property, immediately before his death, or after he formed the resolution of dying by his own hands, such a man is not to be considered as insane.

15 but often also to vicious passion.

But though a regard for truth prevents us from ascribing suicide in all cases to insanity, we must ascribe it either to insanity or to vicious passion. These two divisions, we imagine, will comprehend every species of it, whether arising from melancholy, *tædium vitæ* or *ennui*, disappointment in schemes of ambition or love, pride, gaming, or a desire to avoid the shame of a public execution; passions which are often increased by false views of God, of man, and of a future state, arising from deism and infidelity. If these be the causes of suicide in modern time, what a disgraceful contrast do they form to those principles which actuated many of the ancient philosophers, the Gentoos, the Japanese, and the worshippers of Odin? When they committed suicide, they committed it from principle, from a belief of its lawfulness, and the hope of being rewarded for what they judged an honourable sacrifice. But in modern times, we are sorry to say, when it is not the effect of madness, it is the effect of vice: and when it is the effect of vice, it proves that the vicious passions are then indulged to the highest degree; for there is no crime which a man can commit that is so strong a symptom of the violence of particular passions. It is from not attending to this circumstance, that it has been found so difficult to refute the arguments in favour of suicide. If the criminality of suicide be confined merely to the violent action, many apologies may be made for it; but if it be considered solely as the effect of vice, as the strongest symtom of ungoverned passion, he who undertakes its defence must undertake the defence of what all men will loudly condemn (A).

It

(A) Several of the heathens entertained a very just sense of the atrocity of suicide. Quintus Curtius introduces Darius with the following speech, when he had lost his empire: "I wait (says the unfortunate monarch) the issue of my fate: you wonder, perhaps, that I do not terminate my own life; but I choose rather to die by the crime of another than by my own.

We cannot refuse ourselves the pleasure of presenting to our readers the following beautiful passage upon this subject from Fitzosborne's letters*: "I am persuaded (says this elegant writer) this disgust of life is frequently indulged out of a principle of mere vanity. It is esteemed as a mark of uncommon refinement, and as placing a man above the ordinary level of his species, to seem superior to the vulgar feelings of happiness. True good sense, however, most certainly consists not in despising, but in managing our stock of life to the best advantage, as a cheerful acquiescence in the measures of Providence is one of the strongest symptoms of a well-constituted mind. Self-weariness is a circumstance that ever attends folly; and to condemn our being is the greatest, and indeed the peculiar infirmity of human nature. It is a noble sentiment which Tully puts into the mouth of Cato, in his Treatise upon old Age; *Non lubet mihi* (says that venerable Roman) *deplorare vitam, quod multi, et ii docti, sæpe fecerunt; neque me vixisse poenitet: quoniam ita vixi, ut non frustra me natum existimem.*

* Letter iv.

"It is in the power, indeed, of but a very small portion of mankind to act the same glorious part that afforded such high satisfaction to this distinguished patriot; but the number is yet far more inconsiderable of those who cannot, in any station, secure themselves a sufficient fund of complacency to render life justly valuable. Who is it that is placed out of the reach of the highest of all gratifications, those of the generous affections, and that cannot provide

A 2 for

Suicide.

16 Unnecessary to enter into the arguments of casuists upon this subject.

It is unnecessary then to enter particularly into the arguments of those casuists who have undertaken the despicable office of advocates for the crime of suicide. Their talents might surely have been employed more usefully to the world, and more honourably to themselves, than in pleading for a crime, which, if it were committed by every man to whom their principles would make it lawful, would totally destroy some of the noblest virtues, fortitude, patience, and resignation; nay, would destroy society itself, and teach us to despise the opinion that this world is a state of preparation for another. "I came into life without my own consent, and may I not quit it at pleasure?" (say the advocates for suicide). If, because we came into life without our own consent, we might quit it at pleasure, why may we not spend our life also as we please? Why may we not rob and murder, and commit every kind of crime, if *mere inclination* is to be the rule of action! Thus upon the principles of suicide the highwayman and murderer may reason, and every man may find a sufficient apology for any crime which he is tempted to commit. Or this absurdity may be otherwise answered: As we came into life without our own consent, we must have come with the consent of some other being; and logic says, that with the consent of that Being only can we lawfully quit it.

17 Its great criminality and imprudence.

It is sufficient shortly to say, that suicide is contrary to the strongest principle of the human constitution, self-preservation; that it is rebellion against God; that it is cruelty to the feelings and reputation, and often takes away the subsistence of a wife, a child, or a father; that it proves a want of fortitude to brave misfortunes; that it delivers only from imagined to plunge into real evils. We may add, that almost every instance of suicide of which we have heard was rash, imprudent, and premature, interrupted a useful life, or prevented a more honourable death. Had Cato's pride permitted him to yield himself to the generosity of Cæsar, his character and his influence might have contributed to retard the slavery of his country, which his death tended to hasten. Had Brutus and Cassius not executed the fatal resolution which they had formed, of dying by their own hands in case of misfortune, the battle of Philippi might have had a very different issue. Had Hannibal surrendered himself to the Romans, instead of swallowing poison, he would have gained more glory in braving their tortures than he won in the battle of Cannæ; for to die innocently and heroically is the greatest exertion of human fortitude.

18 How punished by the Greeks, Ceans, &c.

As suicide was deemed a crime by the most illustrious and virtuous of the Greek and Roman philosophers, it was considered as a crime by the laws, and treated with ignominy. By the law of Thebes suicides were to have no honours paid to their memory *. The Athenian law ordained the hand which committed the deed to be cut off, and burnt apart from the rest of the body. The body was not buried with the usual solemnities, but was ignominiously thrown into some pit. In Cea and Massilia (the ancient *Marseilles*), it was considered as a crime against the state; and it was therefore necessary for those who wished to destroy themselves to obtain permission from the magistrates. † Plutarch acquaints us, that an unaccountable passion for suicide seized the Milesian virgins; from indulging which they could not be prevented by the tears and entreaties of parents and friends: but what persuasion and entreaty could not effect was accomplished by very different means. A decree was issued, "that the body of every young woman who hanged herself should be dragged naked through the streets by the same rope with which she had committed the deed." This wise edict put a complete stop to the extraordinary frenzy, and suicide was no longer committed by the virgins of Miletus.

* *Petite Comment. in Leges Atticas*, p. 523.

† *Plutarch on the Virtues of Women.*

19 By the Romans.

In the early part of the Roman history there seems to have been seldom occasion for framing any laws against suicide. The only instance recorded occurs in the reign of Tarquinius Priscus. The soldiers who were appointed to make drains and common sewers, thinking themselves disgraced by such servile offices, put themselves to death in great numbers. The king ordered the bodies of all the self-murderers to be exposed on crosses, and this put an effectual stop to the practice. It is doubtful whether there was any standing law against suicide during the existence of the republic; but during the reign of the emperors it was thought proper to lay it under certain regulations, though not absolutely to condemn it as a crime. In Justinian's Digests there is a law, by which it was enacted, "that if persons accused, or who had been found guilty, of any crime, should make away with themselves, their effects should be confiscated." But this punishment only took place when confiscation of goods happened to be the penalty appointed by the law for the crime of which the self-murderer was accused or found guilty, and was not inflicted for suicide committed in any other circumstances.

Lib. xlviii. Tit. xxi. par. 3.

20 And by Christians.

When the Christian church had extended its jurisdiction in the Roman empire, it was decreed in the sixth century, that no commemoration should be made in the eucharist for such as destroyed themselves: neither should their

---

for his own happiness, by contributing something to the welfare of others? As this disease of the mind generally breaks out with the most violence in those who are supposed to be endowed with a greater delicacy of taste and reason than is the usual allotment of their fellow creatures, one may ask them, whether there is any satiety in the pursuits of useful knowledge? or, if one can ever be weary of benefiting mankind? Will not the fine arts supply a lasting feast to the mind; or, can there be wanting a pleasureable enjoyment, so long as there remains even one advantageous truth to be discovered or confirmed? To complain that life has no joys, while there is a single creature whom we can relieve by our bounty, assist by our counsels, or enliven by our presence, is to lament the loss of that which we possess, and is just as rational as to die for thirst with the cup in our hands. But the misfortune is, when a man is settled into a habit of receiving all his pleasures from the mere selfish indulgences, he wears out of his mind the relish of every nobler enjoyment, at the same time that his powers of the sensual kind are growing more languid by each repetition. It is no wonder, therefore, he should fill up the measure of his gratifications long before he has completed the circle of his duration; and either wretchedly sit down the remainder of his days in discontent, or rashly throw them up in despair."

Suicide || Suit.

their bodies be carried out to burial with psalms, nor have the usual service said over them. This ecclesiastical law continued till the reformation, when it was admitted into the statute code of England by the authority of parliament. As an additional punishment, however, confiscation of land and goods seems to have been adopted from the Danes, as we learn from Bracton *. At present the punishment consists in confiscating all the personal property of a *felo de se* for the use of the crown, and in excluding his body from interment in consecrated ground. The warrant of the coroner requires that the body should be buried in some public highway, and a stake driven through it to increase the ignominy.

* De Legibus et Consuetudinibus Angliæ, Lib iii. Tract. 11.

21 Difficult to devise a punishment that would be an effectual preventive.

To inquire into the prevalence and causes of crimes, in order to discover the most judicious methods of preventing them, is the duty of the Patriot and the Christian. Suicide, we find, is a common and an increasing evil: but it is a difficult matter to find an effectual remedy; for what motives can be held out sufficient to influence that man's mind who is deaf to the voice of nature speaking within him, and to the voice of nature's God declaring that he is stationed at a post which it is his duty to maintain? His reputation and property are indeed within the reach of the laws, his body may be treated with ignominy, and his property confiscated; but this punishment will not be a preventive, even if it could be always inflicted; and that it is seldom inflicted, though the laws have decreed it, is well known. The humanity of the present age disposes us to sympathise with the relations of the deceased, instead of demanding that the sentence of the law should be executed. It is a generally received opinion, and a just one, that punishments decreed by human laws should be directed only against such crimes as are injurious to society; but when it is hence inferred, that suicide ought not to be subject to the cognizance of human laws, every rule of logic is violated. There is no man, however mean in station and in talents, whose life may not, on some occasions, be useful to the community at large; and to conclude, that a person who fancies himself useless may therefore lawfully put a period to his life, is as false reasoning as it would be to conclude, that by killing a poor man, who lives on the public, we should perform an action not only innocent but meritorious, as we should thereby free society from one of its burdens.

SUIDAS, a Greek writer, according to some, flourished in the 11th century, under the reign of the emperor Alexius Comnenus; according to others, before the 10th century. He wrote in Greek an Historical and Geographical Dictionary or Lexicon; a work which, though not always strictly accurate, is nevertheless of great importance, as it contains many things taken from the ancients that are nowhere else to be found. The best edition of Suidas is that of Kuister, in Greek and Latin, with notes, printed in 3 vols. fol. which has been much improved by Toup.

LAPIS SUILLUS. See *Swine-Stone*, MINERALOGY *Index*.

SUIT, is used in different senses; as, 1. Suit of court, or suit-service, which is an attendance the tenant owes to his lord's court. 2. Suit-covenant, where a person has covenanted to do service in the court of the lord. 3. Suit-custom, which is where one and his ancestors have owed suit time out of mind. 4. It is used for a petition to the king or any person of dignity, where a lord distrains his tenant for suit, and none is due. In this case, the party may have an attachment against him to appear in the king's court.

Suit.

SUIT, in *Law*, the same with action. The Romans introduced pretty early set forms for actions and suits into their law, after the example of the Greeks; and made it a rule, that each injury should be redressed by its proper remedy only. "*Actiones*, (says the Pandects) *compositæ sunt quibus inter se homines disceptarent, quas actiones ne populus prout vellet institueret, certas solemnesque esse voluerunt.*" The forms of these actions were originally preserved in the books of the pontifical college as choice and inestimable secrets, till one Cneius Flavius, the secretary of Appius Claudius, stole a copy and published them to the people. The concealment was ridiculous: but the establishment of some standard was undoubtedly necessary to fix the true state of a question of right; lest, in a long and arbitrary process, it might be shifted continually, and be at length no longer discernible. Or, as Cicero expresses it, "*sunt jura, sunt formulæ, de omnibus rebus constitutæ, ne quis aut in genere injuriæ, aut in ratione actionis, errare possit. Expressæ enim sunt ex uniuscujusque damno, dolore, incommodo, calamitate, injuria, publicæ à pretore formulæ, ad quas privata lis accommodatur.*" And in the same manner Bracton, speaking of the original writs upon which all our actions are founded, declares them to be fixed and immutable, unless by authority of parliament. And all the modern legislators of Europe have found it expedient, from the same reasons, to fall into the same or a similar method. In England, the several suits, or remedial instruments of justice, are, from the subject of them, distinguished into three kinds; actions *personal*, *real*, and *mixed*.

Blackst. Comment.

Personal actions are such whereby a man claims a debt, or personal duty or damages, in lieu thereof; and likewise whereby a man claims a satisfaction in damages for some injury done to his person or property. The former are said to be founded upon contracts, the latter upon *torts* or wrongs: and they are the same which the civil law calls, "*actiones in personam, quæ adversus eum intenduntur qui ex contractu vel delicto obligatus est aliquid dare vel concedere.*" Of the former nature are all actions upon debt or promises; of the latter are all actions of trespasses, nuisances, assaults, defamatory words, and the like.

Real actions (or, as they are called in the Mirror, *feodal actions*), which concern real property only, are such whereby the plaintiff, here called the *demandant*, claims title to have any lands or tenements, rents, commons, or other hereditaments, in fee-simple, fee-tail, or for term of life. By these actions formerly all disputes concerning real estates were decided; but they are now pretty generally laid aside in practice, upon account of the great nicety required in their management, and the inconvenient length of their process; a much more expeditious method of trying titles being since introduced, by other actions personal and mixed.

Mixed actions are suits partaking of the mixture of the other two, wherein some real property is demanded, and also personal damages for a wrong sustained. As for instance, an action of waste; which is brought by him who hath the inheritance, in remainder or reversion, against the tenant for life, who hath committed waste therein,

therein, to recover not only the land wasted, which would make it merely a real action; but also treble damages, in pursuance of the statute of Gloucester, which is a personal recompense; and so both, being joined together, denominate it a *mixed action*.

The orderly parts of a suit are these: 1. The original *writ*. 2. The *process*. 3. The *pleadings*. 4. The *issue* or demurrer. 5. The *trial*. 6. The *judgment* and its incidents. 7. The proceedings in nature of *appeals*. 8. The *execution*. See these articles.

SULLY. See BETHUNE.

SULPHATE, in *Chemistry*, denotes a compound of sulphuric acid with some base.

SULPHUR, a well known inflammable substance. See CHEMISTRY and MINERALOGY *Index*.

SULPHUR-Wort. See PEUCEDANUM, BOTANY *Index*.

SULPHURIC ACID, the name now adopted for the vitriolic acid. See CHEMISTRY *Index*.

SULPICIA, an ancient Roman poetess, who lived under the reign of Domitian, and has been so much admired as to be termed the *Roman Sappho*. We have nothing, however, left of her writings but a satire, or rather the fragment of one, against Domitian, who published a decree for the banishment of philosophers from Rome; which satire is to be found in Scaliger's *Appendix Virgiliana*. She is mentioned by Martial and Sidonius Apollinaris; and is said to have addressed a poem on conjugal love to her husband Calenus, a Roman knight.

SULPICIUS SEVERUS, an ecclesiastical writer who flourished about the beginning of the 5th century, and was contemporary with Rufinus and St Jerome. He was the disciple of St Martin of Tours, whose life he has written; and the friend of Paulinus bishop of Nola, with whom he held an intimate correspondence. The principal of his works is his *Historia Sacra*, from the creation of the world to the consulate of Stilicho and Aurelian, about the year 400; in which his style is elegant beyond the age he lived in.

SULTAN, or SOLDAN, a title of appellation given to the emperor of the Turks.

Vatner will have the word Turkish, and to signify *king of kings*; adding, that it was first given to the Turkish princes Angrolipex and Masgud, about the year 1055: others will have it originally Persian, alleging, in proof hereof, an ancient medal of Cosroe; others derive it from *soldanus, quasi solus dominus*; others from the Hebrew שלט, *schalat* or *sheleth*, "to rule, reign."

It had its rise under Mahmoud, son of Sebecteghin, the first emperor of the dynasty of the Gaznevides, towards the close of the fourth century of the era of the Hegira: when that prince going to Segestan to reduce Kalaf governor of that province, who affected the sovereignty, Kalaf was no sooner advertised of his coming than he went out to meet him, delivered the keys of his fortress, and owned him his *sultan*, that is, his lord or commander. The title pleased Mahmoud so well, that he assumed it ever afterwards; and from him it passed to his descendants, and to other Mahometan princes. It is chiefly confined to the Turkish and Persian monarchs.

SULZER, M. a celebrated philosopher, was born at Winterthur, in the canton of Zurich, October 16. 1720. He was the youngest of 25 children. His early education did not promise much, though it was by no means neglected. He had little inclination for what i[s] called in the schools the study of *humanity*, and mad[e] but a small progress in the learned languages, whic[h] were to prepare him for the study of theology, for whic[h] profession his parents designed him. At the age of 16 when he went to the academical school of Zurich, h[e] had not the smallest notion of the sciences, or of elegan[t] literature, and consequently no taste for study. The firs[t] incident that developed a hidden germ of philosophica[l] genius, was his meeting with Wolfe's Metaphysics this was the birth of his taste for science: but he wante[d] a guide. The clergyman with whom he lodged was a[n] ignorant man; and the academical prelections were, a[s] yet, above the reach of his comprehension. On the othe[r] hand, a sedentary life was not the thing he liked, no[r] to which he had been accustomed; and, moreover, a sociable turn of mind led him often into company, wher[e] he lost much time in frivolous amusements, yet withou[t] corrupting his morals. Who, that observed him at thi[s] period, says Mr Formey in his *Eulogium*, would have thought that Sulzer would one day be numbered among the most knowing and wise men of his time? The learned Gesner was the instrument of Providence that rendered Sulzer's inclination to study triumphant over his passion for amusement and company. Animated by the counsels and example of this worthy and learned man, he applied himself to philosophy and mathematics with great ardour, and resumed the pursuit of Grecian literature and the oriental languages. The contemplation of nature became his noble and favourite passion. An ecclesiastical settlement in a rural scene, that exhibited happy objects and occasions for this delightful study, began to render his days happy and useful; and he published, in 1741, Moral Contemplations of the Works of Nature; and the year following an Account of a Journey he had made through the Alps; which showed at the same time, his knowledge of natural history, and the taste and sensibility with which he surveyed the beauties of nature and the grandeur and goodness of its Author. He afterwards became private tutor to a young gentleman at Magdeburg. This procured him the acquaintance of Messrs Maupertuis, Euler, and Sack, which opened to his merit the path of preferment, and advanced him successively to the place of mathematical professor in the King's College at Berlin, in 1747, and to that of member of the Royal Academy in 1750.

In this last quality he distinguished himself in a very eminent manner, enriched the class of speculative philosophy with a great number of excellent memoirs, and was justly considered as one of the first-rate metaphysicians in Germany. But his genius was not confined to this branch of science. His universal Theory of the Fine Arts is a valuable production. A profound knowledge of the arts and sciences, and a perfect acquaintance with true taste, are eminently displayed in this work, and will secure to its author a permanent and distinguished rank in the republic of letters. The first volume of this excellent work was published in 1771, and the second in 1774. We shall not here give a catalogue of the writings of M. Sulzer; but we cannot help mentioning his remarks on the Philosophical Essays of the late Mr Hume as a work of real merit, which does justice to the acuteness, while it often detects the sophistry, of the British Bayle. The moral character of M. Sulzer was amiable and virtuous; sociability and beneficence

cence were its characteristical lines; and his virtues were animated by that sacred philosophy that forms the Christian, ennobles man, and is the only source of that heart-felt serenity and sedate fortitude which support humanity, when every other object of confidence fails. His dying moments were calm, humble, and sublime; and when he expired, the placid and composed air of his countenance made his mourning friends doubt, for some time, whether it was death or sleep that had suspended his conversation. He had no enemy; and his friends were numerous, affectionate, and worthy of the tender returns he made them.

The king of Prussia distinguished him by repeated marks of munificence and favour. But his royal protector had never seen him before the end of the year 1777, though he had been member of the academy from the year 1750. The audience, indeed, though late vouchsafed, was honourable to M. Sulzer, with whom the monarch conversed for a long time with great condescension.

SUM, signifies the quantity that arises from the addition of two or more magnitudes, numbers, or quantities together.

SUMACH. See Rhus, Botany *Index*.

SUMATRA, an island of Asia, the most western of the Sunda islands, and constituting on that side the boundary of the Eastern Archipelago. Its general direction is nearly north-west and south-east. The equator divides it into almost equal parts, the one extremity being in 5. 53. N. and the other in 5. 56. S. Lat. Acheen Head, at the north extremity of the island, is in longitude 95. 34. east. It lies exposed on the south-west side to the Indian ocean; the north point stretches into the bay of Bengal; to the north-east it is divided from the peninsula of Malacca by the straits of that name; to the east by the straits of Banca, from the island of that name; to the south-east by the commencement of what are called the *Chinese seas;* and on the south by the straits of Sunda, which separate it from the island of Java. It is about 900 miles in length, but from 100 to 150 only in breadth. No account had been given of this island by any Englishman till the year 1778, when Mr Charles Miller (son of the late botanical gardener) published an account of the manners of a particular district, in the 68th volume of the Philosophical Transactions. These were the Battas, a people who live in the interior parts, called the *Cassia Country*. They differ from all the other inhabitants in language, manners, and customs. They eat the prisoners whom they take in war, and hang up their skulls as trophies in their houses. He observes, however, that human flesh is eaten by them *in terrorem*, and not as common food, though they prefer it to all others, and speak with peculiar raptures of the soles of the feet and palms of the hands. They expressed much surprise that the white people did not kill, much less eat, their prisoners. From this country the greatest part of the cassia that is sent to Europe is procured. It abounds also with the camphire trees, which constitute the common timber in use; and in these trees the camphire is found native, in a concrete form. It is remarkable that, in this state, it is sold to the Chinese at the price of 250l. or 300l. per cent.; but these dexterous artists contrive to furnish the Europeans with it at about a quarter of that price. In 1783, Mr Marsden, who had been secretary to the president and council of Fort Marlborough, published a

Brooke's Gazetteer.

History of Sumatra, with very copious particulars of the island. He represented it as surpassed by few in the beautiful indulgences of nature. A chain of high mountains runs through its whole extent; the ranges in many parts being double and treble; their altitude, though great, is not sufficient to occasion their being covered with snow during any part of the year. Between these ridges are extensive plains, considerably elevated above the surface of the maritime lands. In these the air is cool; and from this advantage they are esteemed the most eligible portion of the country, are the best inhabited, and the most cleared from woods, which elsewhere, in general, throughout Sumatra, cover both hills and valleys with an eternal shade. Here too are found many large and beautiful lakes, that facilitate much the communication between the different parts. The heat of the air is far from being so intense as might be expected from a country occupying the middle of the torrid zone; and it is more temperate than many regions within the tropics; the thermometer at the most sultry hour, about two in the afternoon, generally fluctuating between 82 and 85 degrees. Mr Marsden divides the inhabitants into Malays, Achenese, Battas, Lampoons, and Rejangs; and he takes the latter as his standard of description, with respect to the persons, manners, and customs, of the inhabitants. They are rather below the middle stature; their bulk in proportion; their limbs for the most part slight, but well shaped, and particularly small at the wrists and ancles; and, upon the whole they are gracefully formed. Their hair is strong, and of a shining black. The men are beardless, great pains being taken to render them so when boys, by rubbing their chins with a kind of quicklime. Their complexion is properly yellow, wanting the red tinge that constitutes a copper or tawney colour. They are in general lighter than the Mestees, or half-breed, of the rest of India; those of the superior class, who are not exposed to the rays of the sun, and particularly their women of rank, approaching to a degree of fairness. If beauty consisted in this one quality, some of them would surpass our brunettes in Europe. The major part of the females are ugly, many of them even to disgust; yet among them are some whose appearance is strikingly beautiful, whatever composition of person, features, and complexion, that sentiment may be the result of. Some of the inhabitants of the hilly parts are observed to have the swelled neck or goitre; but they attempt no remedy for it, as these wens are consistent with the highest health. The rites of marriage among the Sumatrans consist simply in joining the hands of the parties, and pronouncing them man and wife without much ceremony, excepting the entertainment which is given upon the occasion by the father of the girl. The customs of the Sumatrans permit their having as many wives as they can purchase, or afford to maintain; but it is extremely rare that an instance occurs of their having more than one, and that only among a few of the chiefs. This continence they owe, in some measure, to their poverty. The dictates of frugality are more powerful with them than the irregular calls of appetite, and make them decline an indulgence from which their law does not restrain them. Mothers carry their children, not on the arm as our nurses do, but straddling on the hip, and usually supported by a cloth which ties in a knot on the opposite shoulder. The children are nursed but little; are not confined

Sumatra

confined by any swathing or bandages; and being suffered to roll about the floor, soon learn to walk and shift for themselves. When cradles are used, they swing suspended from the ceilings of the rooms.

The Sumatrans are so fond of cock-fighting, that a father on his death-bed has been known to desire his son to take the first opportunity of matching a cock for a sum equal to his whole property, under a blind conviction of its being invulnerable. When a cock is killed or runs, the other must have sufficient spirit and vigour left to peck at him three times on his being held up to him for that purpose, or it becomes a drawn battle; and sometimes an experienced cocker will place the head of his vanquished bird in such an uncouth situation as to terrify the other, and render him unable to give this proof of victory.

The wild beasts of Sumatra are tigers, elephants, rhinoceroses, bears, and monkeys. The tigers prove to the inhabitants both in their journeys and even their domestic occupations most destructive enemies. The number of people annually slain by these rapacious tyrants of the woods is almost incredible. Whole villages have been depopulated by them; yet from a superstitious prejudice, it is with difficulty they are prevailed upon, by a large reward which the India Company offers, to use methods of destroying them, till they have sustained some particular injury in their own family or kindred. The size and strength of the species which prevails on this island is prodigious. They are said to break with a stroke of their fore paw the leg of a horse or a buffalo; and the largest prey they kill is without difficulty dragged by them into the woods. This they usually perform on the second night, being supposed on the first to gratify themselves with sucking the blood only. Time is by this delay afforded to prepare for their destruction, either by shooting them, or placing a vessel of water strongly impregnated with arsenic near the carcase, which is fastened to a tree to prevent its being carried off. The tiger having satiated himself with the flesh, is prompted to assuage his thirst with the tempting liquor at hand, and perishes in the indulgence. Their chief subsistence is most probably the unfortunate monkeys with which the woods abound. They are described as alluring them to their fate by a fascinating power, similar to what has been supposed of the snake; and, says Mr Marsden, "I am not incredulous enough to treat the idea with contempt, having myself observed, that when an alligator or a crocodile, in a river, comes under an overhanging branch of a tree, the monkeys, in a state of alarm and distraction, crowd to the extremity, and, chattering and trembling, approach nearer and nearer to the amphibious monster that waits to devour them as they drop, which their fright and number render almost unavoidable." These alligators likewise occasion the loss of many inhabitants, frequently destroying the people as they bathe in the river, according to their regular custom, and which the perpetual evidence of the risk attending it cannot deter them from. A superstitious idea of their sanctity also preserves them from molestation, although, with a hook of sufficient strength, they may be taken without much difficulty. The other animals of Sumatra are buffaloes, a small kind of horses, goats, hogs, deer, bullocks, and hog-deer. This last is an animal somewhat larger than a rabbit, the head resembling that of a hog, and its shanks and feet like those of the deer. The bezoar-stone found on this animal [h]as been valued at 10 times its weight in gold; it is of [a] dark brown colour, smooth on the outside; and [the] coat being taken off, it appears still darker, with strie[s] running underneath the coat: it will swim on the top [of] the water. If it be infused in any liquid, it makes [it] extremely bitter: the virtues usually attributed to th[is] stone are cleansing the stomach, creating an appeti[te,] and sweetening the blood.

Of birds they have a greater variety than of beas[ts.] The coo-ow, or Sumatran pheasant, is a bird of uncom[mon] beauty. They have storks of prodigious size, pa[r]rots, dung-hill fowls, ducks, the largest cocks in th[e] world, wood-pigeons, doves, and a great variety of sma[ll] birds, different from ours, and distinguished by the beau[ty] of their colours. Of the reptiles, they have lizard[s,] flying lizards, and cameleons. The island swarms wit[h] insects, and their varieties are no less extraordinary tha[n] their numbers. Rice is the only grain that grows in th[e] country; they have sugar-canes, beans, pease, radishes, yams, potatoes, pumkins, and several kinds of pot-herb[s] unknown to Europe; and here are to be found most o[f] the fruits to be met with in other parts of the East In[]dies, in the greatest perfection. Indigo, Brasil-wood, two species of the bread-fruit tree, pepper, benjamin, coffee and cotton, are likewise the produce of this island, as well as cassia and camphire mentioned above. Her[e] also is the cabbage-tree and silk-cotton tree; and the forests contain a great variety of valuable species o[f] wood, as ebony, pine, sandal, eagle or aloes, teek, manchineel, and iron-wood, and also the banyan tree. Gold, tin, iron, copper, and lead, are found in the country; and the former is supposed to be as plentiful here as in Peru or Mexico. The finest gold and gold-dust are found in the country of *Limong*, immediately contiguous to the presidency of *Fort Marlborough*, to which the merchants repair annually for the purchase of opium, and such other articles as they may be in want of, and give for them gold of so pure a nature as to contain little or no alloy. The native indolence of the *Malay* disposition prevents them from collecting more than is sufficient to supply the few and simple wants of a race of men as yet unenlightened by civilization and science, and ignorant of the full extent of the advantages of the country inhabited by them. The roads leading to this golden country are almost impervious; affording only a scanty path to a single traveller, where whole nights must be passed in the open air, exposed to the malignant influence of a hostile climate, in a country infested by the most ferocious wild beasts. These are circumstances that have hitherto checked curiosity; but perseverance and studied precaution will surmount the obstacles they furnish, and such discoveries might be made as would amply compensate for the difficulties leading to them. The gold merchants who come from the neighbouring and less rich countries, give us such accounts of the facility of procuring gold as border nearly on the marvellous, and would be altogether incredible, if great quantities of that metal produced by them did not in some degree evince the certainty of their accounts.

This great abundance of gold in Sumatra induces Mr Marsden to suppose that island to be the Ophir of Solomon; a conjecture which, in his opinion, derives no small force from the word *Ophir* being really a *Malay* substantive, of a compound sense, signifying a mountain containing

containing gold. The natives, he confesses, have no oral tradition on the subject; and we have elsewhere made it probable that Ophir was situated in a different quarter of the world (see OPHIR). Besides the metals and different species of wood which we have mentioned, Sumatra produces sulphur, arsenic, saltpetre, and bees-wax, with edible birds-nests, which are there commodities of great importance (see *Birds-Nests*).

The English and Dutch have factories on this island; the principal one of the former being Fort Marlborough, on the south-west coast. The original natives of Sumatra are Pagans; but it is to be observed, that when the Sumatrans, or any of the natives of the eastern islands, learn to read the Arabic character, and submit to circumcision, they are said to become Malays; the term *Malay* being understood to mean *Mussulman*. See ACHEEN.

Asiatic Researches, vol. i.

SUMMARY, in matters of literature. See ABRIDGEMENT.

SUMMER, the name of one of the seasons of the year, being one of the quarters when the year is divided into four quarters, or one half when the year is divided only into two, summer and winter. In the former case, summer is the quarter during which, in northern climates, the sun is passing through the three signs Cancer, Leo, Virgo, or from the time of the greatest declination, till the sun come to the equinoctial again, or have no declination; which is from about the 21st of June till about the 22d of September. In the latter case, summer contains the six warmer months, while the sun is on one side of the equinoctial; and winter the other six months, when the sun is on the other side of it. It is said that a frosty winter produces a dry summer, and a mild winter a wet summer.

Summer-Islands. See BERMUDAS.

Summer Red-Bird. See MUSCICAPA, ORNITHOLOGY *Index*.

SUMMIT, the top or vertex of any body or figure, as of a triangle, cone, pyramid, &c.

SUMMONS, in *Law*, a citing or calling a person to any court, to answer a complaint or to give his evidence.

SUMMONS, in *War*. To summon a place is to send a drum or trumpet to command the governor to surrender, and to declare that if the place be taken by storm, all must submit to the mercy of the conqueror. See CAPITULATION and CHAMADE.

SUMMUM BONUM, in *Ethics*, the chief good.

SUMP, in *Metallurgy*, a round pit of stone, lined with clay within, for receiving the metal on its first fusion from the ore.

SUMP, in the British salt-works, where sea-water is boiled into salt, is the name of a sort of pond, which is made at some distance from the saltern on the sea-shore, between full sea and low-water mark. From this pond a pipe is laid, through which, when it is full sea, the water runs into a well adjoining to the saltern; and from this well it is pumped into troughs, through which it is carried to the cisterns, in order to be ready to supply the pans. See SALT.

SUMP, in *Mining*, denotes a pit sunk down in the bottom of the mine, to cut or prove the lode still deeper than before; and in order to slope and dig it away if necessary, and also to drive on the lode in depth. The sump principally serves as a bason or reservoir, to collect the water of a mine together, that it may be cleaned out by an engine or machine.

SUMPTER HORSE, is a horse that carries provisions and necessaries for a journey.

SUMPTUARY LAWS (*Leges Sumptuariæ*), are laws made to restrain excess in apparel, costly furniture, eating, &c.

Most ages and nations have had their sumptuary laws; and some retain them still, as the Venetians, &c. But it is observed that no laws are worse executed than sumptuary laws. Political writers have been much divided in opinion with respect to the utility of these laws to a state. Montesquieu observes that luxury is necessary in monarchies, as in France, but ruinous to democracies, as in Holland. With regard to England, whose government is compounded of both species, it may still be a dubious question, says Judge Blackstone, how far private luxury is a public evil; and as such cognizable by public laws.

The sumptuary laws of the ancient Locrian legislator Zaleucus are famous: by these it was ordained that no woman should go attended with more than one maid in the street except she were drunk: that she should not go out of the city in the night, unless she went to commit fornication: that she should not wear any gold or embroidered apparel, unless she proposed to be a common strumpet; and that men should not wear rings or tissues except when they went a whoring, &c.

Among the Romans, the sumptuary laws were very numerous: By the *Lex Orchia*, the number of guests at feasts was limited, though without any limitation of the charges: by the Fannian law, made 22 years afterwards, it was enacted, that more than 10 *asses* should not be spent at any ordinary feast: for the solemn feasts, as the Saturnalia, &c. an hundred asses were allowed; ten of which, Gellius informs us, was the price of a sheep, and a hundred of an ox. By the Didian law, which was preferred 18 years after, it was decreed, that the former sumptuary laws should be in force, not only in Rome, but throughout all Italy; and that for every transgression, not only the master of the feast, but all the guests too, should be liable to the penalty.

The English have had their share of sumptuary laws, chiefly made in the reigns of Edward III. Edward IV. and Henry VIII. against shoes with long points, short doublets, and long coats; though all repealed by statute 1 Jac. I. c. 25. As to excess in diet, there remains still one law unrepealed. Under King Henry IV. Camden tells us, pride had got so much into the foot, that it was proclaimed, that no man should wear shoes above six inches broad at the toes. And their outer garments were so short, that it was enacted, 25 Edward IV. that no person, under the condition of a lord, should from that time, wear any mantle or gown, unless of such length, that standing upright, it might cover the lower part of the trunk of his body.

SUN, SOL, ☉, in *Astronomy*, the great luminary which enlightens the world, and by its presence constitutes day. See ASTRONOMY *Index*.

Mock-Sun. See PARHELION.

Sun-Fish, a species of shark. See SQUALUS, ICHTHYOLOGY *Index*.

Sun-Flower. See HELIANTHUS, } BOTANY *Index*.
Sun-Dew. See DROSERA, }

SUNDA-ISLANDS, a general name for a cluster of islands

islands in the Indian ocean, between 93° and 120° of east longitude, and between 8° north and 8° south latitude. The particular names of the islands are *Borneo*, *Sumatra*, *Java*, *Bally*, *Banca*, &c.

SUNDAY, or the LORD'S-DAY, a solemn festival observed by Christians on the first day of every week, in memory of our Saviour's resurrection. See SABBATH.

In the breviary and other offices we meet with Sundays of the first and second class. Those of the first class are, Palm, Easter, Advent, and Whitsunday, those of *Quasimodo* and *Quadragesima*. Those of the second class are the common Sundays. Anciently each Sunday in the year had its particular name, which was taken from the introit of the day; which custom has only been continued to some few in lent; as *Reminiscere*, *Oculi*, *Lætare*, *Judica*.

Some are of opinion that the Lord's day, mentioned in the Apocalypse, is our Sunday; which they believe was so early instituted by the apostles. Be this as it will, it is certain a regard was had to this day even in the earliest ages of the church; as appears from the first apology of Justin Martyr, where he describes the exercise of the day not much unlike to ours.

But it was Constantine the Great who first made a law for the proper observation of Sunday; and who, according to Eusebius, appointed it should be regularly celebrated throughout the Roman empire. Before him, and even in his time, they observed the Jewish Sabbath as well as Sunday; both to satisfy the law of Moses and to imitate the apostles, who used to meet together on the first day.

By Constantine's laws, made in 321, it was decreed, that for the future the Sunday should be kept a day of rest in all cities and towns; but he allowed the country people to follow their work. In 538, the council of Orleans prohibited country labour; but because there were still many Jews in Gaul, and the people fell into many superstitious uses in the celebration of the new Sabbath, like those of the Jews among that of the old, the council declares, that to hold it unlawful to travel with horses, cattle, and carriages, to prepare food, or to do any thing necessary to the cleanliness and decency of houses or persons, savours more of Judaism than of Christianity. See SABBATH-*Breaking*.

SUNDAY-*Schools*. See *Sunday*-SCHOOLS.

SUOVETAURILIA, an ancient Roman sacrifice, so called because it consisted of a pig (*sus*), a sheep or rather ram (*ovis*), and a bull (*taurus*). They were all males, to denote the masculine courage of the Roman people. It was likewise called *solitaurilia*, because the animals offered up were always *solida*, whole or uncut.

SUPERCARGO, a person employed by merchants to go a voyage, and oversee their cargo or lading, and dispose of it to the best advantage.

SUPERCILIUM, in *Anatomy*, the eye-brow. See ANATOMY, N° 142.

SUPEREROGATION, in *Theology*, what a man does beyond his duty, or more than he is commanded to do. The Romanists stand up strenuously for works of supererogation, and maintain that the observance of evangelical councils is such. By means hereof, a stock of merit is laid up, which the church has the disposal of, and which she distributes in indulgences to such as need. This absurd doctrine was first invented towards the close of the 12th century, and modified and embell[...] by St Thomas in the 13th: according to which, it [...] pretended that there actually existed an immense [...] sure of merit, composed of the pious deeds and virt[...] actions which the saints had performed beyond what [...] necessary for their own salvation, and which were th[...] fore applicable to the benefit of others; that the g[...] dian and dispenser of this precious treasure was [...] Roman pontiff; and that of consequence he was [...] powered to assign to such as he thought proper a [...] tion of this inexhaustible source of merit, suitable to t[...] respective guilt, and sufficient to deliver them from [...] punishment due to their crimes.

The reformed churches do not allow of any work[...] supererogation; but hold with the apostles, that wh[...] we have done our best, we are but unprofitable serva[...]

SUPERFETATION, in *Physiology*, a second after-conception, happening when the mother, alrea[...] pregnant, conceives of a latter coition; so that she be[...] at once two fœtuses of unequal age and bulk, and is [...] livered of them at different times. We meet with [...] stances of superfetations in Hippocrates, Aristotle, [...] Laurens, &c.: but they are said to be much more fr[...] quent in hares and swine.

SUPERFICIES, or SURFACE, in *Geometry*, the ou[...] side or exterior face of any body. This is considered having the two dimensions of length and breadth onl[...] but no thickness; and therefore it makes no part of t[...] substance or solid content or matter of the body.

The terms, or bounds, or extremities, of a superficie[...] are lines; and superficies may be considered as genera[...] ed by the motions of lines. Superficies are either rect[...] linear, curvilinear, plane, concave, or convex. A recti[...] linear superficies is that which is bounded by right line[...] Curvilinear superficies is bounded by curve lines. Plan[...] superficies is that which has no inequality in it, nor ri[...] sings, nor sinkings, but lies evenly and straight through[...] out, so that a right line may wholly coincide with it in all parts and directions. Convex superficies is that which is curved and rises outwards. Concave superficies is curved and sinks inward. See GEOMETRY.

SUPERFINE, in the manufactories, a term used to express the superlative fineness of a stuff: thus a cloth, a camblet, &c. are said to be superfine when made of the finest wool, &c. or when they are the finest that can be made.

SUPERFLUOUS INTERVAL, in *Music*, is one that exceeds a true diatonic interval by a semitone minor. See INTERVAL.

SUPERINTENDANT, denotes an ecclesiastical superior in several reformed churches where episcopacy is not admitted; particularly among the Lutherans in Germany, and the Calvinists in some other places.

The superintendant is similar to a bishop; only his power is somewhat more restrained than that of our diocesan bishops. He is the chief pastor, and has the direction of all the inferior pastors within his district or diocese. In Germany they had formerly superintendants general, who were superior to the ordinary superintendants. These, in reality, were archbishops; but the dignity is sunk into disuse; and at present none but the superintendant of Wirtemberg assumes the quality of superintendant general.

SUPERIOR, a person raised above another in rank, office, or talents.

Superior ‖ Superstition.

SUPERIOR, in *Scots Law*. See LAW, N° clxiv. 3. clxv. 2. and clxvi.

SUPERLATIVE, in *Grammar*, one of the three degrees of comparison, being that inflection of adjective nouns that serves to augment and heighten their signification, and shows the quality of the thing denoted to be in the highest degree. See GRAMMAR.

SUPERNUMERARY, something over and above a fixed number. In several of the offices are supernumerary clerks, to be ready on extraordinary occasions.

SUPERPARTICULAR PROPORTION, or *Ratio*, is that in which the greater term exceeds the less by unit or 1. As the ratio of 1 to 2, or 2 to 3, or 3 to 4, &c.

SUPERPARTIENT PROPORTION, or *Ratio*, is when the greater term contains the less term once, and leaves some number greater than 1 remaining. As the ratio

of 3 to 5, which is equal to that of 1 to $1\frac{2}{3}$;
of 7 to 10, which is equal to that of 1 to $1\frac{3}{7}$, &c.

SUPERSEDEAS, in *Law*, a writ issued in divers cases, importing in general a command to stay or forbear some ordinary proceedings in law, which in appearance ought to be done or pursued, were it not for the cause whereon this writ is granted.

Thus a man regularly is to have a surety of peace against him of whom he will swear he is afraid; and the justice required hereunto cannot deny it him: yet, if the party be formerly bound to the peace, either in chancery or elsewhere, this writ lies to stay the justice from doing that which otherwise he ought not to deny.

SUPERSTITION, a word that has been used so indefinitely, that it is difficult to determine its precise meaning. From its resemblance in sound to the Latin word *superstes*, "a survivor," it is evidently derived from it, and different attempts have been made to trace their connection in signification. Balbus, in the dialogue *De Natura Deorum* of Cicero, says, that they who prayed and sacrificed whole days that their children might *survive* them, were called superstitious. Lactantius censures this etymology, and says they were not called superstitious who wished that their children might survive them (for this we all wish), but because they who survived their parents worshipped their images. Others again say, that superstition is derived from *superstes*, because it consisted in considering the dead as if they were alive. But these etymologies are solely conjectural; and we consider conjectures as absurd in philology as we do in science; they may mislead, but are seldom of any benefit. The usual meaning affixed to the word *superstition*, both in the Latin and English languages, is so different from *superstes*, that its change of meaning must be owing to some accident which it is in vain to inquire after. If we had not known that the word *paganus*, "a pagan," was derived from *pagus*, "a village," because the heathens in a certain period of the Christian history lived in villages, the whims and fancies of etymologists would not have thrown much light on the subject.

Without labouring, from the aid of etymology, to define superstition, which is a word of a very extensive signification, we will consider to what objects it is applied; and then, by observing what is common to them all, we shall be enabled to fix with some degree of precision the meaning of the term. We apply it to the idolatry of the heathens; we apply it also to the Jews, who made the will of God of no effect by their traditions, and substituted ceremonies in place of the religion of their fathers. We say also that Christians are guilty of superstition; the Roman Catholics, who believe in transubstantiation and in the efficacy of prayers to saints; and those Protestants who esteem baptism and the Lord's supper, and the punctual performance of other ceremonies, without regard to morality, as sufficient to ensure salvation. Those persons are also reckoned superstitious who believe, without any evidence, that prophecies are still uttered by the divine inspiration, and that miracles are still performed. The word is also extended to those who believe in witchcraft, magic, and apparitions, or that the divine will is declared by omens or augury; that the fortune of individuals can be affected by things indifferent, by things deemed lucky or unlucky, or that diseases can be cured by words, charms, and incantations.

Through all the particulars which we have enumerated, there runs one general idea, the belief of what is false and contrary to reason. From this, however, we must not suppose that whatever is false and contrary to reason may be denominated superstition. We think that it is false and irrational to suppose that there ever lived on earth a race of men who walked on one leg, and had their eyes in their breast; or that there were giants 90 feet high: yet we do not call the philosopher who believes these chimeras superstitious, but credulous. Superstition has always a reference to God, to religion, or to beings superior to man. We do not however distinguish all false and irrational opinions in religion by the name of superstition. We do not, for instance, apply this name to the opinions which some of the ancients entertained, that God is the soul of the world, and that men are only portions of him separated for a time, or that the soul after death lives successively in different bodies. If we examine the subject with more attention, we shall discover that the foundation of superstition is ignorance of the moral attributes of God; for we never say a man is superstitious for entertaining erroneous opinions of the natural attributes of God. Some of the Socinians have denied the prescience of God; and a French philosopher has not only rejected the belief that He is a spirit, but has presumed to say that he is composed of a species of crystals. The first of these opinions discovers very imperfect ideas of God, and the second is the height of impiety and absurdity; yet the Socinians have not been accused of superstition, nor can this French philosopher be suspected of it. We do not call every false opinion concerning the unity or moral attributes of God by the name of superstition, as, for instance, the opinion which some sceptics have supported, that God is not good; for, as was mentioned before, superstition always involves the idea of credulity. It does not consist in falsely denying that God possesses any particular moral attributes, but in believing more than what is true concerning them; in forming mean, unworthy ideas of them; in supposing that he is guided by blind passion like mankind, and enjoins upon his creatures commandments which are irrational and absurd.

As superstition arises from ignorance and credulity in the understanding, so it has also a seat in the passions. Fear has been commonly considered as a passion of the human mind from which it chiefly derives its origin;

Superstition.

and there is no doubt that more superstition has arisen from fear united with ignorance and credulity than from any other passion. Yet it would certainly be improper to exclude all other passions. We cannot account for the superstition of the Egyptians, without supposing that much of it arose from gratitude. They worshipped the Nile, because it distributed fertility and abundance over the land of Egypt; and they worshipped some animals, merely because they prevented the increase of other animals which were noxious. Thus they adored the ibis, because it destroyed the eggs of the crocodile.

Having thus endeavoured to analyze the ideas comprehended under the word superstition, we may sum them up in a few words. It respects God and beings superior to man, and extends to our religious opinions, worship, and practices; and may be defined *absurd opinions and actions arising from mean and defective ideas of the moral attributes of God.* Let us apply this definition to the different species of superstition already mentioned.

But before entering upon this application, it may be proper to observe, that superstition involves the idea of a blameable inattention to reason, or a credulity arising from an indolence of understanding. We generally make a distinction between the imperfect opinions which a savage, from the necessary effects of his situation, forms of the attributes of God, and those which civilized nations entertain. We say the savage is ignorant, and we ascribe his ignorance to his situation; but we call the Roman Catholic superstitious, and we blame him for not having those just ideas of God which he might have obtained by opening his Bible, or by the exercise of his understanding in the favourable situation in which he is placed. Superstition then does not originate so much from the natural weakness of the human understanding, as from a misapplication or a neglect of it (A).

We cannot therefore with any propriety apply the name *superstition* to polytheism in general; for what all the ancient philosophers, after much study and reflection, concluded to be true, could never proceed from credulity and inattention, but from their situation. We speak very properly, however, when we call idolatry by the name of superstition; because there is no man so devoid of understanding as not to be capable of discovering, that a piece of metal, or wood, or stone, can neither hear nor answer petitions. *Superstition* was a name which the ancient philosophers gave to those who entertained mean opinions of the gods, or did foolish things to obtain their favour. According to Theophrastus, the superstitious man is one who, having washed his hands, and sprinkled himself all round, leaves the temple with a laurel leaf in his mouth, with which he walks about the whole day. Or, if a weasel should cross the road, he will not advance a step till he has thrown three stones over the road. If he find a serpent in his house, he rears a place of devotion on the spot. He purifies his house often, will not sit upon a grave, or touch a dead person. He is anxious about the interpretation of his dreams, will not offer a sacrifice unless his wife go along with him, or, if she is engaged, he takes the nurse

Theophrastus's Characters, xvi.

and the little children. He purifies himself with onions; and when he sees a mad or an epileptic person, he spits in their bosom. Such was the character of superstition in the days of Theophrastus. All these whimsical ceremonies were done to prevent mischief, and to avert the wrath of the gods; and therefore perfectly correspond with the definition given above.

It is only necessary to consider a little the superstitious opinions and practices among Jews and Christians, to be sensible that they have all arisen from mean and absurd ideas of the moral attributes of God: for they have generally entertained noble opinions of his natural attributes. The Jews considered God as a partial Being, who had a predilection for their nation in preference to all others, and preferred external homage and ceremony to moral purity. If the Roman Catholics think consistently, they must esteem God as a Being who can be prevailed upon by the importunity of one dead man to assist another, or as a Being whose patience would be fatigued with hearing prayers constantly. Hence their practice of praying to saints. They in effect believe, however they may deceive themselves, that God is unjust, or they could not believe transubstantiation; for it supposes that God can give commands directly contrary to those principles of belief with which he has endued the human mind. They consider a strict adherence to a variety of ceremonies, to forms, to pomp, and show, as essential to the worship of God: this is treating God as a vainglorious Being. They thought it their duty to extirpate heretics: this was supposing God a cruel and revengeful Being. Even among Protestants, we are sorry to say, a great deal of superstition remains: we have not yet learned to consider God as a spirit, who is to be worshipped in spirit and in truth, as a pure moral benevolent Being; and hence arise all the superstitious practices which prevail among us.

Besides those superstitious opinions and practices which entirely respect our duty to God, there are others which may be termed *vulgar superstitions.* These also arise from imperfect and mean ideas of the moral attributes of God. To believe vulgar prophecies, which are always the effusions of madness or knavery, is to suppose that God, who has drawn a veil over futurity, and only delivers prophecies to accomplish some great moral purpose, sometimes gives them for no purpose at all, or to gratify idle curiosity, or to disclose such a knowledge of what is to happen as is inconsistent with the free agency of man and the moral administration of the world. Nor is it less superstitious to believe in vulgar miracles. To believe in them, is to believe that God suspends the laws of nature for the most trivial purposes, or to countenance fraud and worldly ambition: it is to receive the most extraordinary facts upon the most unsatisfactory evidence. The belief of witchcraft, of apparitions, and the second sight, may be resolved into the same principle. To suppose that God would communicate the power of doing mischief, and of controuling his laws, to any being merely for gratifying their own passions, is unworthy of God. The belief of apparitions is equally inconsistent with the goodness of God (see SPECTRE). The same

(A) We do not pretend to say that this is the sense in which superstition is always used, because it is often used improperly.

Superstition.

same objection rises against the second-sight as against the belief of vulgar prophecies, and may also be extended to omens, to astrology, to things lucky and unlucky, to fortune-telling, &c. As to the different devices and charms for preventing and curing disorders, they resemble in every respect false miracles.

A judicious history of superstition would be a curious and entertaining work, and would exhibit the human character in a remarkable point of view. Superstition is most prevalent among men of weak and uncultivated minds; it is more frequent in the female sex than among men; and abounds more in the rude than in the refined stages of society. The general features of it have been the same in all ages; but it assumes certain peculiarities according to the diversity of character of different nations. It gained admission into the science of medicine at an early period. He who was endowed with superior genius and knowledge was reckoned a magician. Dr Bartolo was seized by the inquisition at Rome in the last century, because he unexpectedly cured a nobleman of the gout. Diseases were imputed to fascination, and hundreds of poor wretches were dragged to the stake for being accessary to them. Mercatus, physician to Philip II. of Spain, a writer of uncommon accuracy and information, appears strongly inclined to deny the existence of fascinatory diseases: but he is constrained to acknowledge them for two reasons; 1st, Because the inquisition had decided in favour of their reality; 2dly, Because he had seen a very beautiful woman break a steel-mirror to pieces, and blast some trees by a single glance of her eyes.

Manchester Transactions, vol. iii.

As the opinions concerning the cause of diseases were superstitious, those concerning the method of curing them were not less so. In the Odyssey we read of a cure performed by a song. Josephus relates, that he saw a certain Jew, named *Eleazar*, draw the devil out of an old woman's nostrils by the application of Solomon's seal to her nose in presence of the emperor Vespasian. Many different kinds of applications were used for expelling the devil. Flagellation sometimes succeeded admirably; purgatives and antispasmodics were other modes of discharging him. Dr Mynsight cured several bewitched persons with a plaster of assafœtida. How the assafœtida was so efficacious, was much disputed. Some thought the devil might consider so vile an application as an insult, and run off in a passion; but others very sagely observed, that as devils are supposed to have eyes and ears, it is probable they may have noses too.

Nor was it only in medicine these superstitious opinions were entertained; they prevailed also in natural philosophy. The pernicious effects in mines, which we now know are occasioned by noxious air, were confidently imputed to the demons of the mine. Even Van Helmont, Bodinus, Strozza, and Luther, attributed thunder and meteors to the devil. Chemists were employed for centuries in search of the philosopher's stone, with which they were to do miracles. It was a common question among philosophers in the 17th century, whether the imagination could move external objects; a question generally decided in the affirmative.

Though superstition be generally the mark of a weak mind, such is the infirmity of human nature, that we find many instances of it among men of the most sublime genius and most enlightened minds. Socrates believed that he was guided by a demon. Lord Bacon believed in witchcraft; and relates that he was cured of warts by rubbing them with a piece of lard with the skin on, and then nailing it with the fat towards the sun on the post of a chamber window facing the sun. Henry IV. one of the most illustrious of monarchs, was very uneasy before his assassination on account of some prophecies *. Sully declares, that one of the considerations that kept him faithful to his master in the most unpromising state of his affairs, was a prediction of La Brosse, that Henry would make his fortune †. The astrologer Morin directed Cardinal Richelieu's motions in some of his journeys ‡. The enlightened Cudworth defended prophecies in general, and called those who opposed the belief of witchcraft by the name of *atheists;* and the predictions of Rice Evans have been supported in the present century by the celebrated names of *Warburton* and *Jortin.* Dr Hoffman, the father of the Modern Theory and Practice of Medicine, in a dissertation published in the large edition of his works in 1747, says, that the devil can raise storms, produce insects, and act upon the animal spirits and imagination; and, in fine, that he is an *excellent optician and natural philosopher* on account of his long experience. Dr Johnson, the leviathan of literature, is supposed to have believed in the second sight.

* *Memoirs of Sully.*

† *Ibid.*

‡ *Bayle, art. Morin.*

With respect to the effects of superstition on the human mind, they are indeed deplorable. It chains down the understanding, and sinks it into the most abject and sordid state, and keeps it under the dominion of fear, and sometimes of cruelty. Where once it takes possession, it has a tendency to become extreme, and generally becomes so intolerable, that men of reflection and learning conspire its destruction. The Christian religion gave a violent shock to the heathen superstition; the reformation in a great measure demolished the superstition of the church of Rome; and the superstition which remained among Protestants after their separation from that church has been gradually yielding to the influence of enlightened reason, or to the bold and daring attacks of infidelity and deism. We behold the prospect of its ruins with pleasure, and thank the deists for their zeal; but it is from the firm hope that the religion of Jesus will arise in all its beauty and simple majesty, and be admired and respected as it deserves: for mean and contemptible as superstition certainly is, we would rather see men do what they reckon their duty from superstitious principles, than see anarchy and vice prevail, even though attended with all the knowledge and liberality of sentiment which deism and infidelity can inspire.

Superstition ‖ Supine.

SUPERVISOR, a surveyor or overseer.

SUPINATION, in *Anatomy*, the action of a supinator muscle, or the motion whereby it turns the hand so as that the palm is lifted up towards heaven.

SUPINE, in Latin grammar, part of the conjugation of a verb, being a verbal substantive of the singular number and the fourth declension.

There are two kinds of supines: one, called the *first supine*, ending in *um* of the accusative case, which is always of an active signification, and follows a verb of motion; as *abiit deambulatum.* The other called the *last supine*, and ending in *u* of the ablative case, is of a passive signification, and is governed by substantives or adjectives; as, *facile dictu*, &c.

They have their name, says Probus, and after him Vossius, Supine, Supper.

Vossius, *quod ad instar* supinorum *et otiosorum hominum omnia habent confusa*: or, according to Priscian, *quod nascantur a participiis passivis, quæ supina appellata sunt, quia in infimo loco sita, totam conjugationis molem suscipiant.*

SUPPER, the evening repast.—Suppers that are heavy should be avoided, because the stomach is more oppressed with the same quantity of food in a horizontal posture than in an erect one, and because digestion goes on more slowly when we sleep than when we are awake. They should be eaten long enough before bed-time, that they may be nearly digested before going to sleep; and then a draught of pure water will dilute that which remains in the stomach.

1 Definition.

Supper of the Lord, otherwise called the *Eucharist*, is a sacrament ordained by Christ in his church, of which the outward part is bread and wine, and the inward part or thing signified the body and blood of Christ, which the majority of Christians believe to be in some sense or other taken and received by the faithful communicants. See SACRAMENT.

2 Controversies about the outward and visible sign.

There is no ordinance of the gospel which has been the subject of more violent controversies between different churches, and even between different divines of the same church, than this sacrament; and though all confess that one purpose of its institution was to be a bond of love and union among Christians, it has, by the perverseness of mankind, been too often converted into an occasion of hatred. The outward and visible sign, and the inward and spiritual grace, have equally afforded matter of disputation to angry controvertists. Many members of the church of Rome condemn the Greek church and the Protestants for using leavened bread in the Lord's Supper, contrary to the example set them by our Saviour; whilst the Greek church in general, and some Protestant societies in particular, unite with the church of Rome in censuring all churches which mix not the wine with water, as deviating improperly from primitive practice. See EUCHARIST.

That it was unleavened bread which our Lord blessed and brake and gave to his disciples as his body, cannot be questioned; for at the time of the passover, when this ordinance was instituted, there was no leavened bread to be found in Jerusalem *. For the mixed cup, the evidence is not so decisive. It is indeed true, as we have observed under the article EUCHARIST, that the primitive Christians used wine diluted with water; and if we may believe Maimonides †, it was the general custom of the Jews, as well at the passover as at their ordinary meals, to add a little water to their wine on account of its great strength; but that this was *always* done, or that it was done by our *Saviour in particular*, there is no clear evidence. Origen indeed affirms ‡, that our Lord administered in wine unmixed; and he was not a man to hazard such an affirmation, had there been in his days any certain tradition, or so much as a general opinion, to the contrary. On this account we have often heard with wonder the necessity of the mixed cup insisted on by those who without hesitation make use of leavened bread; for if it be essential to the sacrament that the very same elements be employed by us that were employed by our Saviour, the necessit[y of] unleavened bread is certainly equal to that of wine [di]luted by water.

* *Exod.* xii. 15, 19.

† *In Mishnam.*

‡ *Hom.* 12. *in Hieremiam.*

But the mixed cup is said to be emblematical of [the] blood and water which flowed from the side of our L[ord] when pierced by the spear of the Roman soldier, wh[ilst] the absence of leaven is emblematical of no particu[lar] circumstance in His passion. This argument for [the] mixture is as old as the era of St Cyprian, and has si[nce] been frequently urged with triumph by those who sur[ely] perceived not its weakness. The flowing of the bl[ood] and water from our Saviour's side was the consequen[ce] either of the spear's having pierced the *pericardium*, [or] more probably of an *ascites* or *hydrothorax*, occasion[ed] by his cruel and lingering death (see MEDICINE, [N^o] 342, 343). But whatever was the cause of it, how c[an] the mixing of wine with water in the sacrament be e[m]blematical of the flowing of blood and water separatel[y]? such a mixture surely bears a more striking resemblan[ce] to the reunion of the *serum* and *crassamentum*, after th[ey] had been separated by whatever cause. See BLOOD.

We urge not these objections to the mixed cup fro[m] any dislike that we have to the practice. It is unque[s]tionably harmless and primitive; and we wish th[at] greater regard were paid to primitive practices than th[e] generality of Christians seem to think they can claim; but let the advocates for antiquity be consistent; le[t] them either restore, together with the mixed cup, th[e] use of unleavened bread, or acknowledge that neithe[r] the one nor the other is essential to the sacrament. Thi[s] last acknowledgement must indeed be made, if the[y] would not involve themselves in difficulties from whic[h] they cannot be extricated. If either the mixed cup o[r] unleavened bread be absolutely necessary to the validit[y] of the sacrament, why not wine made from the grape[s] of Judæa? why not that particular kind of wine which was used by our Saviour? and where is that wine to be found?

But the controversies respecting the outward part or sign of the Lord's Supper are of little importance when compared with those which have been agitated respecting the inward part or thing signified; and of these we hasten to give as comprehensive a view as the limits prescribed to such articles will admit.

Our Blessed Lord, in the same night that he was betrayed, "took bread, and blessed it, and brake it, and gave it to the disciples, and said, Take, eat; this is my body. And he took the cup, and gave thanks, and gave it to them, saying, Drink ye all of it; for this is my blood of the new testament, which is shed for many for the remission of sins." Such was the institution of the Lord's Supper as it is recorded in the gospel by St Matthew; and we have the same account of it, in almost the very same words, by three other inspired writers, St Paul, St Mark, and St Luke. That it was the bread which Christ blessed and brake that is here called his body, and the wine over which he gave thanks that he styles his blood of the new testament, will admit of no reasonable doubt (A); but in what sense they became so, has been the subject of many controversies.

The church of Rome, which holds, that after consecration, th[e] ... of

D

(A) Some over-zealous Protestants have indeed affirmed, that it was not the consecrated bread and wine, but those

Supper.

cration, Jesus Christ, God and man, is really, truly, and substantially, contained under the outward appearances of the bread and wine, informs us, that about the middle of the mass, when the priest, taking into his hand, first the bread and then the wine, pronounces over each separately the sacred words of consecration, the substance of these elements is immediately changed by the almighty power of God into the body and blood of Christ; but that all the outward appearances of the bread and wine, and all their sensible qualities remain. This more than miraculous change is called TRANSUBSTANTIATION; and is founded on the philosophy of Aristotle, which resolves all bodies into *matter* and *form* (see METAPHYSICS, N° 142—150.); for it is only the *matter* or imperceptible substance which supports the *forms* or sensible qualities of bread and wine, that is changed into the *substance* or matter of the body and blood of Christ, so that this divine matter, coming into the place of the former earthy matter, supports the same identical *forms* which it supported. Hence we are told, "that Jesus Christ, now present instead of the bread and wine, exhibits himself to us under those very same outward *forms* or appearances which the bread and wine had before the change."

Could this doctrine be true, it would be abundantly mysterious; but to add to the mystery, we are farther informed, that under each kind is contained Jesus Christ whole and entire, his body and blood, his soul and divinity; so that when a man eats what has the appearance of a wafer, he really and truly eats the body and blood, the soul and divinity, of Jesus Christ; and when he afterwards drinks what has the appearance of wine, he drinks the very same body and blood, soul and divinity, which not a minute perhaps before he had wholly and entirely eaten! The ingenious author from whose work we have taken this account of the Romish doctrine concerning the real presence, may perhaps reject our inference that the orthodox members of his church must believe the *soul* and *divinity* of Christ to be *eaten* and *drunk* in the Lord's supper; but he cannot deny that, according to his statement of the Catholic faith, the soul and divinity are both received whole and entire into the stomach of each communicant. He says indeed, that "communion consists in receiving Jesus Christ whole and entire, his sacred body, his precious blood, his blessed soul, and his adorable divinity, into our *souls*;" but that which was formerly bread and wine unquestionably goes into the *stomachs* of the communicants; and since, according to him, it is now the body and blood of Christ, the soul and divinity must go thither with it, for these four cannot be separated. This our author himself grants. "The Scripture (says he) positively declares, that *Christ rising again from the dead, dieth no more; death shall no more have dominion over him* (Rom. vi. 9.). Consequently his body, his blood, and his soul, shall never more be separated from one another; and as the union of his divine and human natures can never more be broken, so neither can these, his two natures, united in his divine person, be ever separated. From this it necessarily follows, that wherever the body of Christ is, there also his blood, his soul, and his divinity, must of necessity be in like manner."

Now, whether we suppose, with our author, that the soul and divinity of Christ directly carry his body and blood with them into the human soul, or, trusting, in some degree to the evidence of sense, believe that the body and blood carry his soul and divinity with them directly into the stomach of each communicant—is it credible, is it possible, that the high and lofty One, who inhabiteth eternity, and whom the oracles of truth assure us that even the heaven of heavens cannot contain, should be *substantially* received *whole* and *entire* into a finite spirit like the human soul, or into a body so limited as the human stomach? Our author says it is; declaring that, "by the blessed *presence* of Jesus Christ, *whole and entire within us*, are communicated to our souls all the heavenly graces which are the effects of the holy communion: such as the sanctification of the soul by an increase of justifying grace; the rendering of it more pure, more holy, more beautiful, more agreeable, in the eyes of God; the cleansing of the soul from all those venial sins and imperfections of which we repent, and preserving us from falling into mortal sins; the uniting of us in a most intimate manner with Jesus Christ, who comes to us in this holy sacrament on purpose to dwell in our souls and abide with us; and the giving us a pledge and earnest of a glorious immortality, to the enjoyment of which it brings us at last, if we persevere to the end in the grace of God."

The consequence of the doctrine of transubstantiation is the *sacrifice of the mass*, by which, it is said, God's acceptance of Christ's sacrifice on the cross is obtained for the actual benefit of those persons in particular for whom the mass is offered. In the work so often quoted, we are told, that "Jesus Christ our redeemer, who is both our high-priest and our victim, who, in order to perfect the work of our redemption, and reconcile man with his offended Creator, offered himself once in a bloody

those elements, *together with the whole action* of taking them into his hands, blessing them, breaking the bread, and distributing the bread and wine to the disciples, that Christ calls his body and blood. This novel and singular opinion rests upon no better foundation than a very childish criticism. Our Saviour, after blessing and breaking the bread, gave it to the disciples, saying, in the original, Λαβετε φαγετε ΤΟΥΤΟ εϛι το σωμα μου. Now, say our critics, τουτο, in the neuter gender, can never agree with the antecedent αρτος in the masculine, but must refer to all the circumstances of the action taken together, and considered as one complex neuter noun. But this noun, whether complex or simple, certainly denotes what could be *eaten;* and to suppose that our blessed Lord desired his apostles to eat *actions*, is as repugnant to human reason as any doctrine of the church of Rome. The truth is, that the word τουτο, which is more properly a definite article than a demonstrative pronoun (see GRAMMAR, Chap. II.), refers directly to the thing, whatever it was, which our Saviour held in his hand and gave to the disciples; and the clause when completed, is τουτο ον εϛι το σωμα μου; this *being*, this *substance*, *is my body*. There was no necessity for characterising that substance by any analogy to sex, in order that it might be distinguished from every other substance; for the apostles could not but see it in the hand of their Master.

Supper.

bloody manner upon the cross, in order to communicate and apply to the souls of individuals those graces, which, by his death, he merited for mankind in general, continues to offer himself daily upon the altar in an unbloody manner, by the ministry of his priests, in the *mass*. The sacrifice of the cross and that of the mass are both one and the same sacrifice, because in both the victim is the same and the high priest the same, viz. Jesus Christ. The only difference is in the *manner* of offering. On the cross he offered himself in a bloody manner, and actually died; whereas on the altar he is offered up to God in an unbloody manner, not *actually* dead, but under the *appearance* of death;" so that the communicants not only eat the man Jesus Christ, but even eat him alive (B)!

It is known to all our readers that this doctrine of transubstantiation was one cause of the breach between the church of Rome and those various societies which call themselves reformed churches. The real and substantial change of the bread and wine into the body and blood of our Lord is rejected by every reformer as a change contradictory and impossible, and fraught with the most impious consequences; and volumes have been written to expose the weakness of those arguments which have so often been vainly urged in its support. It has been shown to imply numberless absurdities, such as, that the same thing can be in a million of different places, *whole* and *entire*, at the same instant of time; that it is above 1800 years old, and yet may be not more than one minute; that *forms* or sensible qualities are real things independent of their subject and the sentient beings who perceive them; that the infinite and eternal God, who created and sustains the universe, is himself wholly and substantially comprehended by the human soul; and that the half, or fourth, or tenth part of the body of Christ, is equal to the whole of that body. That these are necessary consequences of transubstantiation has been so completely proved in various works (C) to which every reader may have access, that it is needless for us to repeat arguments so hackneyed; but there are two objections to that doctrine, which, as we do not remember to have met with them elsewhere, and as they appear to us absolutely conclusive, it may be worth while to state in this place.

6
Implies numberless contradictions.

The advocates for the real presence in the Lord's Supper contend, that every word relating to that ordinance is to be taken in the strictest and most literal sense, and they affect to triumph over the Protestants, because their notions of the sacrament cannot be supported without having recourse to figure and metaphor. This however is a very vain triumph; for we hesitate not to affirm, that supposing transubstantiation possible, and even capable of proof, there is not in the whole New Testament a single word or a single phrase which, if interpreted *literally*, gives the slightest countenance to that wonderful doctrine. The reader will remember, that transubstantiation, as we have stated it from a dignitary of the Romish church, and as it is in fact stated by the council of Trent (D), consists in a change of the *matter*, *imperceptible substance*, or *substratum* of the bread and wine, into the *matter*, *imperceptible substance*, or *substratum* of Christ's body and blood; for all parties agree that the sensible qualities of the bread and wine remain, and, according to the Romanist, are after consecration either supported by the *matter* of Christ's body and blood, or hung upon nothing. But the phrase τουτο ἐςι το σωμα μου,

7
is contrary to Scripture,

(B) This whole account of the Romish doctrine respecting the sacrament of the Lord's Supper is taken from a work in two small volumes, called *The Sincere Christian instructed in the Faith of Christ, from the Written Word*. Its author is a man of learning, and great personal worth: and as he fills a high station in the church of Rome, we cannot doubt but that he has given a fair view of the doctrine of that church respecting this and every other article of which he treats. We are sorry however that his zeal should have impelled him, in a *popular* work, to write in the manner that he has done of the salvation of those who are not members of his church, or who cannot embrace all his opinions; for if his doctrine on this subject be implicitly received by those "over whom he has the rule, and for whose souls he is appointed to watch," they must necessarily look upon the majority of their fellow-citizens as reprobates doomed to eternal perdition. Let this be our apology for treating some of those opinions, which he thinks so absolutely necessary to salvation, with less ceremony than perhaps we should have done, had he less positively pronounced our damnation for not having it in our power to embrace them. He is not indeed much less severe on the most virtuous heathens, though they never saw the New Testament, or heard the doctrines of his church preached. But perhaps this severity may be occasioned by the following question of Cicero: "Cum fruges, *Cererem*; vinum, *Liberum* dicimus, genere nos quidem sermonis utimur usitato: sed ECQUEM TAM AMENTEM esse putas, qui illud, quo vescatur, deum credat esse?"—*De Natura Deorum*, lib. iii. cap. 16.

(C) Among other works on this subject, we may confidently recommend to the reader a small tract published by Dr Abernethy Drummond, about thirty years ago, in the form of *A Dialogue between Philalethes and Benevolus*. In that treatise, together with a defence of it, which were both printed for Balfour and Drummond, Edinburgh, the absurd consequences which we have mentioned are, by arguments unanswerable, proved to flow from the doctrine of transubstantiation; and the artful sophistry, by which a very acute genius endeavoured to keep these consequences out of sight, is detected and exposed on acknowledged principles of the soundest metaphysics.

(D) The canon of that council which establishes transubstantiation is thus translated by the author of *The Sincere Christian Instructed*: "If any man shall say, that in the blessed sacrament of the Eucharist the substance of the bread and wine remains along with the body and blood of our Lord Jesus Christ, and shall deny that wonderful and singular conversion of the whole substance of the bread into the body, and of the whole substance of the wine into the blood, the appearances of the bread and wine only remaining, which conversion the Catholic Church calls *transubstantiation*, let him be anathema."

Supper.

μου, if taken in the literal sense, cannot possibly denote the consequence of such a change as this; for every person at all acquainted with the Greek language, especially the language of the Peripatetic school, knows that το σωμα μου signifies, not the *matter* or *substratum* of my body divested of its sensible qualities; but the body of me in its natural state, consisting of *matter* and *qualities*, or *matter* and *form united.* Unless therefore the *sensible qualities*, as well as the *matter* of the bread and wine, give place to the sensible *qualities* as well as the *matter* of our Saviour's body and blood, and unless he appear glorified on the altar as he appeared on the mount at his transfiguration, the words το σωμα μου must be interpreted figuratively. Had the apostles understood their Master's words in the sense in which they are understood by the church of Rome, they would have rendered them into Greek, not τουτο εστι το σωμα μου, "this is my *body*," but τουτο εστι η ὑλη του σωματος μου, "this is the *matter* of my body." In like manner, when St John relates * that Jesus said, "Whoso eateth my flesh and drinketh my blood, hath eternal life, and I will raise him up at the last day," had he understood his adorable Master to speak of his flesh and blood in the Eucharist in the sense in which they are taught to be there by the church of Rome, he would have represented him as saying, not Ὁ τρωγων μου την σαρκα, και πινων μου το αἱμα, but Ὁ τρωγων την ὑλην μου της σαρκος, και πινων την ὑλην μου του αἱματος, "whoso eateth the *matter* of my flesh, and drinketh the *matter* of my blood, hath eternal life, and I will raise him up at the last day."

* Chap. vi. verse 54.

8 and incapable of proof.

But further, supposing this singular conversion possible in itself, it cannot be rendered credible, however stated in any language that ever was or ever will be spoken by man. At first sight it may appear paradoxical to affirm, that a possible fact cannot be so related as to obtain credit; but that transubstantiation, if possible, is such a fact, will be apparent on the slightest consideration.

The relation which subsists between things and words is arbitrary; so that what is termed *body* in English, is σωμα in Greek, and *corpus* in Latin; and the same thing might with equal propriety (had the authors of these languages so pleased) have been expressed in the first by *soul*, in the second by νους, and in the third by *anima.* (See LANGUAGE, N° 3, &c.). The consequences of this are, that there is no universal language spoken; that the natives of one country understand not the speech of those of another; and that different men speaking the same language are perpetually liable to mistake each other's meaning. Between the *substrata* of bodies and their *sensible qualities* there is a relation founded in nature, so that the sensible qualities which indicate the substance to which they belong, to be *gold*, for instance, in one country, indicate the same thing in every other country, and have done so from the beginning of time. The sensible appearances of bodies therefore are an universal language, the language of the Author of Nature, by which he declares to his creature man, that though the ὑλη πρωτη, or primary matter of all bodies, may be the same kind of substance; yet the ὑλη προσεχης of one body, or the internal combination of its primary parts, differs from that of another; that gold, for instance, has a different *substratum* or *basis* from iron, lead, or silver; that the internal organization or structure of the body of an ox is different from that of a horse; and that the *internal substance* or *substratum* which exhibits the appearances of bread and wine is different from that which supports the sensible qualities of flesh and blood (see METAPHYSICS, Part I. Chap. I. and Part II. Chap. I. and II.). Supposing therefore the doctrine of transubstantiation to be possible and even true, it would still be impossible, by any statement in human language, or by any argument urged in its support, to render that doctrine an object of rational belief; for if it be said that the words τουτο εστι το σωμα μου were spoken by a divine person, who could neither be deceived himself nor intend to deceive us, it may be replied, that the sensible appearances of bread and wine, which are confessed to remain, are likewise the language of a divine person, even of the Creator and Governor of heaven and earth; that this language addressed to the sight, the taste, the touch, and the smell, is equally intelligible to all nations; that since the creation of the world its meaning has never been mistaken by the scholar or the clown, the sage or the savage, except in this single instance of our Lord's flesh and blood exhibiting the sensible appearances of bread and wine; and that it is therefore infinitely more probable that the members of the church of Rome should mistake the meaning of the words τουτο εστι το σωμα μου, which, though spoken by Christ, are part of the language of men, and liable to all its ambiguities, than that all mankind should mistake the language of God himself, which is liable to no ambiguities, and which was never in any other instance misunderstood by a single individual. Should transubstantiation therefore be really true, its truth can never be proved or rendered probable, but by an immediate operation of the spirit of God on the mind of man; and he who is conscious of no such operation on his own mind, may rest assured that the Father of mercies, who knows whereof he is made, will never bring upon him, for his incredulity in this instance, any of the anathemas denounced by the church of Rome upon those who place implicit confidence in the universal language of Him who created them, in opposition to her figurative and contradictory interpretations of the written word. Of the transubstantiation of the elements a visible miracle would afford no proof. Had the water been changed into wine at the marriage in Cana of Galilee, for the express purpose of bearing testimony to this singular conversion, what must have been the consequence on the minds of those who witnessed that miracle? Nothing, we think, but scepticism or distrust of their own faculties; for they would have had the very same evidence that *no* substantial change was wrought on the elements, as that the water was *actually* turned into wine.

Though the reformed churches unanimously reject the doctrine of transubstantiation, and of course the sacrifice of the mass, its inseparable consequence, they are far from being agreed among themselves respecting the nature of the Lord's Supper; and the notions of this ordinance entertained by some of them appear to us as untenable as any part of the doctrine of the church of Rome. The Lutherans believe, that the body and blood of Christ are really and substantially present with the bread and wine; that the body is really and truly eaten, and the blood really and truly drunk, by the communicants; and that whatever motion or action the bread has, the body has the same *. According to them, therefore,

9 Doctrine of the Lutherans incredible.

Supper.

therefore, the same sensible appearances are exhibited by two substances united in some inexplicable manner, which is neither a personal union, nor incorporation, nor the inclosure of the body within the bread; nor does it last longer than while the sacrament is celebrating. This union is generally called CONSUBSTANTIATION; but they reject the term, contenting themselves with asserting the real presence, without presuming to define the mode by which the body and blood of Christ are united to the sacramental elements.

It would be superfluous to waste time in replying to this doctrine. Every reader sees that it implies the possibility of the same thing's being whole and entire in a million of places at one and the same instant of time, which has been so often urged as an unanswerable objection to the Romish doctrine; and it is fraught with this additional absurdity peculiar to itself, that two bodily substances may at once occupy the same place, which is directly contrary to our notions of solidity. It may be observed too, that whatever be the real sense of our Saviour's words, he says expressly, "This is my body"—this thing which I give you, and which you see and feel; whereas, had he meant what Luther and his followers teach, he would surely have said, "*With* this bread receive my body, *with* this cup receive my blood."

10 Of the early Calvinists,

The notions of some of the early Calvinists respecting the Lord's Supper are very mysterious, and expressed in language of which we are not sure that we understand the meaning. In the year 1561 an attempt was made in France to bring the Catholics and Protestants to an uniformity of doctrine on this great topic of controversy; and deputies were appointed by both parties to meet at *Poissy*, and debate the question in a friendly manner. The principal managers on the side of the Catholics were the cardinals of *Lorraine* and *Tournon*; those on the side of the Protestants were *Beza* and *Peter Martyr*. After several meetings, disputes, and violent separations, the Protestant deputies declared their faith in the following words: "We confess, that Jesus Christ, in the Supper, does truly give and exhibit to us the substance of his body and blood by the efficacy of his Holy Spirit; and that we do receive and eat spiritually, and by faith, *that very body which was offered and immolated for us*, so as to be bone of his bone and flesh of his flesh, to the end that we may be enlivened thereby, and receive what is conducive to our salvation. And because faith, supported by the word of God, makes those things present, which it apprehends, and by that faith we do in *deed* and *reality* receive the *true natural* body and blood of Christ, by the power of the Holy Spirit; by this means, we confess and acknowledge the presence of his body and blood in the Supper." One of the Catholic delegates expressing his dislike of this last clause, the Protestant ministers gave the following explanation of their sentiments: "No distance of place can hinder us from communicating of the body and blood of Christ, for the Lord's Supper is a heavenly thing; and though on earth we receive with our mouths bread and wine, which are the true signs of his body and blood, yet by faith, and the efficacy of the Holy Ghost, our minds, which are fed with this food, *are rapt up into heaven*, and enjoy the presence of the body and blood; and that by this means it may be said that the body is truly joined to the bread, and the blood to the wine; but after the manner of a sacrament, and not at all according to plac[e] or natural position *."

If the reader can discover the precise meaning o[f] these passages, his sagacity exceeds ours. That th[e] Protestant deputies believed, or professed to believe that the *natural* body and blood of Christ are by th[e] faithful received in the Lord's Supper, is indeed evi[dent]; but their notions respecting the manner of this reception are very unintelligible, if not contradictory. In the former quotation, they confess that Christ's body and blood are really present in the sacrament; that they are made present by faith (we suppose the faith of the communicants); and that the *very body* which was offered and immolated for us is eaten *spiritually* and by *faith*. In the latter quotation, they seem to say that Christ's body and blood are in heaven, at a great distance from the true signs of them; that on earth the communicants receive only these signs, which are bread and wine; but that, by faith and the efficacy of the Holy Spirit, their minds, during actual communion, are rapt up into heaven, where they enjoy the presence of the body and blood; and that by this means the body and blood are truly joined to the bread and wine through the medium of the mind of the communicant, which is at once present both to the sign and to the thing signified. To this mysterious doctrine it is needless to urge objections. Every man who is accustomed to think, and to use words with some determinate meaning, will at once perceive that the authors of this declaration must have had very confused notions of the subject, and have pleased themselves with sound instead of sense, satisfied that they could not be wrong if they did not symbolize with the Lutherans or the Council of Trent.

Of [the] chu[rches of] Bri[tain].

The churches of England and Scotland, in their established doctrines respecting the Lord's Supper, appear to be Calvinistical; but the compilers of the Thirty-nine Articles and of the Confession of Faith must have been much more rational divines than Beza and Peter Martyr. They agree in condemning the doctrine of transubstantiation as contrary to common sense, and not founded in the word of God; they teach, that to such as rightly, worthily, and with faith, receive the sacrament, the bread which we break is a partaking of the body of Christ, and the cup of blessing a partaking of the blood of Christ; and they add, that the body and blood of Christ are eaten and drunk, not corporally or carnally, but only after a heavenly and spiritual manner, by which the communicants are made partakers of all the benefits of his death †. In one important circumstance these two churches seem to differ. The Confession of Faith, as we understand it ‡, affirms, that in the Lord's Supper there is no sacrifice made at all. The thirty-first article of the church of England likewise condemns the Popish sacrifice of the mass as a *blasphemous fable* and *dangerous deceit*; but in *the order for the administration of the Lord's Supper or Holy Communion*, the celebrator "beseeches God most mercifully to accept the alms and *oblations* of the congregation," and again "to accept *their sacrifice of praise* and thanksgiving:" from which petitions many have inferred that, in the Lord's Supper, that church offers a commemorative and eucharistical sacrifice. This inference seems not to be wholly without foundation. In the order for the administration of the Lord's Supper, according to the form of the Book of Common Prayer set forth by act of parliament

† *Ar[ticles] of th[e] Chur[ch of] Engl[and]*, art. 2[8]. *and C[onfes]sion o[f] Faith* chap[.]
‡ Chap[.] § 3.

Supper.

liament in the second and third years of King Edward the Sixth, the elements were solemnly offered to God as a sacrifice of praise and thanksgiving; and though the prayer containing that oblation was, at the review of the liturgy some years afterwards, removed from the prayer of consecration, to which it was originally joined, and placed where it now stands in the post communion service; yet the very act of parliament which authorized that alteration, calls King Edward's "a very godly order, agreeable to the word of God and the primitive church, and very comfortable to all good people desiring to live in Christian conversation."

13 Some English divines hold the Lord's Supper to be a eucharistical sacrifice.

The English church, however, has not positively determined any thing respecting this great question; and whilst she condemns the doctrine of the real presence; with all its dangerous consequences, she allows her members to entertain very different notions of this holy ordinance, and to publish these notions to the world. Accordingly, many of her most eminent divines (E) have maintained that, in the celebration of the Lord's Supper, the elements of bread and wine are offered to God as a sacrifice commemorative of Christ's one sacrifice for the sins of the whole world; that these elements, though they undergo no substantial change, yet receive such a divine virtue by the descent of the Holy Ghost, as to convey to the worthy communicant all the benefits of Christ's passion; that they are therefore called his body and blood, because being, after their oblation, eaten and drunk in remembrance of Him, they supply the place of his body and blood in the feast upon his sacrifice; and that it is customary with our Saviour to give to any thing the name of another of which it completely supplies the place, as when he calls himself the *door** of the sheep, because there is no entrance into the church or kingdom of God but by faith in him. They observe, that the Eucharist's being commemorative, no more hinders it from being a proper sacrifice, than the typical and figurative sacrifices of the old law hindered them from being proper sacrifices: for as to be a type doth not destroy the nature and notion of a legal sacrifice, so to be representative and commemorative, doth not destroy the nature of an evangelical sacrifice. To prove that, in the celebration of the Lord's Supper, there is a real sacrifice offered to God as well as a sacrament received by the communicants, they appeal to St Paul, who says expressly †, that "Christians have an *altar*, whereof they have no right to eat who serve the tabernacle," and who by contrasting the cup of the Lord with the cup of devils, and the table of the Lord with the table of devils ‡, teaches plainly, that those cups and those tables had the same specific nature. That the *table of devils* spoken of by the apostle was the Pagan altars, and the *cup of devils* the wine poured out in libations to the Pagan divinities, will admit of no dispute; and therefore, say the advocates for the eucharistical sacrifice, the table of the Lord must be the Christian altar, and the cup of the Lord the wine offered to God as the representative of the blood of Christ; otherwise there would not be that *absurdity* which the apostle supposes, in the same person drinking the cup of the Lord and the cup of devils, and partaking of the Lord's table and the table of devils. They observe farther, that in all the ancient liturgies extant there is a solemn form of oblation of the sacramental elements, and that all the Christian writers from the second century downwards treat of the Lord's Supper as a sacrifice as well as sacrificial feast, having indeed no value in itself, but acceptable to God as representing Christ's one sacrifice for the sins of the world. Our limits will not permit us to give even an abstract of their arguments; but the reader who shall attentively peruse *Johnson's unbloody Sacrifice and Altar unveiled and supported*, will discover that their notions are better founded than probably he supposes, and that they are totally irreconcileable with the doctrine of transubstantiation and the Popish sacrifice of the *mass*.

† Heb. xiii. 10.

‡ 1 Cor. x. 16, &c.

14 Others, a mere memorial;

Other English divines of great learning, with the celebrated Hoadley bishop of Winchester at the head of them, contend strenuously that the Lord's Supper, so far from being a sacrifice of any kind, is nothing more than bread and wine reverently eaten and drunk, in remembrance that Christ's body was broken and his blood shed in proof of his Father's and his own love to mankind; that nothing is essential to the sacrament but this remembrance, and a serious desire to honour and obey our Saviour as our head; that the sacrament might be celebrated without uttering one prayer or thanksgiving, merely by a society of Christians, whether small or great, jointly eating bread and drinking wine with a serious remembrance of Christ's death; that St Paul enjoins a man to examine himself before he eat of that bread and drink of that cup, not to discover what have been the sins of his past life in order to repent of them, but only that he may be sure of his remembering Christ's body broken and his blood shed; that, however, it is his duty in that as in every other instance of religious worship to resolve to obey from the heart every precept of the gospel, whether moral or positive; and that to partake worthily of the Lord's Supper is acceptable to God, because it is paying obedience to one of these precepts; but that no particular benefits or privileges are annexed to it more than to any other instance of duty. Bishop Hoadley acknowledges, that when St Paul says *, "The cup of blessing which we bless, is it not the communion of the blood of Christ? The bread which we break, is it not the communion of the body of Christ?" he has been supposed by many learned men to affirm, that all the benefits of Christ's passion are in the Lord's Supper conveyed to the worthy communicant; but this (says he) is an idea which the apostle could not have in his thoughts as at all proper for his argument. The Greek word *κοινωνια* and the English *communion* signify only a partaking of something in common with others of the same society; and the apostle's meaning (he says) can be nothing more, than that in the Lord's Supper we do not eat bread and drink wine as at an ordinary meal, but as memorials of the body and blood of Christ, in honour to *him* as the *head* of that body of which we are all *members*. That the word *κοινωνια* is not meant to denote any inward or spiritual part of the Lord's Supper, he thinks evident, because the same word is used with regard to the cup and the table of idols, where no spiritual

Supper.

spiritual part could be thought of, and in an argument which supposes an idol to be nothing†.

† *A Plain Account of the Nature and End of the Lord's Supper.*

To this view of the nature and end of the Lord's Supper, it must appear no small objection, that "he who eateth and drinketh unworthily is said to be *guilty of the body and blood of the Lord, and to eat and drink a judgment to himself, not discerning the Lord's body.*" No doubt it would be sinful to eat and drink a mere memorial of Christ's death without serious dispositions; but we cannot conceive how a little wandering of the thoughts, which is all the unworthiness which the author thinks there can be on such an occasion, should be a sin of so deep a dye as to be properly compared with the guilt of those who murdered the Lord of life. Other divines, therefore, feeling the force of this and similar objections, steer a middle course between the mere memorialist and the advocate for a real sacrifice in the holy

15 and others, a feast upon our Saviour's sacrifice.

Eucharist, and insist that this rite, though no sacrifice itself, is yet a feast upon the one sacrifice offered by Christ and slain upon the cross. The most eminent patrons of this opinion have been Dr Cudworth, Bishop Warburton, and the present bishop of Chester; and they support it by such arguments as the following: "In those ages of the world when victims made so great a part of the religion both of Jews and Gentiles, the sacrifice was always followed by a religious feasting on the thing offered; which was called the *feast upon or after the sacrifice*, and was supposed to convey to the partakers of it the benefits of the sacrifice. Now Jesus (say they), about to offer himself a sacrifice on the cross for our redemption, did, in conformity to general practice, institute the *last supper*, under the idea of *a feast after the sacrifice:* and the circumstances attending its institution were such, they think, that the apostles could not possibly mistake his meaning. It was just before his passion, and while he was eating the paschal supper, which was a Jewish *feast upon the sacrifice*, that our blessed Lord instituted this rite; and as it was his general custom to allude, in his actions and expressions, to what passed before his eyes, or presented itself to his observation, who can doubt, when, in the very form of celebration, we see all the marks of a *sacrificial supper*, but that the divine institutor intended it should bear the same relation to his *sacrifice on the cross* which the *paschal supper* then celebrating bore to the oblation of the *paschal lamb?* If this was not his purpose, and if nothing more was intended than a general memorial of a dead benefactor, why was this instant of time preferred for the institution to all others throughout the course of his ministry, any one of which would have been equally commodious? Indeed any other time would have been more commodious for the institution of a mere memorial; for the paschal lamb and unleavened bread were certainly a sacrifice; and the words used by our Saviour, when he gave the bread and wine to the apostles, were such as must necessarily have led them to consider that bread and wine as bearing the same relation to his sacrifice that the paschal supper bore to the paschal sacrifice. At that Jewish feast, it was the custom of every father of a family to break the unleavened bread, and to give to every guest a portion, saying, "This is the bread of affliction, which our fathers did eat in the land of Egypt:" a custom which, we may be sure, that Christ, as father of his family, would religiously observe. The apostles knew well that they were not eating the identical bread which their fathers did eat in Egypt, but the feast upon the sacrifice then offered in commemoration of their redemption from Egyptian bondage; and therefore when they saw their Master after supper break the bread again and give it to each of them, with these remarkable words, "This is my body which is given for you, do this in remembrance of me," they must have concluded, that his meaning was to institute a rite which should to the end of the world bear the same relation to his sacrifice that the paschal supper bore to the sacrifice of the passover.

This inference, from the circumstances attending the institution, Bishop Warburton thinks confirmed by St Paul's mode of arguing with the Corinthians, on their impiety and absurdity in partaking both of the Lord's table and the table of devils; for "what (says he) had the eaters of the sacrifices to do with the partakers of the bread and wine in the Lord's Supper, if the Lord's Supper was not a feast of the same kind with their feasts? If the three feasts, Jewish, Pagan, and Christian, had not one common nature, how could the apostle have inferred that this intercommunity was inconsistent? *Ye* CANNOT (says he) *drink the cup of the Lord and the cup of devils; ye* CANNOT *be partakers of the Lord's table and the table of devils.* For though there might be *impiety* in the promiscuous use of Pagan and Christian rites of any kind, yet the *inconsistency* arises from their having a common nature, and consequently, as they had opposite originals, from their destroying one another's effects in the very celebration. Sacrifices, and feasts upon sacrifices, were universally considered as *federal* rites; and therefore the Lord's table and the table of devils being both *federal* rites, the same man could no more be partaker of both, than he could at once engage to serve both God and the devil. This is the apostle's argument to the wise men, to whom he appeals; and we see that it turns altogether upon this postulatum, that the Christian and Pagan feasts had the same specific nature, or were both feasts upon sacrifices. If this be admitted, it is easy to see why St Paul deemed those who ate and drank unworthily guilty of the body and blood of the Lord; for if the Lord's Supper be a feast upon his sacrifice, it must have been considered as the means of conveying to the communicants all the benefits of his death and passion; and the profanation of such a rite, by rendering his death ineffectual, might be fitly compared and justly equalled to the enormous guilt of those by whom his blood was shed." In reply to Bishop Hoadley's remarks upon the word *κοινωνια*, his brother bishop observes, that "had the apostle meant what the learned writer makes him to mean, he would doubtless have said *κοινωνια ὑμων εις το σωμα*, 'your communion in the body—your eating it jointly.' St Paul (continues he) knew how to express himself properly, as appears from a passage in his epistle to the Philippians, where, professedly speaking of the joint participation of a blessing, he uses these words, *κοινωνια ὑμων εις το ευαγγελιον*, 'your communion in the gospel.' To the other remark, that no spiritual part could be thought of in the table of idols, because an idol is said by the apostle to be *nothing*, Bishop Warburton replies, "that by St Paul the Gentiles are said to have sacrificed to devils, and those who ate of such sacrifices to have had communion with devils: now the *devil* (continues his Lordship) was in St Paul's opinion *something*." But the inference which

the

the apostle draws from the acknowledged truth, that the cup of blessing which we bless is the communion of the blood of Christ, and the bread which we break the communion of the body of Christ, puts his meaning, our author thinks, beyond all doubt. He says *, that the partaking of one bread makes the receivers of *many* to become *one body*. A just inference, if this rite be of the nature of a *feast upon the sacrifice*; for then *the communion of the body and blood of Christ* unites the receivers into one body by an equal distribution of one common benefit. But if it be only a general commemoration of a deceased benefactor, it leaves the receivers as it found them, not *one body*, but *many separate professors* of one common faith.

* 1 Cor. x. 27.

16 The ordinance not generally understood.

Thus have we given such a view as our limits would permit us to give, of the principal opinions that have been held respecting the nature and end of the Lord's Supper. It is an ordinance which seems not to be generally understood; though, being intended to show forth the Lord's death till he come, it is surely of sufficient importance to engage the attention of every serious Christian. The most considerable Protestant divines who have expressly written upon it are, Johnson in his *Unbloody Sacrifice;* Cudworth in his *Discourse concerning the true Nature of the Lord's Supper;* Hoadley in his *Plain Account;* and Warburton in his *Rational Account*. The notions of Cudworth and Warburton are the same, and perhaps they differ not so much from those of Johnson as many readers seem to imagine. At any rate, the arguments by which Warburton supports his doctrine must have some force, since it is said that Hoadley himself acknowledged they would be unanswerable, if it could be proved that the death of Christ was a real sacrifice.

SUPPLEMENT, in literature, an appendage to supply what is wanting in a book. Books of various kinds require such an appendage; but none so much as a dictionary of arts and sciences, which, from the progressive course of physical science, cannot be completed without it.

SUPPORTED, in *Heraldry*, a term applied to the uppermost quarters of a shield when divided into several quarters, these seeming as it were supported or sustained by those below. The chief is said to be supported when it is of two colours, and the upper colour takes up two-thirds of it. In this case it is supported by the colour underneath.

SUPPORTERS, in *Heraldry*, figures in an achievement placed by the side of the shield, and seeming to support or hold up the same. Supporters are chiefly figures of beasts: figures of human creatures for the like purpose are called *tenants*.

SUPPOSITION, in *Music*, is when one of the parts dwells on a note, while another part makes two or more lesser notes equivalent to it, by conjoint degrees.

Supposition is defined by a late author the using of two successive notes, of the same value as to time; the one whereof, being a discord, supposes the other a concord.

The harmony, Mr Malcolm observes, is always to be full on the accented parts of the bar or measure; but, on the unaccented, discords may transiently pass, without any offence to the ear. This transient use of discords followed by concords, make what we, after the French, call *supposition*.

Concords by supposition are those where the continued bass adds or supposes a new sound below the fundamental bass; whence such concords always succeed the extent of the octave. Of these concords there are three sorts, all which are concords of the seventh: the first, when the added sound is a third below the fundamental sound; such is the concord of the ninth: and if the concord of the ninth is formed by the mediant, added below the sensible concord in the minor mode, then the concord is called the *superfluous fifth*. The second kind is, when the supposed sound is a fifth below the fundamental sound, as in the concord of the fourth or eleventh; and if the concord is sensible, and the tonic be supposed, this concord is called the *superfluous seventh*. The third kind is that where the supposed sound is below a concord of the diminished seventh; if it is a fifth below, i. e. if the supposed sound be the mediant, the concord is called the concord of the *fourth* and *superfluous fifth*: if it is a seventh below, i. e. if the supposed sound be the tonic, the concord is called the *lesser sixth* and *superfluous seventh*.

SUPPOSITORY, a kind of medicated cone or ball, which is introduced into the anus for opening the belly.

It is usually composed of common honey, mixed up with soap or oil, and formed into pieces of the length and thickness of the little finger, only pyramidal. To the composition is sometimes also added powder of scammony, euphorbium, colocynthis, salt, aloes, &c. according to the case of the patient.

The suppository was invented for the convenience of such as have an aversion to clysters; or to be used when the disease does not allow their use.

SUPPRESSION, in *Medicine*, is generally used to signify a retention of urine or of the menses.

SUPPURATION, the second way wherein an inflammation terminates; being a conversion of the inspissated blood and the first adjacent parts, as the vessels and fat, into pus or matter; which disorder, when it has not yet found an opening, is generally called an *abscess*.

SUPRACOSTALES, in *Anatomy*. See *Table of the Muscles* in ANATOMY.

SUPRALAPSARIANS, in *Theology*, persons who hold that God, without any regard to the good or evil works of men, has resolved, by an eternal decree, *supra lapsum*, antecedently to any knowledge of the fall of Adam, and independently of it, to save some and to damn others; or, in other words, that God intended to glorify his justice in the condemnation of some, as well as his mercy in the salvation of others; and for that purpose decreed that Adam should necessarily fall, and by that fall bring himself and all his offspring into a state of everlasting condemnation.

These are also called *antelapsaries*, and are opposed to sublapsaries and infralapsaries.

According to the supralapsarians, the object of predestination is, *homo creabilis et labilis;* and, according to the sublapsarians and infralapsarians, *homo creatus et lapsus*.

SUPRASPINATUS, in *Anatomy*. See *Table of the Muscles* in ANATOMY.

SUPREMACY, the superiority or sovereignty of the king. See SOVEREIGNTY.

SUR, or SHUR, in *Ancient Geography*, a desert of Arabia Petræa, extending between Palestine and the Arabian

Sur, Surat.

Arabian gulf; into which the Israelites, after marching through the Red sea, first came (Exod. xv. 22.). Again (Numb. xxxiii. 8.), it is said, that from the sea they went three days journey into the Wilderness of Etham; whence some conclude that Etham and Shur are the same wilderness; or only differ as a part from the whole, Shur being the general name, and Etham that part of it lying nearest to the place of encampment of the same name. We know so little of the geography of these places, that there is more room for disputation than for decision. As to the route which the Israelites followed in their passage through the Red sea, Mr Bryant, we think, has given the most satisfactory account in his late work on the Plagues of Egypt.—Shur is now called *Corondel*.

SURAT, a city of Indostan, belonging to Britain, on the western coast of the peninsula, a little to the northward of Bombay, and about 16 miles up the river Tappee. It is but of modern date, and is a most remarkable instance of the power of trade to bring wealth and population to any spot where it can be brought to settle. Towards the middle of the 17th century, this place was only the resort of a few merchants, who, under the shelter of an old insignificant castle, laid the first foundations of a city now almost as large as London, with many fine buildings of Indian architecture, partly Gentoo and partly Morisque, and supposed to contain nearly 600,000 souls. The buildings of the greatest note are so contrived, that the gateway is defensible against any sudden irruption of a few armed men. The private apartments lie backwards for the conveniency of the women, of whom the Moors are remarkably jealous. They are fond of having one room, in the midst of which a fountain keeps playing, and which, by its noise, lulls them to sleep, and refreshes the room by its coolness; but thus a damp is produced, which would be very dangerous to Europeans. They have also generally a saloon with fountains playing in it, which, with the variegated flower-beds, in which they are very curious, makes a beautiful prospect. During the intense heats of summer they have country retirements a little way out of town, where they reside, or go in parties to amuse themselves. The streets are irregularly laid out; but have one property which renders it agreeable to walk in them, viz. that a competent width being left at bottom, the upper stories of the houses project over one another in such a manner, that people may with ease converse from them; by which means the street is agreeably shaded, at the same time that a proper ventilation is not impeded, but rather promoted. The shops, notwithstanding the vast trade carried on in this great and populous city, have a very mean appearance, owing to the dealers keeping their goods in warehouses, and selling by samples.

No place is better supplied with provisions than the city of Surat while its communication with the country remains open. Besides the unbounded importation, by which every article is brought here in great abundance, the natural productions of the soil are excellent, though less cheap than in other parts of India, as at Bengal especially; yet in that place, though the cattle and poultry are bought originally at a very low rate, they turn out very dear by the time they are fed for the table. Here, however, all kinds of eatables may be had at a reasonable price, ready for immediate use, and as good as can be found anywhere. The wheat of Surat is famous all over India for its singular substance, whiteness, and taste; and its salads and roots are likewise of an excellent quality. There are also many kinds of wild-fowl and other game to be had at an easy rate; but for wines and spirituous liquors they depend mostly on importation.

Surat was surrounded with a wall in a short time after it had assumed the form of a town. The fortification, however, was meant only to prevent the incursions of the Mahrattas, who had twice pillaged it; so that the place was by no means capable of standing any regular siege. Even the castle appears but a poor defence, being mounted with cannon here and there, without any order, or without any thing like an attempt towards military architecture.

In this city, before the East India Company became invested with the possession of Bombay, was the presidency of their affairs on the western coast. For this purpose they had a factory established there with great privileges by the Mogul government; and even after the presidency was established at Bombay, they continued a factory here at one of the best houses in the city; which yet not being spacious enough to contain their effects, they hired another at some distance from it, and nearer the water-side, which was called the new factory. In the mean time, the city flourished, and became the centre of all the Indian trade, being much more frequented for the sake of foreign merchandise than for either the natural productions or manufactures of the country, though they also made a considerable part of its commerce. In short, there was scarce any article of merchandise but what was to be found at all times in Surat, almost as readily as in London itself. While the Mogul government was in its vigour, there was such a show of justice kept up, as induced merchants of all religions and denominations to take up their residence in the city. The Gentoos especially resorted thither, in order to avoid the oppressions of their own government. Great care indeed was taken that no very flagrant acts of oppression should be committed; so that, in what sometimes happened, appearances were at least kept up; and the oppressions of government were chiefly owing to the animosities and rivalship of the merchants themselves. As an instance of the great extent to which commerce was pushed in Surat, we shall here quote from Mr Grose, what is said by Captain Hamilton of a merchant named *Abdulgafour*, viz. "That he drove a trade equal to the East India Company: for he had known him fit out in a year above 20 sail of ships, between 300 and 800 tons, none of which had less of his own stock than 20,000l. and some of them 25,000l." On the decease of this merchant, the government seized on a million of his money; and his grandson was not only deprived of all that he possessed, but barbarously murdered through the envy and treachery of his brother merchants, and the rapacity of the governor. The imports of this city in the year 1811 amounted to 4,881,410 rupees, and the exports to 3,964,523.

The city of Surat was taken and ruined by the Portuguese in 1520; and it was not till after this misfortune that it became such a celebrated emporium. All the Indian merchants who had been accustomed to trade thither contributed to re-establish it; but it was not till near a century after that it became the general staple of

Indian

Surat, Surcharge. Indian and European merchandise; when the Dutch appearing in the Indian ocean, had deprived the Portuguese of all their conquests on that coast, and almost entirely ruined their trade. The English established a factory here in 1609, the Dutch in 1616, and the French in 1665. In process of time, the Indian seas being greatly infested by pirates, a naval officer was appointed by the Mogul to keep them in awe. This officer was named *Siddee* (A) *Mussoot*, who had been chief of an Ethiopian colony settled at Rajapore. Here he had collected some vessels of considerable force, and carried on some trade, till he was dispossessed by the Mahrattas; upon which he repaired to Bombay, and afterwards to Surat, where he was appointed admiral on that station to the Mogul, with a yearly revenue of about 36,000l. sterling. Though he had no power, independent of the marine, he seized on the castle, encroached on the town, and appropriated to himself a third part of its revenues, under pretence of arrears due in his appointed revenue. Another third was paid to the Mahrattas, to prevent their depredations upon trade in the open country; but they, not satisfied with this stipulation, watched an opportunity to plunder the town, which was kept in subjection by Siddee Mussoot, till his death which happened in 1756.

Siddee Mussoot was succeeded by his son, who soon rendered himself very disagreeable to the inhabitants. In 1758, the English factory was greatly oppressed by him, and the black merchants treated still worse; on which an expedition was sent, under Admiral Pococke and Captain Maitland, to take the castle by force. This was accordingly accomplished. Captain Maitland took possession of the castle with its revenue in the name of the East India company. The Nabob, however, was continued in office till 1800, when his authority was set aside, and the town put under the immediate government of the British. In 1803 the Mahrattas were compelled to abandon their vexatious claims, and the vicinity of the city has been cleared of those armed bands of thieves who formerly infested it.

SURCHARGE OF THE FOREST, is when a commoner puts more beasts in the forest than he has a right to. See FOREST.

SURCHARGE of Common, is a disturbance of common of pasture, by putting more cattle therein than the pasture and herbage will sustain, or the party hath a right to do. This injury can only happen where the common is appendant or appurtenant, and of course limitable by law; or where, when in gross, it is expressly limited and certain; for where a man hath common in gross, *sans nombre*, or without stint, he cannot be a surcharge. In this case indeed there must be left sufficient for the lord's own beasts.

The usual remedies for surcharging the common are by the lord's distraining the surplus number, or by his bringing an action of trespass, or by a special action on the case, in which any commoner may be plaintiff. The ancient and most effectual method of proceeding is by writ of admeasurement of pasture.

Writ of Second SURCHARGE, de secunda superoneratione, is given by the statute of Westm. 2. 13 Edw. I. cap. 8. when, after the admeasurement of pasture hath ascertained the right, the same defendant surcharges the common again; and thereby the sheriff is directed to inquire by a jury whether the defendant has in fact again surcharged the common; and if he has, he shall then forfeit to the king the supernumerary cattle put in, and also shall pay damages to the plaintiff. Surcharge ‖ Surf.

SURCINGLE, a girdle wherewith the clergy of the church of England usually tie their cassocks. See GIRDLE.

SURCOAT, a coat of arms, to be worn over body armour.

The surcoat is properly a loose thin taffety coat, with arms embroidered or painted on it. Such as is worn by heralds, anciently also used by military men over their armour to distinguish themselves by.

SURD, in *Arithmetic* and *Algebra*, denotes any number or quantity that is incommensurable to unity: otherwise called an *irrational number* or *quantity*. See ALGEBRA, Part I. Chap. IV.

SURETY, in *Law*, generally signifies the same with BAIL.

SURF, is a term used by seamen to express a peculiar swell and breaking of the sea upon the shore. It sometimes forms but a single range along the shore, and at others three or four behind one another extending perhaps half a mile out to sea. The surf begins to assume its form at some distance from the place where it breaks, gradually accumulating as it moves forward till it gains not uncommonly, in places within the limits of the trade-winds, a height of 15 or 20 feet, when it overhangs at top, and falls like a cascade with great force and a prodigious noise. Countries where surfs prevail require boats of a particular construction very different from the greater part of those which are built in Europe. In some places surfs are great at high, and in others at low water; but we believe they are uniformly most violent during the spring-tides.

It is not easy to assign the cause of surfs. That they are affected by the winds can hardly be questioned; but that they do not proceed from the *immediate* operation of the wind in the places where they happen, is evident from this circumstance, that the surf is often highest and most violent where there is least wind, and *vice versa*. On the coast of Sumatra the highest are experienced during the south-east monsoon, which is never attended with such gales as the north-west. As they are most general in the tropical latitudes, Mr Marsden, who seems to have paid much attention to the subject, attributes them to the trade-winds which prevail at a distance from shore between the parallels of 30 degrees north and south, whose uniform and invariable action causes a long and constant swell, that exists even in the calmest weather, about the line, towards which its direction tends from either side. This swell, when a squall happens or the wind freshens up, will for the time have other subsidiary waves on the extent of its surface, breaking often in a direction contrary to it, and which will again subside as a calm returns, without having produced

(A) When the Abyssinian slaves are promoted to any office under the Mogul government, they are called *Siddees*.

Surf ‖ Surfeit.

duced on it any perceptible effect. Sumatra, though not continually exposed to the south-east trade-wind, is not so distant but that its influence may be presumed to extend to it; and accordingly at Poolo Pesang, near the southern extremity of the island, a constant southerly sea is observed, even after a strong north-west wind. This incessant and powerful swell rolling in from an ocean, open even to the pole, seems an agent adequate to the prodigious effects produced on the coast; whilst its very size contributes to its being overlooked. It reconciles almost all the difficulties which the phenomena seem to present, and in particular it accounts for the decrease of the surf during the north-west monsoon, the local wind then counteracting the operation of the general one: and it is corroborated by an observation, that the surfs on the Sumatran coast ever begin to break at their southern extreme, the motion of the swell not being perpendicular to the direction of the shore. This explanation of the phenomena is certainly plausible; but, as the author candidly acknowledges, objections may be urged to it. The trade-winds and the swell occasioned by them are remarkably steady and uniform; but the surfs are much the reverse. How then comes an uniform cause to produce unsteady effects?

In the opinion of our author it produces no unsteady effects. The irregularity of the surfs, he says, is perceived only within the remoter limits of the trade-winds. But the equatorial parts of the earth performing their diurnal revolution with greater velocity than the rest, a larger circle being described in the same time, the waters thereabout, from the stronger centrifugal force, may be supposed more buoyant; to feel less restraint from the sluggish principle of matter; to have less gravity; and therefore to be more obedient to external impulses of every kind, whether from the winds or any other cause.

SURFACE. See SUPERFICIES.

SURFEIT, in *Medicine*, a sickness with a sensation of a load at the stomach, usually proceeding from some error in diet, either with regard to the quantity or quality of the food taken. Sometimes, however, a surfeit is only a plethora from indolence and full diet: in which case perspiration is defective; and eruptions appear on the skin.

Fasting for some time, and an attention to temperance afterwards, with some brisk purgatives, will generally remove the effects of a surfeit, when it is unaccompanied with other more permanent affections.

SURFEIT, in *Farriery*. See FARRIERY *Index*.

SURGE, in the sea-language, the same with a wave. See WAVE.

SURGEON, or CHIRURGEON, one that professes the art of SURGERY.

In England there are two distinct companies of surgeons now occupying the science or faculty of surgery; the one company called *barbers*, the other *surgeons*, which latter are not incorporated.—The two are united to sue, and be sued, by the names of masters or governors and commonalty of the mystery of barbers and surgeons of London. 32 Hen. VIII. c. 42.

No person using any barbery or shaving in London, shall occupy any surgery, letting of blood, or other matter; drawing of teeth only excepted. And no person using the mystery or craft of surgery shall occupy or exercise the feat or craft of barbery or shaving, neither by himself, nor any other for his use. 32 Hen. VIII. c. 42.

By the same statute, surgeons are obliged to have signs at their doors.

The French chirurgeons being refused to be admitted into the universities (notwithstanding that their art makes a branch of medicine), on pretence of its bordering a little on butchery or cruelty, associated themselves into a brotherhood, under the protection of S. Cosmus and S. Damian: on which account, according to the laws of their institution, they are obliged to dress and look to wounds *gratis* the first Monday of each month.

They distinguish between a chirurgeon of the long robe and a barber-chirurgeon. The first has studied physic, and is allowed to wear a gown. The skill of the other, besides what relates to the management of the beard, is supposed to be confined to the more simple and easy operations in chirurgery; as bleeding, tooth-drawing, &c.

They were formerly distinguished by badges: those of the long gown bore a case of instruments; the barber, a bason.

SURGERY.

THE term Surgery has usually been employed to signify that department of medicine which treats of those diseases of the human body to be cured or alleviated by the hand, by instruments, or by external applications.

INTRODUCTION.

MEDICINE and Surgery, formerly regarded as one and the same science, were exercised by the same persons during the most remote ages; and their separation is to be considered as a modern institution.

If we consider their origin and end, the knowledge which the practitioner of each requires, and the connection which subsists between the diseases which are supposed peculiarly to belong to each department, it is probable that the first practitioners confounded them with each other; and it is easy to conceive how the same ideas should have passed from one generation to another.

At last, however, the knowledge of the healing art being greatly enlarged, it became separated into different classes, and formed into distinct departments in practice. Accordingly there were not only some who confined themselves to Surgery, but there were Lithotomists, Phlebotomists, Oculists, Aurists, Dentists, &c.

It is not proposed here to enter into any detail in attempting to show how this separation was made, and still less to mention the puerile disputes regarding the pre-eminence of Medicine to Surgery. There are

are few we believe in our days who do not feel that such a pre-eminence does not exist; that medicine and Surgery are one and the same science; that they are coeval with the human race; and to those who are able to appreciate them, they must appear of equal utility and importance. The healing art is one, its principles are the same throughout, and the exercise of its different branches supposes the same fundamental knowledge; but it offers in the detail such a vast field, that few men are able to embrace the whole, and to cultivate all the parts with equal success. It becomes, therefore, an advantage to society that such parts as can easily be separated in practice be exercised by different individuals; and that a man after having acquired a general knowledge of the structure, functions, and diseases of the animal economy, practise in such departments as his talents and acquirements point out.

Some have opposed Surgery to medicine by qualifying the first with the name of art, and in giving to the second that of science. To pretend that Surgery is nothing but the art of treating diseases by external means or by manual operations, is to rank it among the mechanical professions; and to consider the man as a good surgeon who can merely dress an ulcer, apply a bandage, reduce a fracture, amputate a limb, or only perform such like operations, on the living body. We have already mentioned that the healing art is the same in all its branches; the internal organs of the body in a state of health are governed by the same general laws; many of them are analogous in structure to the external parts; and the nature of a local disease can never be understood if we are not acquainted with all the deviations from the natural state, of which the whole animal system is susceptible. If a physician be called to treat a pleurisy, he cannot expect to do so with success unless he have a sufficiently clear idea of the nature of inflammation, or at least of the principal symptoms which characterise it; of its consequences, and of the proper mode of applying the means to remove it. But all this knowledge is not less necessary to the Surgeon who has to treat an wound, the management of which depends chiefly on the precautions necessary to prevent and remove inflammation in the affected parts, without at the same time weakening too much the vital powers. The knowledge of the physician does not therefore merit more the name of *science*, than that of the Surgeon, who ought to be well acquainted with the structure and functions of the animal economy, with morbid changes, and with the progress and termination of diseases.

The student of Surgery has therefore to acquire, not only all that knowledge necessary for the well educated physician, but he has likewise to learn the manner of performing surgical operations. This, though no doubt an essential requisite to the Surgeon, is by no means so important as a competent knowledge of those diseases and states of disease which require such means; and the young Surgeon should endeavour not to cherish that love of operating which is observed in some, and which arises from the eclât which a dexterous operator generally receives.

To become an intelligent and expert operator, several qualifications are necessary; some of which fall to the lot of few individuals. There are many, who, though they have acquired an extensive knowledge of diseases, have not that calmness of mind, that collectedness of thought, which is necessary for a good operator; and there are some who are even deficient in the mechanical dexterity, which, though not requisite in all, is yet necessary in several of the operations of Surgery. These talents, however, are never given in such perfection as not to require cultivation. An early habit of being present, and of assisting at operations, prepares the student to act for himself; and a long and unremitting habit of using the knife, and of performing operations on the dead body, gives a facility in all the mechanical parts, which even experience on the living body does not procure.

History of Surgery.

That Surgery was not only coeval with the other branches of medicine, but antecedent to any of them, will not admit of doubt. The wars and contentions which have taken place among mankind ever since their creation, imply that there would be occasion for Surgeons at a very early period; and probably external injuries would for some time be the only diseases for which a cure would be attempted, or perhaps thought practicable. In the sacred writings is made much mention of balsams, particularly the balm of Gilead, as excellent in the cure of wounds; though at the same time there were some wounds which this balsam could not heal.

Concerning the Surgery practised among the Egyptians, Jews, and Asiatic nations, there is little known. The art descended from the Greeks to us, though they confessedly received it from the Eastern nations. The first Greek surgeons on record are Æsculapius and his sons Podalirius and Machaon. Æsculapius flourished about 50 years before the Trojan war; and his two sons distinguished themselves in that war both by their valour and by their skill in curing wounds. This indeed is the whole of the medical skill attributed to them by Homer; for in the plague which broke out in the Grecian camp, he does not mention that they were at all consulted. Nay, what is still more strange, though he sometimes mentions his heroes having their bones broke, he never takes notice of their being reduced or cured by any other than supernatural means; as in the case of Æneas, whose thigh-bone was broken by a stone cast at him by Diomed. The methods which these two famous Surgeons used in curing the wounds of their fellow soldiers, seems to have been the extracting or cutting out the darts which inflicted them, and applying emollient fomentations or styptics to them when necessary. To these they attributed much more virtue than they could possibly possess; as appears from the following lines, where Homer describes Eurypylus wounded and under the hands of Patroclus, who would certainly practise according to the directions of the Surgeons.

> Patroclus cut the forky steel away;
> Then in his hand a bitter root he bruis'd,
> The wound he wash'd, the styptic juice infus'd.
> The *closing flesh* that instant ceas'd to glow;
> The wound to torture, and the blood to flow.

Till the days of Hippocrates we know very little of what was the practice of the Greek Surgeons. From him, however, we learn, that blood-letting, cupping, and scarification, were known to them; also the use of warm

History. warm and emollient fomentations, issues made with hot irons, pessaries, injections, fumigations, &c. Hippocrates also gives directions for the management of fractures, luxations, ulcers, fistulas. He directs the extension, reduction, bandages, and splints, proper to be used in fractures and luxations of different bones, with several machines to increase extension when necessary. He directs the laxity and tightness of the bandages; the intervals for unloosing and binding them on again; the position and repose of the fractured member, and the proper regimen; and he mentions the time when a callus is usually formed. He treats also of fractures of the skull, and the method of applying the trepan. In his treatment of ulcers, he speaks of reducing fungous flesh by means of escharotics, as alum, nitre, verdigrise, quicklime, &c.

Surgery appears not to have existed in Rome, notwithstanding the warlike genius of the people, for more than 500 years. Archagathus, a Greek, was the first professor of the art in that city; and so frequently employed the knife, hot irons, and other cruel methods of cure, that he was branded with the opprobrious title of *carnifex*, and expelled the city, where no physician or surgeon of eminence again made his appearance for 180 years. At this time Asclepiades undertook the profession of medicine; but seems to have attended little to surgery. Neither have we any thing of importance on that subject till the time of Celsus, who flourished during the reigns of Augustus and Tiberius.—In his work on surgery, all the improvements from Hippocrates to his own days are collected; the most minute and trifling diseases not being omitted. An eminent surgeon, of the moderns, emphatically exhorts every person in that profession "to keep Celsus in his hands by day and by night." Celsus describes the signs of a fractured skull, the method of examining for the fracture, of laying the skull bare by an incision in the form of the letter X, and afterwards of cutting away the angles, and of applying the trepan, mentioning also the signs of danger and of recovery. He observed, that sometimes, though very rarely, a fatal concussion of the brain might happen from the blood-vessels within the skull being burst, the bone remaining entire. After the operation of the trepan, sponges and cloths wetted with vinegar, and several other applications, were made to the head; and, throughout, severe abstinence was enjoined. In violent fractures of the ribs, he ordered venesection; low diet; to guard against all agitation of the mind, loud speaking, motion, and every thing that might excite coughing or sneezing. Cloths wetted with wine, roses and oil, and other applications, were laid over the fracture. The cure of fractures, in the upper and lower extremities, he said were nearly alike; that fractures differ in degree of violence and danger, in being simple or compound, that is, with or without a wound of the flesh, and in being near to the joint. He directs the extension of the member by assistants; the reduction, by the surgeon's hands, of the fractured bones into their natural situation; and to bind the fractured part with bandages of different lengths, previously dipped in wine and oil: on the third day fresh bandages ought to be applied, and the fractured member fomented with warm vapour, especially during the inflammation. Splints, if necessary, are to be applied, to retain the bones in a fixed position. The fractured arm is to be suspended in a broad sling hung round the neck: the fractured leg is to be inclosed in a kind of case, reaching above the ham, and accommodated likewise with a support to the foot, and with straps at the side, to keep the leg steady: in the fractured thigh-bone, the case is to extend from the top of the hip to the foot. He describes the method of treating compound fractures, and of removing small fragments of splinters of bones; and the manner of extracting darts. In luxations of the shoulder, he mentions several methods of giving force to the extension, and of replacing the dislocated bone. One method similar to that of Hippocrates was, to suspend the patient by the arm; the fore part of the shoulder, at the same time, resting upon the top of a door, or any other such firm fulcrum. Another method was to lay the patient supine, some assistants retaining the body in a fixed position, and others extending the arm in the contrary direction; the surgeon, in the mean time, attempting, by his hands, forcibly to reduce the bone into its former place.

If much inflammation was expected to ensue after a wound, that was suffered to bleed for some time, and blood was drawn from the arm. To wounds accompanied with considerable hæmorrhagy, he applied a sponge wet in vinegar, and constant pressure: If necessary, on account of the violence of the hæmorrhagy, ligatures were made round the vessels, and sometimes the bleeding orifice was seared up with the point of a hot iron. On the third day fresh dressings were applied. In considerable contusions, with a small wound of the flesh, if neither blood-vessels nor nerves prevented, the wound was enlarged. Abstinence and low diet, upon all such accidents, were prescribed; cloths wet with vinegar, and several other applications, were to be applied to the inflamed part. He observes, that fresh wounds may be healed without compound applications. In external gangrene, he cut into the sound flesh; and when the disease, in spite of every effort, spread, he advised amputation of the member. After cutting to the bone, the flesh was then separated from it, and drawn back, in order to save as much flesh as possible to cover the extremity of the bone. Celsus, though extremely diffuse in the description of surgical diseases, and of various remedies and external applications, treats slightly of the method of amputating; from which, comparing his treatise with the modern systems, we might infer that the operation was then seldomer practised than at present. He describes the symptoms of that dangerous inflammation the carbuncle, and directs, to burn or corrode the gangrened part. To promote the suppuration of abscesses, he orders poultices of barley-meal, or of marshmallows, or the seeds of linseed and fenugreek. He also mentions the compositions of several repellent cataplasms. In the Erisipelas, he applies ceruse, mixed with the juice of solanum or nightshade. Sal ammoniac was sometimes mixed with his plasters.

He is very minute in describing diseases of the eyes, ears, and teeth, and in prescribing a multitude of remedies and applications. In inflammation of the eyes, he enjoined abstinence and low diet, rest, and a dark room: if the inflammation was violent, with great pain, he ordered venesection, and a purgative; a small poultice of fine flower, saffron, and the white of an egg, to be laid to the forehead to suppress the flow of pituita; the soft inside of warm wheat bread dipped in wine, to be laid to the eye; poppy and roses were also added to his

his collyriums, and various ingredients too tedious to enumerate. In chronic watery defluxions of the eyes, he applied astringents, cupped the temples, and burnt the veins over the temple and forehead. He couched cataracts by depressing the crystalline lens to the bottom of the orbit. Teeth, loosened by any accident, he directs, after the example of Hippocrates, to be fastened with a gold thread to those adjoining on each side. Previous to drawing a tooth, he ordered the gum to be cut round its neck; and if the tooth was hollow, it was to be filled with lead before extraction, to prevent its breaking by the forceps. He describes not only the inflammation, but likewise the elongation, of the uvula: he also describes the polypus, and some other diseases affecting the nose.

He describes several species of herniæ or rupture, and the manual assistance required in those complaints. After the return of the intestines into the abdomen, a firm compress was applied to that part of the groin through which they protruded, and secured by a bandage round the loins. In some cases, after the return of intestinal ruptures, he diminished the quantity of loose skin, and formed a cicatrix, so as to contract over the part, to render it more rigid and capable of resisting. He describes various diseases of the genital parts; the hydrocele or dropsy of the scrotum, a difficulty of making urine, and the manner of drawing off the water by a catheter; the symptoms of stone in the bladder, and the method of sounding or feeling for the stone. Lithotomy was at that time performed by introducing two fingers into the anus; the stone was then pressed forward to the perinæum, and a cut made into the bladder; and by the finger or scoop the stone was extracted. He describes the manner of performing this operation on both sexes, of treating the patient, and the signs of recovery and of danger.

Celsus directed various corrosive applications and injections to fistulas; and, in the last extremity, opened them to the bottom with a knife, cutting upon a grooved instrument or conductor. In old callous ulcers, he made a new wound, by either cutting away the hard edges, or corroding them with verdigrise, quicklime, alum, nitre, or with some vegetable escharotics. He mentions the symptoms of a caries in the bone; directs the bone to be laid bare, and to be pierced with several holes, or to be burnt or rasped, in order to promote an exfoliation of the corrupted part; afterwards to apply nitre and other ingredients. One of his applications to cancer was auripigmentum or arsenic. He directs the manner of tapping the abdomen in ascites, and of drawing blood by the lancet and cupping-glasses. His cupping-glasses were made either of brass or horn, and were unprovided with a pump. He cured varicose veins by ustion or by incision. He gives directions for extracting the dead fœtus from the womb, in whatever position it should present; and, after delivery, to apply to the private parts soft cloths wet in an infusion of vinegar and roses.

In Celsus's works there is a great variety of plasters, ointments, escharotics, collyriums, of suppurating and discutient cataplasms, and external applications of every kind, both simple and compound: Perhaps, amongst the multitude there are a few useful remedies now laid aside and neglected.

The last writer of consequence who flourished at Rome was Galen, physician to the emperor Marcus Aurelius. His works are for the most part purely medical; although he wrote also on Surgery, and made Commentaries on the Surgery of Hippocrates. He opened the jugular veins and performed arteriotomy at the temples; and he used leeches, scarification, and cupping-glasses, to draw blood. He also described with accuracy the different species of herniæ or ruptures.

In the year 500 flourished Aëtius, in whose works are met with many observations omitted by Celsus and Galen, particularly on the surgical operations, the diseases of women, the causes of difficult labours, and modes of delivery. He also takes notice of the dracunculus, or Guinea worm. Aëtius, however, was greatly excelled by Paulus Egineta, who flourished in 640; and whose treatise on Surgery is superior to that of all the other ancient writers. He directs how to extract darts; to perform the operation sometimes required in dangerous cases of rupture or hernia. He treats also of aneurism. Galen, Paulus, and all the ancients, speak only of one species of aneurism, and have defined it to be "a tumor arising from arterial blood extravasated from a ruptured artery." The aneurism from a dilatation of the artery is a discovery of the moderns. In violent inflammations of the throat, where immediate danger of suffocation was threatened, Paulus performed the operation of bronchotomy. In obstinate defluxions upon the eyes, he opened the jugular veins. He describes the manner of opening the arteries behind the ears in chronic pains of the head. He wrote also upon midwifery. Fabricius ab Aquapendente, a celebrated surgeon of the 16th century, has followed Celsus and Paulus as text books.

From the time of Paulus Egineta to the year 900, no writer of any consequence, either on medicine or Surgery, appeared. At this time the Arabian physicians Rhazes and Avicenna revived in the east the medical art, which, as well as others, was then almost extinguished in the west. Avicenna's *Canon Medicinæ*, or General System of Medicine and Surgery, was for many ages celebrated through all the schools of physic. It was principally compiled from the writings of Galen and Rhazes. The latter had correctly described the spina ventosa, accompanied with an enlargement of the bone, caries, and acute pain. In difficult labours, he recommends the fillet to assist in the extraction of the fœtus; and for the same purpose, Avicenna recommends the forceps. He describes the composition of several cosmetics to polish the skin, and make the hair grow or fall off.

Notwithstanding this, however, it was not till the time of Albucasis that Surgery came into repute among the Arabians. Rhazes complains of their gross ignorance, and that the manual operations were performed by the physicians servants. Albucasis enumerates a tremendous list of operations, sufficient to fill us with horror. The hot iron and cauteries were favourite remedies of the Arabians; and, in inveterate pains, they reposed, like the Egyptians and eastern Asiatics, great confidence in burning the part. He describes accurately the manner of tapping in ascites; mentions several kinds of instruments for drawing blood; and has left a more ample and correct delineation of surgical instru-

History.

ments than any of the ancients. He gives various obstetrical directions for extracting the fœtus in cases of difficult labour. He mentions the bronchocele, or prominent tumor on the neck, which, he tells us, was most frequent among the female sex. We are also informed by this writer, that the delicacy of the Arabian women did not permit male surgeons to perform lithotomy on them; but when necessary, it was executed by one of their own sex.

From the 11th century to the middle of the 14th, the history of Surgery affords nothing remarkable except the importation of that nauseous disease the leprosy into Europe.

Towards the end of the 15th century the venereal disease is said to have been imported from America by the first discoverers of that continent.

At the beginning of the 16th century, Surgery was held in contempt in this island, and was practised indiscriminately by barbers, farriers, and sow-gelders. Barbers and surgeons continued, for 200 years after, to be incorporated in one company both in London and Paris. In Holland and some parts of Germany, even at this day, barbers exercise the razor and lancet alternately.

It is within the last three centuries that we have any considerable improvement in Surgery; nor do we know of any eminent British surgical writers, until within the last 130 years. "In Germany (says Heister) all the different surgical operations, at the beginning even of the 18th century, were left to empirics; while regular practitioners were contented to cure a wound, open a vein or an abscess, return a fractured or luxated bone; but they seldom or never ventured to perform any of the difficult operations."

Sixteenth century.

The first surgical work of the 16th century worthy of notice is that of J. Carpus. F. ab Aquapendente, an Italian, published a System of Surgery, containing a description of the various diseases, accidents, and operations. Boerhaave pays this author the following compliment: *Ille superavit omnes, et nemo illi hanc disputat gloriam; omnibus potius quam hocce carere possumus.* About the same period, A. Parey, a Frenchman, made several important additions to Surgery, particularly in his collection of cases of wounds, fractures, and other accidents which occur during war. The ancients, ignorant of powder and fire-arms, were defective in this part of military surgery. Parey pretends to have first invented the method of tying with a needle and silk-thread the extremities of large arteries, after the amputation of a member. The ligature of the blood-vessels is, however, merely a revival of the ancient practice, which had fallen into disuse: Throughout the dark ages, the hot iron, cauteries, and strong astringents, were substituted in its place. B. Maggius and L. Botellus wrote on the cure of gunshot wounds. J. A. Cruce wrote a system of Surgery.

In the 17th century, Surgery was enriched with several systems, and with detached or miscellaneous observations. The principal authors are, M. A. Severinus, V. Vidius, R. Wiseman, Le Clerc, J. Scultetus, J. Mangetus, C. Magatus, Spigellius, F. Hildanus, T. Bartholin, P. de Marchett.

Eighteenth century.

During the last century, Surgery, like all the other sciences, made more rapid progress toward perfection, than during all the preceding periods. This partly arose from the assistance of governments in the different countries. They being convinced that anatomy is one of the most necessary sciences, and the groundwork of the whole healing art, but particularly of Surgery; in many great cities academies were instituted for the cultivation of practical anatomy; and schools were also established for the instruction of the theoretical and practical parts of Surgery.

These improvements in Surgery were chiefly made in England, France, and Germany; and in all these countries a number of very eminent men have since appeared.

The English surgeons, besides possessing an accurate knowledge of anatomy, and great abilities in the operative part of their profession, were the first who endeavoured to bring the art to its present simplicity. They directed also their attention, in a particular manner, to the medical treatment and diet of patients; the neglect of which had caused the unfortunate issue of many operations which had been dexterously performed.

Among the surgeons of later times, we may first mention the name of *Sharp*. He was a scholar of Cheselden, and one of the best surgeons of his day. He wrote a Compendium of Surgical Operations, 1746; and also a Critical Inquiry into the State of Surgery; both of which works are still in high estimation.

In the year 1719, *Dr Monro*, after visiting the schools of London, Paris, and Leyden, where he was a pupil of the great Boerhaave, came to Edinburgh; and this may be considered as the date of the foundation of the Edinburgh medical school. He began by giving lectures on Anatomy and Surgery, the first which were delivered in Edinburgh; and in the year 1721 he was appointed professor of Anatomy and Surgery to the university. This eminent anatomist and surgeon, besides filling his chair with the greatest reputation, contributed to the advancement of our knowledge in many important parts of Anatomy and Surgery. His works, published by his son, besides his Treatise on Osteology, which is certainly the best description of the bones that has ever been given, will be found to contain many interesting and valuable observations on various surgical diseases.

Joseph Warner, surgeon of Guy's Hospital, in London, published his Cases and Remarks in Surgery, in the year 1754, a work which contains many very important practical remarks. He afterwards published a very good work, containing a description of the human Eye and its adjacent parts, in which he particularly rejects the fastening of the eye during the operation of cataract. He also published An Account of the Testicles, their Common Coverings and Coats, &c.

Percival Pott, surgeon of St Bartholomew's Hospital, may be justly considered as one of the principal English surgeons of his time. He was not only a successful practitioner, but an industrious and excellent though diffuse writer. The merits of Pott are indeed considerable. He threw much light on the doctrine of wounds of the head, by his accurate arrangement of the different kinds of injuries to which the head is subject. He also gave a good account of hydrocele and the other diseases of the testicle. On the operation of the fistula in ano, he made material improvements. He has given many useful hints on fractures and dislocations; and he was a great champion in favour of the operation for cataract by couching. He was the first person who described

History.

described the chimney-sweeps cancer; and on herniæ, polypus, and curvatures of the spine, he has made many judicious pathological and practical observations.

Charles White, surgeon in Manchester, published an excellent practical work in the year 1770, in which he recommends amputation of the foot, a little above the ankle joint, instead of under the knee, as had usually been practised. He also shows the effect of sawing off the ends of bones; and discusses several other interesting points in surgery. In the same year, *Mr Else* of St Thomas's Hospital, published his treatise on the hydrocele, in which he recommends the use of caustic in the cure of that disease.

In the year 1770, *Mr Dease*, of Dublin, wrote an excellent treatise on the wounds of the head. *Mr Bromfield*, of St George's Hospital, and *Mr Hill*, surgeon at Dumfries, also distinguished themselves; Mr Bromfield for his Chirurgical Observations, and Mr Hill for his Observations on Cancers.

In the year 1778, *Mr Benjamin Bell* published the first volume of his System of Surgery. The reputation of this work was soon such, that it was translated into the French and German languages; and it has since gone through several editions in these, and many in English.

This work presented the most complete System of Surgery which had ever appeared; and in every part of it there is displayed a talent for practical observation and clearness of thought which must render it ever a useful and valuable present to Surgery. Like all such extensive works, it is not without faults, and the language in which it is written is in some places prolix and diffuse; but notwithstanding all its errors, it certainly must be considered as the most useful body of Surgery that ever had appeared in this country.

Besides these, mention must be made of two other eminent surgeons, *William* and *John Hunter;* the former rendered immortal by his splendid work on the gravid uterus; and the latter by his treatise on the venereal disease, and also his treatise on the blood, inflammation, and gun-shot wounds.

Many very eminent men arose, both in France and Germany, during the last century. The transactions of their academies leave a lasting monument of their zeal and industry.

In France we have the names of Petit, Arnaud, Garangeot, Morand, Le Dran, Le Cat, Louis, David Levret, Le Blanc, De la Faye, David Chopart, Dessault, Janin, Jourdain, Pouteau, André Lombard Wensel.

In Germany, Surgery has been enriched by the works of Vogel, Platner, Albert Haller, Bilguer, Weitz, Seibold, Brambilla, Theden, Smucker, Stork, Plenk, Isenflamm, Rougemont, Conradi, and Richter.

Arrangement of surgical diseases.

Most authors who have written systems of Surgery have described diseases according to the parts of the body where they were situated; beginning with the head, and describing the organs in succession, according to their situation.

Besides this mode of arrangement being unphilosophical, it has many serious disadvantages. Diseases which have no analogy to each other, are treated of in the same place; and similar diseases are treated of separately, instead of being classed together, and considered in one general point of view, thus causing a repetition of what may be considered as the generic characters of the disease. The utility of nosological systems in practical medicine and in pathology, is indispensable. Diseases which have common characters are thus brought together, and arranged under classes, orders, genera, and species. Nosology is, therefore, to be considered as an important step in order to facilitate the means of acquiring knowledge of the diseases of the human body, and to give clear and comprehensive views of them; for it is equally important, to be able to distinguish diseases, as to point out how they should be treated.

All nosological writers have not, however, constructed their systems on similar principles; and their efforts have been often frustrated by the false theories and hypotheses with which they have set out.

Bichât's views of the structure of the body.

The world is indebted to the ingenious and celebrated *Bichât*, for the first truly philosophical view of the structure of the human body. The simple division of it into its component parts, which that great anatomist and philosopher pointed out, must be considered as the groundwork of all future anatomical and pathological inquiries.

Bichât demonstrated, that most of the organs of our body are made up of a variety of elementary parts or *textures;* each of which, in whatever organ it is found, uniformly has the same physical properties, and present the same morbid phenomena. These he considers as the elementary parts; which, by the diversity of their combinations, produce all the modifications of structure and functions exhibited in the different organs of animals. This method of considering organized bodies, accords with every phenomenon with which we are acquainted, and seems to arise from the essential nature of their constitution. We may trace this view of the structure of the body in the observations of many of the older anatomists; and particularly it may be considered as the basis of some of the most ingenious philosophical theories of the late ingenious Mr John Hunter.

In order to fix the characters of the elementary textures, Bichât employed various modes of inquiry. He performed numerous experiments on living animals; persevered in tedious and minute dissections; employed chemical reagents to supply the place of the knife; and examined with minuteness all the varieties of morbid structure. Having by these means accomplished his object in tracing the character of each separate texture, he next proceeded to investigate their combinations as they are found in the different organs.

Their application to pathology.

The effects of this mode of analyzing the structure of the human body when diseased, must be at once obvious. We learn from it, that diseases at their commencement are generally confined to one texture of an organ; the other textures of which the organ is composed remaining sound.

There is no organ of the body from which this important truth may not be deduced. It may be readily illustrated from considering the diseases of the mucous, serous, and muscular textures, which compose the stomach and alimentary canal; the cellular texture of the lungs; the mucous membrane of the bronchi, the serous one of the pleura, and many others.

But diseases are not only confined to one individual texture of any organ, as in the cases just mentioned; the symptoms and morbid changes are likewise uniformly the same in textures of a similar structure, in whatever parts

History.

parts of the body these textures may happen to be found. Thus the serous membranes which invest the lungs, the brain, the heart, the abdominal viscera, have one common character when affected with any specific disease: so also have the mucous membranes, whether in the mouth, the nose, the vagina, the urethra, or covering the eye-ball; and the same may be observed of every individual texture which enters into the composition of our bodies.

Besides the symptoms and morbid changes which are common to all textures whose structure is similar in the natural state, there are others which are determined from the particular functions of the organ in which the diseased texture exists. For example, when any of the serous membranes are inflamed, the nature of the pain, the degree of fever, and the duration of the symptoms, are the same, in whichsoever it may have taken place. But to these symptoms are added, cough, difficulty of breathing, when it happens to be connected with the organs of respiration, as in the case of pleuritis; costiveness, strangury, delirium, loss of vision, when the intestines, the bladder, the brain, or the eye, are involved in the disease.

This view of the subject naturally suggests a correspondent division of the symptoms. The first class are general, and characterise a whole genus of textures; the second are in a manner accessory, and depend on the relative situation or the particular functions of the organ into the composition of which the affected texture enters.

But here we must set bounds to this theory;—the history and progress of diseases shew, that we ought not to confine our observations within such narrow limits. The principles which have been stated, indeed, account admirably well for the propagation of some affections, and for some of the sympathies which subsist between different parts of the body; but there are other disorders which advance in a very different manner. In some diseases which are termed chronic, for example, the whole structure of an organ becomes gradually altered, although the primary affection be confined to one of its component textures. This is often to be observed in cancer, scrofula, and lues venerea. When cancer attacks the mamma, it is at its commencement generally confined to a small portion of that gland; but if allowed to proceed, it ultimately involves the whole gland, and the adjacent cellular and cutaneous textures, in one mass of disease.

These general observations will be sufficient to give an outline of the principles of a pathological system, founded on the basis of anatomical knowledge; and in giving an account of those diseases which more properly belong to a system of surgery, we have ventured to apply these principles. We shall, in the first place, therefore, consider the diseases of the Cellular Membrane; the diseases of the Skin; of the Mucous, Serous, and Sinovial membranes; of Bone and Cartilage; of the Vascular and Nervous systems; and of the Glands. In the second place, we shall treat of diseases which occur only in particular organs, whether from the peculiarity of their structure or functions: such are the diseases of the eyes, ears, nose, teeth, mouth, and fauces, and the organs of urine and generation. In the third place, we shall take notice of malconformations, distortions, and protrusions; and in the last place, of wounds, fractures, dislocations, and such operations as are occasionally necessary to be performed on different parts of the body, as amputation, sutures, &c,

Chap. I.

Of the Diseases of the Cellular Membrane.

Sect. I. *General Remarks on the Pathology of the Cellular Membrane.*

The cellular membrane is distinguished from other textures, by the power which it has of throwing out granulations, by its being capable of elongation, of reproduction, and of growth when it has been divided*. Suppuration also takes place in the cellular membrane, with a rapidity of which there are few examples in other textures. The fluid which is the result of this suppuration, is well known. Its colour, its consistence, and all its external qualities, have become the criterion by which we form our ideas of *pus;* in consequence of which, all discharges which do not resemble it, have been commonly considered as pus of a bad kind, or as *sanies.* This opinion, however, is false; and has been formed in consequence of a too superficial view of the different circumstances attending different kinds of discharged fluids. Certainly the pus which is discharged from a bone, from a muscle, from the skin in erysipelas, from the mucous membranes in catarrh, is of a good kind whenever the inflammation runs through regularly its different periods, and notwithstanding it is quite different in all these cases from the pus produced by suppuration of the cellular membrane. But as the latter is most frequently observed, from it we have formed an idea of *laudable* pus, and of *sanies.* The cutaneous pus, the mucous pus, the osseous pus, &c. have all their proper sanies; which differ from one another as much as the natural structure and functions of the organs from which they are produced.

There are few parts of the body which have a greater number of exhalents than the cellular membrane; and this exposes it to various alterations of structure, such as being preternaturally distended by the different substances which it exhales; and these, sometimes presenting a solid appearance, sometimes producing a lardy substance, sometimes a gelatinous matter, and sometimes a much firmer and harder mass. The numerous absorbent vessels which are also distributed on the cellular membrane, is another cause of various diseases; every small cell being a reservoir common to the exhalents which terminate in it, and to the absorbents which arise from it.

There are some diseases, too, which produce a change in the elasticity and powers of distension, which the cellular membrane naturally possesses. In health it has enormous powers of distension, as may be observed in emphysema and anasarca; and whenever these diseases are removed, it regains its natural bulk and form. In inflammations, this property is in part destroyed, and it happens also in many of the different indurations to which it is liable. Its elasticity is also less remarkable in people advanced in life, than in children. When an old man turns quickly thin, the skin becomes flaccid, and forms

Of the Pathology of the Cellular Membrane.

forms into folds; but when a young man is emaciated, the skin is applied exactly to the subjacent organ, and preserves its tension.

The cellular membrane, when diseased, becomes sometimes extremely sensible, and the seat of acute pain, though it seems to possess no sensibility in its natural state. When either blood, milk, or lymph, are effused in it, its sensibility is not altered, and these fluids are absorbed. On the contrary, the sensibility is so much altered by the contact of urine, of bile, of saliva, and of the other fluids destined to be thrown out of the body, that often the inflammation which succeeds the effusion prevents their absorption.

As the cellular membrane enters into the composition of every organ, it is often difficult to distinguish in diseases what belongs to it from that which is the attribute of the other textures with which it is found. These connections, however, become manifest under several circumstances: In acute and chronic diseases it is very susceptible of being influenced by the disease of the organs. We do not speak here of the alterations produced from juxtaposition and continuity, but of those diseases which arise in parts of the cellular membrane which have no known connection with the affected organ.

In acute diseases which affect a particular organ, as the lungs, stomach, or intestines, often the cellular membrane becomes sympathetically affected and the seat of inflammation and abscesses. The greater number of critical abscesses arise from this connection which exists between the organ affected and the cellular membrane. In acute diseases too it is commonly the function of exhalation or absorption of the cellular membrane that is affected, and hence the sudden œdema which often accompanies them. In chronic diseases their influence is no less remarkable. It is well known, that in chronic diseases of the heart, of the lungs, of the liver, of the stomach, kidneys, uterus, &c. they have for their symptom during their last stages an anasarca, more or less general, which arises from debility produced in the cellular system.

We observe, that in all acute diseases, the skin receives with great facility the sympathetic influence of the diseased organ, and that it is alternately moist and dry frequently during the same day. It is by no means improbable that the cellular membrane undergoes alterations analogous to those of the skin; and if we could observe what passes in it, we might discover the cells more or less moist, more or less dry, according as it happened to be influenced: It is also to this we ought to attribute the different state of the cellular membrane, in patients who have died of acute diseases; these presenting numberless varieties in the serous effusions.

The cellular system is not only influenced by its sympathy with other organs; but it also exercises a sympathy over them. In a phlegmon or inflammation of the cellular membrane, if the tumour be considerable, often various alterations take place in the functions of the brain, of the heart, of the liver, or of the stomach. The sympathetic vomiting, &c. are those phenomena in great phlegmons which are often present without being considered as belonging to the disease.

Art avails itself of the influence of the cellular system in the diseases of other organs, in the use of *setons*. Often in the diseases of the eye and of joints a seton produces an effect which cannot be obtained by a blister; and this probably arises from the connection which exists between the cellular membrane and the eye or joint, being more active than that which exists between these organs and the skin*.

It ought to be also remarked, in considering the pathology of the cellular system, that there is a manifest difference in the properties of the cellular texture, which is composed of layers and filaments; and in that exterior to the different mucous surfaces, and to the blood-vessels and excretories, which consists of filaments alone. From this difference results the rare occurrence of inflammations and of different kinds of tumors in the latter. It often forms a barrier where the morbid affection of the former stops, and thus protects the organ which it envelopes.

* Vide *Anatomie Descriptive, par Bichat.*

The unfrequency of hemorrhagy when extensive suppurations have laid bare large arteries is a proof of what has been said. We have seen cases where the cellular membrane contiguous to the brachial and femoral arteries has been completely ulcerated, whilst the coats of the arteries remained sound. We have observed the same phenomenon in the urethra and in the intestines. In cases of suppuration of the prostate gland and cavernous bodies of the urethra, the canal has remained untouched in the midst of a large abscess; and in a case of femoral hernia, where the hernial sac, and the cellular membrane covering it, all mortified, the protruded gut remained quite sound.

The cellular membrane has also a powerful influence in the production of a variety of tumors and excrescences, forming as it were their base or parenchyma of nutrition. Encysted tumors are met with alone in the cellular texture of different parts of the body, and various kinds of solid tumors and excrescences are formed by the growth of that texture on the part where the tumor is to be developed: Afterwards different substances are deposited amongst it, the difference in the nature of which constitutes the difference in the specific characters of these tumors. There is nothing more remarkable in the pathology of the cellular membrane, than the circuitous routes which needles take through it after being swallowed by the mouth.

These remarks will be sufficient to give a general view of the pathology of the cellular membrane, and will enable us to form a more comprehensive and connected view of those diseases, which may be more properly considered as coming within the province of Surgery.

The diseases of the cellular membrane which are treated of in this chapter are, 1. Inflammation of the cellular membrane, or phlegmon. 2. Panaris or whitloe. 3. Sinuses. 4. Carbuncle. 5. Encysted tumors. 6. Steatom. 7. Sarcoma. 8. Œdema. And, 9. Emphysema.

Sect. II. *Of Phlegmon.*

In most accounts which surgical authors have given of *inflammation*, they have taken the description of its general phenomena from inflammation of the cellular membrane.

Local symptoms.

Inflammation of the cellular membrane, or Phlegmon, is characterized by a tumor more or less elevated and circumscribed, visible or not visible, according to the part where it is situated. It is always accompanied with an increased sensibility of the part, with a lancinating or beating pain, a degree of heat greater than natural, a bright redness, which becomes more livid as the disease advances, an elevated point; and it gradually, Of Phlegmon.

ly turns softer from the centre to one part of the circumference.

Constitutional symptoms.

These are the symptoms which are generally to be observed more or less remarkable in every species of phlegmon. When they are slight, and when the affected part is not extensive, or very important from the nature of its functions, this disease generally has not much influence on the general system. But when they are more considerable, and the inflammation extends far, the pulse becomes commonly full, frequent, and hard; at the same time, the patient complains of universal heat, thirst, and other febrile symptoms.

Its terminations.

When by the efforts of nature, or by the application of proper remedies, the pain, the heat, and the tension go away, the other symptoms, which depend in a great degree or altogether on the first which have been mentioned, disappear also, and the patient quickly recovers his health. This termination, which is commonly the most desirable, is called *resolution*.

But if, notwithstanding the remedies used, the different symptoms augment instead of diminishing, the tumor gradually increases in size and turns soft. A small eminence is observed towards the centre of the tumor or at some particular point, and its surface becomes polished. Soon afterwards the pain diminishes, cold shiverings come on, and the febrile symptoms abate; and on compressing the tumor, the fluctuation of a fluid can be perceived in it, this constituting the second termination of a phlegmon, or *abscess*.

Treatment.

Treatment of Phlegmon.—The principal object to be kept in view in the treatment of inflammatory tumors, is to obtain their resolution; this being the most prompt and most certain mode of cure. There are, however, some cases which are an exception to this general rule; such as some inflammatory tumors which precede fevers, and other internal diseases: for it is commonly supposed that in these cases, suppuration is a mode by which nature throws off certain fluids or humours, pernicious to remain in the system. There are other tumors which seem to arise from internal causes, where it is perhaps better neither to attempt to accelerate their suppuration nor resolution, but to trust them entirely to nature. Such are inflammatory tumors in scrofulous subjects. There are few cases of this kind where suppuration ought to be promoted, for their treatment is always embarrassing whether they are opened naturally or by art. It is well known too, that such tumors often remain a long time without any danger; from whence we may conclude, that it is most prudent not to touch them, but attend only to the constitutional treatment.

In the venereal disease, we have a specific for its cure; and when buboes are opened, or other inflammatory venereal swellings, they generally become very difficult and embarrassing to treat. It is therefore always most prudent to attempt their resolution.

The principal means employed to procure the resolution of an inflammatory tumor, are local and general blood-letting, and the application of heat and moisture. Leeches is perhaps the best mode of bleeding the inflamed part; but should the inflammation take place in the extremities, or contiguous to any of the large veins, one of these may be opened. There is no application which tends so much to remove the tension and pain of an inflamed part as the use of poultices or fomentations. Applications of a sedative nature are recommended by many, such as the different preparations of lead, the sulphate of zinc and vinegar; but as far as we have been able to observe, the use of medicines of this class has by no means such powerful effects as emollients, though it has generally been supposed that emollients hasten suppuration. In applying poultices, they should generally be renewed three or four times in twenty-four hours, and the part bathed with hot water each time the poultice is changed. When fomentations are to be used, many employ hot water alone, whilst others prefer a decoction of chamomile flowers, or of poppy heads. A piece of flannel of considerable size, immersed in either of these, of the boiling heat, is to be forcibly wrung out within a cloth, and applied as warm as the patient can suffer it, to the inflamed part. A second piece of flannel is to be prepared in the same manner, and whenever that first applied begins to cool, the second piece is to be employed; and this practice continued for ten or fifteen minutes, and repeated as often as it is found to relieve. The best mode of applying the sedative remedies in external inflammation, is in the form of watery solution. Half an ounce of the acetate of lead dissolved in four ounces of vinegar, with the addition of two pounds of distilled water, is a convenient form. In making use of this solution, it is of consequence to have the parts affected kept constantly moist, and cataplasms prepared with it generally answer that intention exceedingly well. But when the inflamed part is so tender and painful, as not easily to bear the weight of a poultice, pieces of soft linen, moistened with the solution should be employed. Both should be applied cold, or at least of no greater warmth than is merely necessary for preventing pain or uneasiness. They should be kept constantly applied to the part, and renewed before turning dry and stiff.

When the part affected with inflammation is not very tender, or lies deep, applications of vinegar are often had recourse to with considerable advantage; and the most effectual form of using it, is in that of cataplasm, made with the strongest vinegar and crumb of bread. In such cases, the alternate use of this remedy, with the saturnine solution, has produced more beneficial effects than commonly observed from a continued course of either singly.

In all cases of inflammation, the whole body, but more especially the diseased part, should be preserved as free as possible from every kind of motion, and the patient should be confined to a low cooling diet, and also a total abstinence from spirituous and fermented liquors.

In slight cases of inflammation, a due perseverance in the mode of treatment which has now been mentioned will in general be sufficient; but when there is likewise a full, hard, and quick pulse, with other symptoms of fever accompanying the disease, general blood-letting becomes necessary; and the quantity of blood taken away is always to be determined by the extent and violence of the disease, and by the age and strength of the patient. Evacuations, however, should never be carried to a greater extent than is necessary for moderating the febrile symptoms; for should suppuration take place after the system is too much reduced, its progress becomes more slow and uncertain; nor

Of Phlegmon.

nor is the patient able to support the discharge that ensues. Gentle laxatives, with a cooling diet, are also attended with very good effects.

Besides these different evacuations, it is of great consequence to procure the patient ease and quietness. The most effectual remedy for this purpose is *opium*, and, when the pain and irritation are considerable, as in extensive inflammations very frequently happens, it should never be omitted. In all such cases, the opium should be given in full doses, otherwise, instead of proving serviceable, it may not procure rest; a circumstance which is perhaps the chief reason for opiates having been by some very unjustly condemned in every case of inflammation.

Use of opium.

By a proper attention to these different circumstances, a resolution of the tumor will generally begin to take place in the course of three or four days, and sometimes in a shorter time; at least before the end of that period, it may for the most part be known how the disorder is to terminate. If the heat, pain, redness, and other attendant circumstances abate, and especially if the tumor begins to decrease in size, it is probable that, by a continuance of the same plan, a complete resolution will be finally effected.

Suppuration.

But, on the contrary, if all the symptoms rather increase, and especially if the tumor turns larger, and somewhat soft, with an increase of throbbing pain, we may with tolerable certainty conclude that suppuration will take place. We should therefore immediately desist from such applications as were judged proper while a cure was thought practicable by resolution, and endeavour to assist nature as much as possible in the formation of pus, or what is called the *maturation* of the tumor. To effect this, nothing is more useful than fomentations and cataplasms; and if these have not been employed during the former stage, the cold saturnine applications should now be given up, and recourse had to the emollient remedies.

Dry cupping, as it is termed, viz. using the cupping glasses without the scarificator, applied as near as possible to the part affected, is frequently had recourse to in promoting the suppuration of tumors. It is only, however, in those in which there seems to be a deficiency of inflammation, that it can ever be either necessary or useful; but in all tumors of an indolent nature, and where there is still some probability of a suppuration, no remedy is more effectual. By these different applications, continued for a longer or shorter time, according to the size of the tumor, its situation and other circumstances, a complete suppuration may generally be at last expected.

Whilst an abscess is forming, it extends according as the quantity of purulent matter is augmented, and the extension takes place towards that side where there is least resistance. On this account it is that where an abscess is deep, or covered by an aponeurosis, it extends in the interstices of the neighbouring parts, and dissects, as it were, the tendons, the muscles, and the bones, whilst in common cases it makes its way towards the skin. When matter is collected very near the surface of the body, and is only covered by the common integuments, it speedily makes its way externally; but when it is deep, and surrounded by parts which make great resistance, purulent matter insinuates itself until it arrives at some place where there is nothing to oppose its exit; and it is observed making its escape after having made, in some cases, a very great circuit. It is generally towards the inferior parts of the body that purulent matter makes its route. On this account large abscesses open themselves most frequently at their inferior part, and from thence the advantage which is found by waiting till they open of themselves, or that they indicate the place most convenient for the opening to be made. Thus, we see abscesses formed under the temporal muscles discharge themselves in the mouth, and those of the loins making their appearance near the femoral ring, or on the anterior part of the thigh. Deep abscesses, in certain parts of the body, proceed rather towards the interior than towards the surface, because there purulent matter finds less obstruction in its passage. Those, for example, which form on the surface of the lungs, find great resistance from the ribs and other parts forming the thorax, whilst they easily make their way through the spongy substance of the lungs, and open into the ramifications of the bronchiæ. For the same reason, abscesses formed in the cavity of the abdomen sometimes discharge their contents into the stomach or intestines; but as the parietes of the belly yield more easily than those of the chest, we also see abscesses of the different organs contained in the belly, discharge their contents through its parietes.

When matter is fully formed in a tumor, a remission of all the symptoms takes place. The throbbing pain, which before was frequent, now goes off, and the patient complains of a more dull, heavy, and constant uneasiness. The tumor points at some particular part, generally near its middle, where, if the matter be not deep seated, a whitish yellow appearance is observed, instead of the deep red that formerly appeared; and a fluctuation of the fluid underneath is, upon pressure, very evidently perceived. Sometimes, indeed, when the abscess is thick, and covered with muscle and other parts, though from concurring circumstances there can be little doubt of there being a very considerable collection of matter, yet the fluctuation cannot be readily distinguished. It does not, however, often happen that matter is so very deeply lodged as not to be discovered by careful examination. This, indeed, is a circumstance of the greatest consequence in practice, and deserves more attention than is commonly paid to it. In no part of the surgeon's employment is experience in similar cases of greater use than in the present; and however simple it may appear, yet nothing more readily distinguishes a man of extensive observation and nice discrimination than his being able easily to detect deep-seated collections of matter; whilst nothing, on the contrary, so materially affects the character of the surgeon as having, in such cases, given an inaccurate prognosis.

In addition to the several local symptoms of the presence of pus already enumerated, may be mentioned the frequent shiverings to which patients are liable on its first formation. These, however, seldom occur so as to be remarkable, unless the collection is considerable; but it is a symptom almost constantly observed in large abscesses; and when it takes place, along with other symptoms of suppuration, it always contributes to point out the true nature of the disease.

Of opening Abscesses.—When abscesses come to maturity, Of Abscesses.

rity, the integuments gradually become thinner over the more prominent part of the tumor; and ulcerate in one or more points through which pus is evacuated. In many cases it is advisable to wait for the spontaneous rupture of an abscess; but, on the other hand, it is often more prudent, and indeed absolutely necessary, to give vent to the matter by an artificial opening. It is a general rule not to have recourse to such means before suppuration is completely formed; for if an abscess be opened before this period, and a considerable hardness remain around it, the treatment afterwards becomes very embarrassing and difficult. It is, however, necessary in some cases to depart from this general rule, and to open an abscess much sooner; above all, those which are critical, and those which are the consequence of lingering fevers, or where it is a great object to prevent an unseemly cicatrix.

In many cases there is neither safety nor convenience to be expected from the spontaneous opening of the integuments. In abscesses situated on any of the joints, or either of the cavities of the breast or abdomen, and more especially when they seem to lie deep, they should always be opened as soon as the least fluctuation of matter can be discovered; for when the resistance is on either side equal, it just as readily points inwardly towards the cavity, as outwardly towards the skin; and the consequence of a large abscess bursting into either of the large cavities, is most frequently fatal.

Abscesses are sometimes formed about the face, which point externally, and these should be opened in the inside of the mouth, in order to prevent deformity. Whenever the fluctuation is sensible, this should be immediately done. They cicatrise rapidly, and require no dressings.

Abscesses formed under an aponeurosis, and in general under those parts which are not capable of being extended without much difficulty, ought to be opened early. Such are abscesses situated under the temporal muscles, fascia lata of the thigh, in the extremity of the fingers, under the arch of the palate, round the maxillary bones, behind the ear, above the mastoid processes, &c. All these ought to be opened very speedily, and in particular those last mentioned, on account of the danger of a carious bone.

It is also particularly necessary to open without delay abscesses in the neighbourhood of the anus, or near the urethra; in large abscesses of the extremities, and in particular those which are the consequence of violent inflammation, occupying the whole member. If in such cases the matter be allowed to remain too long, the greater part of the cellular membrane is detached from the subjacent aponeurosis, the muscles are separated, and there often follow large gangrenous sloughs, which in separating lay open extensive surfaces, and often form large bags of pus, which become as many separate abscesses. Often the disorder is such that the whole of the integuments of the member sphacelate and fall off. It is also necessary not to delay the opening of abscesses formed among the large muscles, the interstices of which are filled up with cellular texture; such are those about the thigh, the back of the leg, and axilla. In these situations the matter is very apt to spread, and the abscess to form ramifications in various directions, which, if not treated with much care, are very tedious to heal.

With the exception of those cases which have been mentioned, it ought to be observed as a general rule not to open an abscess until suppuration be complete; for if it be true, that pus is always sufficiently prepared to be evacuated, it is so also, that the more we favour its formation before giving it vent, the more we are sure of diminishing and of reducing the hardnesses in the neighbourhood, and facilitating the cicatrization of the ulcer.

Of the different Methods of opening Abscesses.

There are three different modes of opening abscesses; viz. by caustic, by an incision, or by a seton.

1. *By Caustic.*—The use of caustic is recommended in most cases where suppuration has been slow, and has not occupied the whole tumor; in those where the integuments have suffered much, and where it was necessary to wait long before opening it, on account of some affection of the bottom of the abscess; and in general in all cases of suppuration of glands.

But though there are circumstances which may render it necessary to employ the caustic rather than the incision, yet the latter generally deserves the preference. The pain which it occasions is momentary, whilst that from caustic continues many hours; and when the inflamed part has acquired a morbid degree of sensibility, the pain is very violent. The surgeon also can never limit precisely the extent of the action of the caustic; and whatever attention be paid to it, it often extends too far, and penetrates too deep.

To open an abscess with caustic, an adhesive plaster spread on leather is to be applied over the tumor, with a slit or hole in it of a size somewhat less than what is intended to be made in the skin by the caustic. The slit is to be filled with the caustic reduced into powder, mixed with a small quantity of soap, and wetted, so as to make it operate more quickly. Another adhesive plaster is then to be laid over it, and the whole secured with a firm compress and bandage. The time necessary to allow the caustic to make a sufficient opening will depend on the thickness of the skin and strength of the caustic, but generally it requires two, three, or more hours. When the eschar is made, and the matter has not escaped, we ought to assist its exit with the end of a probe, or the point of a bistoury; and the separation of the eschar is to be promoted by emollient applications.

2. *By the Incision.*—Abscesses which are not very extensive, may generally be opened by making a longitudinal incision with the lancet, see Plate DXIII. fig. 1. For this purpose, when the situation of the abscess permits it, the surgeon is to apply one hand on the base of the tumor, and press the pus towards the skin, by doing which there is no risk of wounding any artery, or important part at the bottom of the tumor, and the lancet penetrates into the cavity of the abscess with more certainty and ease, and with less pain. With the other hand an incision of the integuments is to be made in such a direction, that it may terminate at the most depending part of the tumor; and be made of such length as may appear necessary, in order that the matter may be allowed freely to escape. It is in general supposed sufficient, in cases of small abscesses, that the incision extend two-thirds of the length of the tumor. Some authors have advised, that when the integuments are much distended, an incision should be made through the whole length of the tumor, even where

Plate DXIII. fig. 1.

where it is of a large size; but this practice ought to be rarely adopted. The irritation and consequent inflammation, produced from such an operation, must always be very considerable; and as it scarcely ever happens that the integuments are so much extended as entirely to lose their contractile power, there is always reason to hope that they will recover their natural dimensions. In all very large abscesses, it is the safest practice to make at first a small incision sufficient to allow the contents to be completely discharged; for whenever this is done, the extent of the cavity diminishes; and should it be found afterwards necessary to make a more extensive opening, this can now be done with much advantage. When an abscess has been opened by either of these methods, it is reduced to the state of a simple wound or ulcer, and ought to be treated accordingly.

The mode by incision ought to be preferred to that of caustic, when the matter is collected deep; when it is in the neighbourhood of important nerves or blood-vessels; when it is necessary to make the opening large; when the skin which is to be opened has a natural appearance; and, above all, when it is desirable the ulcer be healed rapidly, and leave little deformity.

Although surgeons generally agree in preferring the incision to the caustic, it has nevertheless its inconveniences. Whenever the incision is made, the matter contained in the tumor is suddenly evacuated; hence it happens, when the collection is considerable, that the patient faints, or has some other disagreeable symptoms; but the principal disadvantage of this method is, that it gives free access to the air over a large extent of ulcerated surface; a circumstance which is sometimes followed by very pernicious effects. A total change takes place in the nature of the matter; a laudable pus is transformed into an ichorous indigested fluid; the pulse becomes quick; colliquative sweats and other symptoms of fever come on, and commonly the patient dies in a short time. Surgeons have too often occasion to observe the dangerous effects which are probably altogether produced by the admission of air; for we see a great number of patients have for a long time after a termination of inflammatory diseases considerable abscesses, where the pus is perfectly formed, without shewing at the same time any symptom of hectic fever. But when these abscesses exceed a certain size, and if a large incision be made into them, there always follow symptoms of fever, generally in forty-eight hours from the time that the abscess had been opened. These accidents, which we have frequently observed in private practice, are still more frequent in public hospitals, where the air is impregnated with putrid exhalations.

3. *By the Seton.*—From the observations which have been already made, it appears necessary that as much precaution as possible should be taken to prevent the contact of air with the internal surface of the abscess. The seton, therefore, has the advantage, not only of being attended with little pain, and emptying the abscess in a gradual maner, but it completely prevents the access of the air. When patients are otherwise in good health, there is another advantage in employing the seton; for frequently a cure is obtained at a period much shorter than that which is usually necessary when the incision has been adopted. On the other hand, if we have reason to wish to keep up for a long time a certain degree of irritation and suppuration in the affected part, the seton ought to be preferred to every other means. There have been various instruments contrived for introducing the seton, and it may easily be done by a lancet and common probe, or by the instruments represented in Plate DXIII. fig. 15. and 16. One of these being threaded with glovers soft silk or with cotton, should be introduced into the upper part of the tumor; but if the blunt one be employed, it will be necessary to have the assistance of the lancet. The instrument is then to be brought out at the under part of the tumor, and the matter allowed to run gradually along the threads. The seton should be changed forty-eight hours after it has been introduced, and as much of it should be pulled out at the under part as is sufficient to allow the removal of that which was shut up in the abscess. The abscess is to be dressed in this manner every day as long as circumstances seem to require.

By means of the seton, we obtain a regular and slow discharge of the matter contained in the abscess; the sides of the abscess are allowed to contract in a gradual manner; the presence and friction of the seton on the surfaces excites a slight inflammation, which contributes to unite them, and to complete an adhesion, much more readily than by any other method. In proportion as the discharge diminishes, the thickness of the seton ought to be lessened; and this is easily done by taking out some of the cotton threads every two or three days. It ought to be entirely taken out when no more matter is discharged than what would be produced by the irritation of the seton alone; and by compressing gently the parts for some days after it has been withdrawn, with a compress and bandage, we can in general depend upon a complete cure.

When speaking of the mode of introducing a seton, we recommended that this should be done from above downwards, because, if the first opening be made at the base of the tumor, a great quantity of matter immediately escapes. Thus the boundaries of the abscess at the upper part become effaced, and the passage of the director through the abscess is much more difficult than when the abscess is opened according to the manner pointed out. In that way the under part of the tumor is left completely distended till the last moment, and only a very small quantity of matter escapes by the superior orifice. Another advantage of this mode is, that the part of the seton left for the future dressings, is easily kept clean and dry.

The method of opening abscesses by a seton has been found particularly useful in suppurations of the joints, and those glandular parts where the admission of air is followed by very pernicious effects. Thus, when it is thought necessary to open a scrofulous tumor, we may generally be able to obtain a more prompt and easy cure from the use of a seton, than by making a larger incision. Venereal buboes, too, when come to maturity, have been said to get well much sooner by this than any other method, when the integuments have not become too thin by great distension long continued. On the other hand, this mode is not without its inconveniencies, for in adopting it we cannot be well assured of the state of the bottom of the abscess, which it is often important to know.

Whatever advantages these different methods of opening abscesses may possess over one another, yet there is not one of them which deserves the preference in all cases, although the caustic, as already mentioned, be the means

Of Sinuses. to which we ought most rarely to have recourse. However troublesome it may be, the action of air on the interior surface of the abscess is not always equally pernicious; and when by properly applied dressings, care is taken not to allow purulent matter to form in any particular cavity, and to prevent the access of cold air on the surface of the wound, and above all when the surrounding air, as that in hospitals, is contaminated with putrid exhalations, daily experience shows, that the method by incision is accompanied with most success. On the other hand, we have seen the seton extremely useful in gradually discharging large abscesses, without exciting much inflammation.

These general principles are to be observed in the treatment of abscesses, in whatever part of the body they are found. There are, however, some modifications, some particular details of practice, which ought to be kept in view, when the disease is seated in particular organs, as the eyes, the mammæ, the cavity of the chest, the groin, the scrotum, &c. Mention will be made of these in giving an account of the diseases of particular organs.

Sect. II. *Of Sinuses* (Fistulæ).

When an abscess, instead of healing, continues to discharge purulent matter, and when this takes place through a small orifice, it obtains the name of a *fistula*. The orifice has smooth and callous edges, and the fistula commonly communicates with one or more cavities of different dimensions, situated in the cellular membrane, between the common integuments and the muscles, or between the interstices of the muscles themselves.

These different cavities, which are generally known by the name of *sinuses*, serve as reservoirs, both for the matter which is formed in the cavity of the ulcer, and for that furnished by their own sides. It is thus that when by compression, the matter contained in the sinuses is pressed out through the ulcers, these discharge a much greater quantity than what might have been expected, by alone considering the extent of their surface.

This description of a fistulous ulcer indicates the most simple form of the disease; but when it has lasted for a long time, its whole internal surface frequently becomes hard and callous, acquiring the properties and structure of a *mucous* surface.

The most frequent cause of the formation of sinuses is, when an abscess bursts, and the purulent matter, instead of being all discharged, remains shut up in some part of the cavity. Remaining there, it naturally falls to the lower part, and gradually insinuates itself among the layers of the cellular membrane, which, from its softness, gives little resistance. It advances by degrees among the interstices of the more solid organs, which are connected by that substance; and at last it makes its appearance on the surface of the body, or penetrates into one of the cavities.

Both recent and old fistulous ulcers are generally curable, provided that the ulcer be situated in such a manner, that the necessary remedies can be applied, and the constitution be otherwise free from disorder. But when the disease has been of very long duration, and, above all, when the sinuses open into any articulating cavity, or are placed in such a manner, that one cannot perform any operation, the treatment then becomes extremely difficult, and the event very doubtful. There is no disease which resists more frequently all the efforts of art than certain species of fistula, and particularly some of those about the anus and perinæum.

Of s

Of the treatment of Fistulæ.—There are several different modes which have been proposed for the treatment of this disease, all of which may be useful in particular cases.

By in tion. Injections, supposed to have a cicatrizing quality, have been proposed by some; and these are no doubt useful in particular cases, in diminishing the quantity of the discharge, and preventing the sinus from increasing. When the disease is far advanced, and the edges become perfectly callous, injections of an escharotic quality have been employed; but these remedies have seldom, if ever, produced any good effects; and their too frequent use has even rendered sinuses hard and callous, which otherwise were of a more benign nature.

By co pressio In some cases, particularly when the disease is recent, great advantage may be derived from the proper application of a compress and bandage. In applying these, the compress should be placed in such a manner, and made of such a form, as to make a firm pressure from the bottom of the sinus towards its orifice; and care should be taken that no pressure be made towards the orifice itself, in order that any matter which is formed may not be allowed to collect, but discharged from it. Indeed in whatever mode we treat sinuses, the object to be held in view, is to allow any matter which is formed to be immediately discharged.

By excisi Some have advised, that, in all Fistulæ of long standing, their cavities should be laid open from one end to the other, and all the parts should be dissected out which have become hard, and thus to convert the whole into an ulcer, to be treated in the ordinary manner. There is no doubt, but that by such an operation, it will often be possible to obtain a cure; but independent of the great pain, and of the large and disagreeable cicatrix which must always follow, the practice is not without danger. It cannot answer, for instance, in those fistulas which extend far up the rectum. No practitioner surely would advise the adoption of such a method in the case of fistulas which penetrate very deep, and extend, as often happens, underneath the blood-vessels, the tendons, and the nerves; and even although this practice was without danger, it ought to be adopted in no case, as we are enabled, by an operation more simple, and much less painful, always to obtain a cure with as much certainty as by a total destruction of the parts.

By incision In the treatment of fistulas, it is necessary to procure an agglutination of the edges of the sinuses, so as to obliterate the cavity. The means most efficacious to fulfil this indication are, to make first an opening, so as to allow the exit of the matter; and then to excite a certain degree of inflammation on the internal surface of the cavity, so as to produce an adhesion between its sides.

Both of these indications may, in some cases, be fulfilled in the most convenient manner, by introducing into the orifice of the ulcer a seton which will follow the whole course of the sinus as far as its opposite extremity. The seton should be of a size proportioned to that of the sinus; and it may be diminished by degrees as the cure advances, by taking away some of the threads day after day. At last, when the cavity of the sinus is nearly

3

Of Sinuses. nearly filled up, and consequently the discharge much moderated, the seton ought to be withdrawn. Afterwards a bandage is to be firmly applied over the part, which should be allowed to continue a convenient time, in order to obtain a complete cure. In all cases, therefore, we ought to discover the direction of the sinus, which can commonly be done by introducing a probe, or by observing the place in which the matter collects, when it has been allowed time to accumulate, and by marking the place from whence it comes, the pressure is to be made on the affected part. A seton ought then to be introduced into each sinus.

Another means of procuring the obliteration of sinuses is, by a longitudinal incision along the whole cavity. In cases where the fistula extends to parts which it is not dangerous to cut, and where the seton has inconveniences which render it inadmissible, we should not hesitate to have recourse to this means. Indeed, the longitudinal incision of the sinus is to be considered in all cases, as the only means which can be adopted with certainty in the cure of the disease; and though in many cases it may be proper to attempt the cure by the milder means which have been mentioned, yet they often fail, and the mode by incision ought always to be held in view.

We may observe here, that this part of Surgery owes much to the celebrated Mr Pott, he having rendered much more simple and successful the treatment of fistulas, particularly those situated about the perinæum and anus. When a fistula is to be laid open, the first thing to be done, is to determine the extent of the incision. The exact extent of the sinus should then be accurately ascertained with a probe, and it is necessary to lay it open to the extreme point, in order completely to secure the filling up of the cavity. The operation may be performed by introducing a director (fig. 9. and 12.), along the whole course of the sinus, and cutting on it with a common scalpel (fig. 1.); or the sharp-pointed bistoury (fig. 4.) may be introduced along the groove of the director, the point of the instrument pushed through at the bottom of the sinus, and then, by withdrawing the director, the incision may be speedily completed with the bistoury.

Plate DXIII.

New mode of opening sinuses.

A still better method is one we have often adopted in cases of sinus with the greatest advantage. It consists simply in putting a small bit of wax, about the size of a pin head, upon the end of a sharp-pointed bistoury, introducing the point of the instrument thus defended along the sinus; and when it arrives at the bottom of it, the point may be pushed through the skin, displacing the wax with very little pressure. When the point has been brought through the skin, the incision may afterwards be completed with one quick motion of the knife. In laying open sinuses in this manner, it is particularly necessary to form an exact idea of the direction of the sinus, and of the extent of the incision to be made, before attempting to introduce the bistoury. For as a very slight degree of pressure is sufficient to displace the wax on its point, any untoward motion upon the side of the abscess would thus expose the point of the instrument, and render the operation more tedious and difficult, and always more painful.

The principal advantages of this mode of laying open sinuses are, that the operation can be much more speedily performed, and that it costs much less pain to the patient. The introduction of the director through a small fistulous opening, and the tedious process of cutting through the integuments with a scalpel, cannot fail of creating much distress, whereas a thin bistoury can be introduced without giving almost any uneasiness; and after the operator has conducted its point to the bottom of the sinus, it may be pushed through the integuments, and the sinus cut open with a *coup de main*.

Of the Whitloe.

All sinuses should be laid open in this manner, which can previously be detected by a careful examination with the probe; and if the edges of the fistulous sore are found to have acquired a great degree of callosity, it is also sometimes adviseable to cut them entirely away.

The sinuses are now to be dressed by placing between the edges portions of caddis dipped in oil, or simple ointment; and great care should be taken that no portion of newly divided parts be allowed to come into contact, as there will be great risk of an adhesion taking place between them, thus frustrating the very objects of the operation. After the pledgets have been introduced between the edges of the wound, it is commonly directed that the whole wound be covered up with a piece of linen spread with ointment. In place of the ointment, we have generally found a poultice answer better. The poultice, by its moisture, prevents any agglutination of the lips of the wound; and it has the power of diminishing the inflammation more than any other application. The wound is afterwards to be treated on the principle of the common ulcer *.

* See *Ulcers*.

Sect. III. *Of the Whitloe* (Paronychia).

The whitloe is a painful inflammatory swelling, occupying the extremities of the fingers, most frequently at the root of the nails. Several varieties of the disease have been described by authors; and these consist in the structure in which the disease is supposed to have been seated. From what we have been able to observe, it appears to be situated chiefly in the cellular membrane immediately underneath the skin, and in the structure connected with the nails; though at the same time the pathology of this disease is not yet well understood.

The first symptom of the whitloe is an uneasy burning sensation over the point of the finger, or root of the nail. The part becomes tender and painful to the touch; and a slight degree of swelling takes place, resembling œdema, attended by little discoloration. A transparent effusion takes place below the epidermis, and forms a vesication round the root of the nail. A purulent discharge takes place round the edge of the nail, and the nail always separates. The peculiarity in this disease is, that it generally affects several fingers, one after the other, and sometimes all the fingers of both hands.

In the more severe forms of the disease, the inflammation extends to the cellular membrane underneath the skin, and even to the tendinous aponeurosis and periosteum of the fingers, producing caries. In such cases the whole hand generally swells, and the swelling even extends up the arm and affects the axillary glands.

Whitloes sometimes succeed a blow or injury of the finger; but they most usually make their appearance without any known cause.

Treatment.—In the treatment of whitloe, two sets of remedies have been employed. Some use fomentations, poultices, Of the Carbuncle.

poultices, and leeches; whilst others apply ardent spirits, vinegar, cold water, and astringents.

Local bleeding and emollients do not seem to give the same relief in this as in idiopathic inflammation. When, however, the inflammatory symptoms and pain are violent, it is always necessary to take away some blood; and this may be best done at the bend of the arm. The affected part should be afterwards immersed in strong brandy, spirits of wine, or strong vinegar. We have also seen the inflammation much abated by immersing the hand, on its first commencement, in a large vessel of cold water.

It is only, however, in the first stages of this affection that remedies of this kind can prove useful: for, when effusion has actually taken place, and suppuration begun, that state of the disease is produced which these remedies were intended to prevent. Emollient remedies should now be employed; and whenever the presence of a fluid can be ascertained, it should be discharged with a lancet. A free incision into the part affected gives more decided relief than any application or remedy whatever, probably from bleeding profusely, and from relaxing the inflamed membrane or sheath of the tendons.

The wound is afterwards to be treated as a common abscess; but we may remark, that here, more than in any other part of the body, it is of the greatest importance to lay open freely every sinus which the probe can detect. Sinuses, situated here, never heal; and, when allowed to spread, are always attended with mischief. They destroy ligaments and tendons, or at least produce a thickening of the parts around the joints, so as afterwards to interrupt their free motion.

Sect. IV. *Of the Carbuncle.*

The carbuncle (*anthrax*) may be considered as a species of phlegmon, attended with a remarkable degree of malignity, and is one of the symptoms of the plague, where that disease rages, or of typhus fever in this country. It consists in a deep-seated and very hard swelling, attended with an intensely painful sense of burning in the part, and considerable discoloration of the skin.

The carbuncle is often sudden in its appearance. The skin is of a dusky red colour at its centre, but much paler and variegated at its circumference. Vesications appear on its surface, and when these are ruptured they discharge a dark-coloured sanies. The disease sometimes commences with symptoms of general inflammation; but most commonly it is attended with rigors, sickness, great restlessness and depression of strength, fainting, delirium, &c. A miliary eruption, or even petechiæ, are also sometimes found dispersed in different parts of the body.

When suppuration takes place, several openings generally form in the skin; a thin ichorous fluid is discharged, and a dark yellow slough is observed at the bottom of the sore.

Carbuncles most frequently take place about the back, neck, and shoulders, and are generally solitary. They are usually two or three inches in diameter, though sometimes they acquire an enormous size.

The cellular membrane and skin seem to be the principal textures affected in this disease; a great part of the former is always destroyed by the formation and

2

separation of very large sloughs, and the latte tensive ulceration.

In the treatment of this disease great attenti cessary, not only to the local applications, but general remedies.

Emollient poultices, and warm anodyne fome ought to be employed during the first stages of ease; and when ulceration of the skin has take the application of an ointment, composed of a c able quantity of the powder of opium, we have relieve very much the pain which the ulcerative generally creates. The use of rags, wet with nitrous acid, or a solution of lunar caustic, ha found of great use in promoting the separation slough, and the granulation of the cavities wh main.

When the constitutional symptoms are inflam at their commencement, it may be necessary to general blood-letting; but the fever being com of a typhoid form, wine, bark, and opium, ough freely administered. It will be also proper to pr a generous diet, and to pay great attention to ke bowels regular.

Sect. V. *Of Encysted Tumors.*

The word *tumor* has been the origin of much sion in the arrangements of diseases adopted by the celebrated nosologists; they have employed it as a to characterise a *class*, and also to express me *symptom* of diseases. A vast variety of diseases thus been included under the class of Tumors, dis which are totally dissimilar, and have no analogy ever. Anasarca, bubo, encysted tumors, scrofulou scirrhous tumors, warts, &c. have all been include der this class, these being as different from one an as any disease with which we are acquainted, ha only one common symptom, that of swelling.

Mr Abernethy has lately made a very laudable tempt to arrange tumors from their structure; like those who preceded him, he has classed dise together, among which no analogy can be discove He divides tumors into sarcomatous, encysted, and seous. Under the sarcoma he includes the stea (adipose sarcoma), medullary sarcoma, and also oth all of which have no resemblance to each other in t history or symptoms.

The word *tumor* ought therefore to be expunged fr nosology, and no longer employed to characteris class of diseases. Its use should be synonymous w that of swelling, and confined to express merely enlargement of any organ of the body, or a n growth; whilst all those diseases, which have be formerly classed among tumors, should be arranged ther according to their specific nature, or to the textu of the body in which they arise. Thus tumors, conne ed with *lues venerea* or *scrofula*, should be included u der these general names. The *steatom*, being a grow of fat, and being always formed in the cellular mem brane, ought to be treated of among the diseases of th texture. Encysted tumors, being also formed in th cellular membrane, ought to be arranged among its di eases; and warts, corns, and other tumors which are di eases of the skin, will with propriety be classed amon them: and the same may be said of all other disease whic which have usually received the general appellation of Tumor. We shall, therefore, in this section, treat of those tumors only which are formed in the cellular membrane.

Under the class of encysted tumors (*tumeurs enkysties, loups, cystides,*) are comprehended all those tumors of preternatural formation, the contents of which are surrounded by a bag or cyst.

Of encysted tumors.

Encysted tumors are generally formed in the cellular membrane, immediately underneath the common integuments. They are moveable, circumscribed, commonly indolent, without heat or any change of colour in the skin; and they are very slow in their formation and progress. They contain a matter more or less thick in consistence; and, according to the nature and consistence of this matter, they are distinguished by different names. They have been denominated *atheroma*, from the contents being of a soft cheesy consistence; *meliceris*, when they contain a matter of the consistence of honey; and *steatoma*, when formed of fat. The steatom, however, ought not to be classed among the encysted tumors, as the thin cellular covering in which it is contained has no analogy in its structure to the *cyst* of the other tumors.

It ought to be observed, that the consistence of the matter contained within the cyst varies in every species of encysted tumor. In the *atheroma* and *meliceris* it has sometimes the firmness of new cheese, and at other times is softer than the most liquid honey. These varieties depend on the length of time which the fluids have remained in the cysts, and in the proportion of coagulable lymph and serum, which have been separated and absorbed, and also on their having been inflamed or not, and on the extent to which this inflammation may have proceeded. Sometimes an encysted tumor is composed of different cysts, each of which contains a substance of a different nature. These different circumstances render in general the diagnosis in the varieties of encysted tumors very difficult; and happily this distinction is not necessary in practice, and perhaps ought also to be omitted in our nosological arrangements. The sac of an encysted tumor is generally pretty firm, and composed of concentric lamellæ. We have observed some of the cysts which were nearly as firm as cartilage, having small chalky concretions formed in many parts between the layers. When the contents of the tumor are washed out, the internal surface of the sac generally appears smooth and polished; but in others, some of the matter adheres firmly to the surface of the sac. In some cases the tumor very much resembles the hydatids found in the liver and other organs; for, besides the firm sac, there is sometimes formed within it, and apparently having no adhesion with it, a thin and very easily torn whitish bag, which contains the fluid.

Encysted tumors are very small at their commencement, and grow by almost insensible degrees. They vary a good deal in their form and size. Those which are formed in the hip, are generally round and smooth; commonly of the size of a nut, and acquire rarely the bulk of a large egg. Those which are seated in other parts of the body are more irregularly formed, and sometimes become of a prodigious size, some having been found which weighed 10, 15, and even 20lbs. They are never painful, at least at their commencement, and the skin covering them, preserves, for a long time, its natural colour; but when they become very large, the veins of the skin become varicose; and the skin on their upper part becomes polished, and acquires a reddish colour, similar to that of a part inflamed. Tumors of this kind seldom give pain or uneasiness, except when they receive a blow. Inflammation and pain then readily come on, and the cyst ruptures if not previously opened by an instrument.

Such is the usual progress of encysted tumors; and although they do not come to a rapid termination, yet this sometimes happens more readily under certain circumstances, and even before they have acquired a large size. In the hip, for example, we perceive the integuments become tender and very thin, and open before the tumor has acquired any considerable size. But on other parts of the body, and particularly the back, shoulders, and thighs, the integuments preserve their natural appearance, even when the tumor has acquired a large bulk. This appears to arise from the skin being more loose in these parts.

The situation of encysted tumors also contributes much to determine the degree of adhesion which they have contracted with the neighbouring parts. In some situations they are so detached, especially while they continue small, that they readily alter their situation by very slight degrees of pressure; but in others, particularly when covered by any muscular fibre, they are more firmly fixed from their commencement. The attachment of encysted tumors is also influenced by their remaining more or less free from inflammation; for they never become inflamed, even in the slightest manner, without some degree of adhesion being produced between the cysts and contiguous parts.

Mode of their formation.

It has generally been supposed that the membrane which forms the cyst of this species of tumor is not a new formation, but produced by a collection of fluid in one of the cells of the cellular membrane, which by its increase dilates the cell, and brings it in close contact with the adjacent cells, so as finally to obliterate them, and increase the thickness of its own coats.

The ingenious Bichât* has shown that this opinion so generally adopted is without foundation, and that the formation of encysted tumors more probably depends on laws, analogous to those which regulate the growth of the different parts of our bodies. He has also shown that there is a great analogy between these cysts and the *serous* membranes. The cysts, like serous membranes, form a species of sac without an opening; they contain the fluid which they exhale, and they have a smooth and polished surface contiguous to the fluid, whilst the other surface is unequal, and connected with the adjacent cellular membrane. The cysts have a similar structure to serous membranes; maceration, &c. proving them both to be composed of a cellular texture. In the natural state neither of them have any sensibility, but when inflamed they both become extremely sensible. The cysts also are evidently secretory organs, exhaling the fluid with which they are filled, and their power of absorption is also very manifest from the spontaneous cures of some encysted dropsies.

* Vide *Anatomie Generale.*

These considerations led Bichât to conclude that there exists a perfect resemblance between the cysts of

encysted

Of Encysted Tumors.

encysted tumors and serous membranes. An important question here presents itself, to know how these cysts are formed, how a membrane which did not exist in the natural state can be produced, and can grow under certain circumstances? The mechanical explanation of these phenomena which has already been mentioned, though at first sight it may appear simple and satisfactory, yet is by no means conformable to the usual proceedings of nature. How does it happen that as the cysts and serous membranes are analogous, these membranes are formed in a different manner, the serous membranes never being formed from a compression of the cellular membrane? How is it, if the cells are applied and compacted with one another so as to form a sac, that the neighbouring cellular membrane does not disappear, or even diminish, whilst the sac acquires a large bulk? These reflections would lead us to believe with Bichât, that the common manner of explaining the formation of cysts is essentially different from the manner which nature generally follows in all her operations.

Bichât ingeniously remarks that all tumors which vegetate externally, or appear internally, are formed and grow in the same manner as the cysts, there being no difference between these two morbid productions but the form in which each of them appears. Most tumors throw out upon their external surface the fluid which they separate. The cyst, on the contrary, exhales that fluid from its internal surface, and preserves it in its cavity. "Suppose a fungous tumor in suppuration (says Bichât), transformed in a moment into a cavity, and the suppuration to be transported from the external surface to the sides of the cavity, that cavity will then become a cyst.—Reciprocally, suppose a superficial cyst, the cavity of which is obliterated, and of which the fluid is exhaled from its external surface, you will then have a tumor in suppuration.

"If therefore the form alone establishes the difference between tumors and cysts, how does it happen that the formation of the latter is not analogous to that of the first? or has ever any one attempted to attribute the formation of external or internal tumors to compression? We ought therefore to conceive the production of cysts in the following manner: they begin to be formed in the cellular membrane by laws analogous to those which regulate the general growth of our bodies, and which appear to be deviations of these fundamental laws of which we are ignorant. When the cyst is once formed, exhalation begins to take place, and though at first in a small degree, it at last augments in proportion to its progress. The increase of the exhalent organ then always precedes the accumulation of the exhaled fluid, in such a manner that the quantity of the suppuration of a tumor is always directly in proportion to its bulk *."

* *Anatomie Generale.*

This mode of explaining the formation of cysts appears much more conformable to the laws of nature than that which has been formerly mentioned and generally received. But it still remains to determine the precise mechanism of the origin and growth of cysts, and consequently of all other tumors. We ought to stop where the first causes commence; and as we do not know the mechanism of the natural growth of our organs, how ought we to guess at that of morbid productions which depend upon the same laws. It is a great deal in the economy of our organs to poin out analogies, and to show the uniformity of a phenomenon not understood with one in regard to which all the world agree. Much would be done for the benefit of science, if in all its branches we could demonstrate that principle on which depends such a great number of effects, that nature, avaricious in her means, is prodigal in her results; that a few causes preside over a multitude of effects, and that the greater number of those regarding which we are uncertain, depend on the same principles as many others which appear to us evident.

Of the treatment of Encysted Tumors.—Encysted tumors, though not dangerous, are often inconvenient from their size, situation, and the deformity which they produce, so that whenever their removal becomes necessary, this can only be done by a surgical operation.

By the seton.

If the tumor be of the *meliceris* kind, which for the most part will be the case when a distinct fluctuation is perceived in it, it ought to be treated as a common abscess. If the tumor be small, the matter may be discharged by puncturing the most dependent part with a common lancet, and treating it in the ordinary way till the sides of the cavity come in contact by adhesion, or by the process of granulation. But when the tumor is more considerable, the free admission of air into the interior of its cavity is always dangerous; and we ought to be attentive to prevent its effects by making the opening in such manner, that the wound be exposed as little as possible. When treating of abscesses, we have recommended the passing of a seton or cord through them, as the best method of opening them when they are of a large size. This method is also very convenient in those encysted tumors, which contain matter of a liquid consistence. It will only be necessary here to observe, that the seton should traverse the whole tumor, from the superior part of it to the most dependent point, and that the inferior opening should be sufficiently large for allowing the matter to be freely discharged. This method often answers extremely well; and cures have by it been performed which could not have been obtained in so short a time in following the ordinary method of treatment by incision. But this method cannot be employed, except in those cases in which the contents of the tumor are so liquid as to be easily discharged by a small opening. When it is of too firm a consistence to admit of the seton, the contents must be emptied, either by making an extensive opening into the cyst, or by dissecting out the cyst and its contents.

When an encysted tumor adheres so firmly to the contiguous parts, as to render its removal tedious and difficult, it is often better not to undertake the operation. In such a case it will be sufficient to lay open the tumor its whole length, and to cut away any portions of the cyst which can easily be detached. The contents of the tumor will in this manner be completely removed, and the cure will be effected, either by keeping the wound open till the cavity of the cyst is filled with granulations; or it may be attempted by drawing the divided edges of the skin together, and applying moderate pressure, so as to produce adhesion with the sides of the cavity. It sometimes happens, however, that from the adhesion being complete, the remaining portion

Of Encysted Tumors.

tion of the cyst forms as it were the nucleus of a new tumor.

Operation.—When it is determined upon to remove the cyst completely, the first step of the operation is to make a free incision, with a common scalpel, through the integuments covering the tumor*. If the tumor is not very large, a longitudinal incision will answer the purpose; but should the tumor be of such a size, that the whole integuments covering it are too large to lie neatly upon the wound, it is much better to remove an oval portion of skin†. The size of this portion must be left entirely to the judgment of the operator, who should always take care that a sufficient quantity is left, completely to cover the wound. After the skin is divided, the cellular membrane should be dissected back, so as distinctly to expose the surface of the sac; and as the sac will be generally found loosely attached to the adjacent parts, it may be easily separated by a very simple dissection. In removing encysted tumors, it is particularly necessary to cut fairly down upon the sac; for if this be not done, instead of the tumor being readily turned out of the sheath of loose cellular membrane which surrounds it, it can only be removed by a very tedious process of dissection. Some surgeons have recommended that the contents of the tumor should be removed, before attempting to dissect out the sac; but if the incision of the integuments be made sufficiently large, this may generally be avoided. We have often observed the operation of extirpating encysted tumors, and indeed tumors of every description, rendered extremely tedious by a want of proper attention to this step of the operation. We would therefore particularly recommend, that, in the extirpation of all tumors, the incision of the integuments extend both above and below the tumor a considerable way, proportioned in all cases to its bulk and easy access.

* See Plate DXIII. fig. 1.

† See *the tumor represented in* Plate DXIII. fig. 19.

In some cases it is adviseable to open the cyst, and remove its contents, before an attempt be made to dissect it out. This practice will only be necessary in cases where, either from the shape or situation of the tumor, it is impracticable to pass the knife round it, and where, from the situation of important parts at its base, the dissection is rendered very nice and delicate. In a case of encysted tumor closely attached to the capsule of the knee joint, great advantage was derived from operating in this manner. Whilst the tumor remained distended, it was impossible to separate it, without great risk of cutting, either into it, or into the cavity of the knee joint. When, however, its contents were removed, the membranes could be readily dissected from one another, without the smallest risk of injury.

After an encysted tumor is extirpated, if any artery bleed very profusely, it ought to be secured by a ligature; but this should always be avoided as much as possible, as ligatures are apt to interfere with the adhesion of the lips of the wound. At the same time it is always necessary that the bleeding be completely stopped before the wound is dressed; for should any hemorrhagy take place after the dressings have been applied, it is very apt to displace the edges of the wound, and prevent them from adhering.

The edges of the wound are to be placed accurately together, and kept in contact with adhesive plaster, a compress and proper bandage being applied over it. In some cases the twisted suture is advantageous. The wound is to be treated in the usual manner, removing the dressings whenever they become soiled, and the application of the adhesive plaster continued till a complete cicatrization has taken place.

Sect. VI. *Of the Steatom* or *Fatty Tumor* (B).

Tumors of this species consist of a mere accumulation of cellular membrane and fat in a particular part of the body. They occur frequently, and are formed most commonly on the front or back part of the trunk of the body, and sometimes on the extremities. They generally grow in a slow and progressive manner, and the blood-vessels are neither large nor numerous. They have always a thin capsule of common cellular substance; and this capsule seems merely to be the effect of that condensation of the surrounding cellular membrane which the pressure of the tumor occasions. "As the growth of adipose tumors is regularly and slowly progressive, and as nothing like inflammation in general accompanies their increase, their capsules afford a striking instance of an investment acquired, simply by a slight condensation of the surrounding cellular structure, unaffected by inflammation*." When the capsule, which is extremely thin, and which adheres but slightly to the tumor, is removed, the tumor within consists of a mere piece of fat, more or less compacted according to its situation in the body, and the length of time which it has remained.

* *Abernethy's Surgical Observations*, p. 27.

Of the treatment of the Steatom.—When a steatom is small, when it causes little deformity, and does not seem to injure the functions of any organ, it is most prudent to allow it to remain. Sometimes they acquire a very large bulk, and from their situation are extremely inconvenient and unseemly; and they then become an object of medical treatment. No external application has ever been known useful in discussing tumors of this kind; and the only means to be employed for removing them is by an operation. There is indeed no species of tumor that can be dissected out with so much celerity, or with such apparent dexterity. In some cases, however, if inflammation has been induced, the capsules even of these tumors are thickened, and adhere so as not to be separated without difficulty.

In dissecting out a tumor of this kind, the same general rules may be followed as have been mentioned when treating of encysted tumors. The external incision should be made very free, and it is also of great importance to cut completely down to the capsule of the tumor, before attempting to dissect it out.

Sect. VII. *Of the Sarcoma* or *Fleshy Tumor*.

Our knowledge of the pathology of tumors of the cellular membrane is yet too limited to be able to arrange them in any systematic form; and it would be foreign to our purpose to attempt the investigation of

(B) Steatoma, *adipose sarcoma* of Mr Abernethy.

Sarcomatous Tumors.

of the subject. We have adopted the term *sarcoma* as very general; and include under it all those swellings or wens of a fleshy feel, which occur in the cellular membrane throughout the body.

The basis of these tumors, as we before mentioned, is the cellular membrane; and the difference in the qualities of the substances deposited in the cells gives the peculiar appearance to the tumor.

The vessels which pervade such tumors are either larger or smaller, and more or less numerous. They are also distributed in their usual arborescent manner, without any apparent peculiarity of arrangement.

When tumors of this kind have attained a considerable size, the superficial veins become very large. They have little sensibility, enduring a rough examination.

This kind of tumor generally grows till the skin is so distended as to ulcerate, and expose the new formed substance, which sometimes sloughs away. In this manner does the disease occasionally terminate; but such is the constitutional irritation attending this process, and the disgusting fœtor and frightful appearance of the part, that the surgeon generally recommends its removal. In some instances sarcomatous tumors are composed of a number of irregular-shaped masses, which from their resemblance to the pancreas have been called by Mr Abernethy *pancreatic sarcoma*, and considered as a distinct species. "This new-formed substance is made up of irregularly-shaped masses, which in colour, texture, and size, resemble the larger masses composing the pancreas. They appear also to be connected to each other like the portion of that gland, by a fibrous substance of a looser texture." Other sarcomatous tumors are composed of a number of cysts, containing sometimes a transparent and sometimes a dark fluid; and have been called by Mr Abernethy, the *cystic sarcomas*.

The *Mammary* and *Tuberculated Sarcomas* are other two species enumerated by Mr Abernethy. In the first the structure of the tumor has been supposed to resemble the natural structure of the mamma, and in the second the tumor "consists of an aggregation of small, firm, roundish tumors of different sizes and colours, connected together by a kind of cellular texture. The size of the tubercle is from that of a pea to that of a horse-bean, or sometimes larger; the colour of a brownish red, and some are of a yellow tint (c)."

These different terms employed to characterize the various kinds of swellings which form in the cellular membrane, are by no means adequate; and tumors will be daily met with which it is impossible to assign to one or other of these species. This subject therefore still remains open for the investigation of future inquirers. And it is probable, that when the subject is better understood, the surgeon will not on all occasions be obliged to have recourse to the knife; but that he will be able to distinguish those which may be allowed to remain as harmless, from those whose nature is more malignant, and require an early extirpation.

Sarcomatous Tumors.

Treatment.—When sarcomatous tumors are painful and tender to the touch, advantage may be had by local blood-letting, either by leeches or cupping. Fomenting the parts with a decoction of chamomile flowers or poppy heads, and applying a solution of muriate of ammonia or of vinegar with acetate of lead, are useful in diminishing their bulk. Frictions with unctuous substances, as mercurial ointment and camphor; camphorated spirits, aqua ammonia and oil; tincture of cantharides, have all been used for the discussion of indolent swellings: Soap and mercurial plasters have also been much commended; but of all these remedies perhaps there is none more useful than friction with the dry hand. The mode by which this practice is to be conducted is particularly mentioned under *Swellings of the Joints*. While these applications are made to the tumor, we ought also to give purgative medicines every second or third day, and enjoin an abstemious diet, with rest. An alterative course of medicine is also supposed to be useful. Small doses of calomel or corrosive sublimate are given for this purpose. The extract of hyoscyamus and calomel, or calomel and the extract of cicuta, has been much extolled by some.

By caustic.—Some surgeons (and it is a favourite practice with all itinerants) have attempted to remove tumors with caustic; and though this mode is much more painful and more clumsy than the knife, yet there are some cases, where, either from the situation of the tumor, or from the patient being timorous, this practice may be resorted to.

When a tumor is to be removed by caustics, the common caustic potass will answer the purpose extremely well. This is to be placed over a sufficient bulk of the skin, and allowed to remain longer or shorter according to the depth of the tumor, and the portion of it intended to be removed. After the dead portion has separated by the assistance of poultices, &c. the caustic may be again renewed until the whole mass is thus destroyed. Equal parts of red precipitate and burnt alum form a very active caustic; but it creates great pain. By mixing opium with the caustics, the pain is alleviated.

By incision.—When a sarcomatous tumor is to be removed by incision, the surgeon should always keep in remembrance, that whilst the tumor is growing, the contiguous cellular membrane is generally condensed, and is thus formed into a kind of capsule. A knowledge of this circumstance not only renders the extirpation of the tumor much easier, but tumors may be cut out from a depth, and from connexions, apparently dangerous. The integuments are to be freely divided, and the incision carried down to the capsule of the tumor, before attempting to dissect it from the contiguous parts. If this be not done, the dissection becomes more tedious and difficult, and more blood is lost than was necessary, from vessels being divided which might have been saved; and if the tumor happen to be deeply seated, its extirpation becomes thus impracticable. The general directions given for the extirpation and after treatment of encysted tumors may also be applied to the sarcomatous tumors.

Sect.

(c) Another species of sarcoma has been termed the *osteo-sarcoma*, from bony matter being formed in the tumor.

Oedema.

Sect. VIII. *Of Oedema.*

Oedema consists in the effusion of a watery fluid in the cellular membrane of any part of the body.

The swelling in œdema is not circumscribed. The skin of the swollen part retains its natural colour, and sometimes becomes paler than natural, having a glossy hue. The part has a cold feeling; and pressure made by the point of the finger forms an impression or dimple, which remains for some time after the finger is removed, disappearing slowly. There is no acute pain, but there is an uneasiness or sense of weight and tightness in the part. If a limb be œdematous, the magnitude of the swelling is always increased or diminished, according as it is placed in a depending or horizontal posture. Oedema always arises from the want of proper balance in the functions of the exhalent and absorbent systems, and it appears both in a constitutional and local form. Contusions, sprains, the long use of relaxing poultices and washes, are often local causes of œdema. More or less œdema is conjoined with erysipelatous inflammation. A part which has been acutely inflamed often remains œdematous for some time afterwards. It is also often owing to some impediment to the return of blood to the heart. Pressure of the gravid uterus on the iliac veins often renders the lower extremities œdematous. Aneurisms and other tumors, by compressing the veins of the extremity, often produce this affection. It also accompanies *ascites*, *hydrothorax*, &c. &c.

Treatment.—As an œdematous swelling is generally the effect of some other disease, the cure must depend upon the original disease being removed.

If the limb be the part affected, it should be kept in a horizontal position. Frictions made with flannel, and a moderately tight roller, applied from the toes upwards, have a powerful effect in diminishing the swelling. The operation of these means is to be assisted by purgatives and diaphoretics. See MEDICINE.

If the tumor become so tense as to create much pain and inflammation of the skin, these may be moderated by the discharge of the fluid by means of a small puncture, rather than by allowing the integuments to burst. A puncture is, however, not void of danger, for wounds in dropsical constitutions, generally excite a great degree of inflammation, and are apt to become gangrenous. The puncture should be made upon the most prominent parts of the swelling with the point of a lancet; and as the fluid which oozes out is apt to create great irritation of the tender skin over which it flows, it is a proper and very useful precaution to keep the skin always covered with some unctuous adhesive substance. For this purpose the *unguentum resinosum* is very well calculated.

Sect. IX. *Of Emphysema.*

Emphysema is an effusion of air into the cellular membrane of any part of the body.

The swelling is without pain, and colourless; and it is easily distinguished from œdema by the noise and particular feeling it has when pressed upon. It makes a crackling noise, and resembles the feeling created by pressing a dry thin bladder half filled with air. The swelling is not heavy. At its commencement, it only affects one part; but it soon spreads over the body, and distends the whole skin. In one case it was limited to one-half of the body.

Oedema.

Emphysema generally arises from a wound of the lungs; often from a spicula of a broken rib *. It has also been known to arise from an ulceration in the lungs; but this seldom happens, as the inflammation attending the formation of matter condenses the contiguous vesicles, and produces adhesions between the lungs and cavity of the thorax.

* See *Wounds of the Thorax.*

Emphysema has also been sometimes observed in some putrid diseases. Dr Huxham has recorded a case of this kind in a sailor who was attacked with putrid fever and sore throat †.

A partial emphysema has also been observed in cases of gangrene. Dr William Hunter has mentioned a case of that kind.

† *Medical Observations and Inquiries*, vol. i.

The treatment of emphysema must always depend on the nature of the original disease. It may be here, however, remarked, that effused air is readily absorbed, and creates no inflammation or any change in the cellular structure where it had been effused.

Chap. II.

Of the Diseases of the Skin.

General Remarks on the Pathology of the Skin.

There are a considerable number of diseases which originate in the different parts composing the skin; and there are others which seem to be the effect of that sympathy which the skin has with most organs of the body.

Of the diseases which attack the skin, there are five classes. In the first, the papillæ are affected; in the second, the cellular membrane contained in the areolæ of the skin; in the third, the rete mucosum or capillary net-work, from which the exhalents arise; in the fourth, the cutis vera or chorion; and in the fifth, the epidermis or scarf skin.

1. Under the diseases of the first class, or those of the papillæ, may be considered all those in which an alteration in the sensibility of the skin takes place. Whenever inflammation affects the skin, this alteration of sensibility is perceptible; and in some of the nervous diseases of women it is very remarkable; for on touching the skin a little roughly, convulsions are produced. The effect of titillation is well known; and perhaps an application of this knowledge might be extremely useful in the treatment of some diseases.

2. We have examples of the second class of diseases of the skin, where the areolæ of the cellular membrane of the cutis vera become inflamed, in boils and perhaps also in smallpox, and in some of those tumors commonly called pimples of the skin.

3. The rete mucosum, from its vascularity, is probably the seat of erysipelas, measles, scarlatina, and that multiplicity of eruptions to which the skin is subject.

4. In elephantiasis, cancer, warts, &c. and in general in all chronic cutaneous diseases, the cutis vera is affected; it appears, however, to be seldom primarily affected in acute diseases.

5. The epidermis is passive in all the diseases of the skin, and is only affected by its continuity. Its sensibi-

lity is never increased, nor is it susceptible of being inflamed, and consequently it never forms adhesions. Its internal surface, too, raised by a blister or any other means, and applied to the parts below, never reunites. The excrescences which form on it, such as corns, &c. are dry and inert, and without circulation; if they are painful, it arises alone from their pressure on the nerves of the subjacent parts.

From all these different affections of the skin, a number of sympathetic affections arise which it is worth while here to remark, though only a few of the diseases of this organ come properly within the limits of a system of surgery.

1. Every time that the papillæ are much excited in irritable people, as by titillation, various organs are sympathetically affected. Sometimes it is the heart; hence follows fainting. Sometimes the stomach, and in two cases mentioned by Bichât, the person vomited. In one case it excited violent coughing. Sometimes it is the brain, as is observed in people, where tickling brings on laughter, and even violent convulsions.

"Medical men," says Bichât *, "are often astonished at the extraordinary effects which quacks produce on the body from the knowledge they have acquired of the sympathies of the skin produced by titillation. But how should we be more astonished at this, than by vomiting produced by diseases of the womb, by diseases of the liver being brought on from an injury of the brain, or by headaches arising from a disordered state of the gastric viscera?" The influence of titillation of the skin may be of much use in the treatment of some diseases. In hemiplegia, &c. would not the excitement of the soles of the feet, which have so much sensibility, as every one knows, answer much better repeated ten or twelve times a day, than the application of a blister, the irritation of which continues only during a short time? †

From this sympathy which the skin has with distant organs, we may perhaps be able to explain the influence which friction has been lately found to have in some diseases. This remedy has been employed to a very great extent in diseases of the joints, and the best effects experienced from it ‡.

2. Whenever the exhalents of the skin, or the exterior capillary system from whence they arise, are affected in any manner, a number of other parts participate, and thence arises a second order of sympathies of the skin.

There are few organs which have more sympathy with the skin than the stomach. The bath, which acts upon the skin, during digestion affects sympathetically the stomach, and disturbs its functions. When that organ is spasmodically affected, it often is restored to a state of health, by the influence it receives from the bath. Bichât mentions a case of a woman who was troubled with constant vomiting, in consequence of suppressed menses; and who was immediately relieved by the warm bath after other remedies had failed.

The action of cold on the skin produces a variety of sympathetic effects; above all when that action takes place during perspiration. It is also well known what a number of phenomena result from a sudden disappearance of some eruptions of the skin.

3. When the cellular membrane contained in the areolæ of the skin, becomes inflamed, as in boils, pustules, &c. a number of sympathies ensue, which may be referred to the cellular system in general.

4. The diseases of the cutis vera and epidermis being all of a chronic nature, their sympathetic affections have the same character, little more being known of them.

Besides diseases of the skin, originating from a change of structure in that organ, there are others which arise from the sympathy it has with other organs. Whenever a cold body enters the stomach whilst there is a perspiration on the skin, the perspiration instantly stops. The entry of warm drinks into the stomach, and an augmentation of the cutaneous exhalation, are two phenomena which coincide at the same moment, in such a manner, that one cannot attribute the second to the absorption of the drink, to its passage to the venous blood through the lungs, and then to the arteries. The production of perspiration is, therefore, analogous to the suppression of it in the former instance. Hence will be found a great variety of phenomena in different diseases, arising from the sympathy existing between the skin and the other organs, various degrees of dryness, of moisture, and of perspiration. Sometimes these phenomena are chronic. In many organic diseases, different kinds of tumors are formed on the skin, in the same manner as we observe petechiæ, miliary eruptions, &c. &c. produced in acute fevers; the difference being merely in the duration of the periods of the sympathetic affections.

The diseases of the skin form a very important class in a system of nosology. There are, however, only a few which ought properly to be considered in a system of surgery.

The skin is the seat of all eruptions, as smallpox, measles, and a vast number of other diseases. It is liable to inflammation, suppuration, and gangrene. It is also subject to diseases and injuries from its exposure to the action of external bodies, and from serving as a defence to the internal parts. It is also subject to cancer, warts, and other excrescences, the treatment of which more properly belong to the surgeon.

Sect. I. *Of the Erysipelas*, or *Rose*.

Erysipelas is sometimes a local disease; at other times it is merely a symptom of some other affection. It differs from all other inflammations in its peculiar shade of red colour, and it is also remarkable for the disturbance which it generally creates throughout the whole system. The part of the skin which is affected becomes of a bright scarlet colour, with a tinge of yellow; and towards the termination of the complaint, the yellow becomes more discernible. Besides the difference in the shade of red, the swelling is neither so hard, so elevated, nor so circumscribed as that of phlegmon. The skin has a glossy smooth appearance, a burning heat, and on its being touched with the finger, the scarlet colour disappears, leaving a white spot, which, however, is almost immediately replaced when the finger is removed. The pain attending the disease is sometimes very great; there is also more or less swelling of the parts in the immediate vicinity; and this seems chiefly to arise from a watery effusion in the cellular membrane.

Erysipelas is very apt to spread rapidly to a great extent;

* Bichât *Anatomie Generale*, tom. iv. p. 730.

† See a case where this practice was successfully employed, in the *Edin. Med. and Surg. Journal*, vol. iii.

‡ *Treatment of the White Swelling of the Joints.*

Erysipelas.

extent; and it frequently changes its situation, growing gradually well on one side, and extending itself on the other. Sometimes it disappears entirely at one place, and attacks some other. As this disease gets well, the cuticle peels off from the affected part.

Erysipelas may be combined with phlegmon (erysipelas phlegmonoides), in which case the inflammation is of a deeper red colour; the swelling is also greater and deeper, and the pain is more acute. There is also a throbbing in the part, and the pulse is full and hard.

There is also a particular species of erysipelas, called *St Anthony's fire*, in which small vesicles are formed on different parts of the skin. These burst, and discharge a thin fluid which forms a scab, and beneath the scab suppuration sometimes takes place.

The true erysipelatous inflammation seldom suppurates, but generally terminates by resolution; very violent cases sometimes cause gangrene.

When Erysipelas is accompanied with inflammation of the cellular membrane, as there are no distinct limits of the disease, the matter which is formed in those cases which advance to suppuration, often extends very far in every direction, and sometimes produces very considerable sloughing, not only of the cellular substance, but of the fasciæ and tendons. Erysipelas is generally accompanied with all the symptoms of general fever, and these occur in a very considerable degree, even where the external inflammation is extremely slight. Languor, lassitude, weariness in the limbs, headach, loss of appetite, oppression about the stomach, precede the appearance of the local complaint. The most violent form of erysipelas is most frequently seen in the face, producing a great deal of general fever, often accompanied with delirium; and in a few cases we have known it to proceed so far as to inflame and suppurate the membranes of the brain. Erysipelas seems to be intimately connected with the state of the general constitution. Persons in the habit of drunkenness and other species of intemperance, and who, when in a state of intoxication meet with local injuries, often have erysipelatous inflammation. In general, erysipelas has its principal source in a disordered state of the chylopoetic viscera, more particularly the biliary secretion. It seems also to be often connected with a suppression of perspiration, for it never recedes until that symptom is relieved.

Of the treatment of Erysipelas.—The mild erysipelas is to be relieved by the exhibition of gentle diaphoretics. A few doses of nitre, in order to promote the ordinary evacuations, and general attention to the antiphlogistic regimen.

It is also of great importance to attend to the state of the bowels, and to give purgative medicines, both with a view of removing any feculent matter contained in them, and as a general evacuant.

When the case is conjoined with phlegmon, and when there are symptoms of inflammatory fever, venesection becomes necessary; and this is particularly the case when the face is the seat of the disease.

When the patient has a very foul tongue, a bitter taste in his mouth, and a propensity to vomit, purgatives and emetics become necessary. Indeed, in almost all severe cases, an emetic is indicated, and ought even to be repeated, should the symptoms continue.

There has been a great variety of opinions with regard to the external treatment of erysipelas; some recommending the part to be kept dry, of a moderate warmth, and excluded from the air: others have used warm or cold moist applications. The practice of Dessault is perhaps the most judicious. In those cases of erysipelas produced from an internal cause, no topical application is to be employed, except, perhaps, dusting the part with flour; but when any species of erysipelas succeeds a contusion, a wound or an ulcer, the regimen and internal medicines are insufficient, if proper topical remedies are not at the same time employed to alleviate the local irritation. In these cases Dessault employed poultices, the good effects of which were confirmed by numerous observations. He considered it, however, as an essential precaution, not to extend this topical application further than the bruised part, or the edge of the wound or ulcer. If any application is made to the erysipelatous surface, it ought to consist merely of a weak astringent solution: that which was always employed at the Hotel Dieu, consisted of a scruple of the extract of lead in a pint of water.

Sect. II. *Of the Furunculus* or *Boil.*

The furunculus appears to be an inflammation of the cellular membrane of the areola of the chorion; the other inflammations of the skin and cutaneous eruptions being seated on the *corpus reticulare*. The furunculus is a circumscribed, very prominent, and hard tumor, of a deep red colour; and they vary, from the size of a pea to that of a pigeon's egg. They are extremely painful, and are seldom attended with much fever. They are most frequent in young people. Boils generally pass into a more or less perfect suppuration. A small white spot is formed on the apex of the tumor, which, when it has reached the skin, discharges but a small quantity of pus in proportion to the bulk of the swelling. Before the tumor begins to subside, a yellow slough, formed by a portion of dead cellular membrane, comes away.

As swellings of this kind almost always suppurate, and as induration constantly remains after an incomplete resolution of them, we ought to promote suppuration by using emollient applications. Emollient poultices are best for this purpose. When a quantity of matter is collected, it is sometimes more advantageous to open the boil with the point of a lancet, than to allow it to remain until the skin ulcerates. Aperients and the antiphlogistic regimen ought not to be omitted.

Sect. III. *Of the Chilblain.*

The chilblain is a painful, and very often an extremely itchy swelling of the skin of an extreme part of the body, in consequence of exposure to extreme cold, or sudden change from a very cold to a warm atmosphere.

Chilblains are most frequently in young people of scrofulous constitutions, and in this country the disease is most prevalent during the winter months. It appears most

Chilblain. most commonly on the toes, heels, and fingers, and sometimes on the nose and parts where the circulation is most languid.

The first symptoms of the disease are a paleness of the part, which is quickly succeeded by more or less redness, a very troublesome itching, and sometimes pain. The skin gradually acquires a purple hue; the part swells, and the cuticle separates from a serous effusion below it. Beneath the cuticle an ulcer appears of a very irritable character, and accompanied with great pain. This ulcer spreads rapidly, has very acute edges, and its surface is of a dark or rather dirty yellow colour. Sometimes the ulceration penetrates as low as the tendons, or even exposes the surface of the bones, producing sphacelation of an extremity.

In the treatment of Chilblains, before the skin has ulcerated, the principal attention ought to be paid to keeping the affected part of an equal temperature, and rubbing it over with stimulating applications. Camphorated spirit, spirit of turpentine, &c. have been generally recommended for this purpose; but the tincture of cantharides, properly diluted, is much more efficacious. A drachm of this tincture to an ounce of the soap liniment, will generally be found to answer extremely well; and this is to be well rubbed on the part once or twice a day.

When vesications begin to appear, and ulceration has taken place, emollient poultices should be employed; but after this process has gone on a certain time, and the pain and irritation abated, much benefit will be experienced by the application of the red precipitate ointment to the ulcers. Under this treatment we have repeatedly observed large ulcers of this kind heal with unusual rapidity.

Rest and a plain nourishing diet will be commonly best suited to people with chilblains; and should symptoms of debility and a sloughing of the sore ensue, it may be then necessary to give freely wine and bark.

SECT. IV. *Of Cancer of the Skin.*

The skin is frequently attacked with cancer. That of the face is more particularly exposed to it; and this no doubt arises from its delicacy, from the great number of vessels which penetrate it, and perhaps also from its more frequent exposure than any other part of the body to external irritations. Cancer, however, is not confined to the skin of the face; it frequently appears on the back of the hands, and on the feet. Wiseman has seen it on the cranium, Gooch on the inside of the thigh, Richter at the umbilicus; and we have seen an example of it in the skin above the pubes.

When cancer affects the skin, it begins in the form of a small, hard, and dark-coloured wart, which increases very slowly in size; the contiguous skin becomes hardened, forming a stool or button around the wart. The progress of this disease in the skin has always been observed to be more slow than cancer in any other part; so that it often remains in the form of a black scab for many years. The scab at last separates, and then an ulcer of the skin is exposed, having all the characters of the true cancerous sore. It has a pale colour, ragged hard edges, and unequal surface; and it gradually extends in an irregular manner along the skin; the hard tumor which forms its basis, at the same time increasing in size. Instead of pus, the ulcer di a thin ichor, which reddens and excoriates the skin. The disease which, when in the form of gave little uneasiness, now becomes painful; patient feels more or less frequently sharp lan pains darting through the tumor, and extendin adjacent soft parts.

When a cancerous affection of the skin is ex after it is removed from the body, it has all t ing characters described in our general obser on cancer *. The great degree of hardness of t bid mass, is produced from the formation of t fibrous-looking matter observed in all schirrous t and the direction of its fibres will be generally extending from the base of the tumor to the sur the skin.

Cancer of the skin follows the same progress a cerous affections of other textures. The cont glands become enlarged and ulcerate; and bo ulcers which these form, and the primary one, over whatever parts they meet, till they destr patient.

Treatment.—The success which has been attri to various medicines, particularly to arsenic and corrosive applications, in the cure of cancer, has chiefly from the use of these medicines in canc affections of the skin. From the disease being obs in the skin before it has far advanced, from its slow gress in that part, and the ready application of r dies, it affords better opportunities for experiment other parts of the body when affected with that ease. Past experience, however, leaves us but room to hope for a cure of cancer in the skin by external application with which we are as yet acqu ed; and we know of no remedy to be trusted to bu complete excision of the diseased parts.

The more early the tumor is removed, the great the chance of a permanent cure of the disease. in whatever part of the body the skin is affected, of the utmost importance to remove every part w there is the least suspicion of contamination. In face, we have often observed the surgeon too anx to save skin, with a view of lessening the blemish an extensive scar; but in a disease so deplorabl cancer, no object of this kind can in any degree c pensate for being exposed to the smallest risk of its turn; the more so, especially as we have often rema ed that a second operation is seldom if ever atten with permanent advantage. The surgeon, theref ought to lay it down as a general rule, that he sh include in the incision a considerable portion of sound skin surrounding the diseased parts.

The particular cases wherein an operation is advisab must be left entirely to the judgment of the surge The operation may be performed in all cases where t diseased parts appear to be within the reach of the knif or if there are any glands affected, if these can be saf ly removed, it may be even under these circumstanc undertaken, though no doubt the chance of a return the disease in such cases is great.

Whenever the periosteum and parts surrounding ar of the bones is affected, there is little chance of any assis ance from art, except when the disease occurs in the e tremities of the body, as in the hands or feet; for in suc cases, amputation of the whole member may be performe

Whe

Cancer of the Skin.

When cancerous sores appear about the eyelids, and spread along the sclerotic *conjunctiva*, it is the only safe practice to remove the whole contents of the orbit. The different parts which compose the eyeball and its appendages, seem to have such a close connection with one another, that it is difficult, perhaps impossible, to mark the boundaries of the diseased action which is going on; and as the loss of any part of the organ prevents the others from performing their functions, it becomes no material object to save any particular part.

It is generally remarked, that the lips are particularly subject to cancer, at least in men; and that the under lip is more liable than the upper one. The diseased part may be removed in this part of the body with great neatness upon the general principles of the operation of harelip. This can only be done when the diseased portion is not very large, and can be included by two incisions forming an angle, inclining towards the chin. See Harelip. When, however, the disease has spread over a considerable portion of the lip, so as to prevent the sound parts from being united, after the diseased parts have been removed, all that can be done is to remove the parts affected, secure the bleeding vessels, and dress the sore like any other recent wound.

By a little contrivance, much may sometimes be done by making the incision in such a manner as to allow the sound parts to be afterwards brought together and united; so that in all cases of extensive disease, the surgeon should consider all the different modes by which the diseased parts may be removed with most advantage.

The operation is performed by some with a common scalpel, by others with scissars. When the scalpel is used, the lip is to be held firmly with forceps by an assistant, and the second incision made along their edge; but when the disease extends beyond the adhesion of the lip to the jaw, no forceps are necessary.

The scissars are, however, the preferable instrument; they divide the lip with much less pain, and with a mathematical precision. When they are used for this purpose, it is necessary that they be thick and strong; as in some people the lip is extremely thick, and apt to slip through the blades, instead of being divided. Giving the cutting edge of the blades a knife edge, will be found an improvement on the common edge given to scissars. It is evident, however, that the scissars can only be employed in those cases where the forceps could be used to aid the knife. All wounds of the lip heal best and most accurately with the twisted suture; so that the edges should be brought together in the same manner as recommended in the case of harelip, and the same mode of after-treatment is also to be pursued.

Sect. V. *Of Warts.*

There are two kinds of Warts which grow upon the surface of the body. One species is connected with the skin by a broad base; is of a hard, firm texture, unequal on the surface, and free from pain. Warts of this description are frequent in young people, and are generally found on the hands.

Warts.

The other species of warts are attached to the skin by a slender pedicle; they have a very unequal surface, appearing as if composed of an aggregate of small tumors. Warts of this kind seldom attain any very considerable size, though we have in a few instances seen them as broad as a half-crown piece. They are seldom troublesome; but in some situations they become extremely irritable, and produce, especially when injured, very disagreeable sensations.

This species of wart is most frequently met with on the prepuce and glans of the penis; on the labia; around the anus, and also frequently upon the hairy scalp. In these situations they sometimes acquire a very large size, numerous warts arising over the whole surface, and forming a mass of a cauliflower appearance. They are most frequent in people advanced in life, and are often connected with the venereal disease.

Besides these, there are varieties of small warts which occur in different parts of the body, which have not been accurately described by authors. There is one of those, where a number of small whitish tumors appear in some parts of the face of children. These contain an opaque white fluid, which when discharged, and allowed to remain upon the contiguous skin, contaminates it, and produces warts of the same description.

Of the treatment of Warts.—A variety of local remedies have been applied for the cure of warts; and these generally possess a corrosive quality.

Lunar caustic is one of those which generally answers best; and it is most easily managed for destroying the first species of warts which we have described. A saturated solution applied to the warts three or four times a day, of the muriate of ammonia, and tincture of cantharides, has also been found beneficial in promoting their absorption.

In the second species, when the excrescences are very large, they should always be removed along with a portion of the adjacent skin, by the knife. In those cases where the warts are very numerous, and where, from their situation, it becomes impossible to remove them with the knife, equal portions of *ærugo æris* and savine powder, or savine powder alone, will be found sometimes to succeed in removing them. In some cases, particularly where the warts are situated about the glans of the penis, we have found a saturated solution of the muriate of mercury in spirit of wine, completely answer the purpose. In those cases connected with syphilis, besides local applications, it is necessary to use mercury. Sometimes, indeed, the warts drop off whenever the mercury begins to affect the constitution.

Sect. VI. *Of Corns.*

A corn is a peculiar hardness and increased thickness of the epidermis, which sometimes extends to the subjacent skin. It frequently elevates itself above the skin, and is not unlike one species of wart. It is hard, dry, and insensible, except when pressed upon the contiguous parts; and it resembles in colour and appearance the thickened cuticle on the hands of workmen. Corns commonly are formed on the toes and sides of the feet, and they are generally owing to the wearing of tight shoes. Sometimes corns do not occasion the least inconveniency; but in other instances they produce so much

Corns. much pain, that the patient walks with difficulty. Corns are generally more painful in warm than in cold weather. The pain seems to arise from an inflamed state of the parts in the circumference of the corn, which state is excited and kept up by the pressure of the induration, and not from any sensibility in the corn itself. They are more painful in dry than in moist weather, because they then become much more hard and dry.

Treatment of Corns.—The pain and difficulty of walking produced by corns, may be alleviated by immersing them in warm water, and with a sharp instrument cutting off their external layers; much relief will also be found by covering the part with a piece of adhesive plaster, and by being careful not to wear shoes which are too tight. But what we have found a most complete cure for corns, is the application of one or other of those corrosive substances which were mentioned for the treatment of warts. The lunar caustic, or the saturated solution of muriate of mercury in spirit of wine, ought to be preferred. They may be applied once every second or third day, until the absorption of the corn be completed; and, before using them, it will be proper to pare off some of the external hard layers of the corn.

Some corn-operators extirpate the corn by a sharp instrument; but this only proves a palliative treatment, for sooner or later a hard substance is again formed.

Sect. VII. *Of Nævi Materni.*

Nævi materni are those marks which frequently appear upon the bodies of children at birth, and which are supposed to originate from impressions made on the mind of the mother during pregnancy. They are of various forms; their colour is likewise various, though most frequently resembling that of claret or port wine. Many of these marks are perfectly flat, and never rise above the level of the skin: these do not require the assistance of surgery; but in some cases they appear in the form of small protuberances, which frequently increase to a great size in the course of a few months. They appear to be soft and fleshy; of a cellular texture, the cells containing liquid blood. They may be removed with little danger when not involving any important organ. They are supplied indeed more plentifully with blood than most other tumors are; and even sometimes they appear to be entirely formed of a congeries of small blood-vessels; but the arteries which supply them may be, for the most part, easily secured by ligature. An operation should never be long delayed; for as the size of the vessels corresponds with that of the tumor, they sometimes are so large as to throw out a good deal of blood before they can be secured. In performing it, the tumor is to be cut out, the arteries taken up, and the remaining skin brought as well together as the nature of the part will allow, and kept so by adhesive plaster or suture.

If the whole tumor be removed, little hæmorrhagy generally follows; but if the smallest portion of the diseased vessels remain, not only a troublesome bleeding follows, but the tumor is quickly reproduced by an increased exuberance. Tumors of this kind have also been removed by ulceration artificially excited by corrosive applications; and a knowledge of this circumstance might be in some cases of practical application.

Chap. III.

Diseases of the Mucous Membranes.

On the Diseases of Mucous Membranes.

General Remarks on the Pathology of the Mucous Membranes.

Though at first sight it may appear that the mucous membranes are very considerable in number, yet when viewed more generally, they appear limited; and we find that in all parts of the body they are subject to the same morbid alterations of structure.

Bichât has described two *general* mucous surfaces, of which all the others are portions. The one lines the interior of the mouth, nose, and the anterior surface of the eye. It is prolonged into the excretory ducts of the parotids, and submaxillary glands. It passes into all the sinuses, forms the conjunctiva, enters the lachrymal points, the lachrymal sac, the nasal canal, and is continued into the nose. It lines the pharynx and eustachian tube, the trachea and bronchiæ. It goes down the œsophagus into the stomach, and passes along the whole intestinal canal till it joins with the skin at the extremity of the rectum. This he calls the *gastro-pulmonary mucous surface.*

The other general mucous surface, the *genito-urinary*, begins in the male at the urethra; passes along that canal into the bladder, lines the bladder, vesiculæ seminales, and vasa deferentia, along with their numerous branches. It also extends into the excretories of the prostate gland, the ureters, and the pelvis of the kidneys. In the female it begins at the vulva, penetrates the ureter, and passes as in the male over the urinary organs. It also enters the vagina, lines the womb and fallopian tubes, and is then continued with the peritoneum. This is the only example of a communication established between the mucous and serous surfaces.

This view of the extension of mucous membranes is strongly exemplified by an examination of their diseases; for it will appear that there is not only an analogy between the different portions of the first, by a simultaneous affection of the whole parts over which it extends, but there is also a line of demarkation between the two mucous surfaces, from the one remaining sound whilst the other is affected throughout. This last circumstance is confirmed in the history of many epidemic catarrhs; one of these membranes having been observed affected throughout, whilst the other remained unchanged. The epidemic observed at Paris in the year 1780 had this character. "This epidemic (says Pinel*) which was very general in Paris, and with which I was myself attacked, was remarkable; for it affected almost the whole mucous membranes, that of the trachea and bronchiæ, the conjunctiva, the pituitary membrane, the palate, the pharynx, and the alimentary canal." The epidemic catarrh of 1752, described in the Memoirs of the Medical Society of Edinburgh, is an example of the same kind; for in all these, the mucous membrane only lining the urinary and genital organs remained unaffected.

* Nosographie Philosophique, tom. ii. p. 205.

We also observe that an irritation of any part of a mucous membrane frequently creates a pain on a part of the membrane which was not irritated. Thus a calculus

Inflammation of Mucous Membranes.

culus in the urinary bladder produces the chief pain at the point of the penis, and worms in the intestines produces itching at the nose.

Among these phenomena, which are purely sympathetic, it is seldom that a partial irritation of one of the mucous surfaces produces pain in any part of the other. The singular connection which subsists between the membranes of the uterus and bronchiæ in mucous hæmorrhagies is, however, an example of this kind. If the blood accidentally cease to flow from the one during menstruation, the other frequently supplies the functions of the first. In cases of stricture, or thickening and disorganization of the mucous membranes of the urethra, the stomach is sometimes affected: this may also arise from the sympathy of the two mucous membranes.

Mucous membranes, from being constantly exposed to the action of the external air, or to the contact of extraneous substances, do not suffer, when displaced, like other parts of the animal economy. In a prolapsus of the uterus or rectum, their mucous surfaces serve all the purposes of skin; and surrounding bodies do not produce more pain on them than on common skin. This is very different from the effects produced on opening a *serous* cavity or the capsule of a joint. The cellular, muscular, nervous, glandular, and other systems, when laid open, produce also very different phenomena.

The mucous membrane, like the skin, is organised in such a manner as to endure with impunity the contact of external bodies; these merely producing an increased secretion of thin mucus. A sound introduced and retained in the bladder produces no alteration in the structure of the mucous membrane of the urethra; and for the same reason, a style or tube can be kept in the lachrymal duct without causing any irritation. The gradual loss of sensibility of mucous surfaces is strongly exemplified in the tricks of the Indian jugglers.

Most of the diseases of mucous membranes come within the province of the surgeon; the others have been already treated of under the article MEDICINE.

SECT. I. *Inflammation of Mucous Membranes.*

The contact of extraneous and irritating substances, acrid vapours, or the sudden exposure to cold air of any mucous surface, is often followed by inflammation.

A preternatural degree of redness is a constant symptom of inflammation in all parts of the body; but the most remarkable character of inflammation in mucous membranes, and that which distinguishes it from all others, is the secretion of a puriform fluid. The mucus, which in the natural state is nearly transparent, and merely moistens the surface, becomes of a yellow colour, and the quantity is so abundant as to form a puriform discharge. It is from the susceptibility of the mucous glands to be acted upon by any irritation which is applied to the extremities of their ducts, that the stone or any tumor of the bladder, polypi of the nose or vagina, are always accompanied by a profuse mucous discharge.

The inflammation is accompanied with more or less thickening of the membrane; and sometimes this remains after all the inflammatory symptoms cease. The abatement of the inflammation is marked by an increase in the thickness of the discharge and a diminution in its quantity.

Gonorrhœa.

We have an example of inflammation affecting the mucous membrane of the nose in coryza, the ear in otitis, the urethra and vagina in gonorrhœa, the bladder in a catarrhus vesicæ, the eye in the puriform ophthalmia, and the lachrymal sac or duct in fistula lacrymalis. In all these diseases the symptoms have a striking analogy, and are varied only from a difference in the functions of the particular organ, the mucous covering of which has been affected.

During life, mucous membranes become gangrenous much more seldom than the skin. This is proved from the consequences of catarrh, compared with those of erysipelas. There are, however, cases where this texture dies, whilst those adjacent continue to live; as in the malignant angina.

SECT. II. *Of Inflammation of the Mucous Membrane of the Urethra.*

Gonorrhœa (*Ecoulement Muceux*).

The term gonorrhœa is employed to signify a discharge of puriform matter from the urethra or prepuce in men, and from the vagina in women; whether proceeding from a syphilitic or any other irritating cause.

The gonnorhœa may be defined a discharge of a contagious, puriform fluid, which comes from the mucous glands of the urethra, and membrane which lines that canal; or from the glans in men, and the interior of the genital organs in women. The disease seems to be produced by a *virus sui generis*.

This disease generally makes its appearance in three or four days, sometimes in six, but rarely later, after impure coition, with the following symptoms. The patient finds a particular itching and disagreeable sensation at the point of the yard, and a slight itching also at the part of the urethra placed immediately under the frenum. These last one or two days, and on the following days the orifice of the urethra becomes sensible and red; it also swells, and a limpid matter of a clear yellow colour flows from it, which tinges the linen. Whilst the flow of this matter continues, the titillation becomes stronger and more painful, particularly in making water; for this leaves a burning impression and sharp pain in the affected part. In some individuals the first symptom presenting itself is the discharge of a thick mucus. In these cases the patient feels from the commencement a burning and painful sensation in making water. These symptoms generally increase in three or four days. Sometimes, however, that does not sensibly happen till after eight or twelve days. The glans acquires a deep red livid colour; the discharge increases, and the matter becomes of a yellow, or greenish yellow colour, resembling pus diluted. The swelling of the glans, and also of the whole penis, becomes considerable; the patient has frequently a desire to make water, and he finds, particularly when he has remained for some time in bed lying on his back, frequent and involuntary erections, so painful that they disturb his sleep, and oblige him to rise out of bed.

Such is usually the progress of the disease when the inflammation is simple, slight, and superficial; but in many cases the inflammation extends farther and penetrates more deeply, affecting the reticular substance of the cavernous

Gonorrhœa.

cavernous body of the urethra. Then the pain becomes excessive, particularly during erections, and the frenum of the glans is drawn downwards as by a cord, in such a manner that the body of the penis is forced upwards by the violence of the erection. It is this symptom which is called *cordee*. It sometimes happens, that the vessels of the urethra are thus torn, and occasion considerable hæmorrhagy. At other times, the discharged matter is mixed with streaks of blood; the prepuce is also so much inflamed and swelled that it cannot be pulled back over the glans, or if it has been pulled back, it cannot be again brought forwards. In some cases the strangulation which accompanies this last accident, produces a mortification of the glans, and even occasions the death of the patient; this, however, seldom happens.

In some persons one or more of the inguinal glands swell, become painful, attended with symptomatic fever. Often the glands of the penis swell also, a cord or knots can be felt on the back of the penis, and the skin is also swelled and painful. Besides these symptoms, the patient often feels, either from his own fault, or on account of bad treatment, a particular uneasy aching sensation, with tension and swelling of the spermatic cord and testicles, accompanied with a diminution, or even a complete suppression of the discharge by the urethra. In other cases the disease makes greater progress; the irritation and inflammation stretching along the canal of the urethra. All the symptoms then become more violent, the pain which is felt in the perinæum, or behind it, in making water, is so violent, that the patient is afraid to make the attempt, at the same time that he is frequently solicited by the fatiguing titillation at the neck of the bladder and anus. There is a perpetual desire to let off the water, whilst he can make no more than a few drops at a time with a burning pain. The whole canal of the urethra is swelled, and in a state of tension; the patient has frequent erections, and lancinating pains along the canal, through the perinæum and anus. He cannot lie down for a long time, nor can he rest seated. In this state the swelling of the glands of the urethra, and the spasmodic contraction of its internal membrane, obstruct the free passage of the urine, and allow it to flow in a very thin bifurcated stream, or drop by drop; and if at the same time the discharge diminish considerably, or totally stop, a complete suppression of urine sometimes succeeds, occasioned by the inflammation and stricture of the neck of the bladder, or by the inflammation and swelling of the prostate gland and adjacent parts.

It sometimes happens that the inflammation of the urethra becomes so violent, that its internal surface, and the orifices of the glands which line it, secrete nothing; the same as we observe sometimes happens in inflammation of the mucous membrane of the nose and of the lungs. It is this state of the disease which some authors have described under the name of *gonorrhœa sicca*.

After the symptoms have continued with more or less violence, or when they have increased during one, two, or three weeks, or even during six or seven, according to the treatment employed, they begin gradually to diminish. The difficulty and the frequent desire to make water cease; the erections are no longer painful; the matter acquires more consistence, and forms into threads between the fingers, and at last the discharge entirely disappears. In other cases, and these the most frequent, the inflammatory symptoms disappear by degrees; but the discharge remains during weeks, months, or even years. It is this form of the disease which is called *gleet*, or simply *blennorrhœa*.

Gonorrhœa.

Sometimes the inflammatory symptoms disappear by degrees, and leave in the urethra an ulcer, from which there is a malignant and purulent discharge, and which occasions an affection of the system. This is what has been called *gonorrhœa complicata* or *ulcerosa*; but it occurs rarely.

In other cases a contraction remains in the canal of the urethra; sometimes a paraphymosis continues, and sometimes there is a tumor of the testicles, a hardening of these parts or of some of the glands of the urethra, an inflammation of the prostate gland, with a more or less complete suppression of urine; at other times, though very rarely, the discharge, when suppressed, produces suddenly a perfect deafness, or most violent ophthalmia *.

The exciting cause of syphilitic gonorrhœa is always the application of the specific virus to some part of the mucous membrane lining the urethra. The contagious fluid, applied to any part of the body of a sound person, acts with more or less difficulty, according to the difference in the structure, the greater or less debility of the part, and also according to the particular constitution of the individual; for we see some people exposed to every danger of infection never have the disease. Perhaps also the violence of the action of the virus depends on the greater or less degree of acrimony of the virus itself.

The seat of gonorrhœa is always at a small distance from the orifice of the urethra; under the frenum, at that part of the canal where we observe a dilatation, called *fossa navicularis*. All gonorrhœas which are situated more anteriorly on the curvature of the penis, in the *veru montanum*, the neck of the bladder, or in the bladder itself, arise from bad treatment, or from some cause which has stopped or suppressed the primary discharge.

Sometimes by the natural progress of the disease, and more frequently from faults committed by the patient, or by the effects of improper remedies, the inflammation and irritation are apt to change their place. They often occupy the orifice of a mucous gland which opens at the first turn of the penis. At other times they affect the two glands of Cowper. Sometimes they occupy the protuberances which cover the orifices of the seminal vesicles; and they also sometimes affect the prostate gland, or the neck of the bladder.

In some rare cases the contagious virus does not penetrate into the urethra, but applied to the extremity of the penis, it fixes itself upon the corona of the glans, and irritating the excretory ducts of the sebaceous glands, produces a discharge which has been called the *gonorhœa of the glands*.

When the urethra of a person who has laboured under gonorrhœa is laid open, no ulcer is almost ever found upon the surface of the internal membrane; and in those who have suffered much in consequence of the disease, there is merely a thickening and contraction of one or more parts

* *Traité de Maladies Veneriens par Swediaur.*

Gonorrhœa.

parts of the urethra. Sometimes, though very rarely, excrescences are formed within it. The ducts of the mucous glands are obliterated, and the prostate gland and bladder changed in their structure.

It has been a matter of great dispute among those who have written on the venereal disease, whether the gonorrhœal and venereal virus are the same. In this controversy a number of very futile arguments have been brought forward. It is a striking fact, however, which the practical man must have always in view, that the venereal disease is never cured without mercury; whilst a gonorrhœa, however virulent, never requires that remedy. This difference in the treatment of the diseases some authors have attempted to explain, from the difference in the structure of the parts affected. It is remarkable, however, that the matter from the gonorrhœa never affects the skin, producing chancre; but that when its virus is applied to the vagina, or to the urethra of another person, gonorrhœa is the consequence. When it affects the prepuce too, it produces, in place of chancre, a morbid discharge from the sebaceous glands of that organ. It is also a striking fact, in the history of gonorrhœa, that however long it may remain, it never produces any constitutional affection. All these circumstances in the history of the disease, in its progress and symptoms, and in its cure, being so dissimilar to those of the venereal disease, are surely sufficient grounds to consider gonorrhœa and syphilis as two distinct morbid affections, and different from one another as much as any two diseases of the animal economy.

Specific nature of the virus.

Treatment.—All the forms of syphilis, when left to themselves, undermine and destroy the constitution; but gonorrhœa ceases without the resources of art, particularly if during its course the patient live a sober and regular life. The irritability of the urethra, the constitution of the patient, faults in diet, in exercise and choice of remedies, and perhaps also the nature of the virus itself, being more or less acrid, and of which the action will be more or less violent, often renders gonorrhœa a very severe disease. Experience confirms, that the sooner proper remedies are applied, and the sooner the patient is cured, the less he suffers; and the more certainly he avoids the disagreeable accidents which are so often the consequence of that disease. From this consideration, it is evidently of importance, either to prevent the disease entirely, or destroy it in its beginning. Two means have been proposed to accomplish these ends; one is, to remove the virus before it can act on the parts exposed to it; the other destroys and alters its nature, and prevents these effects from the moment that it gives the first signs of its action.

Different practitioners have tried and recommended various prophylactic remedies. Some have applied mercurial ointment upon the surface of the glans and prepuce, immediately after coition, and others different lotions and injections, as caustic alkali, lime water, alcohol diluted with water: these preparations being injected seven or eight times a-day, for several days after the commencement of the discharge.

By the use of injections the irritation is diminished, and the progress of inflammation stopped; and when the discharge becomes thicker during their use, they ought to be continued eight or ten days after it has disappeared; for if we were to give up too soon the use of these injections, the inflammation and discharge would increase. In this case it is necessary to make the injection stronger, and to use it more frequently. The advantages to be derived from this practice do not seem, however, to be altogether confirmed; and it is to be wished that enlightened and prudent practitioners would make some decisive experiments to determine whether injections are useful or hurtful in the commencement of gonorrhœa.

When inflammation has taken place, and when the discharge and other symptoms of gonorrhœa are completely formed, a different mode of treatment ought to be pursued. Repose, abstinence from all kinds of irritating food, wine, &c. will contribute much to allay the irritation.

In order to defend the irritable parts against the acrid matter, and to moderate the symptoms of inflammation, authors have recommended the use of mucilaginous, oily, and sedative applications. That which renders the urethra in man so violently affected by gonorrhœa, and so different from catarrh, is not from the difference of structure in the organ, which has been supposed to be more irritable than the mucous membrane of the nose and other parts of the body. It is the salts of the urine passing along the urethra, which keeps up the irritation produced by the virus. It has been proposed, in order to remedy this source of irritation, to give gum arabic or the infusion of linseed internally; but these, when taken in the necessary quantities, generally injure the stomach. An infusion of hemp has been found by Swediaur to answer all the purposes, and not to be subject to the inconveniences of the others. This remedy may be rendered more agreeable to take, by adding a little sugar to it; and in some cases a weak decoction of sarsaparilla may be advantageously added. All these drinks should be taken cold, or at least nearly milk-warm, and in small doses frequently repeated.

The antiphlogistic regimen must also be pursued in the treatment of gonorrhœa. The patient ought to avoid all exercise, or high-seasoned food. Lint, wet with a saturnine solution, should be kept constantly applied to the penis; and the patient should keep his bowels open with saline purgatives. When the symptoms of inflammation are considerable, and the pulse hard and frequent, bleeding becomes necessary, either general or topical: the constant application of fomentations and emollient poultices is also useful. Swediaur has advised, that camphor and the nitrate of potash should be given internally, and this should be continued according to its effects. Camphor alone, taken in the form of emulsion with sugar or fresh egg, is an efficacious remedy in allaying the pain and *ardor urinæ*. The use of camphor has also been recommended externally, with a view to allay the cordee.

These remedies ought to be continued as long as the pain and symptoms of inflammation in the urethra continue. After these are abated, the patient may be allowed a better diet, in order to prevent the urethra from being affected with a chronic gonorrhœa or gleet. Injections made of the extract of opium with acetate of lead, applied frequently from the commencement of the disease, contribute much to shorten its duration, and allay the accompanying pain. Sometimes, however, even the most mild injections do harm, from a particular irritable

Gonorrhœa.

state of the urethra. Great advantage has also been obtained by some, in very aggravated cases of the disease, by frictions of mercurial ointment on the perinæum, and along the course of the urethra, by opiate plasters, or by mercurial fumigations applied to the genital organs, and even by the injection of mercurial ointment into the urethra.

On the other hand, when the symptoms of erysipelatous inflammation prevail; when the patient is feeble, and of an irritable temperament; when he feels better after dinner; when the discharge is clear and profuse, accompanied with sharp pain, often lancinating throughout the whole urethra; and if the pulse is feeble and frequent, it is more adviseable to give him a less rigid diet; to allow him the moderate use of wine, and in some cases to give him opium and bark internally. We are sometimes surprised at the sudden changes which these remedies in such cases produce. The use of opium also contributes much to prevent cordee; and in all cases this ought to be avoided as much as possible, by fixing the penis downwards, and by making the patient lie on his side upon a mattress, which answers better than lying upon the back, and in a feather bed.

If in consequence of the violence of the inflammation the discharge stops, and the posterior parts of the urethra begin to be affected, we should have recourse to bleeding and the warm bath, or apply vapours to the part, by placing the patient upon a vessel containing boiling water, and this should be repeated three or four times a-day; the patient should keep in bed, and an emollient cataplasm be applied upon the penis. All kinds of injections in such cases are hurtful. The same treatment is also applicable when the discharge is stopped by the use of acrid and astringent injections, or by injections improperly used, or by the improper use of turpentine and balsams.

When the prostate glands and the neck of the bladder are affected, and the patient of a plethoric habit, it becomes necessary to bleed profusely, either at the arm, or by applying a number of leeches to the perinæum. In all these cases, a sedative cylster repeated every seven or eight hours, and a general or local warm bath used twice a-day, are the best remedies. Sometimes a blister applied to the perinæum is also useful.

The swelling of the lymphatic glands of the groin which sometimes takes place, is purely sympathetic, and disappears along with the inflammatory symptoms of the urethra.

In all cases of gonorrhœa the patient should wear a suspensory bandage whilst the disease continues *. It is also useful to persons who are obliged to take exercise, to wear a convenient bandage round the penis, which may be united to the suspensory in such a manner, that the penis may be enclosed in a kind of case, and thus defended from external injuries, from cold, and from friction; this bandage being kept constantly clean, by often changing the caddis, which is placed in its cavity. For this purpose, a hole should be left in the bag, covered by the caddis, which the patient can take away each time he makes water. Another general precaution which it is useful to make, is never to keep the penis bound up high, but to keep it low, in order that the matter may flow out freely, and may not pass backwards along the urethra.

* Plate DXIV. fig. 12.

The gonorrhœa of the glans and prepuce is generally easily cured, by injecting frequently warm milk between the glans and prepuce, and by keeping the penis in an emollient poultice. In those cases where the prepuce is so swelled that it cannot be pulled back, we ought to have recourse to sedative injections.

It is a useful general rule, which ought to be observed in all cases of gonorrhœa, to touch the parts affected as little and as seldom as possible; and every time they are touched, to wash the hands immediately afterwards, and with the greatest care, fearing that, by carrying them unintentionally upon the eyes, or nose, these organs might be inoculated with the disease.

In women.

Gonorrhœa in women is seldom followed by so violent symptoms, or by so severe and dangerous consequences as in men. In some cases the symptoms are so slight, that they conceive the discharge, particularly at its commencement, to be nothing but the whites, to which disease a great many are subject, especially in the large towns of Europe.

The gonorrhœa in women has been supposed by many authors to have its seat in the cavities of the urethra. This, however, will not be found the case. The disease is seated, either upon the clitoris, or on the orifice of the urethra; upon the nymphæ, or in the cavity of the vagina; or even upon the inferior commissure.

Treatment.

With regard to treatment, the same indications are to be fulfilled in gonorrhœa in women as in men, with this difference, that one can see the change of structure in these parts, and thus, from the seat of the disease, employ proper injections and lotions from the beginning.

Precautions in using Injections.—The syringe used in men for this purpose ought to have a short point of a conical form and of a thickness proportioned, that not more than its extremity may pass into the orifice of the urethra *. The body of the syringe should be perfectly cylindrical, and the piston play very accurately; for if the piston does not fit the body of the syringe, the injection, instead of passing into the urethra, regurgitates between the piston and the syringe. From the unsteadiness of the motion of the piston, the point of the syringe is also apt to move suddenly on the urethra, and injure its thin and delicate membrane. To prevent any injury of this kind, we have employed with great advantage, particularly if the mouth of the syringe is made of metal, a small strip of caddis wrapped in a spiral manner round the mouth of the syringe, so as merely to expose its point. If the disease be seated near the point of the urethra, the patient should be attentive to compress with one hand the urethra above the arch of the pubis, where the scrotum commences, whilst with the other he holds and guides the syringe. The liquid should be thrown in gently, so as slightly to distend the urethra, and be kept for a minute or two; the same operation being repeated two or three times in succession.

* Plate DXIV. fig. 12.

The liquid employed should always be used warm, which may easily be done by filling a cup with the necessary quantity, and placing the cup in a bason of boiling water.

It often happens, particularly in young people, that after

Gleet.

after having used injections some time with advantage, they become less attentive, and neglect them for a day. This omission is always followed with bad consequences, the discharge returning with double force; and the patient is obliged to continue the injections during some weeks more than would have been necessary, if the use of the remedy had not been interrupted.

In order, therefore, to prevent the danger of a relapse, it is always prudent that patients inject three, four, or even six times a-day, if the circumstances demand it, and to continue the same two or three times a-day regularly for at least ten or fifteen days after the discharge has entirely ceased.

For women the canula ought to be larger and longer. A canula of ivory, an inch in diameter, and two or three inches in length, fixed to a bottle of elastic gum, is the most convenient form of a syringe *.

* Plate DXIV. fig. 15.

Of Gleet.

It very often happens, that even after the specific inflammation of the urethra is removed, from which gonorhœa is supposed to originate, a discharge continues. This discharge is not generally attended with pain, nor can it be communicated from one person to another. The matter which escapes is generally of a tenacious consistence, and of a yellow colour, appearing to be composed of globules, mixed with a mucous fluid. When a cure cannot be procured either by the use of injections, or by bougies, it has sometimes been proposed to inject liquids capable of exciting irritation and inflammation in the affected part of the urethra. It is probably on this principle that some gleets have been cured by violent exercise on horseback, or a long journey. There have also been cases cured by coition; but this is not to be recommended, as there always may be a certain risk of communicating the disease to the women. A blister, applied externally to the part affected, or to the perinæum, has also been found useful. The cold bath has often been recommended in obstinate gleets, from which good effects often result; but there are other cases in which it seems to increase the discharge.

It is also proper frequently to change the injection; for it is observed that an injection less strong sometimes produces a good effect, after a strong one has been employed without success, and *vice versa*. In many cases it is useful to combine internal medicines with external means. The chief are mercurial preparations, balsamic and resinous substances, and tonics. Swediaur has used, with much success, in gleets, pills made of turpentine and oxide of mercury. Among the resinous substances which are employed, the most common is the balsam of copaiba. The best way of taking this remedy is to give from thirty to sixty drops in a small glass of cold water three times a-day, and afterwards to take, in a small glass of water, twenty drops of the elixir of vitriol, which renders the balsam less disagreeable to the stomach. Half a dram of turpentine, of the balsam of Tolu, or of the balsam of Canada, answer the same end. Swediaur mentions the case of a young man, who, having been for a long time distressed with a very obstinate gleet, swallowed at once between two and three ounces of the balsam of copaiba, and was cured.

Sometimes the balsams, combined with tincture of guaiac, or with kino, produce a desireable effect.

Among the corroborant or tonic remedies, the kino, which we have already mentioned, is one of the most useful; the cinchona also in powder or infusion in red wine, or, which is still better, in lime water; tormentilla in powder, or in extract, in the form of pills, joined, according to circumstances, with preparations of iron, are useful and efficacious remedies. The tincture of cantharides, given in a dose from twenty to thirty drops three times a-day, has often been found very beneficial. It is one, however, which ought to be given with precaution, as it may do much harm to people of a delicate and irritable temperament.

There are, however, cases, where all our efforts to cure a gleet are fruitless; and we sometimes see, that nature alone can in time succeed, after we have uselessly tried all the resources of art.

Sometimes there remains a species of cordee or curvature of the penis after all the other symptoms of gonorrhœa have disappeared. Frictions, with mercurial ointment, with camphorated oil, spirituous lotions, or electricity applied to the part, are most appropriate remedies in such cases.

In all cases of obstinate gleet, situated far back in the canal of the urethra, the state of the prostate gland should be carefully examined; for they often arise from a disease in that part. When the prostate is found swelled and hard, Swediaur has seen instances where, after a mercurial treatment, the repeated application of cupping-glasses to the perinæum, and the use of large doses of the *conium maculatum*, has succeeded.

The gonorrhœa of the prostate is a morbid discharge of mucus from that gland, mixed sometimes with the liquor of the seminal vesicles; and it takes place principally through the day, without any venereal desire. This disease is soon followed by feebleness and general debility, with emaciation of the whole body, and even with death; particularly if the patient has not employed proper remedies.

The remedies most efficacious are the cold bath, injections of metallic salts, fomentations of hemlock, blisters to the perinæum, and internally tonic medicines, with a well-regulated diet.

Coryza.

Sect. III. *Of Inflammation of the Mucous Membrane of the Nose.*

Inflammation of the mucous membrane of the nose is generally preceded by dryness in the nostrils, with an itching feeling, and a weight over the forehead. It is also accompanied with sneezing and an increased flow of tears. The secretion of mucus from the nose is at first diminished, and afterwards becomes very abundant. At first it is limpid and irritates the sound skin of the upper lip, over which it passes, and becomes afterwards opaque, of a yellowish white colour, and a disagreeable odour. This state is sometimes accompanied by fever, and it continues for a longer or shorter period. Most commonly it ceases at the end of a few days. It sometimes, however, becomes chronic and indetermined, in which case it is often intermittent, and re-appears at regular

Otitis.

regular periods. Coryza, like all other inflammations of the mucus membranes, terminates by resolution. It sometimes passes into the state of chronic catarrh, and it also occasions an ulceration of the mucous membrane of the nose; but this is extremely rare.

Coryza is frequently accompanied with inflammation of the mucous membrane of the eye, it also spreads in many instances along the eustachian tube, producing deafness, and it is very apt to extend down the trachea and affect the lungs.

The nose is sometimes affected with a discharge of thick viscid mucus, when there is very little apparent redness or pain. Such instances are often connected with the formation of polypi: but we have observed several cases, where no other symptom than the mucous discharge appeared, and where the disease had very much the general character of some discharges from the urethra.

Treatment.—Coryza is commonly an affection so slight, and of such short duration, that it is seldom necessary to employ any vigorous means to produce an abatement of its symptoms. Somtimes, however, the symptoms go to a very high degree, and it is then that emollient vapours directed into the nasal cavities are particularly indicated. If much symptomatic fever accompanies the disease, it may be adviseable to draw some blood from the arm, and in all cases a brisk purgative will be found to relieve the fulness and uneasiness in the head. When the inflammation spreads along the mucous membrane of the trachea, it becomes the more necessary to use every means to alleviate the inflammatory symptoms, and to prevent the inflammation affecting the mucous membrane of the bronchi.

Patients labouring under this disease, feel remarkable relief from living in a warm atmosphere; and the symptoms of inflammation of the nose and trachea will be much alleviated by the internal exhibition of opium.

When the inflammation and the discharge are of a chronic nature, astringent injections, or a dossel of lint dipt in similar solutions, and kept in the nose during the night, are in such cases the most useful applications. They gradually diminish the quantity of the discharge, and render it more thick and tenacious; and the sense of smelling, which is commonly destroyed, is restored.

If the discharge be fœtid, and occasionally mixed with blood, in all probability it originates from the formation of an abscess or ulcer, connected with a carious bone.

SECT. IV. *Of the Inflammation of the Mucous Membrane of the Ear* (Otitis).

In inflammation of the ear, there is the same characters of the disease deduced from analogy of structure, as in other mucous membranes. The principal causes of this disease are sudden changes in the atmosphere; above all, the change from heat to cold, or from dryness to moisture; coldness of the nights, north winds, suppression of any regular discharge, the crisis of acute diseases, metastasis, the presence of an irritating body in the ear, or the imprudent application of oily or spirituous substances.

The inflammation sometimes takes place in the *meatus auditorius*; and in other cases it is confined to the cavity of the tympanum and eustachian tube. In the first case, there is more or less pain, and buzzing in the ears, and afterwards a discharge of thin reddish yellow matter. This matter gradually becomes white and opaque, and increases in consistence till the termination of the disease; when it differs in nothing from the wax of the ear, but in its white colour. This affection generally lasts twelve or fifteen days. It sometimes spreads to the external parts of the ear, and often passes into a chronic state.

When the inflammation is confined to the cavity of the tympanum, it produces an obscure tingling sensation, and a feeling of tension, which the patient supports without much inconvenience; but most frequently the inflammation is propagated from the cavity of the tympanum along the eustachian tube. In this case, the pains become more violent and extend along the contiguous mucous surfaces; they pass from the interior of the ear into the throat; there is great difficulty in swallowing, and the food, when passing through the pharynx, gives a sensation as if the skin had been eroded. The motions of the neck also become uneasy, and the smallest attempt to cough, to sneeze, or blow the nose, produces a painful sensation to the ear. The patient also complains of a stoppage in the nose, of a frequent dry cough, and of pain in the head, and more or less fever in the evening. The ear also feels hard or distended, and there is generally deafness, particularly towards the termination of the disease. Soon all these symptoms diminish except the hardness in the ear, which augments continually till the fifteenth or twentieth day. Most commonly after this period, a quantity of fœtid matter is suddenly discharged into the external ear, or into the throat, and then all the symptoms disappear. This discharge generally diminishes daily, and in a short time ceases altogether. At other times, particularly in young people, it continues, and becomes chronic.

Treatment.—When the inflammation is confined to the external meatus, the disease is generally so slight that it may be allowed to run through its common periods, and it is merely necessary to keep the patient warm. When the inflammation is very considerable, the mildest injections give pain, and in place of moderating the symptoms, they increase the irritation. We ought therefore to do nothing, except, perhaps, to allow some warm vapour to pass into the ear, to apply a poultice externally, and to pursue the antiphlogistic regimen. About the twelfth or fifteenth day, it may be useful to apply tonic medicines, such as a piece of cotton dipped in aromatic alcohol. When the inflammation is in the tympanum, or the eustachian tube, besides emollients, it will also be necessary to give some brisk purgative, or to employ local or general blood-letting. If the membrane of the drum be much distended, and accompanied with violent pains, it has been proposed to make an opening through the tympanum*. When the matter has been discharged from the tympanum either spontaneously or artificially, little more is required to be done, unless the disease assumes a chronic form. This is most frequent in children. We often see the purulent discharge continue in them for many months, and some of the small bones of the ear become carious, and are discharged along with the matter. In such cases small does of calomel, for some time repeated, blisters behind the ear, and injections of lime water

* Nosographie Philosophique par Pinel.

Angina.

water combined with muriate of mercury, acetate of lead and the like, should be employed.

Sect. V. *Of Angina.*

The parietes of the mouth, trachea, and larynx, are often inflamed in catarrhal affections, and present symptoms which vary according to the intensity of the disease, and particular seat of the affected membrane.

Angina has therefore been distinguished according to its seat in the tonsils, the trachea, the pharynx, and larynx.

When the patient has great difficulty in swallowing his food, and when the pain stretches in chewing, to the ear along the eustachian tube, by a sort of crepitation, and if, on inspection of the throat, the amygdalæ and edge of the palate appear much inflamed, along with an abundant excretion of mucus, the angina has its seat principally in the amygdalæ.

Angina affects the pharynx when deglutition is difficult or impossible, and the food is returned by the nose, respiration not being at the same time impeded. This inflammation is also visible by examining the bottom of the mouth. But if the deglutition is difficult; if no redness is perceived at the bottom of the throat, and if the patient has great difficulty in respiring, a sharp pain in the motions of the larynx, the voice acute but weak, and the speech short, we may then conclude that the inflammation has attacked the larynx, or upper part of the wind-pipe. An affection of this kind, though a few cases have been known to take place in adults, generally attacks children under twelve years of age. It is known by the name of *croup.*

When the inflammation affects the amygdalæ, inhaling steams of warm water and vinegar will often be found to give great relief. A poultice, too, applied to the outside of the throat, assists in lessening the tension of the inflamed parts. Though in many cases the inflammation seems to be confined to the mucous covering of the glands, yet in others it spreads into the glandular substance, where it generally advances to suppuration. In such cases, the early discharge of the matter gives great and immediate relief; and though no matter has been formed, puncturing the inflamed part with a sharp instrument often produces an alleviation of all the symptoms. The instrument delineated in Plate DXIV. fig. 14. is well calculated for these purposes. By altering the position of the screw in the handle, the depth of the cutting part of the instrument may be regulated. When used, the fore finger of the left hand is to be introduced down the mouth, and the perforator concealed in the canula introduced as a director. When the extremity of the canula reaches the inflamed part, then the perforator may be safely pushed into it, to a depth which had previously been regulated.

When the inflammation affects the pharynx, relief will also be obtained by inhaling the steam of warm water, and by employing antiphlogistic remedies. In croup, calomel has been found to have a specific effect; and it is astonishing the quantity that has been given to infants for the cure of that disease. See MEDICINE.

When the albuminous effusion which takes place in croup, is chiefly confined to the upper part of the larynx, and produces symptoms of suffocation, it has been proposed to make an artificial opening into the trachea, below the place where the matter is effused, in order to save the life of the patient. See BRONCHOTOMY.

Of the Catarrh of the Bladder.

Sect. VI. *Of the Catarrh of the Bladder.*

The ureters, the bladder, and the urethra, are all liable to be affected with catarrhal affections from general causes, the same as those affections of the mucous membranes which have been already mentioned; and besides, the surfaces of the mucous membranes of these parts are exposed to the action of particular causes, namely, the ureters and the bladder to calculi, and the urethra to the venereal virus.

The catarrh of the bladder is more frequent among men than among women; and old people are more subject to it than those at any other period of life. It is often produced by the internal use of cantharides, and by acrid diuretics. The sudden exposure to cold, suppressed perspiration, the disappearance of different diseases of the skin, of rheumatism, and of gout, are sometimes followed by this catarrh. Other circumstances may also give rise to catarrh of the bladder. The presence of a calculus or any foreign body, the continual application of bougies, a swelling of the prostate gland; and above all, strictures of the urethra.

This disease is marked by pains of the bladder, and at the point of the urethra, both before, and whilst making water. The hypogastric region is tense, and the urine presents a variety of colours; it is sometimes whitish or reddish, or of a deep yellow colour; and it is muddy, exhaling an odour of ammonia, which becomes more sensible a short time after it has cooled. It also forms, in most cases, a mucus, which mixes and comes away with the urine in the form of glairy filaments, and which is afterwards deposited at the bottom of the vessel in the form of a tenacious glairy substance, resembling somewhat the white of an egg.

The chronic inflammation of the mucous membrane of the bladder, may be accompanied with an ulceration of the kidneys or bladder; the mucus discharged then becomes of a greenish yellow colour, sometimes mixed with streaks of blood. It is deposited slowly, is mixed easily among the urine, and in water; it has little viscidity or fœtor, and does not coagulate by ebullition. The other symptoms which accompany this excretion, as fever, pain, wasting of the flesh, sufficiently distinguish this double affection of the bladder. The chronic catarrh is subject to return with great pain in the region of the pubis and perinæum, accompanied with restlessness and anxiety. These intermissions are irregular, and may remain some weeks.

Treatment.—The matter secreted by the mucous membrane of the bladder, and other membranes of the same class, is sufficient to point out the means to be employed in its treatment. The warm bath, and mucilaginous drinks, are particularly indicated at the beginning of the acute catarrh; but the tendency which it has to become chronic, ought to make us cautious in not

prosecuting.

Strictures. prosecuting the use of debilitating remedies too far. Opium should be employed with great prudence, notwithstanding the intensity of the pain; and as this is often the result of distension of the bladder, from the accumulation of urine, it is sometimes necessary to have recourse to the introduction of the catheter.

The chronic catarrh of the bladder is generally difficult to cure, and the more so, if it occur in old age: If it arises from stone in the bladder, there is no cure but the operation of lithotomy; if it arises from metastasis, rheumatism, or any other disease, we ought to employ remedies to the skin and intestinal canal. The uva ursi has also been found a useful remedy. Exercise, dwelling in dry and elevated places, the use of woollen clothes next the skin, contribute often more to the cure of this disease, than the use of medicines, and ought always to be combined with them.

The conjunctiva covering the eye-ball, eye-lids, and lachrymal passages, are also subject to inflammation; but these will be treated of among the diseases of the eye and its appendages.

Sect. VII. *General Remarks on Strictures.*

The term Stricture has been usually applied to a contraction of the urethra; generally arising from a thickening of the mucous membrane lining that canal. This change of structure is not, however, confined to the mucous membrane which lines the urethra; the same morbid alteration takes place in the œsophagus and rectum, in the eustachian tube and meatus externus, in the maxillary sinus, in the bladder, in the lachrymal passages, and in all canals lined by mucous membranes. Strictures, however, occur much more frequently in the urethra, and are there more pernicious than in any other part. They appear also sometimes in the upper part of the œsophagus. A similar change has been observed in the internal part of the bladder. Bichât found the membrane lining the maxillary sinus several lines in thickness, and also the canals of the tympanum much thickened *; and reasoning from analogy, and from what may be observed by an attentive examination of the symptoms in many cases, of what is usually called fistula lachrymalis, there is little doubt but a contraction and thickening often take place of the mucous membrane lining the lachrymal sac and duct.

* *Anatomie Generale*, tom. iv. p. 431.

This change in the structure of mucous membranes is always the consequence of inflammation; and when the membrane is thus altered, the discharge, instead of being healthy mucus, is generally a puriform fluid, apparently a mixture of pure mucus with globules of pus.

Sect. VIII. *Of Strictures in the Urethra.*

The treatment of the diseases of the bladder and urethra has always been considered a difficult branch of surgery, as their true nature is often obscure, and as it is by no means easy to direct the proper means of relief.

Of the great variety of causes which disturb the functions of these organs, strictures in the urethra are perhaps the most frequent, and most serious. They prevent the free evacuation of the bladder; greatly disturb, if not entirely destroy the function of generation; and often give origin to constitutional symptoms which sometimes increase to an alarming degree, and even prove fatal.

Strictures of the Urethra. That the urethra should be subject to many morbid changes, we may infer, not only from our knowledge of the functions it performs, but also from its delicate and no less complicated structure.

One part of this structure is intended for the evacuation of the urinary bladder, the other for the transmission of the seminal fluid; and as in the exercise of this last function, the urethra sympathises, in a greater or less degree, with the whole system, and also with the mind itself, it must have a connection with many of the other organs of the body. Accordingly, we find that patients who have obstructions in the urinary canal, have at the same time other complaints, which get well when the obstruction is removed. And, on the other hand, diseases of other parts bring on morbid affections of the urethra, which are cured along with the primary complaint.

The whole extent of the urinary canal is lined by a delicate membrane, constantly covered with a viscid fluid, secreted by numerous glands, whose ducts open on its internal surface by orifices, which are called lacunæ. It is highly vascular, and is endowed with so much sensibility, that irritating bodies applied to it often affect, or even derange the whole system. It has a considerable degree of contractility, is evidently elastic, and perhaps may possess a muscular power, although no muscular coat has yet been demonstrated; but to whatever cause this contractility be owing, it is well known that it does not contract upon irritation. As a proof of this contractile power, a remarkable case was mentioned by Mr Cline in his lectures, where a stone, lying in the membranous part of the urethra one evening, had been expelled during sleep, and was found among the bed-clothes the following morning.

The contraction which forms a stricture in the urethra may take place round the whole circumference of the canal; it may arise chiefly at a particular point of the circumference; or, it may extend along a considerable extent of surface, thus are produced obstructions of different forms.

The stricture once begun, continues no longer than the cause which first produced it continues to operate. But if the parts are kept long in this state of contraction they generally are attended with a degree of inflammation; the membrane of the urethra acquires a morbid degree of thickness; the surrounding parts are altered in structure; and this change of form and appearance remains after the cause which originally produced them has ceased to operate.

That spasmodic strictures do exist appears from the impressions made on bougies which have been passed through them, and from the examination of the parts after death; for although complete obstructions to the bougie were found when alive, yet not the smallest remains can be observed on dissection. This contraction is peculiarly violent, and from what we have observed is more frequent, at the fossa navicularis than at any other part of the canal. A gentleman, after many attempts to make water during the night, was not able to pass a drop, and he applied for relief in the morning. A bougie was introduced, and met with a complete obstruction at the glans, which yielded

Strictures.

yielded in a few seconds after the bougie was in close contact with it. On being withdrawn the urine flowed freely, and the complaint has never since returned.

Contraction at this place is sometimes so violent as for a long time to interrupt the entrance of the bougie; and in one case, after being introduced, was so strong as nearly to cut the instrument through. This happened repeatedly with the same patient.

When there has been a permanent stricture, the natural structure of the urethra is changed. There is commonly a contraction at one particular part of the canal; and its appearance has been compared to what would have been given had a pack-thread been tied round it. In slight cases it is a mere narrowing *.

When a ridge is formed projecting into the cavity of the canal, it is found to be a doubling of the inner membrane, with the cellular substance lying between the fold. The internal membrane itself is diseased; it assumes a whitish colour; becomes hard, sometimes as hard as cartilage; and in some cases this change is confined to the doubling of the stricture itself, whilst in others it extends into the cavernous bodies. These ridges or folds often form over one another, so that the intermediate portion of urethra becomes preternaturally contracted also; but it never becomes so narrow as at those parts where the original strictures were formed. Instead of a distinct curtain or fold, it happens also in some cases that the urethra has the appearance of a cone gradually converging before the stricture, and diverging in the same manner behind it.

* See Plate DXIV. fig. 6. and 7.

The contraction is generally round the whole of the circumference of the urethra: but sometimes it is only at one side, and in such cases the urethra does not form a uniform tube, but becomes serpentine and contorted in various directions.

When one stricture is formed, the portion of urethra anterior to it is liable to suffer some changes, which probably arise from its not meeting with the ordinary distension, the stream of urine being diminished. It is by no means uncommon, therefore, to find in those cases where the original stricture has been formed near the bladder, another stricture anterior to it, so that when an obstruction is found at the glans or four inches and a half from it, another is generally met with at seven inches, or at the bulb.

Situations of stricture.

From the peculiarity in the form of the urethra, some parts are much more subject to strictures than others. In the adult, and in the relaxed state, the urinary canal is about nine inches long, and nearly of the same diameter as a common quill; but its size varies at three different points, and at these strictures most frequently arise. The contractions are at the glans, the bulb, and the prostate gland (see fig. 5. Plate DXIV.). The narrowest part is just below the bulb, and here strictures most frequently occur.

The natural contraction renders it, in almost every case of stricture, the seat of the disease. This part of the canal seems also to possess an uncommon degree of irritability, as it is here that the contraction takes place in cases of strangury. When strictures continue long, and the violence of the symptoms increase, diseases arise in other parts. The urethra between the stricture and bladder, from the obstruction the urine has to overcome, enlarges, and is sometimes attacked with inflammation.

As the stricture is in most cases attended with a gleet, the glands situated about the neck of the bladder become diseased. The bladder becomes extremely thickened, and its capacity diminished, from the strong exertions it is necessary to make in order to overcome the obstruction, and as it cannot contain much urine, the ureters become dilated.

When the disease advances still farther, so that it is impossible to evacuate the bladder, from the obstruction being complete, the urine escapes by some new channel; for as in such cases the parts between the bladder and obstruction make less resistance than its coats, both on account of their natural structure, and as these parts are generally inflamed or ulcerated, they give way, and the urine takes a new course. When this change has once taken place, so that no urine passes through the meatus urinarius, the other symptoms will differ according as the aperture has been formed by ulceration of the inner membrane of the urethra, or by a sudden rupture. For when the membranous part of the urethra has been eroded, a suppurating cavity must have formed in the contiguous cellular substance, and as the urine cannot so easily be diffused in the surrounding parts, it makes its way without difficulty through the integuments. But when a sudden rupture or ulceration of the inner membrane of the urethra takes place, as the urine meets with no obstruction in insinuating itself into the cellular membrane, it effuses itself in a short time over the perinæum, scrotum, and adjacent parts; extensive abscesses are formed where the urine was diffused; and as these burst in numerous places, fistulous openings are formed, which have either a direct or indirect communication with the bladder, and through which the urine continues to pass till the original obstruction is removed.

Symptoms.—Often this complaint does not become of such importance as to give alarm to the patient till many months, or even years, after the original cause has been forgot. At other times, a few months after a gonorrhœa has been cured, the urine, instead of coming away with the accustomed ease, begins to be passed with difficulty. The stream, in place of being full and even, diminishes and becomes unequal; sometimes it comes in drops after much straining and exertion, has a forked appearance, or scatters in different directions. From the irritable state of the parts, the smallest quantity collected in the bladder, brings on a desire to make water, and a continual uneasiness along the course of the canal, about the perinæum, anus, and lower part of the abdomen. In most cases there is a discharge of matter from the urethra. The gleet is always more severe after any debauch or venereal act. It comes on immediately after such excess, and gradually diminishes or disappears. It is also not unfrequent to find strictures accompanied with that profuse discharge of mucus from the bladder called *catarrhus vesicæ*. The irritation communicated to the bladder in consequence of the disease of the urethra, brings on inflammation, which is followed by a profuse discharge of mucus from the whole of its internal surface, and this mucus comes away with the urine, and is deposited, and firmly adheres at the bottom of the pot in the form of a tough tenacious mass.

Strictures.

Nocturnal emissions are sometimes the only symptoms which lead us to suspect the existence of stricture; for in some cases the disease is neither attended with any fixed pain in the urethra, nor is there any discharge of matter.

Fistulas in the perinæum, and along the course of the penis, often derive their origin from an obstruction of the urinary canal.

When, either from irritating injections, bougies, or any other cause, inflammation comes on, the urethra is completely shut at the place of the stricture, and the internal membrane giving way, the urine is effused in the cellular membrane, which gives rises to abscesses and fistulous openings, through which the urine continues to pass, till the stricture is removed. The inflammation in some cases spreads to the surrounding parts; the mucous glands inflame, suppurate, and burst; and hemorrhoidal tumors often form at the extremity of the rectum.

Besides these, the more usual symptoms of stricture, there are others which accompany that complaint, and arise from constitutional causes. The most frequent is a febrile attack, in the form of a complete paroxysm; but it differs from the common intermittent fever, in its short continuance, its irregularity, and in the violence of its termination. It happens most frequently to those who have been in warm climates; but it is by no means confined to them alone.

People of weak constitutions have often sickness at stomach, nausea, and vomiting, and sometimes an uneasy state of irritability about the stomach, which gets better when the stricture is relieved.

Gout, epilepsy, hydrocele, sciatica, erysipelas, have all been found connected with stricture; but such cases rarely occur.

There are other diseases of these organs which have so many symptoms in common with stricture, that it is necessary to inquire with much attention into the history and state of all the symptoms, before we can judge of the true nature of the complaint; and when there is any reason to suspect that an obstruction exists, it is ascertained only by the introduction of a bougie; but the mode of doing this will be explained when speaking of that instrument.

Diagnosis.

There are diseases that ought to be mentioned as being liable to be mistaken for stricture, and always kept in view in forming the diagnosis. An irritable state of the urethra, proceeding from gonorrhœa, is one that is very frequent. In such a case there is a discharge of matter and a pain in making water. The urine flows in a small stream at the commencement, but before it is all evacuated it is of the natural size. The symptoms come on a few hours after coition, but abate in a short time, and whenever the irritating cause is repeated, they return.

The bladder also, when irritated, brings on diseases of the urethra, as these parts sympathize so strongly with one another; but when the primary affection is in the bladder, there are always symptoms which aid us in discovering the true complaint.

Enlargements of the prostate gland are by far the most apt to mislead our judgment. Scrophulous and schirrous enlargements of that organ were at one time supposed to be very frequent causes of retention; it is now generally believed that they occur seldom, and are chiefly confined to people advanced in life.

It will be afterwards mentioned how swellings of the valvular process of the prostate are apt to be mistaken for stricture when a bougie or catheter is introduced. The obstruction in such a case is always at a distance, as the canal has increased in length from the enlargement of the parts. If attention be paid to this remark, and if the gland be at the same time examined from the rectum, little doubt will remain of the nature of the disease.

It is often difficult to draw off the water when the prostate gland has become thus diseased: to do this, much advantage will be found in using a catheter longer than ordinary, as the common curve cannot reach the extremity of the urethra from the increased length of that canal. Pouches or irregularities are also apt to form from the unequal growth of the gland; and as the ducts of the seminal vesicles and mucous glands become enlarged, the instrument ought to be of a large diameter to avoid being entangled by them.

Causes of stricture.

From the idea we have of the manner in which strictures are formed, we infer that many substances of an irritating nature, whether applied immediately to the parts themselves, or to those connected with them, may, under particular circumstances, produce this disease. The stone irritating the bladder, numerous diseases of that organ and prostate gland, irritations in consequence of gonorrhœa, long and repeated erections or other stimulants, and the natural disposition which the urethra has to contract in some constitutions, are the common causes of stricture. In whatever manner irritation is produced, the symptoms and changes observed in the structure of the urethra, make it probable that there is always a certain degree of inflammation subsequent to or accompanying it. Obstructions in the urethra were supposed by Daran, and others about his time, to originate from causes very different from those now mentioned. They conceived that the discharge from gonorrhœa proceeded from internal ulcers, and that the cicatrices and indurations they left behind were the most common causes of stricture. But since the nature of the discharge from gonorrhœa is found very rarely, if ever, to be purulent, and as ulcers occur seldom, they cannot be considered as a common cause of the disease.

Caruncles were also supposed to be frequent causes of obstruction in the urethra; but these are rarely met with. One preparation of such a case may be seen in the museum of St Thomas's Hospital. Indeed, since the internal membrane of the urethra so much resembles that which lines the cavities of the nose, mouth, and œsophagus, and as ulcers in these parts are more disposed to form skin and heal, than to produce fungi, few cases of obstruction can be ascribed to such tumors.

The other causes which prevent the free discharge of urine, are those which are attended with no morbid change in the structure of the urethra itself.

Such are tumors or indurations of the prostate gland, of the vesiculæ seminales, or parts composing the body of the penis, or of the mucous glands along the course of the canal.

By far the most common of these, is an obstruction into the entrance of the bladder, from a diseased prostate gland.

Strictures.

gland. This proceeds from a new form which the canal has assumed in consequence of an enlargement of its parts. Its cavity becomes deeper from the growth of its sides, and the posterior extremity or valvular process forms a projecting tumor into the cavity of the bladder, which interrupts the passage of the urine, or the entrance of a catheter. From the frequency of this appearance in diseased prostate glands, it is probable that it is the cause of diseases of that organ being often mistaken and treated as strictures of the urethra, and has in numerous instances not only prevented the introduction of a bougie into the bladder, but has been the cause of the formation of artificial passages through the substance of the gland.

Treatment of Stricture.—From the erroneous ideas that the older surgeons formed of the nature of strictures, it was not to be expected that the means of cure they employed were either founded on just principles, or attended with much success. They made use of various external and internal remedies; they prescribed long and tedious courses of mercury, and gave many medicines which were supposed to have peculiar virtues in curing diseases of these organs. They sometimes introduced into the canal mechanical instruments in order to dilate it; and when that was impracticable, a new passage was made by force, or the diseased parts were dissected away, and a new canal formed in the sound parts.

Wiseman's practice.

Wiseman, so far back as the beginning of the last century, exploded many of these rude and dangerous practices, and introduced into use the *waxed candle* or *bougie*, by means of which he said he "crushed the carunculi to pieces." He met with cases, however, where this could not be done; that is to say, cases where it was impracticable to pass small bougies into the bladder; and this led him to adopt another mode of treatment. He consumed them by stimulating applications in the following manner. The wax at one end of the candle was scraped away, and the wick dipped in plasters composed of alum, red precipitate, calcined vitriol, ærugo, and other such substances, and then it was applied to the caruncle. "But (says he), if after doing this you cannot pass the caruncle, you may well conclude it callous; in which case you may pass a canula into the urethra to that caruncle, and whilst you hold that there steady, you may convey a grain of caustic into the canula, and press the caustic to it; and whilst you hold it there, you will perceive its operation by the pressing forward of the caustic. The caruncle thus consumed, cast in a lenient injection daily; and if you take notice of his urine, you may see the separation of the sloughs as rags in it. After which you may with the common medicated candles wear away the remainder, and with the injectious cicatrize it."

The use of caustic proposed by him.

After Wiseman, Daran introduced into use a kind of bougie, the particular composition of which was kept secret. They were supposed to possess very great medical virtues; and it was from these qualities that their superior efficacy was supposed to proceed. Other surgeons soon began to imitate them, and they found that those they made had the same qualities as those of the original inventor. This led them soon after to alter their opinion of their mode of action; and instead of supposing that all the beneficial effects proceeded from the medicines in their composition promoting suppuration, cicatrization, &c. they explained their action on the principle of a simple wedge.

But however successful their practice might have been in alleviating, if not in curing strictures, yet many cases occurred where the obstruction was so complete as altogether to prevent the bougie being introduced. They were therefore obliged to continue forcing past the obstruction, till the mode of treatment described by Wiseman was renewed, and held out as an original invention. The practice, indeed, generally followed by modern surgeons is founded entirely on what Wiseman has written; but since these have been better understood, from the progress of pathological investigation, it has been considerably modified and improved. When we consider the effects of these modes of practice, and try to reconcile them with the ideas we have formed of the causes producing the stricture, it would appear that those very means employed for their removal belong to the same class of bodies with those originally producing the complaint.

Though this cannot be denied, yet it will appear neither surprising nor improbable, when we reason from analogy, and observe the effect of similar applications to other diseased parts, and similar phenomena in other organs. It may here be observed, that the action of any part depends not only on the kind of the stimulus applied, but also on its degree of violence. We know that a slight pressure on the skin produces uneasiness or tickling, whilst in a stronger degree it passes unnoticed. A certain degree of light produces distinct vision, but a more intense one destroys it. The upper part of the throat is thrown into violent action by a slight irritation. Similar phenomena take place in disease; or slight irritations sometimes occasion violent morbid action, whilst those that are more powerful not only produce a lesser degree of disease, but are even employed to remove such as are brought on from a slighter cause. We see this opinion strongly confirmed in ulcers, attended with much local or constitutional irritation. The most emollient applications in such cases, if they do not increase the sufferings of the patient, bring no relief; whilst strong stimulating ones, such as a solution of lunar caustic, or diluted nitrous acid, seldom fail to diminish the pain and promote the cure of the disease*. In toothach, the irritation produced by the external air on the exposed nervous surface excites much pain and even symptomatic fever; but the application of caustic or acid destroys these sensations. The same we will find to take place when we consider the nature and the mode of treating strictures of the urethra; and if we can prove that strictures have all that variety of character which an ulcer or many other diseases have, we will be better able to judge of the comparative merit of the different modes of treatment, and in some degree to account for their mode of action.

* See *Home's Observations on Strictures.*

Of the Bougie.

When surgeons attributed all the beneficial effects of bougies to their mechanical qualities, the principal desideratum was to have them sufficiently pliable to take the

Strictures.

curvature of the urethra, firm and elastic to make resistance, and mild so as to produce no irritation. But however simple such instruments might be in their composition, yet it will appear that their effect is not the same as that which a wedge produces on inanimate matter. That bougies cannot act by their mechanical powers in removing spasmodic stricture, appears from those cases where the mere introduction of the instrument into the urethra, and its contact with the obstruction, removes at once all spasm.

The same thing is observed in those cases of permanent stricture which are attended with occasional spasm. In such cases it frequently happens that a bougie finds a complete obstruction on its first introduction, but after being allowed to remain for some time in the canal it passes readily without force. A remarkable case of this kind happened, where there was not only a stricture in the urethra, but fistulous openings in the perinæum and scrotum, through which most of the urine was discharged. After much trouble, a very small-sized elastic catheter was passed into the bladder, and as it gave no pain it was allowed constantly to remain. For the first five days the urine flowed through the instrument, but afterwards it began to pass along its sides; and gradually as the urethra dilated, larger instruments were introduced with similar good effect. The silver stiles used by Mr Ware seem to act, in removing obstructions of the lachrymal passages, on the same principle as the catheter in the above example. The stile when first introduced, fills up completely the lachrymal duct; but in a short time the tears begin to flow along the sides, and pass into the cavity of the nose. In these examples it is difficult to explain the action of bougies on mere mechanical principles; it seems much more probable that they produce their good effects, either by a change of action of the living body, or by some alteration in the structure of the diseased parts. Says Hunter, "Pressure produces action of the animal powers, either to adapt the parts to their new position or to recede by ulceration."

Mode of introducing the bougie.

When speaking of the symptoms of stricture, it was observed, that in order to determine with certainty their presence, it was necessary to introduce a bougie. To do this, either with a view of ascertaining the state of the urethra, or in order to remove a stricture, a good deal of caution and nicety is required; for as the urethra is generally tender, painful, and easily thrown into spasmodic action, any awkwardness might entirely prevent the possibility of ascertaining the nature of the complaint, or of affording the means of relief.

When, therefore, the operation is to be performed, in order to discover the kind of obstruction, bougies ought to be provided of different sizes, of a soft consistence, and of a cylindrical form *. One of the size of a common goose quill, or even larger, generally passes easily, and is less apt to meet with obstructions before it comes to the stricture, than one of less diameter. Being of a soft consistence, it readily takes an impression of the stricture, and its blunt point prevents its being entangled by any accidental irregularity.

* See Plate DXIV. fig. 2.

As it ought always to be rubbed over with oil before being used, it generally passes with little more force than its own weight, till it comes to the contracted part, where it stops. After changing with much caution the direction of the point, by elevating or depressing the other extremity of the bougie, and perhaps bringing it a little backwards and then forwards, so as to be satisfied of the situation of the stricture, the instrument may be allowed to remain in close contact with it for a few seconds and receive its impression, so that when it is withdrawn, a precise knowledge is obtained of its situation and form.

Some patients are often so irritable, that any foreign body touching the urethra excites much irritation and pain. In such cases it is the more necessary not to employ the smallest force, and to use an application of opium, or hyoscyamus, to the perinæum, to prevent these inconveniences as far as possible.

When the stricture lies near the extremity of the urethra next the bladder, the point of the bougie ought always to be considerably bent previous to its introduction, so that it may readily accommodate itself to the curve of the urethra; for as a large instrument does not bend easily, it is apt to press on one of the sides of the canal, and give rise to the suspicion of a stricture.

It is also of considerable importance that the point of the instrument be not too conical *. When once we are well acquainted with the state of the parts, such formed instruments may be used with much advantage, as the small point enters the stricture, and by pushing the bougie forward it is dilated by the base of the cone.

* See Plate DXIV. fig. 1.

It may be also here remarked, that in some instances a catheter can be easily introduced when no bougie can pass; we ought therefore to make use of that instrument before finally deciding on the nature of the obstruction (D).

When a stricture is discovered, and when bougies are to be used with a view of curing it, the first thing we are to attempt is to pass one through it. As the bougie we employ is most frequently of a very small size, we must attend particularly to the irregularities in the canal which may entangle the point of a small instrument and the occasional bendings it may make, while it is supposed to be passing forwards towards the bladder. As the mouth of the lacunæ are chiefly situated on the superior part of the canal, the point of the bougie ought to glide along its inferior surface to avoid them.

The bending of the bougie is only to be prevented by a forbearance in using force, and in directing properly the point; but as the common bougies are apt to do this, it is often extremely useful to have catgut ones for this purpose; and it is necessary to have them very small.

In order to overcome the obstruction when the bougie reaches it, the situation of the point ought to be changed by shifting it backwards and forwards, and from side to side, and even employing a little pressure, till it passes forwards, provided the surgeon has a clear and distinct idea of the direction of the urethra.

As the introduction of the bougie almost always brings

(D) The silver balls represented in Plate DXIV. fig. 4. have also been found useful in ascertaining the nature of strictures by Mr Charles Bell.

Strictures.

brings on spasm to a greater or less degree on the first attempt, it is often necessary to persevere some time before it can be made to pass the stricture; and we must continue in our endeavours a long time before we declare it impracticable.

Leeches and blisters on the perinæum or loins, fomentations of warm water and spirits, turpentine glysters, dipping the feet or glans in cold water, anodyne applications, and the internal use of camphor, opium, or tincture of iron, all assist in alleviating the spasmodic symptoms when they occur, and may be selected for use according to the judgment of the surgeon.

Attention ought to be paid to the composition of the bougie; for those made of elastic metal, catgut, or elastic gum, often give pain, while those made of soft plaster are mild and harmless.

The time which a bougie ought to remain in the urethra, must depend greatly on the peculiarities of the case, for there are no diseases which appear under more various forms than stricture. In most cases bougies can be introduced with little pain, and can remain for some minutes without inconvenience; but there are others where the introduction not only produces general irritation, but the pain is so violent, as hardly to allow them to enter the canal, and sometimes they give rise to constitutional symptoms. In the first case, from the little pain the patient suffers, their use has been abused, and they have been allowed to remain not only when asleep, but they have been worn during the patient's daily employments. It is found, however, that bougies have a more powerful effect when retained for a short time, and often repeated, than when they are longer continued, but seldomer used; so that in no case, however little pain they may produce, ought they to be allowed to remain for a long time. Many indeed think that all their good effects are obtained after they have remained twenty or fifteen minutes, while others allow them to remain for one or more hours.

In cases of stricture accompanied with much irritation, whatever pain the bougie may bring on, it ought not to be thrown aside, but introduced repeatedly whenever there is the least abatement of the symptoms. This practice should be continued for weeks before we despair of success, as afterwards the pain, from daily habit, will be diminished, and the patient will be gradually more and more able to bear it. Whilst we continue the use of the bougie, it ought gradually to be increased in size as the stricture gives way, and be introduced once or perhaps twice a-day till the obstruction is no longer felt, and till the urine flows in a full, even, and natural stream.

When this happens we are not to consider the cure as altogether complete; for it is very generally found, that if the use of the bougie is at this time given up, the parts soon begin to again contract, having still a disposition to return to their former situation, and the disease in a short time is completely renewed. It will therefore be proper to continue using them at distant intervals, some time after the cure appears complete, and give them up in a very slow and gradual manner.

It may be here mentioned, that it is not necessary to retain the point of the bougie in the cavity of the bladder, but merely to allow it to pass the stricture.

Of the Caustic.

In speaking of the use of bougies, we have supposed it practicable to pass one through the stricture; but cases often occur, where, from the tortuous form the canal has assumed, the smallest bougie is prevented from entering the bladder. In such cases, pressure was employed on the diseased parts, in order to destroy the obstruction by producing ulceration; but as this mode was found in many cases to be followed by violent inflammation, and attended with great pain, it was not often performed. Laying open the sinuses, and dissecting out the diseased parts, was also a painful and no less difficult operation, so that no easy mode was ever adopted till Wiseman employed lunar caustic.

From the delicate structure of the urinary canal, it was not without much caution, and in very urgent cases, that this remedy was first employed; but since its action was found not to be violent, it has been freely used by many surgeons, and its application not confined to the more advanced stages of the complaint.

From the time of Wiseman to that of Mr J. Hunter, we find little worthy of remark in surgical writers regarding the use of caustic. The latter of these authors, however, again introduced it into practice, and applied it to all those cases where he could either do no good with bougies, or when he could not pass them through the stricture. In his first trials he met with success; and as he soon improved the mode of its application, he was enabled to employ it with considerable advantage.

Mr Hunter's mode of applying caustic was first adopted by Wiseman; but as the silver canula which he employed, not only gave much pain, but could not, in many instances, be introduced as far down the urethra as a common bougie; and as the caustic could not be applied directly to the centre of the obstruction, a new mode was invented. A piece of caustic was fixed in the extremity of a common bougie, and covered with the plaster except at the extremity, where a part was exposed, but so small as merely to form the apex of the conical point of the bougie. In this manner it is found possible to apply it to almost all cases, and, in dexterous hands, may be used with considerable safety. When it is to be applied to a stricture, it is necessary that some previous knowledge of the case should have been obtained from the introduction of a soft bougie. This done, the armed bougie must be introduced rather quickly, but steadily, till it meets the stricture, which is known both from the feel, and from the situation previously determined. When brought into contact with the stricture, it is perhaps better merely to touch it with the caustic for the two or three first applications, and afterwards it may be retained longer. When the bougie is to be withdrawn, it ought to be done cautiously; for as it has now become soft, and the caustic not so firmly fixed in it, it might fall out, and be left in the urethra. Although this mode has advantages over the silver canula formerly employed, yet there is a way which we think still preferable, as it not only requires less dexterity on the part of the surgeon, but is less apt to do mischief.

It

Strictures.

SECT. III. *Stricture of the Rectum.*

As far as we know, there is no author who has given any accurate account of the various morbid affections of the extremity of the rectum. Under the general name of *hæmorrhoids*, a variety of tumors very different from one another have been classed; whilst under the name of *schirrus*, have been considered all cases where the diameter of the lower part of the intestinal canal has been diminished. In a practical point of view, these observations are of the greatest importance, as they lead the surgeon to discriminate between those cases which are likely to be aided by the use of medicines, and those which are beyond the reach of art, or which the same mode of treatment might tend more to aggravate than to alleviate.

In many cases of true schirrus, or cancerous affection of the intestine, the disease first appears by the formation of one or more gristly tumors on the internal surface of the canal; and these by increasing in number and in size, and by involving the adjacent parts, contract the canal, and at last ulcerate, forming true cancerous sores. But there is another class of cases, in which the diameter of the intestines becomes narrowed by a thickening of its coats, and which, were we to reason from analogy, might be compared to that thickening which forms stricture in the other mucous canals, as the œsophagus and urethra. It is cases of this description that we suspect Dessault treated with so much success by the use of bougies *; and from the good effects of this mode of treatment in cases of stricture in other parts, it is reasonable to expect benefit from their use in strictures of the rectum. Dessault, however, wishes it to be understood that the practice is to be employed in the true schirrus; but the two cases which are given in detail by Bichât in his edition of Dessault's works, in illustration of this practice in schirrus, are by no means conclusive. The first is a case of tumors of the internal membrane, which were much alleviated by the compression of a bougie; whilst the second was a case which shows the relief to be obtained by the use of bougies in cases of schirrous contraction in the discharge of the fæces, but by no means in the cure of the disease.

* Oeuvres Chirurgicales.

In cases, therefore, of contraction of the rectum which are not of a schirrous nature, besides the strict attention to keep the bowels regular, and render the fæces as soft as possible by the use of laxatives and emollient injections, bougies made of a proper size may be used with relief; and, as we have mentioned in another place, the practice is also highly serviceable in some cases of tumors which grow from this part of the intestine.

SECT. IV. *Of Polypi.*

Of Polypi.

When any part of a mucous membrane becomes elevated above its natural level, so as to form a circumscribed swelling, the disease is called a *polypus*. That polypi are principally composed of a congeries of arteries and veins ramified through a gelatinous substance, seems probable from their disposition to bleed when injured, and their small size when removed from the living body.

Polypi have been found on all the different mucous surfaces; in the nose, frontal and maxillary sinuses, pharynx, gullet, mouth and gums, meatus externus, conjunctiva, stomach, intestines, rectum, uterus, vagina, bladder, and urethra.

There are four different kinds of polypi, varying from each other in their structure. 1st, The *mucous*; 2d, the *fleshy*; 3d, the *carcinomatous*; and, 4th, the *encysted* polypi.

The *mucous* polypi have a slippery surface, and are constantly covered with a quantity of mucus. They are of a grayish or dull white colour, and have a demitransparent appearance, resembling, particularly at their extremities, a piece of softened glue. They are easily torn and bleed freely; they are neither painful nor sensible to the touch; they suffer remarkable alterations from changes in the state of the atmosphere, extending prodigiously in cold and moist, and contracting in a dry and warm air. They are of an irregular and angular shape, and often seem to take the particular form of the cavity in which they grow. They are commonly attached by a narrow neck, and are quite moveable.

The *fleshy* or carcinomatous polypi are of a bright red colour, their surface is smooth and regular. They are of a rounded form, and are attached by a narrow neck. They are firmer and are not so easily torn, nor do they bleed so readily as those of the mucous kind.

The *carcinomatous* polypi are of a darker red or more purple colour than those of the fleshy kind, and sometimes they are of a livid hue. They are supplied by a great number of blood-vessels, which makes them bleed profusely even when slightly injured, or gives them a disposition to bleed of themselves. They are of a very firm structure; some of them being as hard as cartilage. They are more or less painful, and are very sensible to the touch. Sometimes the pain is of that stinging lancinating kind which carcinomatous tumors have in other parts of the body. Their surface sometimes ulcerates, and the ulcer assumes all the characters of a cancerous sore. They are commonly attached by a firm broad basis.

The *encysted* polypi occur least frequently. Richter says that they resemble a reticular sac, which contains fluid sometimes resembling mucus; at other times it is of a thick consistence. In one case we found the mucous membrane covering the superior spongy bones extended, but not much thickened; and between its folds there were several round semitransparent vesicles, containing a thick glairy fluid.

SECT. V. *Of Polypi of the Nose.*

All the four different kinds of polypi have been found growing from the mucous membrane lining the cavity of the nose; we have also seen the superior spongy bone so increased in bulk, as to form a tumor resembling the fleshy polypus.

The first symptom of a polypus in the nose is a preternatural degree of redness of its mucous surface. It becomes spongy and callous, and there is an increased secretion of mucus. The patient has some interruption in breathing, and the voice is rendered more or less indistinct; he feels as if stifled, and he tries to get quit of

Of Polypi.

of something which incommodes him by blowing his nose; for the same reason as a person does who labours under a common catarrh. The sense of smell becomes impaired, and all these symptoms are more troublesome in wet than in dry weather.

The symptoms increase till the extension of the mucous membrane increases to such a degree, as to form a distinct circumscribed tumor; and the progress of the complaint is generally so slow, that its nature is frequently not suspected till it gets this length.

By degrees the breathing through the nose and the sense of smell are entirely destroyed from the mechanical obstruction of the tumor; and the patient himself finds, that by a violent expiration or inspiration, the tumor can be pushed forward or backward in the nose.

The pressure which a *polypus* sometimes makes on the nasal duct prevents the tears from flowing freely into the nose, and is the cause of a watery eye.

When the tumor is large, the septum of the nose is frequently pressed, and pushed to the opposite side, and then the respiration is oppressed in both nostrils. Sometimes the tumor descends, and part of it projects through the nostril; when this takes place, the surface of the part exposed to the air becomes like common skin. This indeed happens when any mucous surface is exposed. We have observed it in the vagina when inverted, and in the eyelid when the palpebral membrane was turned outwards, from a tumor, or any other cause.

Morgagni takes particular notice that the natural position of the septum is apt to be mistaken for disease, as it frequently divides the nasal cavity into two unequal portions.

More frequently polypi extend backward into the pharynx, and can be felt by introducing the finger behind the velum pendulum palati. In one rare instance, we have known a polypus so large, as to descend along the œsophagus into the stomach, and in another to fill up the whole cavity of the mouth and produce suffocation.

It happens also that polypi growing from an extensive base, separate, displace, and produce an absorption of the bones which surround them. The bones of the nose are pushed upward; the maxillary bones and the palate bones are disjoined, and carried outward; the arch of the palate depressed; the inferior margins of the orbits are pressed upward, and push the eyes out of their orbits.

Polypi arise from every part of the nasal cavity; but most frequently from the spongy bones. Many surgeons have conceived that polypi arose from general diseases of the constitution, as scrofula, syphilis, &c.; but it will in general be found to be a mere local disease, and probably arising from whatever tends to produce a continued or repeated attack of inflammation in the part.

Treatment.—If polypi are attached to the upper spongy bones, their removal will be more dangerous, as the inflammation excited by an operation will be reapily conveyed to the brain. When they are attached to the inferior spongy bones, they can be removed with perfect safety.

The most celebrated surgeons have never advised any operation when the tumor is small and gives no distress; but whenever it becomes of such a size as to fill up the cavity of the nostril, disturb respiration, and assume a malign aspect, it ought to be removed.

As long as polypi continue small, or when the mucous membrane acquires that appearance which indicates the commencement of the disease, tonic and astringent remedies are generally recommended; as a decoction of oak bark with alum; strong solutions of white vitriol, saccharum saturni, or muriate of mercury, ardent spirits, and vinegar. Either of these solutions, which may be selected, ought to be thrown up a little warm into the nasal cavity with a syringe, retained there half a minute or more, and repeated four or five times daily; or a piece of charpee wet with them may be put into the nose with a probe, and applied to the deceased surface. Kino, galls, white vitriol, &c. sabine in the form of powder, snuffed up into the nose, as strong as the patient can suffer it, are also useful in stopping the progress of the disease. Mercury has been found rather to make them worse; caustic and other corroding applications have been of use in the softer kind, though they have never produced a cure. Bougies have been recommended by Mr B. Bell, and are said to have been useful; and when the polypus is small, they may act on the same principle as bougies do on tumors of the rectum, a practice so successful in the hands of Dessault.

Polypi may be removed either by tying a ligature round their neck, by tearing or twisting them, or by cutting them out with a knife or scissars.

Operation.—Professor Richter of Gottingen, and several eminent practitioners of this country, use, in general, the forceps; and in those cases where the polypus is attached to the inferior spongy bones, or to any of the inferior parts of the nasal cavity, this mode of operation is much more easily performed, and has the best chance of success. From the soft texture of the superior spongy and ethmoid bones, with which they are connected, there is a considerable risk of tearing and injuring more parts than is necessary for the removal of the polypus; and, as any inflammation excited on these may spread to the membranes of the brain, it is more adviseable to remove polypi attached to these parts by the ligature.

When polypi are completely within the reach of the knife, adhering towards the external opening of the nostrils, they may be easily cut away.

In performing any operation, or even making an examination of the state of the nose, it is of considerable importance to attend to the position of the forehead, and to employ a proper light.

The head should be bent backwards; and in order to enlarge the external nostril, an assistant, on whose breast the head of the patient rests, ought, with the fore-finger of his right hand, to press upward the point of the nose: whilst, with a probe in his left, he spreads out the alæ.

Of removing Polypi with the Forceps.—Forceps for this purpose ought to be six inches or six inches and a half long, and the axis at two-thirds of their length distant from the extremity of the handle; so that the operator may have the advantage of a long lever. See Fig. 1. Plate DXV.

Plate DXV. fig. 1.

The points of them ought to be blunt, rounded on the outside, perforated, and a concavity, made rough, extending

Of Polypi.

extending to near the axis. The two blades ought to be separated at their union, when closed, and not to become parallel till they are opened to a considerable distance, in order that the polypus may be held very firmly. The blades should be strong, and pretty broad.

Even this form of forceps is not always sufficient; and it is useful to have a pair of such as has been recommended by Richter *. They are intended to be employed in those cases, where the polypus is so large as completely to fill the nostril, and so hard, that the upper part of the blades of the common forceps cannot sufficiently dilate to allow their extremity to pass down the nostril, and reach the bottom or neck of the tumour.

* See Plate DXV. fig. 2.

It is of great importance to fix the forceps as near the root of the polypus as possible; for, when that is accomplished, the whole mass may be at once removed: and the hæmorrhagy is never so great as if the polypus was torn through the middle.

Often, however, it happens, that the polypus is so large as to distend the nostrils in such a manner, that it is impossible to discover the root till the extremity is removed. We must, in such a case, remove as much as we are able, and even although the bleeding is profuse, persevere in the operation as long as we can pull any away with safety.

When the operation is to be performed, the patient ought, by his own efforts, to push the body as far forwards as possible; then the surgeon, with a pair of small forceps in his left hand, seizes the point of the polypus, and having kept fast hold of it, he cautiously introduces the polypus forceps on the outside of the others. The more time that is bestowed on this step of the operation, the more the polypus becomes elongated and thinner, the more room is given for the forceps, and therefore the higher up can the polypus be grasped. After it is completely secured between the blades of the forceps, it is to be twisted slowly round, and at the same time pulled outwards. If only a portion of the polypus is removed, what remains is to be extracted in the same manner. The hæmorrhagy is generally profuse, but seldom requires the assistance of art to stop it.

Of Removing Polypi by the Ligature.—The ligatures consist of wire, catgut, silk or cord; and different methods have been employed for passing them round the root of the polypus. In order to remove a polypus, the anterior part of which is situated in one of the nostrils, a ligature (*a*) † is to be introduced through a double canula (*b*), and one end fixed round the ring (*c*); whilst the other end (*d*) being loose, allows the noose at *a*, to be increased or diminished, according to the size of the polypus. The polypus is to be grasped by a pair of forceps put through the noose, and drawn forwards. The ligature is then to be carried to the root of the polypus, either by means of the forked probe (fig. 4.), or by one of the porte-nœuds (fig. 5.), taking care to tighten the wire gradually, the further the instrument is introduced. When the noose reaches the root of the polypus, the ligature is to be firmly drawn, and secured by being twisted round the ring of the canula. If the polypus hang down behind the velum pendulum palati, the doubled wire is to be slowly insinuated through the nostril into the throat. The finger of the surgeon is to be introduced into the mouth, and by opening its doubling the noose passed over the extremity of the polypus, and conducted to its root, by gradually tightening the ligature, and then it is to be firmly fixed. The ligature should be tightened once or twice a-day, until the tumor entirely separates. As there is generally a considerable degree of swelling and inflammation of the tumor before this takes place, if it be so situated as to disturb respiration, it may even be necessary to perform bronchotomy as a preliminary step. Should any part of the polypus remain, it may be destroyed by caustic, or the actual cautery, if practicable.

† Plate. DXV. fig. 3.

Besides this, which is the common and most simple mode of applying the ligatures, there are others which are well adapted for particular cases. The apparatus employed by Dessault is extremely ingenious and well-suited for its purpose, but is more particularly useful in polypi of the vagina and uterus.

Dessault's apparatus.

When this apparatus is to be used, two porte-nœuds (*a a*) ought to be procured, and having pushed the cylinder over the branches of the stalk, so as to shut the rings (*d*) completely, a ligature of waxed thread, catgut, or silver wire, is to be passed through them (*k*), and the extremities may be either held along with the canula or secured at *e* *.

The two canulas, thus armed, are introduced parallel to one another between the tumor and parietes of the cavity in which it lies; and when they reach its base, one is held firm, and the other carried round the base, crossed over the other, forming a noose round it.

* See Plate DXV. fig. 5.

The ligature being pulled tight by an assistant, the two ends are to be put through the hole (*g*) of the other canula, and fixed to the axis at *h*.

The extremity (*g*) is then to be slipt along the ligature close to the polypus; and the ligature being firmly fixed to the other extremity, the two porte-nœuds may be at once removed, by allowing the ring to divide and the ligature to escape.

This being done, nothing remains to complete the operation. The ligature is kept round the polypus till it drops off, and as the parts begin to give way, it ought to be retained always perfectly tight; and this may be easily accomplished by turning the screw at *h*.

The apparatus, too, (fig. 6. Plate DXV.) may also be sometimes useful, from the flexibility of the canula, which conveys and directs the ligature.

2. *Of the Polypus of the Rectum.*

Polypi of the rectum differ considerably from the common *hæmorrhoidal* tumor, in their symptoms and appearances. They resemble the fleshy polypi in other parts of the body, in their colour and external form, and they are also sometimes ulcerated on the surface. On cutting through a large tumor of this kind, we found it composed of a vast number of cells, some of them very large, and all of them filled with blood. Their progress is slow, and we have seen them grow as big as a large walnut. They do not alter their size at different times, as is observed of the hæmorrhoidal tumor, except, that they are apt to swell, when allowed to remain long external to the anus. They are most commonly situated in the rectum, close to the anus; so that when the patient goes to stool they are pushed downwards,

Of Polypi.

downwards, and appear externally. When very large, they are also apt to come through the anus by the least exertion in walking. They are generally attended with more or less pain or uneasiness on going to stool; and when they become so large as to come through the anus in walking, the disease becomes very distressing. They are often accompanied with a discharge of mucus. Sometimes, too, hæmorrhoidal tumors are formed contiguous to the polypus; but the latter is generally pointed out by the patient as the original swelling, and that which gives most pain. These tumors may also be readily distinguished from one another by their difference in colour and form.

Treatment—Astringents, with opium, and bougies, may alleviate the symptoms; but as they seldom give permanent relief, the most complete and safest mode of cure is removing them with the knife, if they can be readily reached; if not, the ligature is preferable, although it gives much more pain; for it sometimes happens, that a very profuse bleeding follows after they have been cut away. The hæmorrhoidal tumors which accompany the polypus disappear after its removal.

When they are tied with a ligature, this can be done in most cases by simply tying a strong silk thread firmly round the base of the tumor. Often the base is larger than the apex, and then it is necessary to pass through the middle of the tumor a curved needle with two ligatures, one to tie each half of it. To prevent any mistake, and accelerate the operation, surgeons make one of the ligatures of black, and the other of white thread. Whilst the mortified part is separating, great attention is necessary to keep the surrounding parts from excoriating; and this is to be done by frequently washing with warm water, or a saturnine solution, and anointing them with saturnine ointments, or the unguentum resinosum. Fig. 7. Plate DXV. gives an outline of tumors of this kind.

3. *Polypi of the Gums*

Most frequently are connected with caries of a tooth, or of the alveolar processes of the jaw bone; sometimes, however, not. They are generally of a firm fleshy texture, rounded form, polished surface, and are very apt to bleed; and they sometimes grow to a very large size, and become malignant. They are best removed by the knife; and, as they bleed profusely, it is often necessary to use the actual cautery to restrain it. If the bone be found carious, the diseased part should, if possible, be removed, or means used to assist and promote its exfoliation; and when this has taken place the polypus often disappears without any operation.

4. *Polypus of the Frontal Sinus.*

This is a very rare disease, and it produces the same dreadful consequences as that of the antrum. Art can perhaps venture to do little, as the close connection to the brain would render any attempt to remove it dangerous.

5. *Polypus of the Antrum Maxillare.*

The surgeon is seldom aware of the presence of this disease until it is far advanced, and has begun to distend the bony cavity in which it is formed. It sometimes acquires a prodigious bulk, separating and rendering carious the bones of the face, pushing the eyeball out of the orbit, and filling up the cavity of the mouth. If the nature of the complaint is early suspected, by removing a portion of the external parietes of the antrum with a trephine, the polypus may perhaps be removed from its attachments; but if that is impracticable, strong astringent applications, caustic or the actual cautery, or removing portions by the knife, may arrest the progress of the disease.

Of Polypi.

6. *Polypi of the Urethra.*

These are what have been called caruncles, and were supposed to be the most common cause of stricture. It is now, however, well known that they occur seldom. If their growth is not checked by the use of a bougie, and if they are not near the meatus urinarius, it may be necessary in some cases to cut in upon the urethra, in order to get them extirpated; but that must happen rarely.

7. *Polypi of the Bladder*

Are beyond the reach of the surgeon, but they occur very rarely; and the distressing symptoms which attend this disease, can only be alleviated by those internal medicines which dilute the urine and allay the irritability of the bladder.

8. *Polypi of the Ear.*

They sometimes grow from the membrana tympani, but they generally arise from the cavity of the tympanum, after the membrana tympani has been destroyed by ulceration. They resemble the common mucous polypi in structure; and they are most frequently accompanied by a discharge of puriform matter and a total loss of hearing. They may be removed with a ligature in most cases very easily; or they may be torn out with forceps; and it is always necessary to touch the part to which they adhered repeatedly with caustic, and to use strong astringent washes, in order to prevent their future growth.

9. *Polypus of the Conjunctiva.*

We have never observed them on the sclerotic conjunctiva; but they are formed on the inner membrane of the eyelids, and most frequently on the upper one. They are soft pendulous masses, which, being loose, float between the eyelids and ball, and sometimes even pass beyond the edge of the lids. They are of the red colour of the inflamed mucous membrane; but those portions which are exposed to the external atmosphere become dry, and often drop off. They are often formed in consequence of the membrane being inflamed by an abscess bursting internally. They are easily removed by the knife; and they are prevented from being regenerated, by slight scarifications or the application of lunar caustic to the base.

10. *Of the Polypus of the Uterus.*

These polypi are found to grow either from the fundus, the lower edge of the os uteri, or from the inside of the cervix. The first is the most, and the second the least frequent. The shape of the uterine polypi is generally pyriform, having a very narrow neck. They are commonly of the sarcomatous kind; though it often happens that polypi are formed in uteri affected with cancer.

Of Aphthæ.

cancer. Polypi protruding into the vagina are apt to be mistaken for prolapsed uteri; and this mistake is more likely to take place in some cases where the polypus acquires a large bulk in the uterus, and is suddenly protruded into the vagina, and strangulated by the os tincæ. Cases, too, of prolapsed uteri have been mistaken for, and treated as polypi.

The safest mode of removing uterine polypi is with the ligature. When it is situated in the uterus, this operation is impracticable; but when it descends into the vagina, it may be very readily done by the apparatus of Dessault (Plate DXV. fig. 5.).

Sect. VI. *Of Aphthæ.*

The formation of aphthæ, when they are examined with care in their different degrees, may probably extend our views of the intimate structure of the mucous membranes. Boerhaave considered them as small superficial ulcerations, and Stahl regarded them as tubercles or pustules. From the present state of our knowledge it is difficult to determine whether aphthæ originate in the chorion of the mucous membrane, in its papillæ, or in its mucous follicles.

Aphthæ are formed on the lips, the gums, the interior of the mouth, the tongue, the palate, the amygdalæ, the œsophagus, and also in the stomach and intestines. They are most frequent in children and old people, and they have been observed in people who inhabit places where the air is tainted, and who live on unwholesome food.

The aphthæ of the adult may be considered as a collection, more or less agglomerated or insulated, of white superficial rounded tubercles, each about the size of a millet seed. These tubercles discharge a serous humour; the pellicle which covers the mucous membrane is detached, and is progressively formed in the different parts of the mouth, and even in the rest of the alimentary canal. They are sometimes disseminated in solitary pustules over the tongue, the angles of the lips, or the back part of the mouth, with a benign character. At other times they are formed and seemingly propagated from the interior of the œsophagus; pass the back part of the mouth, forming a white, thick, and strongly adhering crust; and these are often dangerous from a complication of typhus fever.

Aphthous tubercles vary in colour. Sometimes they are transparent; at other times they are white, with a certain degree of thickness; they are also sometimes of a deep yellow colour, and sometimes they are livid or blackish, a symptom which always indicates a greater degree of danger.

Aphthæ may also be frequently observed in people who have taken many courses of mercury. In these cases, the repeated action of the mercury on the mouth appears to leave on that organ a degree of sensibility or weakness which disposes it to the disease. It happens not unfrequently that aphthæ are considered as venereal sores, in consequence of the venereal disease not having been properly cured; on this supposition a new mercurial course is employed, which only augments the disposition to aphthæ, and makes the sores spread more rapidly.

The aphthæ of children are preceded by a profound sleep, by agitation of the muscles of the face and lips, difficulty of respiration, prostration of strength, feebleness of the pulse, and vomiting. In the mild form of the disease, white superficial spots appear in different parts of the mouth, which are separated from one another, and the interstices are neither red nor inflamed. The bottom of the mouth has often been discoloured, and the heat immoderate; there is no difficulty in swallowing, and the child can readily suckle; the sleep is natural, and there is a slight diarrhœa. The spots during the first days preserve their whiteness and transparency; they afterwards become a little yellow, exfoliate in flakes, and go away entirely about the ninth or tenth day, particularly when the child has a nurse.

Of Hæmorrhagy from Mucous Membranes.

The confluent or gangrenous aphthæ have other characters. The small pustules are contiguous to one another, and spread not only over the lips, the gums, the tongue, and the anterior of the cheek; but we also see them at the bottom of the throat. The mouth of the child is burning; the lips are with difficulty applied to the nipple, and sometimes it is excoriated by their contact. Deglutition is very difficult, and the most simple drinks given in small quantities, and with precaution, do not enter into the stomach but with pain. There is a constant purging of greenish matter, which inflames and excoriates the skin round the anus; the child is very feeble and heavy, the eyes are sunk and shut, and the child screams. The whole interior of the mouth from the lips to the throat becomes at last lined with a white thick crust, resembling coagulated milk. This crust becomes yellow, and forms a slough, which, after it falls off, exposes gangrenous ulcers of a dark brownish yellow colour.

Treatment.—In the benign form of the disease in children, it is of great consequence to get the child a good nurse; and the affected parts may be washed over five or six times a-day with a piece of caddis dipped in a little water gruel, to which has been added a few drops of sulphuric acid. Borax, either in powder or solution, has also been considered by some as a useful application. When the crust has separated, if the remaining ulcer be painful and irritable, its surface may be rubbed over with nitrate of silver, or any other caustic application. Sometimes very malignant looking ulcers remain in the adult, after the separation of the crust. In these cases, caustic may be employed; and we have often seen them heal rapidly by touching their surfaces once a-day with a weak solution of corrosive sublimate or muriatic acid. For the treatment of the confluent aphthæ, see MEDICINE.

Sect. VII. *General remarks on Hæmorrhagy from Mucous Membranes.*

All the mucous surfaces are particularly subject to hæmorrhagy; and this may arise either from a rupture of the vessels, or the blood may be poured out by the exhalents.

The superficial position of the vessels, and consequently their want of firmness and support, exposes them much to rupture by very slight concussions. We have examples of this in the bronchiæ, brought on by coughing; in the nose, by slight blows on the head, or by violent sneezing; and in the rectum, by straining on going to stool. The effect of stones or gravel on the mucous membrane lining the urinary organs is the same; and even

Hæmorrhagy from Mucous Membranes.

even the most cautious introduction of a sound or bougie into the urethra, often causes bleeding; or the slightest friction of polypi of the nose and gums, or the introduction of a probe into the lachrymal passages. When considering the diseases of the skin, we mentioned, that in some diseases, particularly some pestilential fevers, the exhalents of the skin poured out red blood. The same thing happens among the mucous membranes. We often see blood come from the nose, from the bronchiæ, stomach, and intestines, urinary bladder and kidneys, where there has been no reason to suppose ulceration previously to have taken place, or any thing to cause a rupture of any of the vessels. In one case a young woman bled from all the mucous surfaces.

1. *Hæmorrhagy from the Nose.*

Hæmorrhagy from the nose arises from a variety of causes. We often observe this after fevers, and then it has been considered as critical. In young people it occurs very frequently, and from very slight causes; and it has been sometimes known to take place at the menstrual period.

Hæmorrhagy from the nose is generally preceded by symptoms of an increased quantity of blood to the head, pulsating motion of the temporal arteries, feeling of weight about the head, symptoms which are preceded or accompanied by other changes in more distant parts; such as spontaneous lassitude, pains about the belly.

When the means mentioned for this complaint in the article MEDICINE have failed, recourse must be had to compression. Dossils of lint introduced into the nostrils are sometimes effectual; or the gut of some small animal, tied at one end, then introduced by a probe into the nose as far as the pharynx, and filled with cold water, or water and vinegar, and secured by a ligature, by adapting itself to all the parts, and pressing equally on them, has been attended with advantage. When these remedies likewise fail in their effect, a piece of catgut or wire may be introduced through the nose into the throat, and brought out at the mouth; a piece of sponge, or a bolster of lint of a size sufficient to fill the back-part of the nostril, is then to be fixed to it; the sponge is next to be drawn back and properly applied. Another is to be applied to the anterior part of the nostril and secured. The same may be done to the other nostril, if it be necessary; or the sponge may be of such a size as to fill the ends of both nostrils at the same time. By this contrivance the blood not finding an outlet, will soon coagulate, and prevent any farther evacuation.

2. *Hæmorrhagy from the Rectum*, or *Fluxus Hæmorrhoidalis.*

The discharge of blood from the rectum is a disease chiefly confined to those advanced in life. It is often occasioned by full living, change from an active to a very sedentary life, the abuse of purgatives, particularly aloes; violent passions, or habitual melancholy. The symptoms which precede and accompany this disease, are bearing down pains, and a sensation of weight in the back and loins, sometimes a numbness in the limbs, and a contracted pulse, thirst, diminution of urine, flatulency, and sometimes a discharge by stool of a white mucus. The discharge returns commonly in a periodical manner once a month, and thus becomes necessary for the preservation of health; for if it be suppressed, or if it stops spontaneously, it occasions a variety of nervous affections, such as spasmodic tightnings about the chest, colic and vertigo.

Of Hæmorrhagy from Mucous Membranes.

Treatment.—When the hæmorrhoidal flux has become habitual like the menstrual discharge, we not only ought not to attempt curing it, but if it be from any cause suppressed, it ought to be restored. If it be the effect of general plethora, it is to be removed by a vegetable diet and moderate exercise. In order to moderate the discharge, the patient ought to lie in the horizontal posture on a hard bed, avoid all exercise, keep the belly open by cooling laxatives, or even to take acids if the bleeding is excessive, and apply cold to the loins and perinæum. As a sudden suppression of the hæmorrhoidal discharge is the cause of many diseases, it is sometimes of much importance to reproduce it. To effect this, leeches and warm fomentations applied to the anus, are the most efficacious remedies.

3. *Hæmorrhagy from the Bladder* (Hematuria).

Hæmorrhagy from the bladder is a disease most frequent in old people; it is often occasioned by a suppression of the hæmorrhoidal discharge, or any other accustomed discharge of blood. It is sometimes the consequence of excess in living and drinking, and of a sedentary life followed by great exercise. It also arises from a plethoric state of the system, violent exercise on horseback, the internal use of cantharides, a contusion in the region of the kidneys, or from stone in the bladder.

Treatment.—The treatment to be employed is the same as in hæmorrhagy in general. Every thing ought to be avoided which might tend to irritate the kidneys or the urinary bladder. Laxatives, acid drinks, the application of ice to the lumbar region, hypogastrium, and perinæum, or to the inside of the thighs, is of great importance. Under the articles MEDICINE and MIDWIFERY, we have considered the hæmorrhagies from the lungs and uterus. We may here remark the connection and strong sympathy which subsists between these organs, and also between them and the other organs of the body; for a minute acquaintance with these may often lead to a successful mode of treating their diseases. When the menses are suppressed, there is often a hæmorrhagy from the mucous membrane of the lungs; and there are also many cases of obstruction in the bowels which bring on hæmorrhagy both from the lungs and uterus; a hæmorrhagy which never ceases until the primary affection be removed.

SECT. VIII. *General Remarks on the Ulceration of Mucous Membranes.*

Simple inflammation of a mucous surface seldom, if ever, terminates in ulceration, most ulcers of these parts having a specific character. The venereal inflammation rapidly terminates in ulceration; and aphthæ have the same tendency, forming often what are called phagadenic sores.

The mucous membrane of the nose is peculiarly subject to ulceration; ulcers also occur in the different parts of the mouth and gums, in the pharynx, larynx, œsophagus, in the intestinal canal, and also, though

very

Of the Diseases of Serous Membranes.

very seldom, in the urethra. It is the first of these only which are to be treated of in this place.

Of Ulcers of the Nose, or Ozæna.

This species of ulcer sometimes appears in the nostrils, and sometimes in the frontal or maxillary sinus. It generally succeeds a violent coryza. It also sometimes arises from blows on the nose, or from the application of very acrid substances. Ozæna is often accompanied with inflammation, hæmorrhagy, pains, caries of the bones which sometimes destroys the palate bones, cartilages of the nostrils; and by hindering more or less the free passage of the air, it alters the tone of the voice.

Treatment.—In the simple ozæna, much benefit generally arises from the use of astringent washes, such as a decoction of oak-bark and alum, solutions of sulphate or acetate of zinc, or the acetate of lead. The best mode of using these is to inject them a little warmed, with a common syringe, into the affected nostril, three or four times a day; and when the quantity of discharge diminishes and becomes of a better quality, an ointment composed of the flowers of zinc or the like, spread on a piece of lint, should be introduced once or twice a day into the nostril.

When the ozæna is of a more virulent nature, and the bones affected with caries, there is generally great reason to suspect a venereal taint. This can only be determined by the history of the complaint and the constitutional symptoms of the venereal disease being present. In such cases mercury is the only remedy, and along with its internal use the injection of mercurial lotions, and the use of fumigations, will be serviceable. In such ulcers as are obstinate, and which do not partake of any venereal taint, a liniment, with an eighth part of the red precipitate of mercury, or a smaller proportion of the acetate of copper, has been recommended by Mr Bell as an useful application. In some cases too, where, after the venereal taint is destroyed by a proper mercurial course, there remains an obstinate sore, the above liniment may be useful, and a course of sarsaparilla or cinchona has also been found in such cases of much advantage.

Chap. IV.

Of the Diseases of Serous Membranes.

General Remarks on the Pathology of Serous Membranes.

The phenomena of the diseases of serous membranes are very different from any of those of the other textures which have been mentioned. When they are attacked with inflammation, the serous surfaces often adhere together, or if suppuration takes place, it is never accompanied with ulceration or erosion of their substance. However abundant these purulent collections may be, the membranes always remain sound, with only a little additional thickness; the purulent fluid rejected from them, being like the natural fluid formed by exhalation.

The serous cavities are also subject to hæmorrhagy, and to preternatural collections of the exhaled fluid.

Under the article Medicine we have treated of inflammation of the pleura, membranes of the brain and peritoneum, and also of hæmorrhagy from these organs. In this place we shall consider dropsy and hæmorrhagy from the vaginal coat of the testes, as the only diseases belonging to surgery.

Of Ascites.

Sect. I. *Dropsy of the Peritoneum, or Ascites.*

When water collects in a considerable quantity within the cavity of the peritoneum, the skin becomes dry and scurfy, and the superficial veins varicose. In one case they appeared like large tubes half filled with blood, the anterior part of the canal thin and dry, and the posterior portion hard and unyielding. The skin at the umbilicus is sometimes much distended, and the water seen shining through it as in a common blister. The water varies much in its appearance; most frequently it is yellow or brownish. We have seen it as thick and dark coloured as coffee grounds. In one case it was viscid and tenacious, resembling the white of an egg; and in other instances it resembled milk and water, with the milk partly curdled. Ascites is generally accompanied with a disease of some of the abdominal viscera, and most frequently the liver.

It is not confined to any particular period of life, but has been observed more frequently in men than in women.

The symptoms of ascites are, 1. The swelling and sense of tightness over the belly. 2. Laborious and difficult breathing, especially in the horizontal posture. 3. The distinct feeling of fluctuation, upon applying one hand to one side of the belly, and striking it with the other hand on the opposite side. 4. The urine is in small quantity, and of a dark red colour. There is also thirst, a dry skin, often a feeling of heat, and very frequently œdema of the inferior extremities.

Operation.

Paracentesis.—When the swelling becomes large, and internal medicines have no effect in diminishing it, it is adviseable to discharge the water by an artificial opening, an operation which seldom cures the disease, but is always attended with temporary relief, and may be repeated as often as the water is found to collect. Smucker has performed it seventy times, and protracted the patient's life for many years. The operation is to be performed by introducing a trocar* at the linea alba, as used in hydrocele, about two or three inches below the umbilicus. Many surgeons now prefer this place, as it prevents all risk of wounding the epigastric artery, or any other important part. It was formerly the common practice to introduce the instrument on the left side of the abdomen, half way between the umbilicus and anterior superior spinous process of the ileum, in order to avoid the liver and epigastric artery. But those who laid down this rule were not aware of the change in the relative situation of parts when diseased; and it has several times happened to Mr Cline as well as other eminent surgeons, in performing the operation at this place, that they have wounded the epigastric artery, and the patient has died of hæmorrhage. The dissection of the abdominal muscles in patients who have died of dropsy, shows how much the *recti* are extended in breadth, and the situation of the epigastric arteries changed.

* See Plate DXIV.

The place for entering the trocar being determined, and marked with ink, the patient should be placed in the horizontal posture, and in such a situation that the water

Of Hydrocele.

water can be run off readily into a vessel proper to receive it. But as patients are very apt to faint if the water is suddenly removed, and no pressure applied to support the belly as it is emptied, it is necessary to make an equal pressure during, and after the operation. From neglecting this in some cases, dangerous symptoms have arisen, and in one instance the patient died three days after the operation from this cause. A piece of flannel as broad as the belly, and divided into several pieces at each end, and these drawn across each other by assistants, or the bandage *, answers for this purpose. By either of these the belly may be gradually compressed as the water is let out, and the compression continued for several days after the operation. Sometimes the water does not come out readily, a portion of omentum or intestine coming in contact with the end of the canula; but the discharge may be assisted by introducing within the canula a blunt probe, or a less canula within the first, having small perforations at the extremity and edges. After all the water is discharged, a piece of plaster should be applied to the wound, and every care taken to exclude the external air. The bandage should also be kept applied, and it may be worn for some time.

* Plate DXIV.

Sect. II. *Water collected in the cavity of the Vaginal Coat, or Hydrocele.*

The effusion of water in the tunica vaginalis, frequently accompanies hernia, the scrophulous schirrus, venereal and other enlargements of the testicle; but in such cases, it is merely to be considered as a symptom accompanying these disorders. Sir Everard Home mentions cases where it was a symptom of stricture. It occurs also during the abatement of inflammation of the testicle; and sometimes more or less of the water remains after the inflammatory symptoms have disappeared. In cases of this kind the tunica vaginalis is generally found thickened, and there is an effusion of lymph over its surface as well as over the surface of the albuginea. In many cases, the water is collected where there is no apparent alteration in the structure of the parts. The disease in such cases most probably arises either from a diminished absorption or from an increased exhalation. If the disease has been of long duration, the tunica vaginalis is generally thickened, and sometimes to a great degree; and particularly in old people it becomes hard or cartilaginous. We have seen preparations where it was converted into a shell of bone. In two cases a round substance resembling cartilage was found floating in the water of a hydrocele. It is not uncommon to find the vessels also of the spermatic veins more or less varicose. Collections of water of considerable size, form sometimes after birth (*wind rupture*); but in old people they are most frequent. The water is usually collected only in one cavity; but it sometimes happens, that in consequence of adhesions between the tunica vaginalis and albuginea, several irregular shaped bags are formed in which it is contained. The water usually collects in one side of the scrotum, but sometimes in both. The water is generally clear and straw-coloured, sometimes it is coloured with blood, sometimes yellow or brown, and sometimes thick, and like coffee grounds. See Morgagni, Ep. xxxviii.

The quantity of water varies. In the Act. Erud. Lipsiensis 1725. p. 492, there is mention made of a case which contained forty pounds of fluid. Doight saw one which contained four pounds. There are sometimes also hydatids found along with the water. Richter has met with four cases of this kind.

Symptoms.—1. The scrotum is commonly of a pyramidal form, and the corrugations of the external skin are destroyed in proportion to the bulk of the swelling. The shape of the tumor however varies; in some cases, it is very globular, and in others it appears like two swellings joined. It is even altered from the manner in which it is suspended; if a bag truss has been worn it is usually oblong. 2. The swelling generally begins at the lower part of the scrotum, and as its bulk increases, it gradually ascends towards the abdominal ring. 3. It appears pellucid when held between the eye and a candle; but this is not a certain prognostic, as the transparency is destroyed when the tunica vaginalis is thick and hard, or when the water is turbid and dark. 4. It gives the distinct sensation of fluctuation. In some cases, however, the degree of thickening of the tunica vaginalis renders the fluctuation obscure or imperceptible, and also destroys its transparency. 5. The tumor cannot be made to recede or change its situation from pressure or change of posture of the body. 6. The testicle is involved in the swelling, and can be distinguished like a firm unyielding mass usually at the posterior part of it. In cases where adhesions have been formed, the position varies; but the patient generally knows where it lies, and pressure applied to the part of the swelling where it is situated gives pain. Sometimes the testicle is placed at the under part of the swelling, sometimes in the middle. Mr Bell felt it twice forwards. Sometimes along with the water there are hydatids floating in the cavity of the vaginal coat. Somering says, that he has often observed this appearance. 7. The spermatic chord can be readily distinguished unaltered. 8. The tumor gives little or no pain, and the patient suffers merely from its bulk. 9. The growth of the swelling is generally very slow, and sometimes years elapse before it becomes a great inconvenience; sometimes, however, it forms rapidly. When it grows very large, the integuments become think, and the veins varicose; if the swelling extends up to the inguinal ring, the cord cannot be felt, and the penis is sometimes so much involved in the tumor, that it appears like an umbilicus or piece of corrugated skin.

Treatment.—In children, the water generally disappears in a short time, by the application of strong astringent or discutient applications. In some cases, the disease advances so slowly, that it is sufficient to wear a suspensory bandage. Richter mentions a case where it was twenty years old before it was necessary to remove the water. When the swelling becomes so large as to render it necessary to discharge the water, the operation may be either *palliative* or *radical*. The object of the first is merely to remove the water, after which the disease commonly returns; by the second, an adhesion is intended to be produced between the surfaces of the vaginal coat and albuginea, and consequently the cavity in which the water was collected is entirely obliterated. In making choice of these modes of treatment, it is necessary to attend to the following rules. 1. When the

Of Hydrocele.

the hydrocele is large, it is safer to perform the palliative operation; and afterwards when it has again collected in less bulk, the radical one may be employed. 2. When the state of the testicle is not accurately ascertained, it is better first merely to discharge the water, which allows it to be completely examined. 3. The palliative operation should be employed in all cases where the disease is connected with a morbid state of any contiguous organ. 4. In all other cases, the radical operation is preferable.

Palliative Operation.—The matter may be discharged either by a puncture made with a lancet or by a small trocar.

* See Plate DXIV.

When the trocar * is to be introduced, the posterior part of the tumor should be firmly grasped in the left hand, so that the fluid is pushed to the anterior and inferior part of it. A puncture is to be made, with a lancet, through the integuments at the most prominent part of the swelling, large enough to admit readily the trocar, taking care to avoid any large superficial vein. The trocar is then to be pushed through the coats of the tumor perpendicularly; but when it has entered the cavity, which is known by the feeling of a sudden want of resistance, the point should be directed upward, and carried forward a sufficient way; so that the surgeon is assured of its being within the cavity so far that there is no risk of its falling out.

After all the matter has been allowed to flow out, and the canula withdrawn, the wound should be covered with a piece of sticking plaster, and the scrotum supported by a suspensory bandage. If the operation is to be done with a lancet, an incision should be first made through the skin, rather larger than what is necessary into the cavity. Then a puncture is to be made through the tunica vaginalis, which will allow the water to flow out; and the discharge may be assisted by the introduction of a probe, director, or hollow tube, into the opening. The trocar should always be employed for this operation, except when the hydrocele is so small that the testicle is in danger of being wounded by it, or when there is any enlargement of the testicle accompanying the hydrocele, the nature of which is not well understood, or if the tunica vaginalis is extremely thick and the fluctuation not distinct.

Radical Operation.—An obliteration of the tunica vaginalis may be produced either by an infusion of *lymph* on the surfaces of the tunica vaginalis and albuginea, or by the process of *granulation*. The first is effected by injecting into the cavity a stimulating fluid to produce inflammation and adhesion; the second by laying open the cavity to produce inflammation and suppuration, and cause it to fill by granulation.

By Injection.—Dr Monro *primus* first proposed and adopted this ingenious, yet simple mode of cure; and it is now that which is most generally practised in all cases of hydrocele not attended with any peculiarity or puzzling symptom. The fluid contained in the tunica vaginalis, is to be discharged by a trocar, in the manner recommended in the *palliative* treatment. The trocar for this purpose should be of a rounded form, which is either altogether cylindrical, or only a small slit at its extremity; for that of *Andrè*, which is flat and slit up at both sides, is apt to allow the fluid to be effused into the cellular membrane of the scrotum; an accident which we have seen repeatedly happen, and always frustrates the object of the operation.

The fluid is then to be injected through the canula either by a syringe (Plate DXIV.), which has a moveable *stop-cock*, that it may be filled as frequently as is necessary, or by an elastic bottle, which has a valve in its pipe, so as to allow the fluid to pass forward, but to prevent its exit. It is not necessary to inject as much fluid, as there was water in the hydrocele; it answers well to fill the cavity moderately, and by gentle strokes on the scrotum agitate it over the whole surface. The fluid most commonly employed is *port wine*. Some recommend it to be diluted, but it is better to use it pure, and allow it to remain a longer or shorter time according to the degree of pain it excites, and the general irritability of the patient. In hospitals, other fluids are used, as being less expensive. Mr Cline of St Thomas's hospital employs a solution of the sulphate of zinc ℥i. ad lbi. From five minutes to a quarter of an hour is in most cases a sufficient length of time to allow the wine to remain. If it excite severe pain in the testicle or cord, it may be detained more or less time. A considerable degree of uneasiness is always to be wished for in order to secure success in the operation. After the wine is withdrawn, the wound should be covered with a piece of sticking plaster or caddis; the scrotum well supported with either pillows or a truss, and the patient put to bed. The operation excites more or less swelling in a longer or shorter period. The medium effect on the testicle is to cause it to swell about the bulk of a turkey's egg in four or five days; and the surgeon should, by pursuing the antiphlogistic regimen, moderate as far as in his power the inflammatory symptoms to that pitch, and by an opposite treatment bring them up to that degree should they be too mild. Low diet, local or even general blood-letting, purging, the horizontal posture and fomentations, are the most powerful means to arrest inflammation; but if the patient has little pain, he should live on a nourishing diet, and some local stimulant may be applied over the scrotum until a sufficient degree of inflammation comes on. If the inflammatory symptoms abate, the swelling disappears; and it is adviseable to wear always afterwards a bag truss to support the whole scrotum. In some cases the water again collects, and then the operation should be repeated; but it requires caution, as the relative situation of parts is sometimes altered from some partial adhesions having formed between the tunics.

We have seen frequently cases where it was thought that the water has been regenerated a few days after the operation, which swelling afterwards disappeared. This probably arises from an effusion in the cellular membrane, but it requires no particular treatment.

By Incision.—After grasping the tumor firmly, an incision is to be made through the skin with a scalpel, from its superior to its inferior part. A puncture is to be made towards the upper part, with a lancet, large enough to admit the point of the fore finger; the fluid is allowed gradually to escape through the opening; and the tunica vaginalis is to be laid open its whole extent with a probe-pointed bistoury in the same direction as the incision through the integuments. Pledgets of lint dipped in oil,

Of Hydrocele.

oil, or covered with simple ointment, are to be put between the lips of the wound, down to the bottom of the cavity, one on each side of the testicle; and the edges of the scrotum are to be brought together either by straps or suture. A single ligature put through the integuments opposite the testicle, answers best, and prevents the testicle from being pushed without the edges of the wound in consequence of the degree of swelling the operation occasions. The whole should be covered with a pledget of ointment, and suspended in a tight bandage.

In three or four days after the operation, the external dressings should be removed; and in one or two days more, the pledgets interposed between the tunica vaginalis and testicle may be taken away and renewed. The ligature should be cut out whenever the swelling of the part begins to abate, or at any time when it appears to create irritation. During the cure, great care should be taken, first, by the introduction of slips of plaster, to prevent the union but from the bottom; secondly, to guard against the collection of matter in any cavity; thirdly, to prevent the lips of the wound separating far, thus exposing the testicle and protracting the cure; and fourthly, to lay open freely any sinuses which may form. The cure goes on much more rapidly by persevering in the horizontal posture, and keeping the scrotum well supported. The bowels should be always kept open and regular, and when suppuration has begun, the patient's strength should be supported by a nourishing diet and bark or port wine, if necessary. The cure takes from three to eight weeks in most cases. This mode of operating is the most eligible when there is any ambiguity in the case, as it allows the testicles to be accurately examined, and castration performed if necessary. It ought also to be performed when the tunica vaginalis is much thickened and hardened, and it is sometimes necessary, even to cut away some of the hardest portions. The modes of curing hydrocele by a *seton*, *caustic*, &c. are now generally given up.

When to be adopted.

Sect. III. *Dropsy of the Thorax*, or *Hydrothorax*.

The fluid is sometimes confined to one, and sometimes affects both sides of the chest. It is commonly of a brown or yellow colour; sometimes it is reddish from a mixture of blood. Its chemical qualities are those of serum. When it is accumulated in a large quantity, the lungs are more or less compressed. Dr Baillie has seen a lung not larger than the closed fist. It is also in some instances accompanied with adhesions between the surface of the lungs and pleura.

The existence of water is known by the following symptoms. Respiration is short and difficult; and the patient cannot rest in bed, except the head and trunk be elevated from the horizontal posture. The sleep is often interrupted by alarms and disagreeable dreams, and the patient suddenly starts from it with a sense of suffocation: he is unable to stoop much forward, or raise any thing from the ground. There is sometimes a teasing cough, with little expectoration. During the progress of the disease, the pulse is very variable; but it is generally irregular. The countenance is pale, and the lips and cheeks of a purple hue. The urine is diminished in quantity, and of a high colour. The bowels are generally constipated. The feet and legs are commonly anasarcous. The undulation of a fluid may be heard by the patient himself, and moving the body by sudden jerks will sometimes assist in discovering the disease. The affected side has in some cases been observed to be enlarged.

Of Hæmatocele.

This disease is treated by the exhibition of internal medicines, where the quantity of water is small; but when it collects in such a quantity as to threaten suffocation, it ought to be discharged by an opening made into the cavity of the thorax. The incision ought to be made between the fifth and sixth ribs, half way between the sternum and spine; two inches in length through the skin. The subjacent parts ought to be cautiously divided; and the incision should be directed rather towards the upper part of the sixth rib, to avoid wounding the intercostal artery and nerve, which creep along the inferior edge of the fifth rib. The pleura, which is distinguished by its bluish colour, should be carefully cut with the point of the knife; so that, in case of adhesion, the lung is not wounded: and if the water flows out, a canula should be introduced into the opening. If it does not, in consequence of adhesion, another incision must be made. Great care should be taken to prevent the admission of air, and for that purpose, the opening should be made valvular, by pulling up the skin which is to be cut through. If the quantity is very great, it may be drawn off at two different intervals; or if it is collected in both cavities of the thorax.

Sect. IV. *Dropsy of the Pericardium*.

Water is sometimes found in the *pericardium* when there is none in any other cavity of the thorax, but it is generally accompanied with a collection of water in some of them. The symptoms of this disease are nearly similar to those of hydrothorax; and we find that Dessault and other very eminent surgeons have not been able to distinguish them. Dr Baillie says, "that the feeling of oppression is more accurately confined to the situation of the heart; and the heart is more disturbed in its functions in dropsy of the pericardium than in hydrothorax." It is also said, that a firm undulatory motion can be felt at every stroke of the heart.

If the existence of this complaint is ascertained, and if the quantity of water is suspected to be great, it may be perhaps advisable to discharge it, as practised in one case by Dessault, by making an opening between the sixth and seventh ribs of the left side, opposite to the apex of the heart.

Sect. V. *Blood effused in the Tunica Vaginalis.* (Hæmatocele).

The effusion of blood within the cavity of the vaginal coat is characterised by the sudden appearance of the tumor, by its wanting the transparency of a hydrocele, by its greater weight, and by its being more commonly occasioned by some accident. It is usually produced by the trocar used in performing the *palliative* operation wounding a vessel which pours its blood into the vaginal cavity; it is still more apt to happen when a lancet is used and a varicose vessel punctured. It also takes place from the rupture of a varicose vessel by the sudden depletion of a large hydrocele.

If the swelling is small, it may disappear by the local use

Of the Diseases of the Bones. Carus.

A bone may become carious first in its internal parts; and that from external injury, as well as from a vitiated state of the animal fluids. Authors seem not to agree as to the technical term for this kind of disease of the bones; some calling it *cancer* or *gangræna ossis;* others, *spina ventosa*, from the pointed extuberances usually attendant on this disorder of the bone; and some again, *teredo*, from the appearance of the carious bone, like wood that is worm-eaten.

Abscess.

It is universally allowed, that this disease takes its rise from matter being formed either in the diploe, or in the marrow: whenever obstruction is begun in the vessels expanded on, or terminating in, the medullary cysts, the consequence will be inflammation, and, if not early removed, matter will form; for this reason this case may be called *abscessus in medulla.* Whenever, then, a patient complains of dull heavy pain, deeply situated in the bone, consequent to a violent blow received on the part some time before, though the integuments appear perfectly sound, and the bone itself not in the least injured, we have great reason to suspect an abscess in the medulla. Children of a bad habit of body, though they have not suffered any external injury, will often become lame, and complain of the limb being remarkably heavy; and though not attended with acute pain, yet the dull throbbing uneasiness is constant. If rigors happen during the time the patient labours under this indisposition, it generally implies that matter will be formed within the substance of the bone. If the extremities of the diseased bone swell, or if it becomes enlarged throughout its whole extent, it may be known to be an abscess in the medulla, or the true spina ventosa, as it is called: if neither of these symptoms take place, the great insensibility of the bone in some subjects will prevent that acuteness of pain usual in other parts where matter is formed, though the acrid matter is eroding the bone during the whole time it is contained within it. This matter at length having made its way through, arrives at the periosteum, where it creates most violent pain. The integuments then become swelled and inflamed, and have a sort of emphysematous feel. On being examined by pressure, the tumor will sometimes be lessened, from part of the matter retiring into the bone: from this appearance to the touch, most likely the name of *ventosa* was added to the term *spina*.

When we are assured of matter being under the periosteum, we cannot be too early in letting it out, as it will save a considerable deal of pain to the patient, though probably it may not be of any considerable advantage in respect to the carious bone; for, where the fluids in general are vitiated, no chance of cure can be expected from topical remedies; but where the constitution is mended, nature will sometimes astonish us in her part, as the carious bone will be thrown off from the epiphyses, or the teredines will be filled up by the ossific matter that flows from the parts of the bone where some of the spinæ have come away.

If proper medicines are given, the children well supported, and the parts kept clean and dry, patience and perseverance will frequently give great credit to the surgeon. In case it should have been thought advisable to apply a trephine, to give free discharge to the matter, the washing it away, as well as the small crumblings of the carious bone, by means of detersive and drying injections, has been known to contribute greatly to the curing this kind of caries, after the habit of body in general had been mended.

Besides those above mentioned, the bones are liable to two opposite diseases; the one termed *friabilitas*, the other *mollities;* the former peculiar to adults, the latter more frequent in infants, though sometimes seen in adults, from a vitiated state of their juices.

Rickets.

From repeated salivations, the bones in old people have been rendered extremely brittle; insomuch that in many subjects they have been fractured merely from their weight and the action of the muscles: but in such cases, this is not owing to the friability of the bones, but to the loss of substance, from the erosion of the bone by an acrimonious humour thrown on it: to which cause perhaps may be attributed the disease called *rickets* in children. The effects of scorbutic humour in rendering the bones soft in many instances, have often been remarked.

By proper diet, gentle friction, exercise, and cold bathing, rickety children will frequently get their constitution so much changed, as that, by the time they arrive at the age of 20 years, there shall not remain the least vestige of their former disease. The epiphyses are generally most affected in this species of the disorder. For want of early attention to invalids of this sort, we find that their bones not only become soft, and yield to the powers of the muscles, but remain distorted during the rest of life, though they have acquired a perfect degree of solidity. In such cases, therefore, the assistance of a skilful mechanic is necessary both to support the parts improperly acted on, and to alter the line of direction of the distorted osseous fibres.

Though the curvature of the extremities, or thickness of the ends of the bones near their articulations, may give the first alarm to those who are constantly with children, yet there are other symptoms that give earlier notice; which if they had been timely discovered, it is highly probable that the curvature of the limbs in many children might not have happened. The belly generally becomes larger in this disease, from the increased size of the contained bowels; the head then becomes enlarged; then a difficulty of breathing succeeds, which is generally supposed to be the effects of taking cold. The sternum is elevated and sharp, and the thorax becomes contracted; the spine is protruded in several parts; the pelvis altered, according to the pressure of the parts within, and habitual inclination of the patient to obtain that line of direction in which the perpendicular from the centre of gravity may fall within the common base of the body; the extremities of the cylindrical bones, and the ends of the ribs next the sternum, become enlarged; soon after this the bones in general become soft and flexible, yielding in such directions as the strongest muscles determine.

Where the affection of the mesenteric glands is evident, Mr Bromefield asserts, that after a dose or two of the pulvis basilicus to empty the intestines thoroughly, the purified crude quicksilver is by much the most efficacious medicine to remove obstructions in those glands. When the belly begins to soften and subside, the chyle passes without interruption, and the child begins to get flesh; then the cold bath becomes truly serviceable, and the decoction or cold infusion of the Peruvian bark is a proper

Of the Diseases of the Bones.

proper restorative; but the cold bath used too early, or the bark given before there is a free circulation of chyle through the lacteals, would be very injurious.

Palsy of the lower extremities.

Among the diseases of the bones we may likewise take notice of that *palsy of the lower extremities* which takes place, as is generally supposed, in consequence of a curvature in some parts of the spine. To this distemper both sexes and all ages are liable. When it attacks an infant of only a year or two old or younger, the true cause of it is seldom discovered until some time after the effect has taken place. The child is said to be uncommonly backward in the use of his legs, or it is thought to have received some hurt in the birth. When the child is of an age sufficient to have already walked, and who has been able to walk, the loss of the use of his legs is gradual, though in general not very slow. He at first complains of being very soon tired, is languid, listless, and unwilling to move much or at all briskly. Soon after this he may be observed frequently to trip and stumble, though there be no impediment in his way; and whenever he attempts to move briskly, he finds that his legs involuntarily cross each other, by which he is frequently thrown down without stumbling; and when he endeavours to stand still in an erect posture without support, even for a few minutes, his knees give way and bend forward. As the distemper advances, it will be found that he cannot, without much difficulty and deliberation, direct either of his feet exactly to any one point; and very soon after this, both legs and thighs lose a good deal of their natural sensibility, and become quite useless. In adults, the progress of the disease is much quicker, but the symptoms nearly the same.

Until the curvature of the spine is discovered, the complaint generally passes for a nervous one; but when the state of the back bone is adverted to, recourse is almost always had to some previous violence to account for it. That this might have been the case in some few instances might be admitted; but in by far the greatest number some predisposing cause must be looked for.

Mr Pott, who has written a treatise upon this disease, recommends it to our observation, that though the lower limbs are rendered almost useless, or even entirely so, yet there are some circumstances in which it differs from a common nervous palsy. The legs and thighs, though so much affected, have neither the flabby feel of a truly paralytic limb; nor have they that seeming looseness at the joints, nor the total incapacity of resistance, which allows the latter to be twisted almost in all directions: on the contrary, the joints have frequently a considerable degree of stiffness, particularly the ankles; by which stiffness the feet of children are generally pointed downward, and they are prevented from setting them flat upon the ground.

At first the general health of the patient seems not to be at all, or at least not materially affected; but when the disease has continued for some time, and the curvature is thereby increased, many inconveniences and complaints come on; such as difficulty in respiration, indigestion, pain, and what they call *tightness at the stomach*, obstinate constipations, purgings, involuntary flux of urine and fæces, &c. with the addition of some nervous complaints, which are partly caused by the alterations made in the form of the cavity of the thorax, and partly by impressions made on the abdominal viscera.

Mr Pott was led to a knowledge of the true cause and cure of this distemper, from observing the case of a youth of 14, who was restored to the use of his limbs immediately after a seemingly accidental abscess near the part. From this he was inclined to think, that the curvature of the spine was not the original cause of the disorder, but that the surrounding parts were predisposed towards it by some affection of the solids and fluids there; and he was confirmed in these suspicions by a variety of appearances, which he observed both in the living body and upon dissection of the subject after death; all of which are narrated at full length in his treatise upon this subject.

"The remedy (says he) for this most dreadful disease consists merely in procuring a large discharge of matter, by suppuration, from underneath the membrana adiposa on each side of the curvature, and in maintaining such discharge until the patient shall have perfectly recovered the use of his legs. To accomplish this purpose, I have made use of different means, such as setons, issues made by incision, and issues made by caustic; and although there be no very material difference, I do upon the whole prefer the last. A seton is a painful and nasty thing: besides which it frequently wears through the skin before the end for which it was made can be accomplished. Issues made by incision, if they be large enough for the intended purpose, are apt to become inflamed, and to be very troublesome before they come to suppuration; but openings made by caustic are not in general liable to any of these inconveniences, at least not so frequently nor in the same degree: they are neither so troublesome to make or maintain. I make the eschars of an oval form, about two-thirds of an inch in diameter on each side of the curve, taking care to leave a sufficient portion of skin between them. In a few days, when the eschar begins to loosen and separate, I cut out all the middle, and put into each a large kidney-bean: when the bottoms of the sores are become clean by suppuration, I sprinkle, every third or fourth day, a small quantity of finely powdered cantharides on them, by which the sores are prevented from contracting, the discharge increased, and possibly other benefit obtained. The issues I keep open until the cure is complete; that is, until the patient recovers perfectly the use of his legs, or even for some time longer: and I should think that it would be more prudent to heal only one of them first, keeping the other open for some time; that is, not only until the patient can walk, but until he can walk firmly, briskly, and without the assistance of a stick: until he can stand quite upright, and has recovered all the height which the habit or rather the necessity of stooping, occasioned by the distempers, had made him lose."

Chap. VII.

Of the Diseases of the Arterial System.

Sect. I. *General Remarks on the Diseases of the Arterial System.*

Of the Diseases of the Arterial System.

The diseases of the vascular system form an important class in systems of Nosology. In the diseases of every organ, the action of the arteries and veins is more or less influenced, though the changes of structure to which these vessels are subject are very limited. The only diseases

Of Varicose Veins.

Astley Cooper. There are several instances of this artery having been successfully tied, so that there is sufficient encouragement to adopt the practice in future cases, where there is room to tie the artery above the sternum. The operation is to be done by making an incision on the side of the artery next the trachea, laying bare the vessel, and carefully avoiding the par vagum and the recurrent branch in placing the ligature.

Sect. VI. *Of the Axillary Aneurism.*

Mr Keate of St George's Hospital, tied with success the axillary artery, where it passes over the first rib; and Mr Ramsden has lately tied the subclavian artery for an axillary aneurism. The patient, however, died. A similar operation was attempted by Mr Cooper, but he failed in tying the ligature round the artery, from the bulk of the tumor. Mr Blizzard completely succeeded in performing this operation. The great difficulty felt in these operations was the passing of the ligature below the vessel on account of its depth.

Chap. VIII.

Of the Diseases of the Venous System.

Sect. I. *Of Varicose Veins.*

When the veins of any organ become preternaturally dilated, they are said to be *varicose*. This state of the veins is most usually met with in those which are superficial, and seems to arise either from some mechanical cause preventing the ready flow of blood through them, or from the veins themselves losing the necessary support of the skin and adjacent parts. The gravid uterus, by pressing on the iliac vessels, frequently renders the veins of the lower extremity varicose. Various tumors produce similar effects. We also see the veins of the integuments of old people become tortuous and swelled from no mechanical pressure.

Varicose veins are a frequent attendant on ulcers of the leg, and it has been observed that the ulcer seldom or ever heals until the varix is cured.

Varicose veins of the extremities may generally be much relieved by the application of a proper bandage from the toes upwards; and in cases where this does not give relief, the venous trunk should be tied with a ligature as directed in aneurism.

Sect. II. *Varicose Spermatic Veins* (Varicocele).

The veins of the spermatic cord often remain varicose after inflammation of the testicle, and also in early life without any known cause. The disease is generally easily distinguished by the tortuous irregular swelling. It sometimes, however, acquires a large size; but even then its nature may be readily distinguished by placing the patient in a horizontal position, and applying pressure to the tumor.[a] By this the swelling disappears, and if the upper part be grasped so as to allow nothing to pass out of the abdomen, the swelling will nevertheless be again formed.

The disease occurs most frequently in the left side, and this may arise from the vein in that side not terminating directly in the vena cava, but in the emulgent.

Of the Diseases of the Testicle.

Treatment.—The use of astringents, along with a proper suspensory bandage, will generally afford relief. It has also been proposed to tie a ligature round one or more of the varicose vessels. In one case this was done with complete success.

Sect. III. *Of Hæmorrhoidal Tumors.*

The hæmorrhoidal tumor consists in a dilatation of the veins about the anus and extremity of the rectum. They are round smooth tumors of a purple colour, and more or less painful. They vary in their size and number. Sometimes they are accompanied by a regular periodical discharge of blood (bleeding piles), and in other cases no such discharge takes place (blind piles), and then they are more subject to inflammatory attacks.

Hæmorrhoids occur more frequently in women than in men, and they commonly arise from a long continued pressure on the rectum; as obstinate costiveness, prolapsus, gestation, calculus or tumors about the bladder, uterus, or vagina.

Treatment.—When they are inflamed, local bleeding, fomentations and poultices give much relief, care being taken at the same time to keep the tumors within the anus, and to keep the bowels very open by mild laxatives and clysters.

In some cases the piles acquire a very considerable bulk, and form a number of large and loose tumors round the anus, which prevent the free discharge of fæces. In such cases the tumors ought to be removed, and this may be best done with the knife; or, as sometimes happens, if they be so situated as to render this dangerous, they may be removed by a ligature.

Chap. IX.

Of the Diseases of the Glandular System.

General Remarks on the Pathology of the Glands.

We observe a vast variety of diseases of the glandular system, and the greater number of these arise from a morbid state of their secretions. We see striking examples of an increased secretion in diabetes, in the mercurial salivation, and in many bilious disorders: on the other hand the natural secretion is diminished in suppression of urine, in dryness of the mouth, &c.

An alteration in the secretory function is not, however, the only disease of this system; there are a great number of organic alterations of structure with which they are affected, and a variety of tumors are also found to form in them. As, however, most of the principal glands of the body are situated within the larger cavities, few of their diseases come within the province of the surgeon.

Sect. I. *Of the Diseases of the Testicle.*

1. *Of the Schirrus and Cancer of the Testicle*, (Sarcocele).

This affection is liable to a considerable variety in its appearances; and as in the description of it which has been given by authors, they have included symptoms of diseases

Of the Diseases of the Testicle.

diseases which are very different from the true scirrus.

The most remarkable symptom of scirrhous testicle is a gradual enlargement and induration of the body of the gland or epididimis, advancing from one point, without marks of inflammation or pain. Along with its increase in bulk it acquires additional hardness, and its surface, from being smooth, turns by degrees unequal and knotty. The integuments become of a purplish red, at last ulcerate, discharge a fœtid ichor, and a cancerous fungus grows from the wound. The spermatic chord also becomes enlarged, knotty, and hard, and the glands of the groin swell, the health of the patient becoming entirely destroyed, and at last carrying him off in the greatest misery.

Symptoms.

The progress of this disease is in general slow, and is commonly attended with an aching sensation about the testicle, and severe pain darting from it to the loins, particularly when the testicle is not supported. The disease is most frequent in the advanced stages of life. It commonly arises from an unknown cause. It has at times been known to succeed a venereal affection, but this is by no means common, and it is sometimes preceded by a blow or some accident which excites inflammation.

Appearances on dissection.

When the scirrhous testicle is examined by dissection, Dr Baillie observes that "it is found to be changed into a hard mass of a brownish colour, which is generally more or less intersected by membrane. In this there is no vestige of the natural structure, but cells are frequently observable in it containing a sanious fluid, and sometimes there is a mixture of cartilage." Sometimes water is found collected in the cavity of the tunica vaginalis, but more frequently the tunics adhere to each other. When the spermatic chord is affected, that exhibits the same changes of structure as the testicle itself.

Treatment.—When a testicle is known to be affected with the true scirrhus, all prospect of a cure by the exhibition of internal or external remedies becomes hopeless, as there is no fact better known and more severely felt in the history of scirrhus and cancer in every organ of the body, than its resisting all means of relief, but by the complete removal of the diseased part. In a few rare cases, by a moderate diet, keeping the bowels open, suspending the tumor, avoiding violent exercise, or any thing which may prove a source of irritation, the disorder has been said to be not only prevented from increasing, but has in a gradual manner entirely disappeared; but we much suspect that these cases whose termination was so favourable, have not been of a schirrous nature. This is probable from what is known of the termination of scirrhus in other organs of the body, and also from the difficulty we have in forming an accurate diagnosis in the diseases of the testicle. There are, we hesitate not to say, many testicles extirpated which might have been saved; for our imperfect knowledge of the various morbid changes of this organ, has made it too much an established practice to extirpate all testicles which are enlarged and hard, and which do not yield to mercury.

When, however, by an attentive examination of the history and symptoms of the disease, no doubt is entertained of its scirrhous or cancerous nature, the more speedily the tumor is removed, the better chance there is of a permanent cure. In performing the operation, care should be taken to remove completely every part suspected to be diseased, and no part of the skin should be left with a view of covering the wound more completely which has the least discolouration or mark of disease.

Mode of extirpating the Testicle.

The parts being previously shaved, the patient is to be laid upon a firm table covered with a blanket or mattress. His legs should hang over the table, and be supported by assistants. An incision is to be made through the integuments with a common scalpel, extending from a little above the external abdominal ring to the bottom of the scrotum. The cellular membrane around the spermatic chord is to be dissected back, and the chord laid fairly bare; and this part of the operation is much more easily accomplished when the incision through the skin is very free. A ligature of considerable thickness is to be put underneath the chord, and it may be introduced with a blunt-pointed needle or instrument (fig. 17. Plate DXIII.). The extent of the disease in the chord should now be examined as accurately as possible, and the ligature should be tied firm with a running knot, as far above the diseased part as possible. If any hardness extends to the external abdominal ring, the chord may be even dissected up along the inguinal canal, and the ligature put on at that place. The chord may be divided one-fourth of an inch below where the ligature has been applied, and then the whole of the testicle and its vaginal coat may be readily dissected away, taking care not to cut into the vaginal cavity of the opposite side of the scrotum. After the testicle is removed, the ligature should be loosened, and the spermatic artery and veins included in separate ligatures. The ligature upon the spermatic chord is to be left loose, so as to act as a tourniquet if a hæmorrhagy should ensue. Much care should also be taken to secure any arteries of the integuments of the scrotum which are seen bleeding; as we once met with a very troublesome hæmorrhagy from one of these retracting among the loose cellular texture, and not being seen after the operation. It therefore will be a good general rule to tie those with ligatures immediately after they are divided.

The wound is to be dressed, so as to be healed if possible by adhesion; and this may generally be accomplished, except at the upper part where the ligatures come through. With this view the wound and scrotum are to be carefully washed, and two or three stitches, as may be thought most expedient, are to be put through the edges of the wound; for in a part like the scrotum, where the skin is loose and puckered, it is hardly possible to apply adhesive straps with sufficient accuracy, so as to serve the purpose. Small pieces of adhesive plaster, however, should be neatly placed between each of the stitches, along the whole extent of the wound, and a pledget of simple ointment and compress afterwards to be laid over it, the whole being secured with a T bandage.

After the operation, the patient is to be put to bed, being directed to lie on his back with a pillow between the thighs, so as to support the scrotum.

Opiates should be given to allay pain, and if any inflammatory symptoms supervene, bleeding at the arm should be had recourse to without the least hesitation; for

Of the Diseases of the Testicle.

for we have made a general remark, that after almost all surgical operations, there has scarcely ever an instance occurred where the patient died from loss of blood, and on the contrary, that almost all patients who have lost much blood, or who have been previously much emaciated, have recovered more quickly than these in full health. The antiphlogistic regimen in almost every case should be rigidly pursued, until at least all inflammatory appearances of the wound are gone, and a healthy suppuration commenced.

Mode of dressing the wound.

About four, five, or six days, according to circumstances, the dressings should be removed, and if the wound is healed by adhesion, the stitches may be withdrawn, and the edges of the wound kept together by adhesive plasters. The ligature on the spermatic chord may now be safely taken away, and that round the spermatic artery and veins generally comes readily away before the tenth dressing. In this manner the wound should be dressed daily until it is cicatrised. When the wound, instead of healing by adhesion, suppurates, the stitches may be taken away as soon as it appears that the edges of the wound can be accurately kept together with the adhesive plasters; for if the stitches are allowed to remain long, they generally ulcerate the contiguous skin, and form sinuses, which continue to discharge matter after the rest of the wound has healed. The wound should be dressed once or even twice in twenty-four hours if the discharge be profuse, and care should be taken to wash away with a sponge any matter which may be deposited on the sound skin of the scrotum or groin. The edges of the wound should be brought accurately together at each dressing, any matter collected in different parts of it should be gently squeezed out, so as to prevent any lodgement from taking place. Should the patient become weak from the continuance of the discharge, he should be ordered a nourishing diet, with a proper proportion of wine; and if the discharge be at any time thin and very profuse, we have found much benefit in such a case from the internal use of bark (cinchona).

2. *Inflammation of the Testicle* (Hernia humoralis).

Symptoms.

Inflammation is one of the most frequent diseases of the testicle. Sometimes the inflammation is confined to the substance of the testicle, at other times it affects the epididimis, and in some cases it spreads to the albuginea and vaginalis. The surface of the inflamed testicle is uniform and smooth, more or less sensible to the touch, equally firm and tense throughout when pressed upon, and the integuments are generally discoloured, having a blush of redness, and interspersed with varicose veins. When examined by dissection, the testicle exhibits, according to Dr Baillie, precisely the same appearances as the inflammation of the substance of other parts. The vas deferens sometimes partakes of the inflammation, its coats becoming considerably thickened, and in other instances the veins of the spermatic chord become varicose. Inflammation of the testicle most frequently is preceded by gonorrhœa, but it also occurs from a variety of causes. It occurs sometimes from exposure to cold, from violent exercise, and is often excited from blows, riding on horseback, &c.

The inflammation of the testicle concomitant of gonorrhœa generally begins by spreading along the vas deferens from the prostate gland through the inguinal canal till it comes to the testicle; it is in most cases attended with excruciating pain from the rapidity of its progress; and as it commonly comes on when the gonorrhœal discharge diminishes or disappears, and subsides when the discharge returns, many authors have supposed that it was a true metastasis of the venereal matter.

If the disease be left to itself, the body of the testicle becomes more hard and painful, with all the symptoms of local inflammation, and the tumor sometimes acquires an enormous bulk. Sometimes the inflammation is accompanied with violent fever, with a pulse hard and strong in the plethoric, and feeble and rapid in constitutions which are delicate and irritable. The patient also often complains of pains in the loins, and has nausea and vomiting. In general the discharge from the urethra diminishes considerably, and often it ceases altogether before the testicle becomes affected; but sometimes that does not happen in any remarkable degree till one or two days after the swelling has begun to appear. It never happens that both testicles are affected at the same time, but when the swelling of one disappears, often the other begins to be attacked.

The testicles sometimes swell and inflame from the absorption of the matter of a chancre, and as the progress of the swelling is in such cases slow, and generally more irregular, it has sometimes been mistaken for a schirrous testicle; but an investigation into the history of the case, and particular attention to the appearance of the skin of the scrotum, and any symptoms of the venereal disease in other parts of the body, will generally lead to a knowledge of the true nature of the case. It sometimes happens that inflammation is chiefly confined to the spermatic chord, and in many cases it affects the epididimis alone. The extent of the disease is always easily ascertained by a careful examination of the parts. It seldom happens that both testicles are inflamed at once; we have, however, remarked this to take place. Inflammation, such as has now been described, generally abates by the application of proper remedies: in some cases, however, an induration of the testicle remains. It terminates, though rarely, in suppuration.

Treatment.—When an inflammation has arisen from a blow, from exposure to cold, or from any injury done to the testicle, it ought to be treated according to the general plan laid down of treating inflammation of other organs. Local bleeding by leeches is a most useful remedy, and ought to be the first thing employed if there is the slightest pain, tenderness, or redness of the scrotum. Fomenting the scrotum with warm water, or a decoction of poppy heads, chamomile flowers, or tobacco leaves, often gives much relief, and great attention should be paid in supporting the testicle with a silk net truss (Plate DXIV.). Some have also used with success the application of ice or snow to the part. If the symptoms and pain are very violent, bleeding at the arm may be necessary. The bowels should be kept open, and even purged; the patient should be confined to a low diet, and he should keep as much as possible to the horizontal posture, as this is found to be of the greatest importance in promoting the cure.

When the inflammation arises from gonorrhœa, particular attention must be paid not only to the disease in the testicle, but to that of the urethra. Indeed it is of much importance in the treatment of gonorrhœa to use means

Of the Diseases of the Testicle.

means to prevent the testicles from becoming inflamed; and as every thing which causes a suppression of the discharge tends to produce a swelling of the testicle, it is natural to suppose, that in order to prevent this troublesome disorder, every thing should be avoided capable of increasing the irritation and inflammation of the urethra, as exposure to cold, violent exercise, ill chosen injections, and balsamic medicines; but, above all, the use of a suspensory is most efficacious, and Swediaur * recommends one to be worn in every case of gonorrhœa from the commencement of the disease, to prevent all risk of the testicles becoming inflamed. When the inflammatory symptoms are severe, the treatment should be adopted as we have recommended in common inflammation of the testicle. If the discharge from the urethra is stopt, means should be used to restore it. Whenever the inflammatory fever is rendered more mild, Swediaur recommends, with this view, a dose of opium to be given, and according to circumstances, an injection composed of two or three ounces of oil of linseed and decoction of barley, along with fifty or sixty drops of the vinous tincture of opium. This may be repeated every ten or twelve hours, taking care always to have the bowels well opened before using it. Swediaur has found the extract of hyoscyamus in many cases answer better than opium. Fomentating the penis and adjacent parts with warm vinegar and water, injecting warm oil, and the use of bougies, may also be advantageous in promoting the discharge from the urethra.

* *Traité sur les Maladies Vénériennes.*

3. *Induration of the Testicle.*

After the inflammatory symptoms have abated, it generally happens that a degree of swelling and hardness of the body of the testicle, but still more frequently of the spermatic cord or epididimis, remains, and in many cases continues for months, or even during life. This effect takes place from whatever cause the inflammation may have arisen. In many cases the testicle itself remains quite sound, and the epididimis is converted into a very hard unyielding mass, which feels as if it were injected with quicksilver. Sometimes the testicle, whilst it remains hard, diminishes in size, and becomes much smaller than natural. When the testicle is examined by dissection, it is found to have lost its natural structure, and is sometimes changed into a hard brown-coloured mass (Voigtel), intersected more or less by membranous bands; sometimes parts having a cartilaginous quality appear in it, and sometimes cells are formed which contain matter. The seminal vessels are so changed and hardened, that they cannot be distinguished from each other. In some cases the whole testicle has been found converted into a cartilaginous mass, and in a few instances some parts of it have been converted into bone.

Treatment.

The treatment usually recommended in cases of induration of the testicle preceded by inflammation, are strong stimulating and astringent applications; such as solutions of the muriate of ammonia, acetate of lead, sulphate of zinc, &c. either applied by moistening with them a piece of linen, which is to be kept constantly wet, or by using them in the form of a poultice. Frictions with mercurial ointment, either singly or combined with camphor, over the scrotum and perinæum, sometimes produce a good effect; mercurial fumigations to the genital organs have also been recommended. In some cases the internal use of mercury has been found necessary. A mercurial plaster with camphor, or the common soap plaster, is also a good application, and is very useful in defending the testicle.

The internal and external use of the hemlock (*conium maculatum*) has been much recommended by Plenk. Electricity has also been successfully employed. The muriate of lime, and the muriate of barytes, have been used by some authors. Swediaur says that he has known some affections of the testicle produced by gonorrhœa, and also some diseases of the eye from the same cause, cured by the patient getting a fresh infection. In a few cases of induration, and swelling of the testicles, we have employed blistering with good effects. The scrotum should be shaved before this is done; and it is often necessary to repeat the blister several times before the hardness or swelling begin to abate.

4. *Abscess of the Testicle.*

Symptoms.

It sometimes, though rarely happens, that the testicle suppurates. The matter which is formed, is commonly a tough, thready, yellow-coloured substance, which adheres to the surface of the cavity in which it is contained. Sometimes there is only one abscess; in other cases the matter is contained in several small irregular shaped cavities. Sometimes the matter is formed in the very middle of the body of the testicle; in other cases we have observed small abscesses in different parts of the epididimis, the body of the testicle remaining quite sound. When an abscess is formed in the testicle, the structure of the gland becomes more or less changed; generally instead of being soft, and the tubes of which it is composed being easily separated, it degenerates into a hard firm mass.

Treatment.

Abscesses of the testicle should be opened as soon as possible, in order to prevent the substance of the testicle from being destroyed. The presence of matter is learnt by a fluctuation which can be felt externally: but it is often extremely difficult to determine the true situation of the abscess, whether it is formed in the body of the testicle, in the epididimis, or between the albuginea and tunica vaginalis, or in the cellular membrane external to the tunica vaginalis; for when such a degree of inflammation has taken place as to terminate in the formation of an abscess, the accompanying swelling destroys the natural form of the parts, and converts the whole into a shapeless mass. Richter remarks, that there are sometimes soft spots in the testicle, in which it is believed there is a fluctuation. When such swellings are opened no matter is discharged, nothing but blood appears, and the inflammatory symptoms are afterwards increased. The more matter discharged from an abscess of the testicle, the smaller the testicle grows, as the matter is sometimes formed partly of the thready substance of the testicle. Cases have occurred where the whole testicle has been pulled away, the surgeon having mistaken the seminiferous tubes for sloughs. Abscesses of the substance of the testicle seldom heal, and generally a fistulous opening remains, through which there is a permanent oozing of the seminal fluid.

5. *Fistulous Sinus of the Testicle.*

As far as we know, no author has taken notice of this appearance. In one case we observed it very remarkable. The epididimis alone was swelled, and there was

Of the Diseases of the Testicle.

a thickened portion of scrotum adhering to one part of it, in which there was a small *sinus*, and through which the seminal fluid constantly oozed. In a similar case the sinus was laid open, but with no good effect; for a small opening remained unhealed, through which the semen continued to be discharged.

6. *Scrofulous Testicle.*

Symptoms.

When the testicle is affected with scrofula, it presents some of those general characters of scrofula in other glandular parts. Its tubular appearance is destroyed; it becomes enlarged; and when cut, it is found to be composed of a dull white substance, of the consistence of curd, which in some parts is mixed with a thin puriform fluid. The scrotum is in almost all cases involved in the disease; it becomes red and inflamed, and the vaginal coat adheres to the albuginea. Abscesses also form in various parts of the cellular membrane of the scrotum, which sometimes communicate with the body of the testicle. This disease generally occurs during the early periods of life, and most commonly only one testicle is affected with it. Sometimes, however, when one recovers, the same disease attacks the other.

Treatment.

In most cases of this kind surgical aid does not avail much, for the progress of the disease cannot be checked by any internal and external remedies. All that can be done is to relieve the inflammatory symptoms, to allay pain, and to prevent the formation of sinuses. With a view to alleviate the symptoms of inflammation, nothing is so beneficial as the application of leeches to the scrotum, and the use of fomentations and poulticing, or solutions of the acetate of lead. Opiates and laxatives may be also freely given, unless in cases where from experience these are known to disagree. When matter has once formed, the sooner it is discharged the better, and this should be done by a small incision. After one abscess has healed, others are very apt to form in succession; these should be treated in the same manner, and if at any period of the disease sinuses form, they should be at once laid completely open to the bottom; or if they are very deep and extensive, a seton may be introduced; if this, however, does not produce an adhesion of the cavity, they should be laid open with a bistoury in the manner directed when treating of *sinuses*.

7. *Testicle preternaturally small, or wanting.*

After violent attacks of inflammation, or in cases of abscess, the testicle sometimes diminishes greatly in size, is almost entirely absorbed; and in a few instances people have been born with them much smaller than natural (Baillie). Sometimes a testicle has been known to waste away without any known cause, so as to disappear altogether. Sometimes one testicle, and sometimes both remain in the cavity of the abdomen through life; so that a person appears to have only one testicle or to be without them altogether. Mr Hunter suspects that in these cases they are not so perfect as when they descend into the scrotum; and if we were to reason from what is observed in other animals, in the horse particularly, where this by no means unfrequently takes place, it is highly probable that when the testicles do not descend into the scrotum, they are not capable of performing their functions.

These cases, though they cannot be relieved by medical aid, yet they are worthy of the notice of medical men.

8. *Fungus of the Testicle.*

There sometimes arises from the testicle a species of fungous tumor, which was first accurately described by Mr Lawrence, demonstrator of anatomy at Bartholomew's hospital, in London.

Symptoms.

The patient generally assigns the origin of the complaint to some injury. In some cases, it is the consequence of *hernia humoralis*, and in others it appears spontaneously. The scrotum, after a certain length of time inflames, and adheres to the testicle already swelled; at last the skin ulcerates, and the opening thus formed, instead of discharging matter, is filled up with a fungous tumor, which is of a firm texture, and generally insensible. Whilst the fungus is increasing, the inflammation of the scrotum diminishes; and if the fungus is at this time removed, a cicatrix is formed in the skin, which adheres to the testicle. There is sometimes a copious and very fœtid discharge from the whole surface of the fungus. On dissection, the fungus is found to arise from the pulpy substance of the testicle, more or less of which remains according to the duration and extent of the disease.

It may be worth while to remark here, that we have met with one case, where, from an abscess and ulceration of the scrotum, the testicle itself slipt out at the ulcerated orifice, and exhibited very much the appearance of the fungus above described.

Treatment.

This species of tumor may be safely removed by the knife, by ligature, or by escharotics; the removal by the knife is perhaps the safest, and certainly the most expeditious method.

For an account of *Fungus Hæmatodes* in the testicle, we refer to *Wardrop's Observations on Fungus Hæmatodes.*

SECT. II. *Of the Diseases of the Mamma.*

Of the Diseases of the Mamma.

General observations.

From the changes which take place in the female breast at the age of puberty, during the menstrual discharge, and before and after the birth of the child, we ought to expect a considerable variety in the diseases of this organ; and, in considering these, we should always keep in view the powerful sympathy between that gland and the uterine system.

The gland of the mamma is subject to inflammation and abscess. Scrofulous tumors also form in it; it is subject to a particular disease, called milk abscess, to scirrhus, and to other indurations, the nature of which is not well ascertained.

The nipple and integuments around it are subject to particular kinds of excoriations and ulcerations; the lymphatic glands which lie close to the mamma, are also frequently diseased, and the contiguous cellular membrane is subject to those diseases which are met with in the cellular membrane of other parts.

At the age of puberty, when the uterine system becomes fully developed, the female breast swells, turns hard, and becomes tender, or even painful. A change also takes place during pregnancy; the breast enlarges, becomes very tender and painful, and a dark-coloured zone is observed round the nipple. In women who are suckling about the ninth or tenth month after parturition, and sometimes sooner, the menses reappear; and if

Of the Diseases of the Mamma.

if the woman afterwards continues to suckle, at each monthly return a remarkable change takes place in the milk; it loses its sweetness, acquires a bitterish taste, becomes of a reddish colour, and excites a temporary derangement in the system of the child. Obstructions of the menses, their final cessation, and all the diseases of the womb, affect more or less the mamma; and at the age of puberty, the time of menstruation, during pregnancy, in the early months of suckling, and at the time of the cessation of the menses, blows and other injuries are most apt to produce disease in the mamma.

This consent between the mamma and uterine system ought to be always kept in view when forming our opinion of any disease in these organs; and it is particularly worthy of the notice of surgeons when operations on that organ become necessary.

1. *Of Inflammation and Abscess of the Mamma.*

This disorder occurs most frequently in nurses by the stoppage of the milk, which is always occasioned by sudden or imprudent exposure to cold.

Treatment. In the early stages of the affection, resolution is to be attempted, unless the swelling appears to have an evident tendency towards suppuration. The remedies used in inflammation, in general, seem useful in every case of inflammation of the breasts. When the patient happens to be nursing, a sudden evacuation of blood is apt to diminish the quantity of milk: In such cases, therefore, blood is to be extracted in small quantities at a time. The application of cooling saturnine poultices is adviseable. When suppuration is taking place, fomentations and poultices are to be used, and the matter is to be discharged by making an incision in the most depending part of the tumor.

2. *Of Scirrhus and Cancer of the Mamma.*

Cancer has been met with in the female breast more frequently than in any other part of the body. We have also seen an example of it in that gland of the male; but such instances are extremely rare.

The commencement and progress of a scirrhous tumor in the female breast, is extremely various in different people; and has been often the cause of scirrhous tumors, and tumors of a more benign nature, being mistaken for one another.

Symptoms. Scirrhous tumors have generally made some progress before they are taken notice of. Sometimes they are first felt like a pea underneath the skin, and lying loose over the gland of the mamma; in other instances, a portion of the central part of the gland is found indurated. Of whatever bulk, and in whatever situation the swelling be discovered, it is remarkable for its unyielding and incompressible hardness, and its rugged unequal feel.

When the tumor is small it seldom gives any pain, and the patient generally discovers its presence by accident. In some cases its existence is discovered by an acute pang darting through the breast leading to its examination; but in many cases it acquires the bulk of a large hazel nut or walnut, particularly when the patient is fat, before any circumstance leads to its discovery.

As the tumor increases in bulk, it advances towards the surface of the body and adheres to the skin. The skin then becomes thickened, inflamed, and ulcerated. If the tumor be situated near the nipple, the disease speedily affects that part, sometimes enlarging and hardening it; and in other cases puckering it and drawing it inwards. When the nipple becomes involved in the disease, the sanious fluid formed in the tumor often escapes before the skin ulcerates, by the lactiferous tubes.

The pain which accompanies the tumor in its more advanced form, is generally of a lancinating kind; but its frequency and degree is susceptible of great variety. Sometimes sharp stinging pains pass frequently from the tumor as a centre, and extend through the whole breast; in other cases there is more of a burning heat in the part.

The progress of the disease is generally very slow, and in many cases three, four, or more years elapse before it ulcerates. When ulceration has taken place, the appearance of the ulcer is similar to that we have described when treating of cancer of the skin *; and the progress of the ulceration is often so slow, that many years elapse before the disease proves fatal.

* See Chap. II. sect. IV.

Scirrhous tumors have been met with in the mamma, from the age of twenty or twenty-five, to a very advanced period of life; but they occur about that period, when the catamenia disappear, much more frequently than at any other.

Treatment.—There is no part of practice about which less has been satisfactorily established, than the treatment of scirrhus in the mamma. The good effects of an early extirpation of cancer in the skin is very generally admitted; but the want of success in removing scirrhous mammæ in the hands of many, has not only led some surgeons to desist from performing an operation, except in very recent cases, but has even deterred others from attempting their removal in the first stages. There are no doubt many patients who submit to a painful operation from which no relief can be reasonably expected; on the contrary, the irritation and fever occasioned by it seem to hasten the progress of the disease. But there are others where this practice has had a happier effect, and where the patients have lived for many years without a return of the disease. Whenever, therefore, a scirrhous tumor appears in the mamma, which is moveable and distinctly circumscribed, past experience warrants us in removing it. On the other hand, when any of the absorbent glands have become enlarged and hardened, or when the skin has ulcerated, we believe that the operation should not be resorted to. Some solitary examples of the disease, assuming this form, may have occurred to individuals, where an operation has arrested the progress of the disease; but these, opposed to the vast number of unsuccessful cases, are by no means sufficient to warrant the operation.

Method of Extirpating the Mamma.—In extirpating the mamma, which we shall first suppose is to be done where the skin is sound, and where the tumor has no uncommon adhesion to the pectoral muscle, the patient ought to be placed horizontally in a bed, or upon a table covered with a mattress. Two incisions are to be made with a common scalpel through the skin and cellular substance along the whole extent of the tumor, including a small portion of skin. When the longest diameter of the tumor is across the body, instead of a longitudinal incision, a transverse one is to be made. The integuments being dissected from the mamma on both sides of the incisions, the patient's arm is to be extend-

Of the Diseases of the Mamma.

ed to save the pectoral muscle; and the whole glandular part is to be detached from the muscle, though a small portion only should be diseased, beginning at the upper side, and separating downwards. After the diseased parts are removed, the wound is to be cleaned with a sponge wrung out of warm water, which will generally render the small bleeding vessels more conspicuous. These are to be tied, and the integuments are to be closely applied to the parts underneath, and retained there by adhesive straps. A large pledgit of simple ointment is now to be laid over the whole; and this is to be covered with a compress of lint, tow, or soft linen; and the dressings to be kept in their place, and moderate pressure made by a circular roller and scapulary bandage.

3. *Of Sore Nipples.*

Women are more generally affected with sore nipples in suckling their first child than at any future period. This may, in some measure, be owing to the smallness of the nipple; but very often it arises from their being unaccustomed to the irritation of sucking. In some cases, the nipples are so flat, and so much sunk in the breast, as to render it difficult for the child to lay hold of them. Here assistance can sometimes be given, by the mother pressing back the prominent part of the breast, so as to make the nipple project between two of her fingers. Should this be insufficient, the nipple may be made to project by applying to it a stout child several months old: but when this cannot be done, breast-glasses * may answer the same purpose. By applying these to the nipple, and sucking out the air, the child will commonly be enabled to lay hold of it.

* See Plate DXV.

The nipples at this time are liable to excoriations, cracks, or chops; which, though not attended with a formidable appearance, are frequently more distressing than large ulcers. Mild, astringent, and drying applications are most to be depended upon in such complaints; saturnine water, or lime-water, will answer; and either ought to be applied warm. After bathing the parts with any of these, the nipple should be covered with Goulard's cerate. Even a little soft pomatum frequently rubbed upon the part, and covered with a soft linen rag, is sometimes found to give considerable relief. But the nipple should be perfectly cleared of these applications before the child is laid to the breast; and this may be done with a little port wine, or equal parts of brandy and vinegar. If proper attention be paid to these remedies, they will commonly be found to have the desired effect; but if the contrary should happen, another remains to be mentioned, which, in different instances, has given great relief: it consists in the application of a thin skin to the nipple, as the neck and part of the body of a swine's bladder with an aperture in it; which, being properly moistened and fixed to the breast, will completely protect it in the time of sucking. As long as the nipples remain any way affected, small cups of glass or tin are useful for retaining the dressings, defending the nipples from the friction of the clothes, and receiving any milk which may fall from the breast.

Anomalous swellings of the mamma.

Swellings and hardnesses are found in the breast which are not of a scirrhous nature. Scrofulous indurations are particularly frequent. They often become old and hard, and are then commonly considered as cases of the *scirrhus*. If the surgeon succeeds in discussing them by means of any kind of remedy, he is apt to think that he has discussed a scirrhus. These scrofulous swellings sometimes inflame, and the progress of the inflammation is very tedious. The breast is long painful before any softening or fluctuation can be perceived. The surgeon then perhaps considers it as an occult cancer, extirpates it, and thinks that he has successfully cured a *cancerous* affection. If the surgeon opens such a suppurating knot before all the hardness is dissolved by the suppuration, and if he makes a large opening, there commonly follows a very malignant ulcer, which may be mistaken for a cancerous sore. Many cases, where ulcerated cancers have been supposed to have been extirpated with success, may have been of this kind.

Venereal indurations are not unfrequent in the breast, and also cause similar mistakes in practice. Encysted tumors are also met with in the breast, and are most commonly of that kind called *meliceris*.

In the breast of young girls, ten or twelve years of age, hardnesses sometimes appear, which disappear as soon as menstruation takes place. Sometimes they do not go away until the first delivery. Sometimes the breast swells to an enormous size, and becomes indeed not hard, but throughout firm, like muscular flesh. In such a case the extirpation has been successfully performed.

Sometimes considerable and often quite hard swellings appear in the breasts, which proceed merely from blood. In such cases blood flows from the nipple at each menstrual period. When the menses disappear with years, the discharge of blood no longer appears from the breast; but then there is a hard not painful swelling arises, which often acquires a considerable size. If it is opened, coagulated and fluid blood is discharged, and a fistula follows, which discharges a purulent fluid, and sometimes pure blood, and often continues several years, without giving great uneasiness. The swelling, which was at first quite hard, sometimes becomes soft, and then the surgeon is commonly induced to open it. Sometimes such swellings are observed in women who have the menstrual discharge; and in such cases the swelling always becomes greater at each period. Sometimes hectic fever and death follow the opening of these tumors. (Monro). The mamma is also subject to *fungus hæmatodes;* for an account of which, we refer our readers to Wardrop's *Observations on Fungus Hæmatodes.*

Sect. III. *Of the Diseases of the Tonsils and Uvula.*

Of the Diseases of the Tonsils and Uvula.

1. *Of the Enlargement of the Tonsils and Uvula.*

The tonsils sometimes grow so large and hard as to become incurable, and even to threaten suffocation. The tumors have been commonly considered to be of a scirrhous nature; but they are neither attended with shooting pain, nor are they apt to degenerate into cancer; neither do swellings return after the tonsils have been extirpated: hence they ought not to be removed till by their size they essentially impede deglutition or respiration; but whenever they do this, they may be removed with safety. The only proper method of removing them is by ligature, which is not only void of danger,

Treatment.

danger, but seldom fails to perform a cure. If the base of the tonsil be smaller than the top, the ligature is to be used as for polypi in the throat; but however broad the base of it may be, much difficulty will seldom occur in fixing it, for the swelling is always very prominent. In diseases of this kind both tonsils are generally affected; but if the removal of one of them forms a sufficient passage for the food, the other may be allowed to remain. When, however, it is necessary to extirpate them both, the inflammatory symptoms produced by the extirpation of the first should be allowed to subside before any attempt be made to remove the other.

Of the Diseases of the Tonsils and Uvula.

When the form of the tonsils happens to be conical, so that the ligature would be apt to slip over their extremities, Mr Cheselden has recommended a needle (Plate DXV.) with an eye near the point: a double ligature being put into the eye, the instrument is to be pushed through the centre of the base of the tumor, and the ligature being laid hold of by a hook and pulled forwards, the instrument is to be withdrawn; then the ligature is to be divided, and so tied that each part may surround one half of the tumor. This method, however, is scarcely ever found to be necessary.

Enlargements of the uvula.

Enlargements of the uvula, from inflammation or from other causes, may generally be removed by the frequent use of astringent gargles, as of strong infusions of red rose-leaves or of Peruvian bark. But when these fail, and the enlargement is so considerable as to give great uneasiness by impeding deglutition, irritating the throat, and so causing cough, retching, and vomiting, extirpation is the only treatment upon which any dependence can be placed. Excision is the readiest method when the uvula is only elongated; but when the size is considerable, dangerous hæmorrhagies sometimes attend this method; on which account a ligature is preferable.

Treatment.

In performing the operation, the speculum oris (Plate DXV.) is necessary to keep the mouth sufficiently open, and the uvula should be laid hold of by a pair of forceps or a small hook, so as to keep it firm, and prevent it from falling into the throat. After the operation, if the bleeding be considerable, it may be checked by astringent gargles, or by touching the part with lunar caustic; but this will seldom be necessary.

When a ligature is to be employed, it may be readily done according to the method recommended in the extirpation of polypi. A double canula with a ligature may be passed through the nose, or the ligature may be applied according to Cheselden's method in extirpation of the tonsils.

2. *Of Scarifying and Fomenting the Throat.*

In inflammatory affections of the throat, the means commonly employed are gargles, fomentations, emetics, scarification, or topical bleeding. Gargles are useful for cleaning the fauces from mucus, or in cases of ulceration. In relaxation of the parts, they are employed with advantage when made of astringent materials. Fomentations may be of some use when externally applied; but the steam of water, &c. drawn into the throat, by means of Mudge's inhaler (fig. 1.) is preferable. Sometimes it is necessary to draw blood from the part affected. Here recourse may be had to scarifying, which may be readily done by the scarificator (Plate DXIV.

Plate DXV. fig. 11.

fig. 14.). After a sufficient number of punctures have been made, the flow of blood may be promoted by the patient's frequently applying warm water to the punctures. When an abscess forms, notwithstanding the use of these remedies, the matter may be discharged with the scarificator already mentioned.

Chap. X.

Of the Diseases of the Eye and its Appendages.

Of the Diseases of the Eye.

In the account of the diseases of the eye, we shall follow the same principles of arrangement as we have already adopted, and treat of the diseases of each particular texture of which the eye is composed, in the order in which they appear most natural; as the diseases of the *conjunctiva, cornea, iris, crystalline lens*, &c.

Sect. I. *Of Inflammation of the Conjunctiva.*

General remarks.

The general phenomena of inflammation of the conjunctiva, are analogous to those which have been already enumerated, when treating of the inflammation of *mucous* membranes *. Along with the symptoms there enumerated, there are others which arise from the peculiar functions of the organ. The eye cannot endure the usual quantity of light, vision becomes obscured, and there is an increased secretion of tears. The inflammation is sometimes confined to the palpebræ, sometimes to the conjunctiva covering the white of the eye, in some cases to that portion of it which forms the external layer of the cornea, and in others it spreads over the whole of these surfaces. These differences merely regard the extent of the inflammation: but there are others which arise from a difference in the specific nature of the disease, forming three distinct species; 1. The purulent ophthalmia; 2. The purulent eyes of new-born children; and, 3. The gonorrhœal ophthalmia.

* See Chap. III.

1. *Of the Purulent Ophthalmia.*

Symptoms.

The purulent ophthalmia appeared in this country as an epidemic after the return of our troops from Egypt in the year 1801. Since that period, it has spread with the greatest violence over most part of Britain. This disease generally begins with a peculiar purple-coloured redness over the whole eyeball and inner membrane of the eyelids. There is a sudden pain produced in the eye, as if sand or some foreign substance was lodged between it and the eyelid. As the redness increases, the conjunctiva becomes swelled, from the effusion of a transparent fluid in the loose cellular membranes, between it and the sclerotic coat. There is at first a profuse discharge of tears from the eye, and the eyelashes are glued together when the patient awakes. There is soon created intense pain in the ball of the eye, and a dull aching pain in the forehead. The cornea sometimes becomes opaque; and if the violence of the inflammation continues, it ulcerates and ruptures, allowing the aqueous humour to be discharged; after which, an abatement of the inflammatory symptoms generally takes place.

Before the disease advances thus far, the eyelids are generally considerably swelled; and, besides the flow of tears,

Of the Diseases of the Eye.

tears, there is a profuse discharge of a puriform fluid. The inflammation usually attacks both eyes, and it begins in one several days before the other.

Treatment.—In slighter cases of the disease, fomenting the eye with a decoction of poppy heads, and a brisk purge, have been found sufficient to abate the inflammatory symptoms. In other cases, however, it has been necessary to draw blood to a very great extent. When the disease occurs in a strong plethoric person, recourse should be immediately had to the lancet, and the operation repeated on any recurrence of the symptoms. It has been the usual practice of Dr Veitch, and of those who have had extensive opportunities of treating this disease, to draw the blood from the arm. A smaller quantity, however, taken from the temporal artery or external jugular vein, would be found to have an equally good effect.

When the purulent discharge becomes profuse, some have recommended the use of collyria, in the form of injections. The aqua camphorata is recommended by Mr Ware; and a weak solution of corrosive sublimate, with opium, has been found to have equally good effects. In those cases where there are much pain and tension in the eyeball and brow, along with a turbid state of the anterior chamber, and ulceration beginning in the cornea, the discharge of the aqueous humour has been attended with much success *. This operation may be easily, and at all times safely performed, by making a puncture with a common extracting knife, through the sound part of the cornea, near its junction with the sclerotic coat.

* See Mr *Ware's Treatise on the Purulent Ophthalmia.*

2. *Of the Purulent Ophthalmia in Children.*

The symptoms of the purulent eyes of children are very similar to those which have been mentioned. The disease generally appears a few days after birth by an increased redness of the palpebral membrane, more or less swelling, and a puriform discharge. Sometimes the membrane swells so much as to evert the eyelids, and render it impossible to examine the eyeball. The cornea becomes obscure, ulcerates, and allows the aqueous humour to be discharged. The disease generally affects both eyes. From what we know of the origin of purulent ophthalmia, and from some ingenious observations of Mr Gibson of Manchester †, it appears probable, that the origin of this disease is communicated by the lodgement of an acrimonious discharge upon the eyes of the child, from the vagina of the mother. In a great proportion of cases, Mr Gibson found the mothers of those children, affected with purulent ophthalmia, had leucorrhœa; and it is probable, that this, as well as other acrimonious discharges, which we know take place from the mucous membranes of these parts, may produce the disease.

† See *The Edinburgh Medical and Surgical Journal*, vol. iii.

Treatment.—Solutions of saccharum saturni and opium, injected between the eyelids, or the aqua camphorata of *Beates*, ought to be employed in the first stage of the disease; and the eyelids ought to be likewise covered with some mild unctuous application. When ulceration has advanced so as to endanger a rupture of the cornea, that may be prevented by discharging the aqueous humour. In the second stage of the inflammation, scarifying the eyelids, and applying the red precipitate ointment, will generally be found to be useful in allaying the inflammation and swelling of the eyelids, and is restoring the transparency of the cornea.

3. *Of the Gonorrhœal Ophthalmia.*

The gonorrhœal ophthalmia occurs very rarely; and it has been known to arise from the suppression of a gonorrhœa, or from the accidental application of the gonorrhœal matter to the eyes. In this respect, its origin is very similar to the common purulent or Egyptian ophthalmia, and to the purulent ophthalmia which occurs in children.

The symptoms and progress of the disease are also similar, only that its progress is much more violent, and it generally completely destroys the organ.

Treatment.—When it is suspected that the disease has arisen from a suppressed gonorrhœa, such means ought to be employed as are most likely to restore the discharge from the urethra; such as the introduction of a bougie, the injecting of warm oil, and the application of poultices and fomentations to the perinæum. If the inflammatory symptoms run high, powerful evacuants should be employed. Besides purgatives, blood should be taken from the arm or temporal artery.

The local applications should consist of weak injections of corrosive sublimate and opium, or acetate of lead and opium; and the swelling and redness may be also relieved by the application of the red precipitate ointment, or the ointment of Janin.

SECT. II. *Of the Pterigium.*

The word pterigium denotes all those morbid changes in which that portion of the conjunctiva covering any part of the cornea or sclerotic coat becomes thickened, vascular, and opaque. If the disease be confined to a particular part of the conjunctiva, the disease is observed at its commencement like a small globule of fat, or condensed cellular substance, situated most frequently near the junction of the cornea and sclerotic coat; and this spot extending imperceptibly along the surface of the conjunctiva at length passes over the cornea, the conjunctiva on the adjoining part of the sclerotic coat becomes puckered, and as if it were forcibly drawn over the cornea. The portion of it which lies on the sclerotic coat is commonly loose, and can be easily elevated, but that which is on the cornea adheres more firmly. This species of pterigium has generally a triangular form; one of the angles of the triangle advancing towards the cornea, or covering a portion of it, and the base lying on the sclerotic coat. Sometimes the thickening of the conjunctiva is first perceived on the cornea; the conjunctiva covering the sclerotic coat remaining quite sound. A pterigium is always considerably elevated above the adjacent cornea; but the degree of its thickness varies from that of a thin membrane to that of a fleshy mass.

Pterigia arise most commonly at the nasal angle of the eyeball. They are formed, also, at the temporal angle; and they sometimes occur at both places in the same eye. In one case there were two pterigia in each eye. They are formed very rarely on the upper and under parts of the eyeball.

Treatment.—The only mode of removing this disease is by excision. This may be done by elevating the diseased portion of the conjunctiva with a pair of forceps; and separating it at its base by cutting it through with a pair

Of the Diseases of the Eye.

pair of scissars; and then carefully dissecting it off to its apex. If any portion of it has been allowed to remain, or if the wound shews any tendency to form a fungus, lunar caustic ought to be applied to it, and the application repeated as often as may appear necessary. Any slight inflammation or weakness in the eye which may continue after the operation, may be speedily removed by the application of the vinous tincture of opium.

Sect. III. *Of Pustules* (Ophthalmia pustulosa).

Symptoms.

Pustules are small tumors which are formed both on the cornea and sclerotic coat, but they occur most frequently near the junction of these membranes. A pustule commonly first appears like a dusky yellow or reddish spot, a little elevated above the surface of the cornea or sclerotic coat; and in a short time it becomes a distinct conical tumor. The adjacent part of the cornea is always more or less dim; and a considerable degree of inflammation accompanies it, which is either confined to the white of the eye contiguous to the pustule, or is spread over the whole eyeball. Whilst the pustule is forming, the inflammation is generally confined to that part of the white of the eye which is in its immediate vicinity. The blood vessels are of a pale livid hue; they appear superficial, and can be readily elevated by a pointed instrument; each trunk can be distinguished, for they are never so numerous as to appear confused, or like one red mass. They sometimes run in various directions, anastomose freely with one another, forming net-works upon the white of the eye.

If the inflammation and pustule remain for some time, the pustule generally advances to suppuration. When suppuration takes place, the apex of the pustule ulcerates, and frequently a chalky white spot appears at the centre of the ulceration; and the opacity of the cornea at the same time daily increases around it. In other cases, the opaque matter separates, and leaves behind it a deep ulcerous excavation.

Sometimes the suppuration proceeds more like a common pimple or phlegmon of the skin; a small quantity of a thick matter collects within the pustule, and when it is discharged, a conical tumor remains, which has a depression at the apex. When the pustule contains a watery fluid, the fluid is most frequently absorbed in a gradual manner; but at other times the pustule breaks, and an ulcer is formed.

If, in either of these cases, the contents are artificially discharged, all the accompanying inflammatory symptoms are much increased.

Most frequently there is only one pustule, and only one eye affected; but in some cases there are several both on the cornea and sclerotic coat of each eye.

The disease, at its commencement, is almost invariably accompanied with the sensation of a mote in the eye, and the whole conjunctiva covering the sclerotic coat has often a yellowish and shining glassy colour before the redness appears. There is often also a degree of redness and swelling, chiefly of the upper eyelid; and the tarsi are found adhering together in the morning, from the exudation of a yellow matter among the ciliæ. There is frequently an unusual dryness felt in the eye; but if it be exposed to a bright light, or if an attempt be made to use it, the secretion of tears is increased.

This species of inflammation is always accompanied with a much greater degree of general fever, in proportion to the severity of the local symptoms, than any other ophthalmia. The pain is rarely acute till the pustule ulcerates; but, if that takes place, it is commonly very severe.

An eye which has been once affected with pustule, is very subject to repeated attacks of the disease. Pustules of the cornea are met with in people of all ages; but they are more common in young people than in those advanced in life.

Treatment.—Sudorific medicines, cooling diluent drinks, and purgatives, ought to be employed in the first stage of the disease; and given according to the violence of the constitutional symptoms. The eye, and parts around it, should be fomented three or four times a-day, with a decoction of poppy heads; to which may be added a small quantity of spirits. When the symptomatic fever abates, and the redness assumes a more purple hue, the vinous tincture of opium may be applied to the eye once or twice a-day; and this will be found equally useful whether the pustule is in a state of suppuration or not; and it ought to be continued as long as there are any remains of the disease.

Sect. IV. *Of Matter collected between the Lamellæ of the Cornea.*

Purulent matter is sometimes collected between the lamellæ of the cornea, when the disease is termed *unguis* or *onix*; or in the anterior chamber, when it is called *hypopion*.

When the matter is collected between the lamellæ of the cornea, it appears in the form of a yellow spot; and as the quantity increases, the spot becomes larger, but does not alter its situation from the position of the head.

When the matter is collected in the anterior chamber, it generally appears like a small yellow globule between the iris and cornea, occupying the inferior part of the cavity. These abscesses are commonly the effect of violent ophthalmia, occasioned by a blow, or injuries of the eyeball; they are also formed, though rarely, without any accompanying inflammatory symptoms.

Treatment.—Though the purulent matter may be more or less absorbed on the abatement of the accompanying inflammatory symptoms; yet it would be found a good general practice to evacuate the matter whenever it apears, by making an incision through the cornea. The discharge of the aqueous humour along with the matter, never fails to diminish the inflammation; and this perhaps may be the reason why the practice is so useful. Besides this, fomentations, brisk purges, and cupping at the temples, may be necessary if the inflammatory symptoms are severe.

Sect. V. *Of Ulcers of the Cornea.*

Ulcers of the cornea have been divided by some authors into a number of species, from differences in their size, in their duration, in the degree of the severity of the accompanying symptoms, and from the various causes from which they have been supposed to originate.

The most frequent variety of ulcer is that which remains after the cornea has suppurated and burst; either in consequence of a pustule or of an abscess.

When a pustule suppurates, the central part of it generally

Of the Diseases of the Eye.

nerally gives way; and as the disease continues, the ulceration extends in all directions from that point. Ulcers of this kind are generally circular, and the edges rounded and smooth; having sometimes the appearance of a small artificial dimple: in other instances they have an irregular shape, and their edges are jagged and acute. The size of ulcers is very various; in some cases they do not appear larger than a depression made by the point of a pin, whilst in others they cover a large surface. Most frequently the part of the cornea contiguous to the ulcer becomes more or less dim; and in some cases red vessels may also be traced in it.

Treatment.—The acute pain which generally attends most ulcers, particularly those which are the consequence of pustules, will generally be much relieved by the application of the vinous tincture of opium, repeated two or three times a day. When this produces no good effect, and the ulcer spreads rapidly, attended with acute pain, much relief will be obtained by touching the surface of it with lunar caustic, or if there is a risk of the ulcer eroding the whole thickness of the cornea, and a prolapsus of the iris to take place, it may be advisable to prevent this by discharging the aqueous humor.

Sect. VI. *Of Specks of the Cornea.*

There are three forms of the corneal speck; the *first* and most simple variety, is when a particular part of the cornea loses its natural transparency, and appears clouded; objects being seen by the patient as if looked at through a mist or smoke. Some of these specks are undefined, others distinctly circumscribed, and they have each an equal degree of opacity throughout, or one part is more opaque than the rest. They are most commonly of a circular form; but in some cases their shape is very irregular. This size varies from the smallest spot, to such an extent as occupies the whole cornea.

In the *second* form of the corneal speck, the opacity is of a darker shade, giving the cornea a bluish, or in some parts a milky appearance. It is seldom equally opaque through its whole extent; being generally more so at the centre, and becoming gradually of a lighter shade towards the margin. In some instances the shade is very unequal in the different parts of the speck.

In the *third* form of the corneal speck, the cornea becomes of the opaque glistening white colour of common pearl, and the opacity generally extends through the whole of the lamellæ of the cornea; so that if even several of those layers which are external be removed, the remaining ones completely interrupt vision. Specks of this description sometimes produce a slight thickening of the cornea and are accompanied by adhesions between the cornea and iris. They are almost always distinctly circumscribed, though generally not so opaque at the edge. When they are of any considerable size, they are nourished by one or more red vessels.

In the first form of speck, the iris can be seen through the diseased portion of the cornea; but in the second and third form of the disease, the degree of opacity is such, that nothing can accurately be distinguished behind it. If there is an external inflammation accompanying the speck, the red vessels will be seen in a cluster on that part of the sclerotic coat nearest to it; and some of the branches can often be traced passing over the edge of the cornea, and terminating in the substance of the speck. As the accompanying inflammation abates, the number of the red vessels on the cornea commonly diminishes; but sometimes one or more trunks remain, and are distributed on the speck. In some cases, there are large specks with numerous blood-vessels supplying them during the continuance of active inflammation; and although the opacity remains extensive after the inflammation abates, yet no red vessels continue to nourish it. The number of blood-vessels is in no case in proportion to the degree or extent of the opacity during any stage of the accompanying inflammation. For we frequently observe a net-work of blood-vessels on a cornea which has very little obscurity, and at other times there is a large opaque spot, with only one, or even without a single red vessel supplying it. Specks appear on every part of the cornea, but most frequently towards its centre.

Specks appear to be formed most frequently on the external lamella of the cornea; but it is difficult to determine accurately their situation. They vary in number. Commonly there is only one; but it frequently happens that there are two, three, or more distinct spots on one cornea, all of which differ in their size, shape, and in degree of opacity.

Specks impede vision in proportion to the degree of their obscurity, and according to their situation. Even a speck of the slightest shade, which is hardly perceptible to a common observer, if it be placed directly opposite the pupil, materially injures the sight; whereas those of the opaque kind, if placed beyond its circumference, diminish the sphere, but not the distinctness of vision. In those cases where the speck is of a moderate size, and placed towards the centre of the cornea, the patient sees better in a dull, than in a clear light. For in a clear light the pupil contracts so much, that it becomes covered by the speck, and the rays of light are prevented from entering; but in a dull light it becomes larger, so that the rays of light enter by its edge.

Specks, most commonly, are either preceded or accompanied by inflammation of the cornea. Likewise wounds, if they do not unite without suppuration, and ulcers of the cornea, are followed by a speck.

Specks are formed at every period of life; but they occur most frequently in young people; probably because in them the cornea is much softer, and more spongy; and also as they are more subject to inflammatory complaints of the eye than adults.

Treatment.—Those specks which have been described under the *first* and *second* form of the disease, generally disappear either by the use of remedies, or in some cases after the inflammatory symptoms abate.

When the eye is inflamed, and the eyelids turgid with blood, slightly scarifying the eyelids, and immediately after the bleeding ceases, applying a quantity of an ointment composed of the red oxide of mercury (ten grains to a dram of simple ointment), will be found a very active remedy. And the scarifications along with the ointment should be repeated every second or third day as long as any inflammation continues. When there is no inflammation accompanying the speck, the ointment may be applied alone. The unguentum citrinum, and various powders composed of the sulphate of alum, sulphate of zinc, sub-borate of soda, diluted with from a fourth to an eighth

Of the Diseases of the Eye.

eighth part of sugar, may also be advantageously employed. In specks of long duration, it will be found useful to vary the application, and to employ two or three of the above medicines ten days or a fortnight alternately.

Those specks of the *third* form, seldom become more transparent, even by the use of the most active remedies. In those cases where only a small central portion is of that description, the size of the speck may be diminished by the treatment already mentioned; and in some cases, much benefit has arisen from cutting away an external layer of the most opaque part; and afterwards using the above applications. It often happens, however, that if portions of a very old and opaque speck be cut away, the part is regenerated by an equally opaque matter.

The specks which are formed rapidly, are in general most speedily removed. They go away, too, much more quickly in children than in old people; and in them, also, a much greater degree of obscurity can be made entirely to disappear. When a part of the cornea has become opaque, the opacity begins to disappear at the circumference of the speck, or at that portion of it nearest to the circumference of the cornea. In some cases it may also be observed, that the external laminæ of the cornea first regain their transparency.

Sect. VII. *Of the Staphyloma.*

When the cornea, besides losing its transparency, swells to such a degree, that its internal surface comes in contact with, and adheres to the iris, and when it forms a prominent tumor externally, the disease has generally been called *staphyloma*. When the whole cornea is affected, it generally assumes a more or less conical form; loses entirely its natural transparency; and vision is completely destroyed. The opacity is generally most remarkable towards the apex of the tumor, and is generally of a pearl white colour diffused through the whole corneal substance. The internal surface of the cornea adheres to the iris, and the pupil is in most cases altogether obliterated.

In many cases the cornea does not project beyond the eyelids: but in others, particularly in children, a large tumor is formed, which projects beyond the eyelids, and is attended with pain and inflammation, which, in some instances, renders the other eye weak and irritable.

Treatment.—When a part of the tumor gives way, and allows the contents of the tumor to be discharged, the patient always experiences a speedy relief, but the tumor is soon formed again; so that in order to prevent its growth, it is necessary not only to discharge its contents, but also to remove a portion of the diseased cornea of such a size as to prevent the humors from again collecting. A common extracting knife may be passed through the tumor, so as to divide a segment nearly equal to half the cornea, and the other half may be readily cut away with scissars. Inflammation and suppuration succeed; and the eyeball finally collapses if there be not a sufficient degree of inflammation excited. A pointed instrument may be introduced through the wound, so as to allow the crystalline lens, or any portion of the vitreous humour which may have remained, to be pressed out.

Sect. VIII. *Of Inflammation of the Iris.*

Inflammation seldom affects the iris alone, though in some cases it appears to be the principal diseased part of the organ. The disease is accompanied with intense pain on exposure to light; discoloration of the iris from the addition of red blood; disposition of the pupil to contract; and lymph to be effused on the surface of the iris and pupil.

Treatment.—Copious bleedings from the arm, or temporal artery, are generally necessary; and in order to prevent any permanent contraction of the pupil from taking place, much benefit will be derived from keeping it dilated by the action of an infusion of *belladona.*

Sect. IX. *Of the mode of Making an Artificial Pupil.*

The iris, whether from previous inflammation or other cause, has been often found with the pupil so much contracted, and adhesions formed between it and the capsule of the crystalline, to such a degree, as to prevent vision. The pupillar edge of the iris, too, sometimes adheres to the cornea, and is contracted; and sometimes a portion of cornea opposite to the pupil is a cause of blindness. In all such cases it has been repeatedly attempted to make an artificial pupil; but this operation has seldom been successful. Various modes have been proposed to perform it, but that recommended by Scarpa is entitled to most attention. This method consists in introducing a curved couching needle (Plate DXVII. fig. 20.), as in the operation of couching the cataract, passing its point through the iris at the place where it is intended the new opening should be made, and then forcibly tearing down a portion of iris from its connection with the ciliary ligament. After the operation it will be found useful to keep the iris for some time under the influence of belladona. We understand that Mr Gibson, an ingenious surgeon in Manchester, has operated with great success in a new manner. He makes the punctuation of the cornea at its transparent part with an extracting knife (Plate DXVII. fig. 1.), and presses the eyeball so as to squeeze the iris through the incision of the cornea; or if any adhesions render that impracticable, he drags it out with a hook (Plate DXVII. fig. 19.), and afterwards cuts away with a scissars the prolapsed portion. Then immediately the perforated iris falls back into its natural situation, leaving a proper opening.

Sect. X. *Of the Cataract.*

The most common disease of the lens is a loss of its natural transparency; and this arises either from a change in its structure, or from a deposition of new matter. The capsule of the lens is also subject to opacities. These diseases are known by the name of *cataract.*

There are *four* species of cataract generally enumerated. In the first, the crystalline lens itself becomes opake (*cataracta crystallina*). In the second, the capsule is changed in its structure (*cataracta membranacea*). In the third, the liquor Morgagni becomes opake (*cataracta interstitialis*); and when all those parts are affected at the same time, it has been denominated the mixed cataract, (*cataracta mixta*).

Of the Diseases of the Eye.

Consistence of cataracts.

When the crystalline lens becomes opake, the opacity generally begins towards the central part of the lens, and extends towards its circumference; in other cases a general obscurity extends over the whole lens.

The consistence of the lens varies very much in the different kinds of cataract. Sometimes it is converted into an aqueous or milky fluid, or like thin jelly; at other times it becomes harder and firmer than natural; and in several cases it has been found converted into bone, or into a chalky looking substance. It has been generally remarked, that the fluid or milky cataract is most frequent in children, but we have also met with it in those advanced in life. The solid or concrete cataract, on the other hand, has been generally found in adults. At the same time, we have observed the lens of young people converted into a hard and white substance resembling chalk.

Colour of cataracts.

The colour of different cataracts is very various; and they never appear of the same colour in the eye as when removed from it. The most usual colour of them in the eye is a bluish white or gray; sometimes clouded in different parts or striated, sometimes of a lead colour, sometimes greenish, and sometimes of a yellow or amber colour. When taken out of the body, those which appeared white or gray are generally dark yellow or amber; and those of a yellow tinge in the eye often appear white when extracted.

Diagnosis between hard and soft cataracts.

There is scarcely any diagnostic mark of a soft and hard cataract which can be altogether depended on. The colour proves nothing, those of a milky colour being often quite hard, and sometimes those of a pearl colour are quite soft. Neither is there any thing to be learnt from the degree of the opacity; for it will be found that those who see no more than to be able to distinguish light from darkness have the lens quite soft, whilst those who can distinguish colours and large objects have the lens quite hard. Richter, however, has remarked two symptoms, which he says have seldem deceived him in ascertaining this point. The softer the lens is, the larger and thicker it is in general, and therefore approaches nearer to the plane of the iris or to the edge of the pupil. Hence he always concludes that the cataract is soft when it is near the pupil. In order, however, to judge of the space between the pupil and lens, the surgeon must look into the patient's eye from one side; and in general it requires much experience to judge of this with accuracy.

We are also able, in some cases, to discern points, streaks, or inequalities, in the shade of a cataract. If, after having observed the place, figure, and disposition of them, we find that in some days afterwards, or upon rubbing the eye pretty hard, they have undergone any change in their figure, situation, or shade of colour, we may then conclude with certainty that the cataract is soft; only we must be cautious not to draw an opposite conclusion, viz. that we are not to conceive the cataract to be hard if these changes should not be perceptible.

"A perfectly *hard* cataract," says Beer,* "shows itself very plainly before the operation; the pupil is equally opake in its whole circumference; there are not to be observed any points, streaks, or spots, of a clearer or darker colour; the lens is evidently separated from the iris, so that a sufficient number of rays of light can enter, and the patient is still capable of distinguishing some objects from the side of the eye; the motions of the pupil are extremely lively, and it never remains considerably enlarged. The opacity behind the pupil at the commencement of the disease is first observed in the middle, and it then extends, but very slowly, towards the circumference. Such patients, if the middle part of the pupil is completely opake, can for the most part read writing by the assistance of a magnifying glass, and distinguish small objects. The colour of the hard cataract is gray, passing more or less to a greenish hue; and the smooth level of the lens may be very plainly remarked."

* See *Bemerkungen, uber den Grauer Star.*

Cataract generally a local disease.

In most patients the cataract is to be considered as a local disease, though there are also many cases where an opacity of the lens comes on after or along with other diseases of the eye. It has been observed in gouty and rheumatic constitutions, and in such people there is reason to suspect that it is more or less connected with the general constitutional affection. This observation is of importance; for when an operation is performed in such cases, a total blindness is usually the consequence. Richter operated on a man who had been much troubled with gout, and his sight was restored. In seven months afterwards the pupil gradually contracted, at last closed, and a second blindness followed. In one case of a similar kind on which we operated, an attack of gout succeeded the operation, the eye suppurated, and the inflammation has never altogether disappeared, though two years have elapsed since the operation. Even in such cases the operation is not to be entirely forbidden: the success is less certain, and the patient will require a very careful preparation before it, and much attention after it.

Hereditary cataract.

There are some varieties of cataract which are considered to be hereditary. Richter extracted a cataract from a man whose father and grandfather were both blind from that complaint. Maitre Jean and Janin have both met with similar cases. Richter also saw three children, born of the same parents, who had all cataracts at the age of three years. We have known several similar facts, and particularly one of twins, who both were affected with cataract when one year old.

Cataract of the capsule.

When the cataract is seated in the capsule above, it in general arises from a blow or wound with a pointed instrument. Sometimes the whole anterior portion is opake and very much thickened, whilst that which is posterior remains transparent; and in some cases the capsule has been extracted in the form of a bag, having become altogether opake, and containing within it the crystalline. Such cases have been called by Richter the *cataracta cystica.* He says he has only met with one case of that form of the disease; Beer, however, mentions many; and from meeting with them he has been led to propose the extraction of the capsule along with the crystalline in all cases of the disease.

The *cataracta membranacea primitiva* of Scarpa is also another form of the disease. In this variety the lens disappears, and leaves the capsule opake, or at most in its interior a speck not larger than a pin-head. This kind of cataract, Scarpa remarks, occurs most frequently in infants, or in people under twenty years of age. It may be distinguished by its resemblance to a very thin scale, or by a very white point, at the centre or at the circumference of the crystalline.

Trembling cataract.

The *tremulous* cataract (*cataracte tremblante* of the French), is another variety of the disease which deserves to be noticed. It is generally of a very opake white colour,

Of the Diseases of the Eye.

colour, and seldom large. It moves about on every motion of the eye, and the whole iris trembles and fluctuates to and fro. Sometimes they altogether disappear, at times passing behind the iris, but they soon regain their situation. In one example of this disease we observed that the opake lens sometimes fell into the anterior chamber through the pupil. In this form of the disease it generally happens that the functions of the retina are impaired or lost; though this is not always the case.

Cataract combined with amaurosis.

Cataract is often accompanied with a complete amaurosis. In some cases of this kind there is a great dilatation and immobility of the pupil, and the opake lens is observed of a very large size behind it. The patient can seldom distinguish light from darkness; and the want of sight generally precedes any obscurity of the lens. In some cases, where there is a combination of cataract and amaurosis, the pupil remains of its natural form, and alters according to the quantity of light. But, as in the former variety of the disease the opacity of the lens most commonly precedes the amaurosis, it generally too comes on suddenly, preceded by sparks of fire appearing before the eyes, or clouds flying before them, or headach, and pains about the brow or temples. We have seen an instance of a simple cataract in one eye, and in the other cataract and amaurosis combined.

Commonly cataract affects both eyes simultaneously; but there are also many examples of the disease affecting only one eye. It also happens, that first one eye is affected, and many years afterwards the second. We have in general observed, that when the cataract takes place only in one eye in young people, or when it succeeds a blow, the other eye is seldom affected. But on this we should not trust much, for it is an undeniable fact, that a great sympathy exists between the two eyes; and that when one of them becomes diseased, the other is very apt to become similarly affected. We have seen a case where a staphyloma arose in one eye in consequence of a wound, and in a few years afterwards the other eye became staphylomatous. A man who received a blow on one eye, which produced amaurosis, had soon afterwards a cataract formed on the other. Richter mentions an analogous case. St Ives mentions a very remarkable case of a man who was wounded in the right eye with a small shot, and shortly after that eye was affected with a cataract. Some time afterwards the same disease took place in the left eye, but which gradually disappeared after the cataract had been extracted from the *right* eye. These observations on the connection between the two eyes, have led some surgeons to advise operating for cataract when only one eye is affected, in order to prevent the second eye from becoming diseased. There are a few cases where this practice has been successfully adopted, and there are others where it has failed. We know of one gentleman, now upwards of seventy years of age, who was couched for a cataract in one eye when twenty years old, and the disease has never attacked the other eye. Richter once performed the operation on a woman who had a complete pearl-coloured cataract in the *left* eye, and an incipient one in the right, which, before the operation took place, was beginning to advance rapidly. After operating on the left eye, the progress of the disease in the *right* seemed to be checked, and for years after the operation it had not made the smallest progress. On the other hand, we have operated in several cases where the disease was just commencing in one eye, and when the operation did not appear to arrest its progress in the second one. It is therefore a point not yet determined in what cases it would be advisable to operate when only one eye is affected; for in those where the progress of the disease in the second eye cannot be arrested by an operation on the first, no operation should be performed on either eye until vision is nearly altogether destroyed.

Progress of the disease.

The progress of this disease is very various: sometimes it proceeds so slowly as not to destroy vision for many years; at other times a complete obscurity of the lens has been known to take place almost instantaneously. Richter and Eschenback both relate cases where people labouring under gout, which suddenly retroceded, were entirely deprived of their sight in one night. We have observed analogous cases, though we could not determine the existence of any constitutional affection.

From the sound crystalline being chiefly composed of *albumen* and a small quantity of *gelatine*, whatever might produce a coagulation of these, would destroy the pellucidity of the lens. Whatever too would produce inflammation of the capsule of the lens might also render it obscure; for when any serous surface is inflamed, and to that class belongs the capsule of the lens, its transparency is destroyed, and it becomes thickened from an effusion of albuminous matter on its surface. Cataracts arising from wounds are probably produced in this manner.

In old people there is often distinguishable a slight obscurity of the lens, and sometimes it even forms a complete cataract. In such cases the obscurity probably arises from a want of balance in the secreting and absorbent systems, or the necessary perfection of these functions to preserve the natural state of parts, which we observe to decay in many other organs, as well as the eye, in those far advanced in life.

Symptoms remarked by the patient.

Besides the symptoms which are to be observed in an eye affected with cataract, there are others remarked by the patient. Objects appear to him as viewed through a mist or cloud; and as the opacity of the lens increases, the cloud appears greater until it finally prevents even the largest objects from being distinguishable.

The patient, at the commencement of the disease, can distinguish objects better in a moderate than in a bright light; and the same thing happens if the light be interrupted by the interposition of the hand or any other shade. The reason of this is obvious; because the pupil is more dilated in a moderate than in a bright light, and thus still admits a certain number of rays of light by means of the pellucid circle of the lens.

When the exterior part of the lens is less obscured than the centre, the patient sees those objects much better which are placed by his side, than those which are opposite to him.

If the obscurity has not affected the middle of the lens, but some part of its edge, any circular body looked at by the patient, appears to have its edge imperfect. It has been also remarked that some patients see every thing with perforations in them. The cataract is seldom accompanied with any pain. When it is brought on from internal causes, both eyes are generally affected.

Of the Diseases of the Eye.

Of the Treatment of Cataract.

In the treatment of cataract, recourse has generally been had to a surgical operation. Some have pretended to cure cataract by internal medicines. Small doses of *calomel*, *electricity*, *extractum hyoscyami*, *aqua laurocerasi*, have been extolled; but their use is now very generally given up. In some cases of cataract which have arisen from an injury of the eye, Mr Ware has seen them disappear by an external application of æther, which promoted the absorption of the opaque body *.

There are two operations which have been proposed for the cure of the cataract; the one called *extraction*, and the other *couching*. In the first, an incision is made into the cornea, and the lens removed by pushing it through the pupil. In the second, the lens is taken out of its capsule, and lodged in some part of the vitreous humour, where it may be entirely out of the axis of the eye. Each of these methods has been much practised; and though a decided preference seems at present to be given by the most distinguished surgeons to the mode by extraction, yet there are also cases attended with peculiar circumstances, in which the operation of couching may be successfully employed. Both operations ought therefore to be well understood by every surgeon.

* See his *Surgical Operations.*

Preparatory steps.

It was formerly the custom, before performing either of these operations, to confine the patient for several weeks, or even months, to a strict antiphlogistic regimen; but this precaution, except in very particular cases, may be generally dispensed with. People who have become blind, generally lead a quiet life, and are not exposed to any of those dissipations which are likely to affect the constitution. It will therefore generally be found sufficient precaution, before attempting an operation, to enjoin the patient to live moderately; to avoid spirituous liquors, and take a few doses of any of the common laxative medicines. If he be strong and plethoric, it will be necessary to pursue such a course a little further; to give doses of laxative medicines for a longer period, and even to bleed the patient in the arm. Many surgeons lay it down as a general rule, to take some blood on the morning of the day of the operation, either from the arm, from the temples, or from the neck by cupping; and either of these methods is to be preferred, according to the quantity of blood which is intended to be taken. In old people of a healthy constitution, we have often found it unnecessary to use any of these means, no inflammatory symptom having arisen during the progress of the cure. In many cases, instead of bleeding before the operation, we have preferred doing it after the operation was performed, when the patient was put quiet in bed. Blood taken at this period may be reasonably supposed to have a more powerful effect in giving check to any inflammatory attack which might be apt to succeed the operation, than if an equal quantity had been taken away before it. The bleeding too, immediately after the operation, we have often observed, renders the patient calm, and more disposed to rest, whereas at the same time any of those disagreeable symptoms are avoided during the operation, which are apt to remain for several hours after bleeding, when the patient is in the erect posture. It is also of importance before the operation is performed, the patient being so situated, that he can be easily put to bed. The operation should therefore be performed in the same chamber in which he is to remain, or in one immediately adjoining; and he should be clothed in a bed-gown or some loose dress, so as to enable him to get into bed without much trouble. The bed should be placed in such a position in the room that the light does not fall directly on the patient's face, so that during the cure, all glaring lights may be easily avoided.

Of the Extraction of the Cataract.

In this operation the object of the surgeon is to make a wound in the cornea, and to extract through it the opake lens. In performing it there are four steps which require to be particularly considered. The *first* of them is the means to be employed for securing the eye during the operation. The *second* is the mode of making the incision through the cornea; the *third*, the mode of opening the capsule of the crystalline lens; and the *fourth* is the extraction of the lens. All these shall be considered separately.

Mode of securing the Eye and Eyelids.

One of the great improvements in modern surgery is the simplicity of the mechanical means employed in performing operations. A great variety of contrivances have been proposed, in order to secure the eyeball and eyelids during the extraction of the cataract. Experience, however, shows, that almost all these are completely useless, and most of them extremely hurtful. To dispense, therefore, with these instruments, and to be able to execute with the fingers alone those parts of the operation for which they were employed may be justly considered as a material improvement. The eyeball and eyelids may be completely secured in almost all cases, by the fingers of one hand of the operator, and those of an assistant. The assistant will generally find that, with the fore finger of one or of both hands placed upon the tarsus, one upon the internal, and another towards the external angle of the eye, he will be easily able to raise the upper eyelid, so as to expose the cornea; and by the finger being placed towards the internal angle he will be also able to assist the operator in preventing the eyeball from being turned inwards, when the incision into the cornea is about to be made. The operator is to secure the under eyelid by the fore and middle fingers of his left hand. They are to be placed in such a manner over the edge of the tarsus, that they may come in contact with the eyeball; and the middle finger is to be pressed pretty firmly in the internal angle of the eye, between the eyeball and lachrymal caruncle, so as effectually to prevent the motion of the eye towards the nose. In this position of the fingers of the operator and assistant, those who are accustomed to perform operations on the eye, find that they are completely master of the motions of the eyeball; and by altering the positions of the points of the fingers, and applying more or less pressure, they are able to counteract any untoward motion of the organ. Before attempting to secure the eyeball, the operator should be prepared to advance in every step of the operation; for it will be generally found, that if an attempt has been made to open the eyelids forcibly, a certain degree of irritation and watering of the eye takes place; so that, when a second attempt is made, with

Of the Diseases of the Eye.

with a view of proceeding to the other steps of the operation, more difficulty is met with in holding the eye than at first would have been the case. It is a good precaution, however, for the surgeon to take an opportunity, before the day of the operation, to try to fix the eye, and to explain to the patient this step of the operation; for it often happens, that patients start, and make great resistance by squeezing the eyelids, when the operation comes to be performed; so that by habituating them to the mode of securing the eye, it is more easily accomplished. The first thing to be attended to, before attempting to fix the eye, is a proper light, the position of the patient's head, and the height of the chair in which he is to sit. The light of the room should come from one window, and the patient sit in such a manner that the light falls obliquely over his nose upon the eye to be operated on. If he be placed so that the rays of light from the window fall in the direct line of the eye, the surgeon will find that he is obliged, either to sit in his own light, or that the reflections upon the cornea tend to embarrass him. As soon as the other eye is covered, so as to prevent it from having any motion, and communicating that motion to the eye on which the operation is to be performed, the assistant is to be placed behind the patient, and the patient's head to be supported firmly on his breast. The height of the chair on which the patient is to be placed, will depend on the height of the patient, and always should be so low, that the assistant is able to look over the head, and completely command the motion of his own fingers. The operator and assistant should open both eyelids at the same time, which will more readily secure the eyeball in a proper position. The eyeball, however, is apt to be turned upwards, so that the cornea is thrown out of view. When this happens, the upper eyelid should be first raised, and the assistant should be always ready with the points of his fingers, to press in such directions, that when the eyeball at any moment places itself in a proper position, he may be ready to secure it. When, on the other hand, the eyeball is thrown downwards, the operator himself must place it in a proper position, and in this manner both the operator and assistant are to co-operate with each other, and the one or the other placing his fingers in such a manner as to counteract most effectually any awkward position of the eyeball. When the eyeball appears steady, the incision of the cornea ought to be immediately performed. But before entering the knife, it will be found a useful precaution to touch the cornea frequently with its back, and see if the patient starts, or if the eyeball remains quite steady. It will often happen, that whenever the point of the instrument touches the eyeball, it is suddenly thrown into motion; and was the incision of the cornea to have been begun at this moment, much difficulty would have arisen. If, however, the eye be repeatedly touched with the knife, the starting motion will sooner or later cease, and then the incision of the cornea may be begun with every possible advantage. When the knife has passed through both sides of the cornea, there is no danger of any motion of the eyeball hindering the operation.

It sometimes happens that the eye is extremely small, and that it is sunk deep in the orbit. In such people the operation becomes much more difficult; and we have met with cases, where, from these circumstances, it was almost impossible to secure the eyeball with the fingers; the room which the fingers necessarily take preventing the knife from being properly managed, and covering a portion of the cornea. In such cases, the speculum contrived by M. Pellier will be found to be a useful instrument. See Plate DXVII. fig. 8. The speculum consists of a piece of silver wire, bent in the manner represented in the plate; and though in itself extremely simple, it requires a good deal of management and nicety in using it. The curved edge of the wire (*a*) is to be placed upon the inside of the *ciliæ* on the horizontal plate of the tarsus; the skin of the upper eyelid being previously stretched upwards. The assistant is then to move the speculum upwards, imitating, as it were, the natural motion of the eyelids; and, when the eyeball is sufficiently exposed, the speculum, with the handle (*b*) resting on the brow of the patient, is to be kept firm and steady in the same position. In using the speculum, it is necessary to make a considerable pressure on the eyeball, in order to prevent the eyelid from slipping from underneath the speculum. At the same time as little pressure should be employed, as will prevent this from taking place. Many surgeons, in using the speculum, place it behind the *ciliæ;* and whenever any watering of the eye takes place, from the irritation of the instrument, it is very apt to slip from the moisture of the skin. In order to prevent this, we have found very material benefit from simply folding round the speculum a thin fold of crape, which, from its roughness, effectually prevents the risk of the speculum slipping. The operator is to manage the under eyelid in the same manner as if the upper eyelid was covered by the fingers of an assistant; and it more particularly rests with him to prevent the eyeball from rolling inwards, the speculum merely serving to support the upper eyelid.

After the knife has penetrated both sides of the cornea, the assistant is to be aware that no pressure is to be made upon the eyeball. When, therefore, this step of the operation is completed, the assistant, if he be using the speculum, is to be particularly careful in taking off any pressure which it may make, and merely to support the eyelid.

Mode of making the Incision of the Cornea.

The great object to be kept in view in making an incision of the cornea is, that it be of sufficient size to allow the easy extraction of the crystalline lens, and that any cicatrix which may remain may not interrupt the entrance of the rays of light through the pupil. The mode which has been recommended to effect these purposes, is to make a semicircular incision, parallel to the circumference of the cornea, and about half a line distant from the junction of the cornea and sclerotic coat. One of the knives (Plate DXVII. fig. 1, 2, 3.) is to puncture the cornea half a line distant from its circumference, to be carried across the anterior chamber to the opposite side, and brought through the cornea at the same distance from the sclerotic coat to where it was entered; afterwards the incision is to be finished by pushing the knife forwards till the incision is completed.

Instead of making the incision in this manner, Mr James Wardrop has proposed another form of incision, in order to remove several objections to which the former operation was liable *. The disadvantages which Mr Wardrop

* See *Edinburgh Medical and Chirurgical Journal*, vol. iv.

drop supposes to arise from the usual mode recommended are,

1. The cornea being of very considerable thickness, a great part of the semicircular incision will be carried through between its laminæ, and therefore the length of the incision of the internal lamina will be much less than that of the external one. This he explains by two plans, Plate DXVII. fig. 11. and 12. where besides the external form of the incision (*aaa*), there is drawn a second line (*b*), intended to represent the incision of the internal lamina. The dark space, therefore, included between these two lines (*b* and *a*) is intended to represent that portion of the incision which is made between the laminæ.

2. The external form deceives us in the extent of the internal incision, and much more difficulty is met with in bringing the lens through it, than from its apparent length could have been expected; for, as the line of the internal incision has a very slight curvature, the thickness and tension of the cornea admit the edges of the wound to be separated only a little way from one another.

3. When the cornea is divided nearly at its union with the sclerotic coat, and when the aqueous humour and lens have escaped, the portion of the iris opposite to the centre, and most depending part of the wound, loses its natural support given to it by the cornea, and is pushed forward, so that it comes in contact with the cornea, and even insinuates itself between the edges of the incision. The greater the opening is, the more danger there is of a prolapsus, both of the iris and vitreous humour; for it would seem as if these two parts of the eye were pushed forwards in consequence of the contraction of the coats of the eye, which takes place as soon as the incision is made; and if two-thirds of the cornea be cut, there is certainly much less resistance than when the half only has been divided. Thus, the iris and cornea form permanent adhesions in consequence of the inflammation which always follows the operation. The pupil becomes of an irregular form, is drawn from the centre of the eyeball; is sometimes very much contracted, and retains but a very limited sphere of contraction and dilatation.

4. The contraction of the muscles of the globe of the eye pressing forward the contents of the posterior chamber, are very apt to push a portion of the vitreous humour through the pupil and wound of the cornea. When this happens, the pupil becomes irregular, and drawn down towards the incision, the form of the eyeball is somewhat altered, and the prolapsed vitreous humour inclosed in its capsule, appears externally in the form of a round transparent tumor.

5. As the external edge of the semicircular flap of the cornea is very thin, and lies loose, the smallest movement of the eyelids, particularly of the upper one, is apt to catch and raise it out of its proper situation, and thus that speedy union is prevented which would take place if the two divided surfaces had been kept in accurate and constant contact.

6. and lastly; As the internal edge of the incision is often unavoidably made, from the smallnes of the anterior chamber, and the flatness of the cornea, nearly opposite to the inferior margin of the pupil; and as all the extent of the cut surface *ab* (Plate DXVII. fig. 12.), sometimes remains opaque after the wound is healed, the opacity of the cicatrix must diminish the sphere of vision.

All these disadvantages in the usual mode of making an incision of the cornea, appeared to Mr Wardrop to arise chiefly from the want of a sufficient portion of the cornea being left at the inferior part of the wound, to support the iris, and to prevent the pressure of the parts contained within the eyeball, and the occasional action of the muscles pushing forward the iris towards the wound of the cornea; he therefore conceived that if the incision could be made in such a manner that a larger portion of the cornea could be left at the inferior part of the wound, being at the same time made of such a form as to allow the easy extraction of the cataract, and the cicatrix not afterwards to interfere with vision, a considerable improvement would be made in the operation. With this view he made the incision in the following manner.

Of the cornea knife.

The best knife for the purpose is of the same size and shape with that delineated in Plate DXVII. fig. 1. The blade is of a simple triangular form, the back being one continued line with the handle, except merely the point. The point, though extremely sharp, should be made firm, and the blade should turn gradually thicker from the point towards the handle. The point of the knife must be sharp on both edges for at least the breadth of a line, in order that it may penetrate the cornea quickly and easily. The back of the knife should not be left angular, but the edges rounded off and made smooth, so that it be convex on both sides. Particular care ought to be taken that the point of the knife be well conditioned; and it is not only necessary that it be sharp, but that the metal of which it is made be neither too hard nor too soft. This may be easily ascertained by pressing the point upon the nail; for if it bend readily, not being so brittle as to break through, and sufficiently elastic to recover the straight line, we may be confident that it will answer the purpose. It is also a good precaution to have the knife sharpened the day before, or the morning of the operation; and in case of any accident happening to the point, the operator himself should carefully examine by trying how it penetrates a thin piece of leather, immediately before using it. From the point of the knife being too brittle, we have known a case where the point of it was broken off, when attempting to penetrate the inner part of the cornea; and from the point being too soft, we in one case, after puncturing the cornea, found it impossible to penetrate with the knife the opposite side, and this we found had arisen from the point of the knife bending round.

Having previously smeared the knife with oil, or smoothed the edge of it upon the palm of the hand, in order to make it cut more keenly, its point is to be thrust through the cornea at its transverse diameter, and at least half a line distant from the sclerotic coat, and in a direction as if it was to wound the iris, or nearly perpendicular to the spherical surface of the cornea (see Plate DXVII. fig. 13. and 15. *a*). When the point of the knife reaches the plane of the iris, it is to be turned towards the opposite side of the cornea, by moving the blade upon the incision already made, as a fulcrum. It is then to be carried forward, so that the cornea is again punctured at its transverse diameter *b*, at the same distance from the sclerotic coat at which it had been entered on the

Of the Diseases of the Eye.

Of the incision of the cornea.

the opposite side (fig. 13.) By these two incisions the blade of the knife has cut perpendicularly, or very nearly so, to the spherical surface of the cornea, and the gradual thickening of the knife, by filling up the wound as fast as it is made, prevents any of the aqueous humour from making its escape. The eye is now completely secured with the knife, and the assistant who has been supporting the upper eyelid, should receive a signal from the operator, to take away all pressure from the eyeball, and merely to support the eyelid sufficiently to allow the inferior half of the cornea to be seen. When the knife has been pushed forward a little way, as is represented in fig. 15. the incision is to be finished by turning round the blade on its axis, and thus keeping the edge turned outwards, in such a manner, that the remaining part of the incision is made a straight line, and therefore nearly perpendicular to the lamellæ of the cornea (fig. 13. *c*). Whenever the last step of the operation is begun, the aqueous humour begins to escape, which allows the knife to cut the cornea readily and in any direction.

Supposing, therefore, that the cornea, instead of being spherical, were a plain surface, the incision now described would be represented by the lines *a*, *b*, and *c*, fig. 13.; but as it is a segment of a sphere, the form will more resemble that represented in fig. 14.; at least this is the form of the incision which the operator should have in view when performing the operation. By the inspection of these figures (13 and 14), it appears,

1. That a large portion or ring of the cornea is left attached to the sclerotic coat, and must form, from its thickness, a complete support to the iris.

2. That as the incision is made throughout nearly perpendicular to the lamellæ of the cornea, the length of the incision of the internal lamella will be nearly equal to that of the external one, and will be greater than when it is made in the usual manner, by the semicircular incision; and consequently the cataract will be more easily extracted through it.

3. The upper edge of the internal incision is at a greater distance from, or further below the edges of the pupil.

4. As the flap of the cornea is very small, the external edge thick, and not easily moveable, or apt to be caught by the motion of the eyelids, the edges of the incision are not liable to be displaced, and consequently the wound has a much better chance of uniting by adhesion.

Lastly, the cicatrix which remains is scarcely perceptible, and cannot even be distinguished when the cornea is looked upon in a direction perpendicular to its surface. The incision should be made so that the inferior edge of the wound (fig. 3. *c*) is half way between the circumference of the cornea and the edge of the pupil, supposing the pupil to be in a moderate state of dilatation. If it be made nearer to the sclerotic coat, then the advantages to be expected from this mode of operating will be lost; and on the other hand, if it be made at too great a distance from the sclerotic coat, and consequently too near the pupil, the edge of the pupil will be apt to pass through between the lips of the wound. In one case in which this accident happened, partly on account of the incision being at too great a distance from the sclerotic coat, and also from the knife having been entered too far above the transverse diameter of the cornea, the wound was long in uniting, and after it was healed, the pupil remained very irregular and contracted.

In making the incision of the cornea in the manner that has been directed, another circumstance also particularly deserves notice, which is, that after having punctured both sides of the cornea, in giving the knife the motion round its axis, some of the aqueous humour escapes, and there is a great risk of a fold of the iris turning over the cutting edge of the knife. An operator who meets with this for the first time, is apt to think a wound of the iris is inevitable; but if he cautiously stops the progress of the knife by gliding the point of the fore-finger over the cornea, and pressing the iris from its edge, the incision may be completed with perfect safety.

It sometimes happens that after the knife has entered the cornea, the eyeball makes a sudden motion inwards, towards the nose, and a considerable part of the cornea is thus thrown out of view. This accident happens either from a fault in the operator or his assistant, and ought to be particularly guarded against; for when it has taken place, it is irremediable. When this happens, the operator must not attempt to proceed any further, but immediately withdraw the knife, allow the wound of the cornea to heal, the aqueous humour to be regenerated, and after any slight inflammation which might succeed, has gone off, the operation may be a second time attempted without any additional risk.

It sometimes happens that, on puncturing the cornea on the nasal side, the point of the knife does not come through at the proper distance from the sclerotic coat. If it pass through too near the centre of the cornea, as is represented in Plate DXVII. fig. 17. considerable disadvantage arises; for besides the incision being too small, so that the lens is extracted with difficulty, the eye is apt to receive considerable injury, and the cicatrix afterwards to interfere with vision. When this accident happens, it will be the most prudent practice to proceed no further in the operation, but to allow the wound to heal by adhesion, so that a second operation might be afterwards attempted with all the advantages of a first attempt. It is astonishing the rapidity with which a wound of the cornea made by a cutting instrument heals, and except it be very large, scarcely can the most acute eye detect any cicatrix. It is therefore much more prudent, whenever any fault in the incision arises, that the wound be allowed to reunite, so that afterwards a second operation may be successfully performed, instead of attempting by scissars or other instruments to correct any bungling. If the knife passes through the cornea too close to the sclerotic coat, it is not attended with such bad effects as when it passes too far from it; and was it not for the danger of wounding the iris, it would be advisable in all cases to lay it down as a general rule to make the knife come out very close to the sclerotic coat. See fig. 18.

Of the Mode of opening the Capsule of the Lens.

After the operator has completed the incision of the cornea, he should make a pause, and allow the patient to compose himself a little, in case of any involuntary motion of the eyeball injuring any part of its structure. It sometimes happens, indeed, that the moment the incision of the cornea is finished, the lens suddenly follows the

Of the Diseases of the Eye.

the knife; but this is a circumstance never to be wished for, as the same cause which throws out the lens may also push after it some of the vitreous humour. When the incision of the cornea is finished, and nothing has escaped but the aqueous humour, the patient should be directed to turn his eye from the light, and to keep his eyelids shut, taking great care not to squeeze them, so that the pupil may be allowed to dilate. In most surgical operations, particularly those attended with much pain, it is of importance to finish them as quickly as possible. This, however, is not the case in the extraction of the cataract. It will be in general found that the severity of an injury done to any part of the body depends, not only on its extent, but on the sudden manner in which it is inflicted. Thus, a small drop of blood suddenly effused on the surface of the brain, often produces a series of much more distressing symptoms than a large collection of purulent matter in that organ. It is therefore reasonable to expect that if the different steps of the operation for the extraction of the cataract are gone through in a rapid manner, the eye will be much more injured than if the same operation be performed more slowly. There is another advantage too, derived from performing the operation in a cautious manner; by holding the eye firmly for some time, the muscles become fatigued, and during the latter steps of the operation, when there is the greatest danger of injuring the organ, the power of resistance to the operator is much diminished.

Mode of puncturing the capsule.

The next step of the operation is to make a puncture in the capsule of the crystalline lens, so that the lens may be brought through the pupil. On opening the eyelids, it will generally be found that the pupil has a very irregular appearance, which an inexperienced observer may suppose to be in consequence of a wound of the iris, though no such accident has happened. Some surgeons employ an assistant to support the upper eyelid, whilst others take both eyelids completely under their own management; and when the operator finds that he can easily accomplish this last mode, he should always prefer doing so. When the eyelids are opened in such a manner as to expose the incision of the cornea and pupil, the point of the instrument called the *curette* *, is to be introduced through the wound of the cornea and pupil, to puncture the capsule of the lens. Richter advises that the capsule should be punctured several times with the point of this instrument, in order that a large opening may be made into it. When the lens is soft and milky, this may be necessary, but when it is of a firmer texture, if one puncture be made, it sufficiently tears the capsule so as to allow itself to come away easily. Before introducing the *curette*, moderate pressure should be made on the eyeball, which has the effect not only of keeping the eye steady, but also of dilating the pupil. The convex part of the instrument (*a*) is then to be introduced through the wound of the cornea, and conducted to the central part of the pupil. When it reaches the pupil, from the curvature of the instrument, a very small turn of the handle will place the point upon the capsule of the crystalline lens, and by pushing the point upwards, the capsule will be readily punctured. It is not necessary that the point of this instrument be very thin and delicate; a rounded point will answer all the purposes of puncturing the capsule; whilst from this form there will be less danger of wounding the iris from any unexpected motion of the eyeball. Very little force is necessary to puncture the capsule, and when the point of the curette passes through it, it gives the sensation as if puncturing a piece of very fine paper with a pin.

* See Pl. DXVII. fig. 19.

This part of the operation we have often found to be one of the most difficult; for in many patients the eye becomes extremely unsteady, and whenever an attempt is made to hold it firm, or introduce the point of the curette, the eyeball is immediately rolled upwards under the roof of the orbit. The eyeball, too, is apt to make some untoward motion, after the point of the curette has been introduced into the anterior chamber; so that if the operator be not on his guard, the iris may be caught and torn by the point of the curette. In one case where, after the point of the curette was introduced through the pupil, the eye turned suddenly upwards, and the hooked part of the instrument catching the edge of the iris, pulled it downwards, though fortunately without tearing it.

Mode of Extracting the Lens.

Whenever the capsule of the lens is punctured, the lens in many cases begins to move forward, and the pupil to dilate. The operator, carefully watching this change, should keep up an equal and moderate pressure upon the eyeball, which will assist the lens in getting through the pupil. Whilst the lens is making its escape, and appears to press very much on the inferior part of the pupil, the iris should be supported by the back of the spoon, (*b* Plate DXVII. fig. 19.) which is generally, for conveniency, fixed upon the opposite end of the handle of the curette. In applying the pressure on the eyeball, it is of great importance that it be kept up uniformly, and it should always be proportioned to the effects which it appears to produce on the dilatation of the pupil. In most cases a very moderate pressure will be found to answer the purpose. We have met with other instances, however, where it was necessary to compress the eye with a good deal of force, before it was possible to remove the lens.

Any small portion of opaque lens which now remains in the capsule, or on its surface, must be extracted by means of a small scoop. When the fragment lies on the surface of the capsule, or in any part of the anterior chamber, it is in general easily removed; but when the opaque body remains within the capsule, it becomes necessary, that the scoop should enter the capsule through the opening which was made in it. When this opening is large and wide, the scoop will easily get in, and reach the opaque fragment; but, on the contrary, when the opening is small, the scoop may be moved about in every direction, in hopes of laying hold of it, for the scoop is on the outside of the capsule, and cannot procure an entrance. It has happened accordingly, that every endeavour to extract the remaining fragment has been fruitless, and in such cases it was supposed by the operator to adhere to the capsule. It was more probable, however, that the capsule had not been sufficiently opened, and that the scoop could not reach the small fragments. In all cases, however, it is an object of importance, completely to remove the opaque body; for though any remaining portions be ultimately absorbed, yet in the mean time the operation is by no means so complete as it would have been, had nothing been allowed to remain. It has been advised by some, (and the practice has certainly been attended with

Of the Diseases of the Eye.

with good effects), that after the principal part of the lens is removed, any fragments which may remain, and which are not visible, may be brought into view by shutting, and cautiously rubbing the eye-lids with the finger.

Of the Extraction of the Capsule.

When, after the crystalline lens is removed, the capsule is found to be opaque, it is absolutely necessary that it be at the same time taken away. Opacities of the capsule are generally situated in its anterior parts, which renders the removal of them much more practicable. The forceps for this purpose (Plate DXVII. fig. 9.) are to be cautiously introduced through the wound of the cornea and pupil, and any opaque portion laid hold of, and cautiously removed. It has been observed that though the capsule did not appear opaque during the operation, yet in consequence of inflammation, which occurs more or less afterwards, the capsule has become opaque. This circumstance has led to a proposal, that in all cases the capsule should be extracted along with the opaque lens. From the natural structure of the eye, and the strong adhesion which exists between the posterior part of the capsule of the lens and the interior portion of the capsule of the vitreous humour, it would appear impracticable to separate them from each other, so as to extract the capsule entire. Many cases, however, are recorded by different authors, where, in performing the common operation, the lens inclosed in its capsule has made its escape. In these cases, however, it is probable, that the natural adhesion between the capsules of the two humours had been destroyed by some morbid alteration of structure. Such cases have probably been the cause of the proposal to extract in all cases the capsule of the lens. Mr Beer, a celebrated oculist in Vienna, has published a work *, in order to recommend and describe the mode in which such an operation should be performed. After some general observations on the bad consequences which arise from portions of the capsule remaining behind after the lens is removed, he describes his mode of operating in the following words.

* *Practische Beobachtungen.*

" Immediately after dividing the cornea, I dilate the pupil as much as possible, by a gentle pressure on the eyeball with the finger. I then introduce the lancet (Plate DXVII. fig. 4.) through the wound of the cornea, and plunge it into the lens; one surface being turned upwards, and the other downwards, so that none of the lancet is visible. It is particularly to be recommended to the instrument-maker, that this lancet have a pretty thick body, by which means, the moment of introducing it, the lens will be somewhat pressed back, and its weak anterior adhesion will be separated. The lancet must now, when in the middle of the lens, be moved upwards and downwards, in order to divide its connections above and below. Lastly, the instrument must be turned suddenly on its axis, and moved to the inner angle of the eye, and then drawn out in a straight direction. The lens often follows with its capsule, immediately after the lancet is withdrawn, or at least it comes out quite easily, along with its capsules, on a continued pressure of the finger. There is not merely a sleight of hand, which must be carefully observed in the use of the lancet; experience has taught me many precautions which must not be neglected the moment that the lens comes out, otherwise the capsule may be very easily rubbed off from the lens, either in passing the pupil, or in the wound of the cornea.

" In order to avoid this, the opening of the cornea should be made as large as possible, and it is best to divide two-thirds of it; thereby the operator has the following advantages.

" 1. The pupil dilates of itself after the division of the cornea by the pressing forward of the lens; and this dilatation may be easily increased by the slightest pressure.

" 2. The more the pupil is dilated, the better the operator can observe the management of the lancet; he can move his instrument more freely in different directions in the lens, and consequently separate more quickly and more surely, the lens along with the capsule, from all its connections.

" 3. The lens with its capsule passes more easily through the pupil, the wider the opening in the cornea, (which indeed requires in most cases much space), and the further and more easily the pupil dilates, the less danger there is of the capsule being separated on coming out. If the wound of the cornea is small, the capsule will be either separated from the lens in the pupil, or in the wound of the cornea, or passed back again either entirely, or at least partly, into the posterior chamber of the eye."

To those who are accustomed to perform operations on the eye, the method which we have detailed will at once appear to be difficult, extremely dangerous, and in many cases totally impracticable. The causes of failure in the operation for cataract seldom arise from an opacity of the capsule of the lens, and when this does occur, it is always in consequence of a violent or long-continued inflammation of the eyeball. Whenever, therefore, the inflammation which takes place after the operation is checked by proper remedies, a cataract of the capsule will seldom be met with.

Of the Treatment after the Operation.

After the lens has been extracted, and the eyelids allowed to remain shut for a short time, the eye ought to be examined, in order to ascertain that the edges of the wound of the cornea are in their proper place; that no portion of the iris has passed through it, and that the pupil is quite regular. When the incision of the cornea is made in the manner and of the size already described, the edges of the wound, from their firmness and thickness, accurately apply themselves to each other; and if the iris has sustained no injury, it will remain in its natural situation, and the pupil will become perfectly circular. When the pupil is not regular, it has been generally recommended to expose the eye to a bright light, in order to make it contract, and thus detach it from any part to which it might have adhered. When a portion of the iris protrudes through the wound, this generally arises, not from any injury in that part, but in consequence of the incision of the cornea having been made too large. If the incision be more than semicircular, (or two-thirds of the circumference of the cornea as directed by Mr Beer) this accident will almost constantly happen; and when it does take place, can never, as far as we know, be remedied. In such cases the operator should be careful not even to attempt with the spoon, nor any such instrument, to replace the prolapsed iris; for it has always been observed, that attempts of this kind are fruitless, and never fail to increase the inflammation which succeeds the operation.

In applying the necessary compresses and bandages on the eye, the objects to be held in view are, to keep the eyelids in such a position, that they cannot disturb the wound of the cornea by their motion, and that the eye be not exposed to any light. The upper eyelid will be completely secured, by placing over it, and in the hollow of the orbit, a small stripe of wet caddis. The piece of caddis should not be so large as to press much upon the eye, and from its being wet, it will be readily kept in its situation. Above the caddis should be placed a piece of linen covered with simple ointment, large enough to cover both eyes; and this may be secured by one turn of a bandage round the head. In applying the bandage, care should be taken to place it so that the pins are put in at the forehead and temples. The conveniency of this will be afterwards found, the bandage being easily removed without moving the patient's head from the pillow. The patient should now be put cautiously to bed, and his head kept extremely low. The room in which he sleeps should be made so dark, that no light may pass through the bandage to the eye. In an hour or half an hour after the operation, when the patient has become composed, he should be bled in the arm, if from the previous state of the patient's health that should be deemed a proper precaution. Rest, quietness, and abstinence, ought to be rigidly adhered to for the first day after the operation; the patient should be allowed none but liquid food, in order that any motions of the jaw may be avoided, and the food should be given through a tea-pot, in order to prevent any motion of the head. Sixteen or twenty hours are sufficient to produce an adhesion of the cornea in favourable cases; and after this period the compress of wet caddis placed upon the upper eyelid, becomes no longer necessary; for if it be allowed to remain any longer, it becomes hard and dry, and will be apt to irritate. The bandage and plaster ought therefore to be loosened, and the piece of caddis removed. The eyelids will now be found to adhere, and the patient will find much relief by cautiously wetting the ciliæ with cold water, in order to liberate the eyelids. From this period it is advisable to keep the eyelashes constantly greasy with an unctuous application.

In all cases, the symptoms which we are particularly to guard against after this operation, are those of inflammation: for when these arise, various effects may be produced which might frustrate all our endeavours to restore the patient's sight. If the wound in the cornea, instead of uniting by adhesion, goes through a tedious process of suppuration, the pupil becomes irregular and contracted; or if there is an effusion of lymph in the pupil, or if an opacity of the capsule takes place, these effects, all of which may arise in consequence of inflammation, might either greatly impair, or entirely destroy vision. The patient, therefore, ought to be carefully watched every six or eight hours for several days, and on the evening of the day of the operation, or at any future period, if symptoms arise which indicate the commencement of inflammation, he ought to be freely bled. The symptoms which are to guide us in adopting such means, are pain and uneasiness darting through the eye or head, and a frequent and full pulse. We have often remarked, after this operation, that even in those cases where no bleeding is necessary, the pulse becomes unusually full. This symptom alone would not, therefore, be sufficient to warrant us in proceeding far in adopting such a practice. We have long believed, that the success of all surgical operations, depends much on the adoption of the means to prevent any inflammatory action. The danger of amputation, and such operations in a vigorous and healthy constitution, is well known; it is equally well known the speedy recovery of patients from operations, who have been much debilitated from previous disease; and we have repeatedly remarked that patients who have lost much blood from some accident, after an operation, have recovered much more speedily than those to whom no such accident had happened. Aware of these circumstances, we have invariably adopted rigorously the depletive system after the operation for the cataract; and in many of those patients from whom a very considerable quantity of blood has at different periods been taken, we have observed that the success of the operation has been more speedy and more complete. The surgeon will sometimes find cases where, from the mildness of the symptoms, he is led to hesitate on the propriety of bleeding. In such a situation it is the safest plan to have recourse to it; for in general, wherever no symptoms have arisen which may indicate the impropriety of such a practice, if it be not useful, it is at least never followed by any bad consequences.

Venesection at the arm is the easiest and best mode of extracting the blood; but should any circumstances occur which render the operation at this place impracticable, or should it be thought necessary to take away the blood nearer to the inflamed organ, an opening may be made in the temporal artery. For the first two or three nights after the operation, the patient's arms should be watched, or secured in such a manner, that when he is asleep, he shall not be able to raise his hand towards his eye; for the most gentle stroke upon the eye, even several days after this operation, is attended with most excruciating pain, and is generally succeeded by violent inflammation. The patient should be enjoined to lie on his back, or on the sound side of the head; and after the first twelve hours he may be allowed to raise his head to the usual height. Most authors who have laid down rules to be followed after this operation, have directed that the eye should be kept shut up, and in total darkness for many days after the operation. We have, however, found an opposite practice attended with the most beneficial effects, and we have always considered it as a general principle to be followed, that the eye, from the very day after the operation, be gradually restored to its natural state, that the globe of the eye and eyelids be allowed to move, and that day after day the quantity of light to which it is exposed be gradually increased. In regulating the quantity of light, and the motion of the eye and eyelids, we should be entirely guided by the patient's feelings. Whatever be the quantity of light to which the eye is exposed, or its extent of motion, if it does not create uneasiness or pain, it will never be found to prove injurious; but on the contrary, if such a quantity of light be admitted as to create uneasiness, or if any motion of the eyes or eyelids gives pain, these circumstances will all tend to increase the inflammatory symptoms.

Of the Diseases of the Eye.

It has been already mentioned, that on the first day after the operation, the wet caddis should be removed, and the eyelids separated and covered with some unctuous substance, so that the patient may, from time to time, cautiously move the eyelids, provided it gives him no uneasiness. The pledget of ointment covering the eyes will prevent, during this day, any light from entering.

On the second day the pledget of ointment may be removed, and both eyes covered with two or three folds of old linen, the patient being directed to bathe his eye frequently with a little warm water, so as to remove any glutinous or concreted matter from the eyelids. He should also continue frequently to move the eyelids, and by opening them, to expose the eye to the small quantity of light which passes through the linen. On the following days, the light is to be admitted more and more freely into the room, and by degrees the patient will find that he is able to look down upon the bedclothes, or any large object without uneasiness. People are often apt, from the joy which they feel in having their sight restored, to make too much use of the eye, and to render it weak and painful. Too much care, however, cannot be taken, to avoid any accident of this kind; and though the patient may feel his eye perfectly easy, and has no other complaint, yet it is always prudent to confine him to his bed for the first six or eight days. After the second or third day he may raise the head or body safely in bed; but we have repeatedly observed that when patients began to sit up early, and particularly when they approached too near a fire, they have been seized with a peculiar headach and inflammation of the eye, which were attended with much distress, and very difficult to remove. In ten or twelve days after the operation, the patient is commonly able to use the eye with considerable freedom, and to look even at minute objects without pain or uneasiness. It sometimes happens that after this period, a slight irritability of the eye remains, but this in general is speedily removed by the use of the vinous tincture of opium, or sometimes by the application of a weak ointment composed of the red oxide of mercury. The application of the vinous tincture of opium will be found peculiarly useful; and we have known many instances of patients who have undergone this operation, who were frequently, for a long time afterwards, attacked with slight pain or inflammation of the eye, which were always speedily and completely removed by the use of this medicine. It is scarcely necessary to observe that during the whole of the after treatment, the antiphlogistic regimen should be rigidly pursued, and that the patient should avoid every kind of food which from experience he knows to be apt to disagree with him; and that above all he should abstain from the use of wine and spirituous liquors of every description.

Of Couching.

By this operation the lens is depressed from its natural situation behind the pupil, by introducing a needle into the posterior chamber.

The operation may be performed by introducing a needle (Plate DXVII. fig. 20.) through the sclerotic coat, about two lines distant from its junction with the cornea. The point of the needle is to be directed immediately over the opaque lens, and the lens to be depressed a little with the convex surface of the end of the needle. The point is to be pushed in a transverse direction as far as the inner edge of the lens. Then the operator is to incline the handle of the instrument towards himself, by which means its point will be directed through the capsule into the substance of the opaque lens, and by inclining the needle downward and backward, the former will be lacerated and conveyed with the latter deeply into the vitreous humour. The treatment to be employed after couching is similar to that after extraction.

Sect. XI. *Of the Fistula Lacrymalis.*

When the lacrymal sac is distended with a puriform fluid, or when it has ulcerated, and the tears do not pass freely down the nasal duct, the disease is called *fistula lacrymalis*. In the first stage of the disease, a distinct tumor is formed in the situation of the sac, out of which, when compressed, a quantity of puriform fluid flows upon the eyeball through the puncture, or some of it passes through the nose. In the second stage of the disease, the integuments covering the sac ulcerate, and the puriform fluid and tears are constantly oozing through a fistulous opening. The eyelids are affected most commonly in the second stage of the disease, and sometimes also in the first, though not always. From the affection of the internal palpebral membrane, Scarpa has supposed that all the puriform fluid contained in the sac was secreted by it, but this does not always happen.

Treatment.—When the disease has originated in the mucous membrane of the eyelids, applications to it alone will be sufficient to remove the accumulation in the sac. A collyrium of the oxymuriate of mercury, and the daily application of the ointment of Janin, or of an ointment composed of the red oxide of mercury, are well suited for this purpose. When the sac has been the original seat of the disease, a solution of corrosive sublimate, acetite of zinc or of lead, will be useful, and these may be used by allowing them to be absorbed by the puncta into the sac, along with the tears, or by injecting them into the puncta by a proper syringe, (see Plate DXVII. fig. 23.).

If there be a complete obstruction in the nasal duct, these remedies generally fail, and it becomes necessary to open the sac, and remove the cause of obstruction in the duct. The sac may be readily opened by plunging a common lancet into it while distended with matter. The sac should then be examined with a probe, and the probe passed down into the nose in the direction of the natural canal. A surgeon well acquainted with the situation and direction of the duct, can never fail in introducing the probe; for we never met with any case where the obstruction could not be overcome. A style, (Plate DXVII. fig. 24.) such as has been recommended by Mr Ware, is to be introduced in place of the probe, and allowed to remain until the canal is quite open. When the parts around the sac appear healthy, the style may be withdrawn, and the opening of the sac then heals. In many cases the disease returns, and in such, after the parts are a second time healthy, a tube (Plate DXVII. fig. 25.) may be introduced and allowed to remain during life. This operation requires that there be a free external opening, and that the head of the tube be pressed completely

down

down below the edge of the skin. Generally the external opening heals in a few days. When the sac has ulcerated, there will generally be found some sinuses in the integuments covering the sac, all which should be freely laid open, and the style introduced as in the former case. After the skin and sac are apparently healthy, the tube may be introduced as in the former case. Besides the use of the style, it is also requisite to apply the eye-waters and ointments recommended in the first stages of the disease.

Sect. XII. *Of the Psorophthalmia.*

In this disease there are numerous small brown coloured eminences formed at the roots of the ciliæ of both eyelids, and generally both eyes are affected. The adjacent skin has a brownish red tinge, and becomes scurfy; the ciliæ drop out, and the patient has a difficulty and uneasiness in opening the eyelids, particularly in candle-light. The blood-vessels of the internal palpebral membrane are also turgid, and preternaturally numerous. This disease affects often many branches of the same family.

Treatment.—The unguentum citrinum is a specific remedy in this disease. When there is much inflammation of the eyelids, they ought to be scarified, and the ointment applied immediately after. A collyrium composed of a weak solution of corrosive sublimate is also sometimes useful.

Of the Ophthalmia Tarsi.

In many people who use their eyes much, particularly in candle light, and in those who live freely, the internal membrane of the eyelid often becomes gorged with blood; a thick puriform fluid glues the ciliæ together in the morning, and the patient complains of an inability to move the eyelids, or to look at an object in a bright or dazzling light, without much uneasiness being excited. In other instances the eyelids become affected with scrofulous inflammation, the glands of Meibomius swell and suppurate, the ciliæ drop out, and the eyelids lose their natural form.

Treatment.—Scarifying the inflamed vessels, and applying immediately afterwards a quantity of the red precipitate ointment, seldom fails in bringing relief, and in many instances the ointment alone will answer. In some cases the disease in the eyelid is much aggravated by, and connected with affections of the stomach and bowels, and in such the greatest attention becomes requisite to keep the belly regular, and even to purge.

Of the Entropion.

When the eyelids are inverted, so that the tarsus with its ciliæ come in contact with the eyeball, the disease is called *entropion*. This disease, Mr Crampton has shown, arises in some cases from a thickened and diseased state of the internal palpebral membrane. In others the ciliæ are turned in upon the eye from repeated and tedious inflammation altering the form of the tarsus, and in some old people where the integuments are very loose, the whole tarsus is inverted by the action of the orbicularis muscle.

Treatment.—In the first case, Mr Crampton has ingeniously recommended that the tarsi be divided at their junction towards the external canthus, and that the eyelids thus liberated be kept in their proper situation by plasters, compresses, and when in the upper eyelid by fixing the speculum of Pellier, until such time as the wound has healed. In the second case little can be done but pulling out from their roots any of the ciliæ which may have taken a wrong direction, and repeating the operation whenever they grow again. In the third case, the disease may be cured by removing an oval portion of the skin the whole length, and close to the tarsus, and uniting the wound by one or two stitches and adhesive plasters. This operation may be also advisable along with that of Mr Crampton, when one is not sufficient to cure the complaint.

Chap. XI.

Of the Diseases of the Ear.

The functions and structure of the internal membrane of the external meatus, and also of the eustachian tube and cavity of the tympanum, prove that it belongs to the mucous system, and that it is not a continuation of the periosteum as many anatomists have supposed. The analogy in the diseases of this organ prove the same. In catarrhal affections of the pituitary membrane of the pharynx, the ear is always more or less affected, and often the function of the organ is much impaired. Polypi also grow from the cavity and membrane of the tympanum of a similar structure to those found in other mucous surfaces. See *Polypi*. It is also subject to hæmorrhagies, and when it becomes inflamed, instead of suppuration taking place, there is a discharge of a puriform fluid from the surface, the same as what is observed in inflammation of the urethra, nose, &c.*

The internal membrane of the ear is also subject to the same kind of thickening and contraction of the canal, as takes place in the urethra and lacrymal sac, &c. in consequence of long continued inflammation †. This we might conclude from analogy, but the fact has been proved in one instance. Bichât dissected the body of a person who had been exposed during his life to a puriform discharge from the ear, in which he found a very remarkable thickening of the membrane of the tympanum, but no mark of erosion could be detected.

* See *Inflammation of the Mucous Membranes.*

† See *Strictures of Mucous Membranes.*

The most common disease of the ear, and almost the only one which the surgeon can relieve, is a collection of wax in the meatus externus. Its presence can always be determined by the inspection of the ear; and it can be removed by directing the patient to drop some warm water into the ear for a few successive nights, and afterwards syringing out the softened wax, an operation which may be performed with a syringe (such as is represented in Plate DXVII.), having fitted for it a pipe of considerable length.

Chap. XII.

Of the Diseases of the Nervous System.

Sect. I. *General Remarks on the Pathology of the Nerves.*

A great number of diseases have been considered under the class of *nervous;* and much obscurity has been thrown on this department of medical science, from

Of the Diseases of the Nervous System.

from our imperfect knowledge of the laws which regulate this part of the natural system, and from mere symptoms having often been considered as primary affections.

Pathological investigations have been also unsuccessful; and in only a few cases has the most skilful anatomist been able to detect any morbid alteration of structure in nerves, which, during life, had been the seat of agonizing disease. In a few cases, where tumors have been found growing in their substance, it is not unlikely, that the cellular structure, connecting their fibrillæ, has been the part first affected. Their arteries and veins are subject to the diseases of these vessels in other organs; we have seen an aneurismal tumor as big as a hazel nut formed in the nutrient artery of the popliteal nerve; and Bichât mentions having seen the veins of the sciatic nerve varicose in a paralytic limb. Sir E. Home has described in the Philosophical Transactions a particular tumor of one of the axillary nerves, in which it is difficult to ascertain if the medullary portion be affected; and in the *Encyclopedie Methodique* there is a description of a case of disease, resembling, in some respects, that mentioned. The disease was in the middle of the radial nerve; and as the hand had neither lost its sensibility nor the movement of any of the fingers, this circumstance led to the supposition, that the *medullary* portion of the nerve was not affected, but merely its *neurilema*. In the *fungus hæmatodes*, it is by no means improbable that there is a morbid alteration in the medullary matter of the nerves; though this fact can only be determined by an accurate examination of the disease in various organs.

Most diseases belonging to this system have been fully treated of in the article MEDICINE. There is only one which becomes an object of surgical treatment.

SECT. II. *Of the Tic Doleureux* (Nevralgie).

Affections of this kind are distinguished by the nature of the pain, which is sharp, gnawing, and, particularly at its commencement, accompanied with torpor, and sometimes with pulsations. It is attended with no heat or redness, or any tension or swelling of the part. It comes on in paroxysms, more or less long, and at different intervals. Sometimes the attack is periodical.

The pain is always fixed in the trunk or branch of a nerve; and, during the paroxysm, it darts from the part first affected through all the ramifications of the nerve.

Many nerves of the body have been found affected with this disease. The first pair of the loins (nevralgie ilio-scrotale), the posterior crural (ischias nervosa postica), the crural, but particularly the nerves of the face are subject to it. When the disease affects the face, it is generally situated either in the frontal nerve, in the infra-orbitar nerve, or in the submental nerve. Sometimes the pain affects not only all the branches of these nerves, but it extends to their anastomosing branches, and spreads to one or more of the trunks.

This disease appears to be produced from a variety of causes, according to which its symptoms are varied. Sometimes it has been known to succeed a local irritation, such as an injury on the trunk of the nerve; and in other cases, the affection of the particular nerve is sympathetic of a disease in some distant organ.

Of Herniæ.

In some instances we have observed this disease arise from an affection of the primæ viæ; so that in all cases it becomes the first object of the surgeon to trace the cause of the disease.

Treatment.—When the stomach or intestinal canal are disordered, along with the particular affection of the nerve, the nervous affection will often cease when they are restored to their natural state. This is to be accomplished in most cases by emetics, and a course of laxative medicines, pursued according to the qualities and quantity of the evacuated matter.

In some cases, particularly in the affection of the frontal nerve, we have found great relief from the repeated application of small blisters over the nervous trunk. In some instances, too, the patients have experienced great relief, and have even completely recovered, by a continued attention to a very spare vegetable diet, or to a milk diet. The celebrated Marmontel was a remarkable instance of this kind.

There are, however, cases where these means fail, and where the disease appears to depend on some fixed cause of irritation in the affected nervous trunk. In such cases, it is the usual practice to divide the trunk of the nerve. This operation generally gives instant relief; but its effects have, we believe, in most cases, been but of short duration. It is a fact completely established, that the ramifications of the nervous as well as of the vascular system, though divided, are gradually regenerated. The numerous anastomoses preserve the life of the part on which the divided trunk was distributed, and the divided edges of the trunk gradually coalesce; so that the nerve is again able to perform its natural functions. This reunion of the nerves does not take place so rapidly as we observe it in the arteries, in the skin, cellular membrane, or muscle; and months elapse before it is completed: but, from this reunion, it is probable, that the morbid action in tic doleureux, of the nature of which we are ignorant, the operation, in most cases at least, brings merely temporary relief.

When the operation is to be performed, the necessary steps are extremely simple. Some have contented themselves with introducing a sharp-pointed bistoury through the integuments towards one side of the exit of the nerve, passing the point underneath it, and then dividing it; thus leaving only a small puncture of the skin.

When, however, the operation is done in this manner, the divided extremities, from being separated only a little way, are apt immediately to reunite; a circumstance which should be prevented. We could therefore advise that a free incision be made immediately above the nerve; that the nerve be completely divided, and either a portion cut altogether away, or the divided extremities separated to a distance, and the wound allowed to heal by suppuration.

CHAP. XIII.

Of HERNIÆ.

THE word hernia has been used to signify a protrusion of any viscus, from its proper cavity; but we shall only treat in this place of abdominal hernia. The viscera of this cavity are most frequently protruded at the inguinal and

Of Herniæ. and crural rings and the umbilicus. They, however protrude also at the *foramen ovale*, at the *perinæum*, through the *ischiatic notch*, and *diaphragm*.

The names that have been given to different kinds of hernia, have been derived both from the contents of the hernia, and from its situation. If they contain omentum only, they are called *omental hernia*, or *epiplocele*; if only intestine, *intestinal* hernia; if both, omentum and intestine, *entero-epiplocele*; if the stomach is contained in the tumor, *gastrocele*; if the liver, *hepatocele*; if the bladder, *cystocele*; if the uterus, *hysterocele*.

The peritonæum generally protrudes prior to any of the viscera, forming a bag called the *hernial sac*, in which the protruded viscera are afterwards contained. The protruded portion of peritonæum is not dragged from its natural situation, but becomes elongated by gradual distension; and it is usually not only lengthened, but more or less thickened.

Sect. I. *Of the Inguinal Hernia.*

In an inguinal hernia, the protruded viscus enters the *abdominal* ring, passes along the inguinal canal, and comes out either at the inguinal ring, and goes into the scrotum (scrotal hernia), or bursts through the tendon of the external oblique muscle (inguino-abdominal). Or, it passes through the tendon of the transversalis, and internal oblique, and appears at the inguinal ring (abdomino-inguinal).

Inguinal hernia is more frequent in men than women, the round ligament of the uterus being of a smaller size than the spermatic chord. It sometimes appears on both sides, but most frequently on the right side.

Appearances on dissection. When the skin of the scrotum of an inguinal hernia is removed by dissection, a fascia is found lying underneath it, which varies in thickness according to the bulk and duration of the tumor. This fascia comes off from the tendon of the external oblique muscle above the abdominal ring. Below this fascia is the cremaster muscle, which is united both to the fascia and hernial sac, though easily separable from them by dissection. When the fascia and cremaster muscle are removed, the hernial sac is exposed. The epigastric artery is situated on the *pubic* side of the sac. The spermatic cord lies generally behind the sac; sometimes to one side, and sometimes on its anterior part. Often the vessels of the cord are split, the epididimis passing along one side of the sac, and the artery, veins, and absorbents, on the other. Sometimes there are more than one hernial sac on the same side. Mr Cooper found, in one case, two within the inguinal canal. This arises in some cases from wearing a truss.

In the *inguino-abdominal herniæ*, the sac enters the abdominal ring; and, instead of being continued along the inguinal canal, it passes through the tendon of the external oblique muscle. The hernial sac, in this case, is composed of two distinct layers; the one internal and peritoneal, the other external, and produced by an elongation and gradual thickening of the aponeurosis of the external oblique muscle *.

* Merry and Petit.

In the *abdomino-inguinal* hernia, the sac passes through the tendon of the transversalis or the tendons of both the transversalis and oblique muscle, enters the inguinal canal, appears at the inguinal ring, and then passes down into the scrotum. In this case, Mr Cooper observes, that the spermatic cord lies on the upper or outer part of the sac. The epigastric artery lies on the outside of the sac †.

† Richter, Dessault, Rougemont.

The inguinal hernia is generally pyriform, small towards the ring, and enlarging as it descends. It may be distinguished from other swellings of these parts, by the following symptoms: 1. When the patient is desired to cough, the tumor becomes immediately distended, owing to the pressure of the abdominal muscles forcing into the sac more of the viscera or of their contents. 2. When the patient can remember that the tumor used to disappear when in the horizontal position. 3. When the progress of the tumor has been from the groin to the scrotum. 4. When the tumor contains intestine, it is elastic and uniform; and, when pushed up into the abdomen, it returns with a gurgling noise. When omentum is contained, the tumor is less equal on its surface, receives an impression with the fingers, and does not return with a gurgling noise. Most commonly, however, both intestine and omentum are contained in the sac. 5. The functions of the viscera are somewhat interrupted, producing eructations, sickness, constipation, colicky pains, and distension of the abdomen.

The inguinal herniæ ought to be carefully distinguished from hydrocele of the vaginal coat, from encysted hydrocele of the spermatic cord, from enlargements of the testicle, from hæmatocele, and from varicocele. Hydrocele and hernia, too, are often combined, particularly omental herniæ.

Sect. II. *Of reducible Inguinal Hernia, and of Trusses.*

Herniæ are either reducible, irreducible, or strangulated. In the reducible state, the parts may be returned into the cavity pf the abdomen. To prevent the escape of the bowels, and the danger of such an accident, a constant pressure should be applied at the part where the hernia opens into the abdomen, to shut the mouth of the sac, and thus oppose an effectual resistance to the protrusion of its contents. To accomplish these purposes, various *trusses* have been contrived. The truss should be made of steel, and the spring not stronger than is sufficient to keep up the bowels; for, if the pressure be great, the abdominal muscles, where it is applied, are weakened, and even absorbed. Mr Cooper advises the pad to be made of a conical form, the apex of which should rest on the mouth of the sac. But, as there will be found much variety in the situation and size of the opening through which the hernia passes, it will often be necessary to vary the form and bulk of the pad. The truss ought to be applied so that it makes pressure not on the inguinal ring where the hernia comes out, but upon that part where the spermatic cord, and with it the hernia, first quit the abdomen; and this point may always be determined, by making the patient cough after the hernia has been reduced, and ascertaining the furthest part from the inguinal ring, where the hernial sac is found to protrude. On this point the pad should rest. If the pad be too large, and press merely on the inguinal ring, it will allow the bowels to pass through the internal or abdominal ring, and enter into the inguinal canal. On the other hand, the pad should not

Of Inguinal Herniæ.

not be too small, so as to press into the mouth of the sac and plug it up, for that would prevent all chance of a permanent cure; the bowels may be prevented from entering into the sac; but the pad will act as a dilater or bougie, keep the mouth of the sac constantly open, and even increase its diameter. The pad, therefore, ought always to be made of such a size and shape, as to make a pressure on the abdominal ring, inguinal canal, and inguinal ring.

Sect. III. *Of Irreducible Herniæ.*

Herniæ become irreducible when the protruded parts are suffered to remain long in the hernial sac and increase much in bulk, when membranous bands form across the sac and entangle its contents, or when an adhesion takes place between the sac and its contents, or amongst the contents themselves.

Treatment.—In such cases, a bag truss ought to be worn, so as to keep up a uniform and steady pressure on the scrotum. The application of ice, too, has been known to procure the return of a hernia which appeared irreducible.

Sect. IV. *Of Strangulated Herniæ.*

A hernia is said to be strangulated when not only the intestine and omentum are irreducible, but when the protruded bowels are inflamed, and when the passage of the fæces through the strangulated portion is completely interrupted.

Symptoms. The tumor is attended with considerable pain, which sometimes extends through the abdomen, and is often situated at the umbilicus. Hiccup and vomiting succeed; at first the contents of the stomach only are evacuated, but afterwards those of the lower portions of the alimentary canal. The bowels are completely obstructed, except that portion below the seat of strangulation. The pulse is commonly quick and hard; sometimes, however, it is full. If the disease continues, the skin covering the tumor becomes discoloured and slightly œdematous, and the abdomen tender and tense; the pulse becomes small and thready, the countenance has an expression of anxiety; and all these symptoms are subject to exacerbations. They are greatly mitigated for a while, but soon recur with increased violence.

After having suffered great pain during the first stage of the disease, the patient becomes suddenly easy, and the tumor becomes of a purple colour, and has a crackling feel. The abdomen becomes more tense, a cold sweat covers the body, and the pulse is weak and intermittent. At last the patient, deluded with the hopes of a recovery, sinks under the complaint.

Appearances on dissection. On dissection, the hernial sac is generally found to contain a quantity of dark bloody serum. The intestine is of a dark chocolate brown, with black spots interspersed over it, which are easily torn on being touched with the finger. The surface is covered with a layer of coagulated lymph. Even when the intestine is not mortified the colour is extremely dark, but then the black spots do not appear. Within the abdomen the whole intestinal canal sometimes appears quite natural; at other times portions of the intestines appear inflamed, and in some rare cases they are glued together by an effusion of lymph.

On examining the seat of stricture, it will be found to take place either at the abdominal or inguinal ring. In large herniæ, Mr Cooper has remarked that the stricture is most frequent at the external opening, and then it may be often seen from the particular shape of the tumor, a constriction being distinguishable at that part. In other cases the stricture is seen at the entrance of the spermatic vessels into the inguinal canal; so that, in operating for hernia, it is not sufficient to dilate the external ring, but it becomes necessary to dilate the upper part of the canal.

Treatment.—In the treatment of strangulated hernia, the leading object which is to be kept in view, is to return the displaced viscera as speedily as possible, and, at the same time, while doing this, to diminish the symptoms of inflammation or prevent their accession.

Taxis. The first thing to be attempted, except when the tumor is much inflamed and painful, is the *reduction* of the hernia. In doing this, it is necessary to attend to the position of the patient and the mode of applying the pressure. The body of the patient should be placed on an inclined plane, with the head downwards, and the thighs bent towards the trunk of the body. The pressure which is employed on the tumor should always be directed upwards and outwards along the course of the spermatic cord, and it may be persevered in from a quarter to half an hour. Besides these mechanical means, tobacco clysters and cold have been useful in accomplishing the reduction. Ice is the easiest and best mode of applying cold to hernial tumors; but, when this cannot be procured, Mr Cooper uses a mixture of equal parts of sal ammoniac and nitre. To one pint of water in a bladder, ten ounces of the mixed salts are added, the bladder tied up, and then laid over the tumor. If, after four hours, the symptoms become mitigated, and the tumor lessens, this remedy may be persevered in for some time longer; but if they continue with equal violence, and the tumor resist every attempt to reduction, no further trial should be made of the application.

Operation. The operation which it is now necessary to perform, consists in making an incision through the integuments along the upper part of the tumor, making an opening into the hernial sac, and extending it, so as to allow the contents to be examined, and the fore finger to reach the seat of stricture. The stricture will be readily detected by the point of the finger, and may be easily divided by introducing the bistoury along the finger, till the point of it passes below the stricture *. A very slight pressure of the edge of the instrument will be sufficient to divide the stricture, and allow the bowels to be returned into the abdomen. If merely the stricture is divided, and it is never necessary to extend the incision further, it is of little importance in which direction the incision is made; though surgeons have been at great pains to point out the dangers which might arise were it of too great an extent.

* See Plate DXIX.

Sect. V. *Of Femoral Herniæ.*

In femoral hernia, the hernial sac lies beneath the crural arch, being pushed through an opening between the edge of the broad insertion of Poupart's ligament and the pubic side of the femoral vein †. As the tumor enlarges, instead of falling downwards like the inguinal hernia,

† See Plate DXX.

Of Femoral Herniæ.

hernia, it passes forwards, and often turns over the anterior edge of the crural arch. As it proceeds, the swelling increases more laterally than upwards or downwards; so that it assumes an oblong shape. In the crural hernia, the sac has two coverings besides the integuments; the superficial fascia of the external oblique muscle, and the *fascia propria* of Mr Cooper, which is formed by the protrusion of the fascia which naturally covers the opening through which the hernia passes, and the fascia of the crural sheath. The taxis and use of trusses are the same in femoral as in inguinal hernia; and the same series of symptoms indicate the necessity of an operation in both when strangulated.

Operation.—Mr Cooper recommends that the incision of the integuments be made in the form of a T, beginning one incision about an inch and a half above the crural arch, in a line with the middle of the tumor, and extending it downwards below the arch, and meeting a second incision nearly at right angles with the other, the whole length of the tumor. The two fascias are next to be divided, and the hernial sac opened at its lower part, sufficiently large to admit readily the finger. The seat of the stricture is to be ascertained by the introduction of the point of the fore finger under the crural arch, and it may be readily divided in a direction upwards and inwards, of a sufficient extent to liberate the intestine; generally a very slight motion of the edge of the bistoury will be found sufficient for that purpose.

Chap. XIV.

Of Hare-lip.

The hare-lip is a fissure in the upper lip, very seldom in the under one.* It is attended with want of substance, and has its name from a resemblance to the lip of a hare. In general it is only a simple fissure, though sometimes it is double.

*See Plate DXXIV.

In proceeding to the operation, the patient, if a child, should be secured upon a table; but if an adult, he is to be seated upon a chair, in a proper light. The frænum connecting the gums to the upper lip is to be divided; if a fore-tooth project so much as to prevent the parts from being brought properly together, it is to be extracted; or when the fissure runs through the bones of the palate, if a small portion of the bone project, this must be removed. The operator is then to lay hold of one side of the fissure between the thumb and fore-finger, or between the forceps †, then with a pair of sharp and very strong scissars, or with a scalpel, to cut off a thin portion of the lip, and to repeat the same thing upon the other side of the fissure, so as to render the whole edges of the fissure completely raw; by which, if the operation be properly performed, a piece will be separated in form like an inverted V. After the incisions have been made, the vessels should be allowed to bleed freely to prevent inflammation; and when the bleeding has ceased, the sides of the wound are to be brought accurately together, and kept in that state by the twisted suture. The first pin ought to be as near as possible to the red edge of the lip; another is to be inserted near the upper angle; and if the patient be an adult, a third pin will generally be necessary, half way between the other two. In passing them, they ought to go rather deeper than half through the lip, that the edges of the wound may be kept properly in contact. An assistant now keeps the parts together, while the operator applies a firm waxed ligature first to the under pin; and having made three or four turns with it in the form of an eight figure, it should then be carried about the second, and in a similar way about the third, care being taken that the thread be drawn of a proper tightness. When, from a great want of substance, the retraction has been considerable, some advantage is derived from the use of adhesive plasters applied to the cheeks and tied between the pins. During the time of the cure the patient should be fed upon spoon-meat, and prevented from making any exertion with the lips, otherwise the cure might be considerably retarded. At the end of five or six days the pins may be taken out, when the parts will commonly be found completely united.

† Plate DXXIV.

Amputation.

In the case of a double hare-lip, the operation should be first done upon one fissure; and when a cure is completed there, it may be done safely upon the other.

Chap. XV.

Of Amputation.

There are two modes generally employed for performing amputation; the common operation by two circular incisions, and the *flap* operation. We shall describe in detail both these modes of operating in the thigh.

Amputation of the thigh.

The patient should be placed on a table of a convenient height, in such a manner that the diseased limb may hang over the edge of it, and be secured by an assistant seated on a low chair before him; the other limb and the arms are also to be secured by proper assistants. The tourniquet (see Plate DXVI.) is to be placed on the thigh, three or four inches below Poupart's ligament, where the femoral artery may be most easily and completely compressed. Dessault preferred to the tourniquet, the finger of a strong and intelligent assistant. A cushion fixed on a handle answers very well for making pressure on the artery when a tourniquet is not to be used; and it is a useful instrument to have in readiness, in case the tourniquet should go wrong; or when it becomes necessary to amputate the thigh so far up, that a tourniquet cannot be safely fixed.

After the operator has determined on the place for the incision of the integuments, an assistant should grasp the limb with both hands a little above where the skin is to be divided, and draw it upwards as far as possible. The operator then with the knife (see Plate DXXII. fig. 10.) makes a circular incision through the skin and cellular membrane, down to the muscles; and this may be done, either by one stroke of the knife, or by first making one semicircular incision round the under part of the limb, and afterwards another incision upon the upper part corresponding with the former. When this is made, the integuments retract considerably from their natural elasticity, and they are to be separated from the muscles and dissected with the point of the knife, as far back as to leave a sufficient quantity of skin to cover the stump. The skin being turned back, the operator, Amputation. operator, by a second incision carried close to its inverted edge, cuts the muscles perpendicularly down to the bone. During this part of the operation, care should be taken to avoid wounding the edge of the skin, by tracing attentively the edge of the knife during the whole course of the incision. After the muscles are divided, a considerable retraction takes place, and any muscular fibres attached to the periosteum should be separated from it by the point of the knife, in order to allow the bone to be sawn through as high as possible, and thus secure to it a firm fleshy covering. All the soft parts are next to be drawn upwards as far as their separation from the bone will admit of. They are to be kept in this situation by an instrument called the *retractors*, until the bone is sawn through. The retractors may be either made of iron plates (see Plate DXXII. fig. 5.), or a piece of linen or leather cut as represented in fig. 6. The assistant who uses either of these instruments, should take care when he applies them, that the soft parts are completely out of the reach of the saw, and that they are held back as far as the place where the bone is to be divided. Any sharp edges which may be left on the end of the bone after it has been sawn through, should be taken away with pliers, Plate DXXII. fig. 8. The arteries are next to be tied, and both the femoral artery and vein may be included in one ligature. The bleeding being stopped, and the wound cleaned, the tourniquet is to be altogether taken away, and the soft parts drawn down, so as to cover the extremity of the bone. In order to keep them in this situation, a bandage of thin flannel or cotton cloth, not exceeding two inches and a half in breadth for an adult, is to make one or two circular turns round the body above the ilium; it is then to be carried obliquely over the groin, and turned round the upper part of the thigh pretty firmly two or three times, forming as it were at this place a point of support to the muscles and skin. It is afterwards to be passed in a spiral manner downwards to near the edge of the wound, taking care to pull the soft parts towards the stump, whilst applying each turn of the bandage. The turns should not be so tight as to cause pain, but sufficient to keep the parts in the situation in which they are placed. The surface of the muscles and the edges of the skin are now to be accurately brought together in such a direction, that the wound forms a straight line, extending from the anterior to the posterior aspect of the limb. Strips of adhesive plaster, about half an inch in breadth, and eight or ten inches in length, should be applied, in order to keep the lips of the wound in this position. Those over the middle part of the wound ought to be put on first; and great attention is necessary in their application, to prevent the edges of the skin from overlapping and puckering. They should be of such a number as completely to cover the surface of the wound, leaving only a small opening for the ligatures of the arteries to be brought out at that part of the wound nearest the place where the artery is situated. The wound is to be afterwards covered with a piece of linen or caddis spread with simple ointment, and a compress of fine tow laid over it, the whole being secured by a few turns of the roller.

The bedclothes should be kept from pressing upon, and coming in contact with the stump, by a frame or cradle, as it is called. (See Plate DXXIII. fig. 11.).

Lithotomy. Flap operation. When this operation is to be performed, the incision of the integuments may be made, either with a common scalpel, or with the end of the amputating knife, as represented in Plate DXXII. fig. 10. After the skin is divided, it is of importance to allow it to retract as much as possible, by cutting the fibres of cellular membrane which connect it with the fascia of the thigh, before dividing the muscles. If the limb be much emaciated, the division of the muscles may be also made with the scalpel; if, on the contrary, the limb be bulky, the incision ought to be made by a common amputating knife, in order that the surface of the flaps be plain and uniform. After dividing the muscles obliquely upwards down to the bone, they should be separated from it a sufficient way, so as to leave enough to cover the end of the bone, and they should be allowed to contract as much as possible before the bone is sawn through. After the limb is amputated, and the circular bandage applied, the flaps will be found to meet very accurately together, and to form a round and smooth stump. From the angles of the skin being removed, no puckering or corners are left, and the two surfaces and muscles being applied to each other, and covering the end of the bone, give it a firm and fleshy covering, whereas in amputations performed in the common mode, the bone is covered by integuments alone. The adhesive plasters are to be applied in the same manner, and the patient is to be treated afterwards as in the other modes of operating.

The general rules to be attended to in amputation in other parts of the body, are the same as those already mentioned; and in Plate DXXII. and DXXIII. we have delineated the place and direction of the incisions.

Chap. XVI.

Of Lithotomy.

The manner of preparing the patient for this operation depends upon a variety of circumstances. If he be plethoric, a few ounces of blood should be taken away. and at proper intervals the bowels ought to be emptied by any gentle laxative which will not gripe. The diet should consist of light food for some time previous to the operation. If the pain be violent, opium is necessary. Sometimes it is relieved by keeping the patient in bed with the pelvis raised, so as to remove the stone from the neck of the bladder. He ought not to sit up, or take any exercise, in the time of preparation. The warm bath ought to be used two or three times, and the patient should remain in it half an hour at each time. A laxative ought to be given on the day preceding the operation, and an injection a few hours before it is performed. The patient ought to drink plentifully of some diluent liquor, and to retain the urine several hours previous to the operation. If this cannot be readily effected, a slight compression, by means of a ligature, may be made upon the penis, so as to have the bladder sufficiently distended, that there may be no danger of the posterior surface being hurt by the end of the gorget. The perinæum and parts about the anus should be well shaved.

A table somewhat more than three feet in height, and of sufficient strength, is to be firmly placed, Lithotomy. and properly covered with blankets, pillows, &c. Upon this the patient is to be laid and properly secured; and for this purpose there ought to be two pieces of broad firm tape, each about five feet in length, which are to be doubled, and a noose formed upon them. A noose is to be put upon each wrist, and the patient desired to lay hold of the middle of his foot upon the outside. One end of the ligature is to go round the hand and foot, and the other round the ankle and hand, and cross again, so as to repeat the turns in the reverse way. A running knot is to be tied, by which the hand and foot will be properly secured. The buttocks are then to be made to project an inch or two over the table, and to be raised considerably higher than the shoulders by a couple or more pillows, and one pillow ought to be put under his head.

The operator is now to introduce a grooved staff (Plate DXXI. fig. 5.) of proportionable size, and open to the end, through the urethra into the bladder; and having fully satisfied himself of the existence of a stone, he inclines the staff, if he be right-handed, obliquely over the right groin, so that the convex part of the staff may be felt in the perinæum on the left side of the raphe. He then fixes it, and delivers it to his assistant, who is to hold it with his right hand, desiring him to press it gently, in order to make the sulcus of the staff project in the direction in which he received it. With his left hand the same assistant is to raise and support the scrotum.

The thighs of the patient being sufficiently separated by the assistants, and the surgeon being seated upon a chair of a proper height, and in a convenient light, he makes an incision with a common convex-edged scalpel through the skin and cellular substance, below the symphysis of the ossa pubis, which is a little below the scrotum, and where the crus penis and bulb of the urethra meet, and on the left side of the raphe, and continues it in a slanting direction downwards and outwards to the space between the anus and tuberosity of the ischium, ending somewhat lower than the basis of that process, by which a cut will be made of three or four inches in length. This incision ought not to be shorter than is here directed, otherwise there will not be room for the rest of the operation. As soon as the integuments are divided, he ought to introduce two of the fingers of the left hand. With one he keeps back the lip of the wound next the raphe, and with the other he presses down the rectum. He ought likewise particularly to guard against cutting the crura of the penis, which he can readily feel, and separate at their under part with one of his fingers. He next makes a second incision almost in the same direction with the first, but rather nearer to the raphe and anus, by which he preserves the trunk of the *arteria pudica*. By this incision he divides the transversalis penis, and as much of the levator ani and cellular substance within these as will make the prostate gland perceptible to the finger. If any considerable vessel be cut, it is immediately to be secured, though this is seldom necessary. He is now to search for the groove of the staff with the fore finger of his left hand, the point of which be presses along from the bulb of the urethra to the prostate gland which surrounds the neck of the bladder. He keeps it there; and turning the edge of the knife upwards, he cuts upon the groove of the staff, and freely divides the membranous part of the urethra, till the staff can be felt perfectly bare, and that there is room to admit the nail of the finger; and as the finger assists in keeping the parts stretched, and effectually prevents the rectum from being hurt, the incision into the urethra may be made with perfect ease and safety.

The next part of the operation, viz. dividing the prostate gland and neck of the bladder, might, by a dexterous operator, be safely performed with a common scalpel with the edge turned the opposite way. But to guard against accidents, a more convenient instrument, called the *cutting gorget*, is now in general use. It was originally invented by Mr Hawkins of London, and since his time has undergone various alterations *. The membranous part of the urethra being now divided, and the fore finger still retained in its place, the point of the gorget, previously fitted to the groove, is to be directed along the nail of the finger, which will serve to conduct it into the groove of the staff; and as this is one of the nicest parts of the operation, the most particular attention is required that the point of the gorget be distinctly felt to rub in the bare groove.

* See Plate DXXI. fig. 1.

The operator now rises from his seat, takes the staff from the assistant, raises it to near a right angle, and presses the concave part against the symphysis of the ossa pubis; satisfies himself again that the point or beak is in the groove, and then pushes on the gorget, following the direction of the groove till the beak slip from the point of the staff into the bladder. The gorget is not to be pushed farther than this, otherwise it may wound the opposite side of the bladder, &c.

The gorget having now entered the bladder, which is readily known by the discharge of urine from the wound, the staff is to be withdrawn, and the finger introduced along the gorget to search for the stone, which, when felt, will point out the direction to be given to the forceps; at any rate, the introduction of the finger serves to dilate the wound in the bladder; and this being done, a pair of forceps † of a proper size, and with their blades as nearly together as their form will allow, are to be introduced, and the gorget withdrawn slowly, and in the same direction in which it entered, so as to prevent it from injuring the parts in its return. After the forceps are introduced, and passed till they meet with a gentle resistance, but no farther, the handles ought to be depressed till they are somewhat in an horizontal direction, as this will most correspond with the fundus of the bladder. One blade of the forceps is to be turned towards the symphysis of the pubes, to defend the soft parts there; the other of consequence will guard the return. After they have distinctly touched the stone, by moving them a little in various directions, they are then to be opened, and the stone laid hold of, which may generally be done with considerable ease. It frequently happens, however, that when the stone is small, it is not readily felt with the forceps; and instances may happen where the under and back part of the bladder may be so depressed as to conceal the stone. In such a situation, nothing will more readily bring it in the way of the forceps than to introduce the finger into the rectum, and elevate this part of the bladder. Straight forceps are generally used; crooked ones, in some very rare cases, however, may be necessary, and therefore the surgeon ought to be provided with them.

† Plate DXXI. fig. 6. & 7.

After

Lithotomy. After the forceps has laid hold of the stone, if it be small and properly placed, it may readily be extracted: but if, on the contrary, the handles of the forceps are now observed to be greatly expanded, it is certain the stone is improperly fixed, or that it is remarkably large: in either case it should not be held fast, but allowed to move into the most favourable situation; or the finger is to be introduced so as to place it properly for extraction. If this cannot be done with the finger, it ought to be allowed to slip out of the forceps, in order to get it more properly fixed; and as the most common form of the stone is flat and oval, or somewhat like a flattened egg, the forceps should have hold of the smallest diameter, while an end presents to the neck of the instrument. The stone should be grasped with no greater firmness than is merely sufficient to bring it fairly out, and it should be extracted in a slow gradual manner.

EXPLANATION OF THE PLATES.

SURGERY.

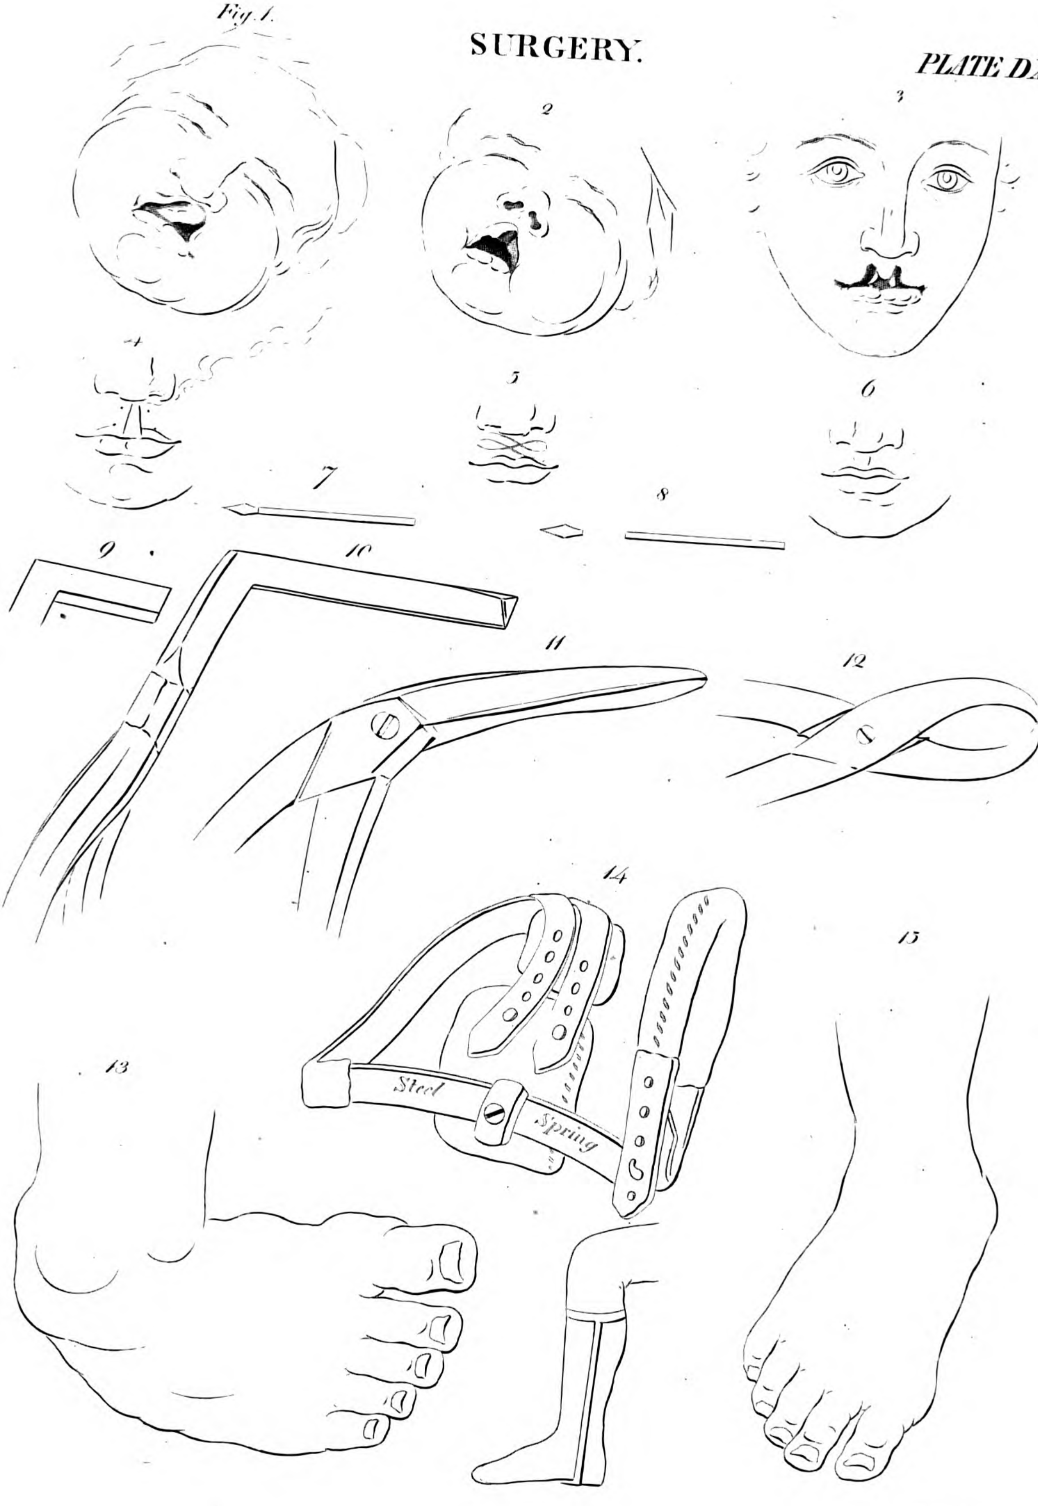
PLATE DXXIV.



E. Mitchell, Sculpt.

SURINAM, a country of Guiana, which extends about 75 miles along a river of the same name, in N. Lat. 6. 16. This river is navigable for 90 miles up the country. The chief productions of Surinam are, wood for dyeing, indigo, cotton, sugar, tobacco, gums, and different species of fruit. Prodigious numbers of monkeys infest the woods, as well as very large serpents. This settlement was ceded to the Dutch in 1674, as an equivalent for New York; was retaken by the British in 1799, and restored in 1814. Paramaribo is the capital. N. Lat. 6. 16. W. Long. 56. 0. The productions of this country, when in the hands of the Dutch, yielded, in the year 1775, the sum of 822,905l. sterling; and it may be presumed that the value of these will not diminish in the hands of its present proprietors. Population about 100,000 persons.

Demerara.—Connected with Surinam we may notice the colony of Demerara, which surrendered to the British troops in 1781; and after some other changes was secured to Britain in 1814, along with Berbice and Essequibo. Its productions cleared from the port of Demerara, from January 1806 to the same month of 1807, were 19 337 hogsheads, 474 tierces, and 801 barrels of sugar; 4722 puncheons and 17 hogsheads of rum; 23,604 bales, two bags of cotton; 12,390,102 pounds of coffee; and 1694 casks of melasses; a produce which we hope will be constantly increasing under the mild and humane conduct of the British government. It is deemed a valuable acquisition, on account of its flourishing condition. Stabroek is the capital of Demerara. See DEMERARA, SUPPLEMENT.

Essequibo, on the banks of a river of the same name, was first founded in 1698, but came into the hands of the British much about the same time with the preceding. The unaccountable neglect shewn by Holland towards her colonies rendered them an easy conquest.

Berbice is situated between Demerara and Surinam, containing about 104 small plantations, scattered at considerable distances from each other, the produce of which was long ago valued at 100,000l. sterling, but may be expected to have a rapid increase. Population between 8000 and 9000 persons of various descriptions. See BERBICE, SUPPLEMENT.

Pomaroon is a country which has a rich and fertile soil; yet the inhabitants chiefly confine themselves to the cultivation of cotton, for the produce of which it is found to be admirably adapted. It is not so well fitted to yield good crops of coffee or sugar, as the land is by far too rich, and strongly impregnated with saline matters. In 1799 and 1800, a thirst for planting cotton was greatly increased, as the crops of that article were then the largest ever known to be produced in the colonies.

SURMOUNTED, in *Heraldry*, is when one figure is laid over another.

SURMULLET. See MULLUS, ICHTHYOLOGY *Index*.

SURNAME, that which is added to the proper name for distinguishing persons and families. It was originally distinguished from *sirname*, which denotes the name of the *sire* or progenitor: thus Macdonald, Robertson, are sirnames expressing the son of Donald, the son of Robert. The word *surname*, again, signified some name superadded to the proper name to distinguish the individual, as Artaxerxes *Longimanus*, Harold *Harefoot*, Malcolm *Canmore*. From this it is evident that every sirname was a surname, though the reverse was not so. In modern times they are confounded; and as there is now no occasion to preserve the distinction, Dr Johnson has rejected the word *sirname* altogether. See NAME.

Surnames were introduced among all nations at an early period, and seem to have been formed at first by adding the name of the father to that of the son. This was the practice among the Hebrews, as appears from the scriptures. Caleb is denominated the son of Jephunneh, and Joshua the son of Nun. That the same thing was customary among the Greeks, every one who has read the poems of Homer must remember. We have an instance of it in the very first line of the Iliad: Αχιλλῆος Πηληιάδεω, "Achilles the son of Peleus." This is perhaps the general origin of surnames, for it has been common among most nations (A).

The Romans generally had three names. The first called *prænomen* answered to our Christian name, and was intended to distinguish the individuals of the same family; the second called *nomen* corresponded to the word *clan* in Scotland, and was given to all those who were sprung from the same stock; the third called *cognomen* expressed the particular branch of the tribe or clan from which an individual was sprung. Thus Publius Cornelius Scipio, *Publius* corresponded to our names John, Robert, William; *Cornelius* was the name of the clan or tribe, as Campbell was formerly the name of all the duke of Argyle's clients, and Douglas the name of the retainers of the duke of Hamilton's progenitors; *Scipio* being added, conveyed this information, that Publius, who was of the tribe of the Cornelli, was of the family of the Scipios, one of the branches or families into which that tribe was divided. Respecting the three names which were common among the Romans, we may say that the first was a name and the other two surnames.

Du Chesne observes, that surnames were unknown in France before the year 987, when the lords began to assume the names of their demesnes. Camden relates, that they were first taken up in England, a little before the conquest, under King Edward the Confessor: but he adds, they were never fully established among the common people till the time of Edward II.; till then they varied with the father's name; if the father, e. gr. was called *Richard*, or *Roger*, the son was called *Richardson*, or *Hodgson*; but from that time they were settled, some say, by act of parliament. The oldest surnames are those we find in Domesday-Book, most of them

(A) This might be supported by examples borrowed from many nations. The old Normans used *Fitz*, which signifies son; as Fitzherbert, Fitzsimmons, the son of Herbert, the son of Simmons. The Irish used *O*; as O'Neal, the son of Neal. The Scotch Highlanders employed *Mac*; as Macdonald, the son of Donald. The Saxons added the word *son* to the end of the father's name, as Williamson.

Surveying. of the field, as B, and a pole, or other mark is to be left at A. The length AB is to be measured by the chain, and a proportional length marked off on the paper, in the direction *a*, *b*, from a plotting scale, or scale of equal parts. Proceeding as at first, a line is to be drawn from *b* towards *c*, in the direction of the side BC, and marking the measure of the angle CBA. In this manner, by placing the plane table successively at each corner of the field or plot of ground, the outline figure of the whole will be transferred to the paper, and *a*, *b*, *c*, *d*, *e*, *f*, will be the plan of the field A, B, C, D, E, F.

If it be not convenient to place the plane table at the corners of the ground to be surveyed, the plan may be taken by placing the instrument any where within the area, as at E (fig. 3.) in the middle of the field A, B, C, D. Fig. 3. In this case we can readily find the direction of the lines EA, EB, EC, ED, and the angles which they form at the point E. By measuring the distances from E to the several angular points, and transferring the proportional distances from the plane scale upon the paper, and then joining the points thus found, there is easily traced the outline of the whole field.

It may happen that no part of the ground to be measured is accessible, except one line, as the line AE in the space A, B, C, D, E, F, G, (fig 4.). Fig. 4.

In this case, the plane table is to be fixed at the point A, of the base line AE, and a point made on some part of the paper at pleasure, to represent the station A, and the base line AE is in the usual manner to be ascertained and laid down. Then from the station A, the situation or direction of the points B, C, D, E, F, G, are to be observed through the sights of the index; and lines corresponding to the lines AB, AC, AD, AE, AF, AG, are to be laid down on the paper, but of an indefinite length. When this is done, great attention must be paid to preserve the table steady and perfectly horizontal. The length of the base line AE being determined, the table is now to be removed to the other extremity E, and so disposed that the base line on the paper may be exactly over the base line EA of the field; and proceeding as before, the directions of the lines EA, EB, EC, ED, EF, EG, are to be determined, and corresponding indefinite lines drawn on the paper. The points where these last lines cross those before traced, are to be carefully noted, and the outline joining all these points of section, will correspond to the outline of the plot to be surveyed.

The following general directions to be observed in using the plane table, are given by Dr Hutton. 1. Let the lines on which stations are made be directed towards objects as far distant as possible; and when any such object is set, go round the table and look through the sights from the other end of the index, to see if any other remarkable object be directly opposite; if there be none such, endeavour to find another forward object, such as shall have a remarkable backward opposite one, and make use of it, rather than the other; because the back object will be of use in fixing the table in the original position, either when you have measured too near to the forward object, or when it may be hid from your sight at any necessary station by intervening hedges, &c.

2. Let the said lines, on which the stations are taken, be pursued as far as conveniently can be done; for that will be the means of preserving more accuracy in the work. Surveying.

3. At each station it will be necessary to prove the truth of it, that is, whether the table be straight in the line towards the object, and also whether the distance be rightly measured and laid down on the paper. To know whether the table be set down straight in the line, lay the index on the table in any manner, and move the table about, till through the sights you perceive either the fore or back object; then, without moving the table, go round it, and look through the sights by the other end of the index, to see if the other object can be perceived; if it be, the table is in the line; if not, it must be shifted to one side, according to your judgement, till through the sights both objects can be seen. The aforesaid observation only informs you if the station be straight in the line; but to know if it be in the right part of the line; that is, if the distance has been rightly laid down: fix the table in the original position, by laying the index along the station line, and turning the table about till the fore and back objects appear through the sights, and then also will the needle point at the same degree as at first. Then lay the index over the station point and any other point on the paper representing an object which can be seen from the station; and if the said object appear straight through the sights, the station may be depended on as right; if not, the distance should be examined and corrected till the object can be so seen. And for this very useful purpose, it is adviseable to have some high object or two, which can be seen from the greatest part of the ground accurately laid down on the paper from the beginning of the survey, to serve continually as proof objects.

When from any station, the fore and back objects cannot both be seen, the agreement of the needle with one of them may be depended on for placing the table straight on the line, and for fixing it in the original position *. * See Hutton's Mensurer.

5 Method of measuring offsets. The foregoing examples are extremely simple, as the bounding lines are straight and regular. Here, therefore, it is not requisite to measure what surveyors call the offsets, or the perpendicular distances between a base line, and the several angles which it subtends. It seldom happens, however, that the work can be carried on in so regular a way, as the bounding lines, even of small pieces of ground, are generally more or less crooked.

Let us suppose A, *l*, *m*, *n*, *o*, *p*, *q*, *r*, (fig. 5.) to be a crooked hedge, or other boundary of a piece of ground, and AB the general base line subtending its several angles. Fig. 5. In measuring along this base, when the surveyor comes opposite to any of the bendings or corners of the fence, as at *c*, *d*, *e*, &c. he measures the perpendicular offsets *cl*, *dm*, *en*, &c. either with the offset staff, or, if they are of considerable length, with the chain. These offsets are to be noted down, as will be explained immediately.

When the offsets are not very large, their places may be determined pretty exactly by the eye, especially when assisted by laying down the offset staff in a direction perpendicular to the base, and opposite to the angles; but when the offsets are very large, their positions are best determined by the cross, or the plane table, in the following manner. In measuring along AB (fig. 5.), when

Surveying.

when coming nearly opposite to *l*, where an offset is likely to stand, the cross or plane-table is there to be fixed, as at *c* in the line A B, and its index is to be turned till the extremities of the base A and B can be seen through the sights, both backward and forward. Then looking along the cross sights of the cross, or the cross line on the index of the plain table, it is easy to observe whether the station of the instrument be exactly opposite to the corner. If it be not, the instrument must be moved backward or forward along the line A B, preserving the index in the same situation till the station and the point *l* be exactly opposite to each other. The exact measured distance between A and *c*, is then to be noted and registered, and the measure of the offset *c l* is to be set down opposite to the former, and on the left hand of it, as the work is advancing from A to B. In the opposite direction the offsets would of course appear on the right hand. In this method, no field book or register is usually necessary, but where the survey is more extensive, and where the theodolite or other complex instruments are required, it is necessary to have recourse to some method of registering the successive operations.

6 Use of the field-book.

The field book employed on these occasions is variously constructed, according to the taste or particular object of the surveyor. The following is a specimen of the usual field book, as described by Dr Hutton.

Offsets and remarks on the left.		Stations, Bearings, and Distances.	Offsets and remarks on the right
		⊙ 1	
		105° 25	
		00	25 corner.
	92	73	
		248	Brown's hedge.
Cross a hedge,	24	610	35
		954	00
		⊙ 2	
		53° 10′	
		00	00
House corner,	51	25	21
		120	29 a tree.
	34	734	40 a stile.
		⊙ 3	
		67° 20′	
		61	35
A brook,	30	248	
		639	16 a spring.
Footpath,	16	810	
Cross hedge,	18	973	20 a Pond.

Of the three columns which compose this field book, the middle or principal column is for noting down the stations, angles, bearings and distances, as they are ascertained, and the columns on the right and left are for the offsets to the right and left of the principal course, which are placed against their corresponding distances in the middle column, as also for occasional remarks or memorandums, to which it may be useful to refer in drawing the plan of the surveyed lands.

Here ⊙1 is the first station, where the angle or bearing is 105° 25′. On the left, at 73 links in the distance or principal line, is an offset of 92; and at 610 an offset of 24 to a cross hedge. On the right, at 0, or the beginning, an offset 25 to the corner of the field; at 248 Brown's boundary hedge commences; at 610 an offset 35; and at 945, the end of the first line; the 0 denote its terminating in the hedge. And so on for the other stations. A line is drawn at the end of every station line, to prevent confusion.

7 Crocker's field-book.

Various improvements have been made on the field-book, especially by Mr Abraham Crocker, and Mr John Bodham. We shall give a specimen of each.

Fig. 6.

Fig. 6. represents a page of Mr Crocker's field-book, exhibiting a part of the survey of an estate called the Mill Estate; the outlines of which were surveyed with the theodolite, and the interior parts filled up with the chain. In this book the operations are noted down, so as to begin from the foot of the page, carrying them on upwards.

In surveying after this method, Mr Crocker advises to choose two or more eminences, as principal stations, and measure a general base line from one station to the other, noting each hedge, brook, or other remarkable object as it is passed by; measuring also such short perpendicular lines to such bends of hedges as may be near the base. From the extremities of this base line, or from any convenient parts of it, the surveyor must proceed with other lines to some remarkable object situated towards the sides of the estate, without regarding the angles they make with the base-line or with one another, remembering to note every hedge, brook, or other object by which he passes. These lines, when laid down by intersections, will with the base line form a principal triangle on the ground to be surveyed; several of which, if necessary, being thus laid down, the surveyor may proceed to form other smaller triangles and trapezoids, on the sides of the former; and so on till the several enclosures are finished.

This principal triangle being completed, and laid down on the rough plan paper, the parts, exterior as well as interior, are to be completed by smaller triangles and trapezoids.

When the whole plan is laid down on paper, the contents of each part of the estate may be calculated by the methods already explained under MENSURATION.

In countries where the lands are enclosed with high hedges, and where many lanes or roads pass through an estate, a theodolite may be employed with advantage, in ascertaining the angles of such lands; and by these means an outline of the estate may be obtained, and the lane lines serve as the bases of such triangles and trapezoids as are necessary to fill up the interior parts.

Plate DXXVI. fig. 8.

To illustrate this method, let us take AB in the plan of the estate, (fig. 8) for the principal base line. From B go off to the tree at C, noting down in the field book every cross hedge as you measure on, and from C measure back to A, noting down every thing remarkable, as before directed. This figure also illustrates the method of measuring the cross lines, offsets, and interior parts and enclosures.

8 Rodham's field book, Fig. 7. and 9.

Fig. 7. represents a page from Mr Rodham's field book. His method of procedure is as follows:—Like Mr Crocker, he begins from the bottom of the page, and writes upwards; denoting the crossing of fences, by lines

Surveying. lines drawn across the middle column, or only a part of such a line on the right and left opposite the figures, to avoid confusion, and the corners of fields, and other remarkable turnings in the fences, towards which offsets are taken, by lines joining like the fences, as will be best seen by comparing the specimen at fig. 7. with the plan at fig. 9.

The marks called *a*, *b*, *c*, &c. are best made in the fields, by making a small hole with a spade, and placing there a chip or small piece of wood, with the particular letter marked on it, to prevent one mark being taken for another, on any return to it, though in general the name of a mark is very easily seen, by referring in the book to the line in which it was made. After the small Italic letters have been gone through, the capitals may be next employed, and the Roman letters afterwards, and so on. Perhaps it would be preferable to distinguish the marks by figures.

The letters in the left hand corner at the beginning of each line, denote the mark or place measured *from;* and that at the right hand corner of the end, is the mark measured *to.* But when it is not convenient to go exactly from a mark, the place measured from is described *such a distance* from *one mark* towards *another;* and where a mark is not measured to, the exact place is ascertained by writing, turn to the right or left hand, *such a distance* to *such a mark*, it being always understood that those distances are taken in the chain line.

The characters used are for ⌈ *turn to the right hand*, ⌉ for *turn to the left hand*, and ʌ placed over an offset, to shew that it is not taken at right angles with the chain line, but in the line with some straight fence, being used chiefly when crossing their directions, and is a better mode of ascertaining their true places than by offsets at right angles.

When a line is measured whose position is determined, either by former operations (as in the case of producing a given line or measuring from one known place or mark to another) or by itself (as in the third side of a triangle) it is called a *fast line*, and a double line is drawn across the book at the conclusion of it; but if its position be not determined (as in the second side of a triangle) it is called a *loose line*, and a single line is drawn across the book. When a line becomes determined in position, and is afterwards continued, a double line is drawn half through the book.

Fig. 9. When a loose line is measured, it becomes absolutely necessary to measure some line that will determine its position. Thus, the first line *a b*, (fig. 9.) being the base of a triangle, is always determined, till the third side *j b* is measured; then the triangle may be constructed, and the position of both is determined.

At the beginning of a line to fix a loose line to the mark or place measured from, the sign of turning to the right or left hand must be added (as at *j* in the third line); otherwise a stranger, when laying down the work, may as easily construct the triangle *h j b*, on the wrong side of the line *a h*, as on the right side; but this error cannot be committed, if the sign above named be carefully observed.

In choosing a line to fix a loose one, care must be taken that it does not make a very acute or obtuse angle, as in the triangle *p* B *r;* by the angle at B being very obtuse, a small deviation from truth would make the error at B when constructed very considerable; but by constructing the triangle *p* B *g*, such a deviation is of no consequence.

When the words *leave off* are written in the field book, it is to signify that the taking of offsets is from thence discontinued; and of course something is wanting between that and the next offset *.

9 Practical directions for the use of the theodolite. The general use of the theodolite in measuring separate plots, has been described under MENSURATION. The following practical directions for the use of this instrument are given by Mr Crocker, and apply to his field book, exemplified at fig. 6. and the plan at fig. 10.

Suppose the surveyor to plant his theodolite in the road ⊙ 1, and having duly adjusted it, by placing its head exactly horizontal, by the levels; and setting the index part of the limb exactly at 360°; and by moving the whole head about till 360° in the compass-box comes to the line in the north end of the needle; there fixing all fast, by the screw under the head, between the legs, he will have his instrument completely adjusted.

Fig. 10. The theodolite thus adjusted, the surveyor sends one of his assistants forward as far as he can conveniently see how to measure a straight line, as at ⊙ 2. Taking then his angle of observation, by his telescope, to the picket at that station, he finds it to be 69° from the north part of his magnetic meridian line towards the east, which he enters in his field book, noting it with NE, as a memorandum on which side of the magnetic meridian it lies. He is now to fasten his limb to the other part of the head, by a screw for that purpose.

His chain-man having laid the chain in the direction to the picket ⊙ 2, in order to measure the line, he makes such offsets to the right and left, in his first chain's length, as may be necessary. At his first station, he finds that on the right, the general road fence is 30 links, and also a nook of 40 links more, and 30 links broad; and that on the left of his station he has an offset of 10 links, all of which he must note in his field book. Proceeding forward on this line, he finds at 300 he has an offset of 25 on the right, where is a gate, which he has to notice; and, on the left 20, which determines the breadth of the road at that spot. At 400, he will find 10 on the right and 20 on the left to be the breadth; and at 700 (the end of the line) he will find 35 on the right and 15 on the left to be the breadth of the road; where also he will find a small road branching off to the right. Thus the first station line is finished.

To this spot (which is his second station) he brings the theodolite; and after setting it level, he unlocks the under screw, and turns the whole head about, till, through the telescope, he sees the back picket or station staff to be cut by the cross hairs. Here, again, locking the head of his theodolite firm by the under screw, he must unscrew the limb, and turn it about, till through the telescope, he has a view of the picket at ⊙ 3; the bearing of which he will find to be 253° 10′ from the north to the eastward, which he will enter in his field book. Measuring on from ⊙ 2, towards ⊙ 3, he will find at 130 links, that he is come to a turnpike, where the breadths at the right and left are 30 and 15. At 200, he has an offset of 15 on the left, and a break off at the right of another road, at 25 from his line, with two other offsets, as expressed in the field book. It must

* Hutton's Math. Dict. art. Surveying.

Surveying. must be noted where this road leads to. At 265 he has offsets of 30 on the left, and 20 on the right. Thus ends the second station line.

Now bringing his instrument to ⊙3, he is to adjust it in the manner before directed at ⊙2; and turning the limb about towards the picket forward, he will find the angle of bearing to be 57° 45′, still from the north to the eastward. At 20 links he will be opposite to a cross hedge on the left, belonging to the estate he is surveying. At 293 he ends the line of this station, where the offsets are 5 and 35, as noted in the field book.

Coming next to ⊙4, and having adjusted his theodolite, he finds his next angle =226° NE. At 120 his offsets are 20 and 15. At 410, they are 15 and 30, where, on the left, is a cross hedge, of a backward direction. At 480 his offsets are 5 and 25, where is another cross hedge. At 750, is a break-in of the fence, and the offsets are 30+15 on the left, and 10 on the right. At 1050, the offsets are 20 on each hand, and another cross hedge on the left. At 1150 are offsets of 20 and + 20, where stands a house. At 1300, the offset of 30 on the right terminates the house; and at 5 on the left is a cross hedge, of a backward direction. 1350 ends this line, where roads diverge to the right and left.

At ⊙5, the instrument being adjusted, the angle is found to be 284° 50′ nearly W. At 50, his offset to the hedge is 15; at 220 it is also 15, where is a cross hedge, the other end of which was noted at 1050 in the last line. At 320 the offset is 25; at 350, the end of the ⊙, the distance from the fence is 15.

At ⊙6, the bearing is 305° 35′ N. W. At 130 the offset is 30, where a cross hedge goes off to the point which was noted at 750, in the line from ⊙4 to ⊙5. At 160 the line is nearly close to the fence, ending at 210.

At ⊙7, the angle forward is 106° 25′ N. W. The line is 143 long, with an offset at the end of 15.

At ⊙8 the bearing is 269° 20′ N. W. At 100 and at 300 the offsets are 15 and 10.

The bearing at ⊙9 is 70° 45′ S. W. At 30 the measurer finds it expedient to cross the fence, and proceed within the bounds of the estate. At 90 he has an offset of 30 to the right, where he crosses a hedge. At 880 he crosses another hedge, having there an offset of 20: at 940 is an offset of 50. At 990 he again crosses the hedge; and at 1020 is an offset of 20 to the left: at 1040 he again crosses the hedge: at 1080 he comes to the corner of the farm house; and 1165 ends his line, where is a small curve at the right.

At ⊙10, the bearing is 204° S. W. At 70 is an offset of 5 at the right: at 200 is 15 at the left, and a cross hedge: at 600 is 25 on the left, and 20+15 on the right: 690 ends the line, where are 15 on each side, where there is also a cross hedge.

The angle at ⊙11 is 355° 30′ S. E. At 280 is an offset of 30 on the right, and 10 with a cross hedge on the left: at 400 is an offset of 30, and another cross hedge on the left; and 470 ends the line, where are offsets of 10 and 20 on the right and the left.

At ⊙12 the angle is 155° S. E. At 60 is a cross hedge: at 219 the offsets are 10 and 15; and at 229 he comes to close his work at ⊙1, from which he set out.

Having thus taken the circuit of this estate, the measurer must proceed to plot the same on paper, with some convenient scale *.

* Crocker's Elements, p. 235.

10 Description and use of the plotting-scales. Figs. 11. and 12.

The scale usually employed for this purpose is that called the *plotting scale*, *plane scale*, or *scale of equal parts*, represented at fig. 11. and 12.

This instrument contains different scales or divided lines, on both sides. There are on one side a number of plane scales, or scales of equal divisions, each of a different number to the inch, and also scales of chords for laying down angles, and sometimes the degrees of a circle marked on one edge, answering to a centre marked on the opposite edge, by which means it also answers the purpose of a protractor. There are several diagonal scales on the other side, of different sizes, or different dimensions to the inch, serving to take off lines expressed by numbers to three dimensions, as units, tens, hundreds, as also a scale of divisions which are the 100th parts of a foot. The most useful of all the lines which can be laid down on this instrument, though not always done, is a plane scale on the two opposite edges, made thin for the purpose. This line is very useful in surveying; for by laying down the instrument on paper, with its divided edge along a line whereon several distances are to be laid off, for the places of offsets, &c.; these distances are all transferred at once from the instrument to the line on the paper, by making small points or marks against the respective divisions on the edge of the scale.

11 Directions for plotting or planning.

The business of *plotting* or laying down a plan of an estate from the memoranda of a field book, is a very important branch of the surveyor's office. This will best be understood by an example, which we shall take also from Mr Crocker. It is adapted to the page of his field book, already alluded to; and the plan, when completed, is seen at fig. 10.

The vellum or paper on which the plan is to be drawn, being smoothly laid on a drawing board, the magnetic meridian is to be represented by a line drawn from the bottom to the top.

A point is to be made about the middle of this line, on which is to be laid the centre of the circular protractor, placing the straight edge in such a manner as to coincide with the said meridian line: draw a pencil line around at the edge of the protractor.

The protractor being thus placed, and firmly fixed by means of pins in that position, or by a lead weight, the field book is to be inspected for the quantity of the angle at ⊙1, which, in the present case is stated at 69° north-easterly. This degree is then to be looked for on the circular edge of the protractor, and a mark made on the paper with a fine plotting-pin, at that number, which is to be marked 1, denoting ⊙1.

The field-book is then to be inspected for the ∠ at ⊙2, which in this case is 253° 10′, where a mark is to be made as before.

A similar process is to be followed with all the other angles, till the surveyor comes to the close on ⊙1.

All the angles being thus marked off, the protractor is to be removed.

The place where the beginning of the work should be placed is then to be considered, that the whole may come within the compass of the paper laid down; where a mark is to be made, noting it as ⊙1, the beginning of the plot.

The fore edge of the parallel ruler is then laid from the

Surveying.

the central point where the protractor lay, to the mark on the pencilled circle denoting ⊙ 1. The fore edge of the parallel ruler is next moved till it touch the point determined on for the beginning of the plot, from which a pencil line in the direction from the north to the eastward, is drawn, about the length of the whole line of this ⊙ = 760.

A feather-edge scale is applied to this pencil or obscure line, the 0 division of it at the beginning, marking off every progressive number where any offsets have been made, as at 300, 400, and 760.

The scale is then turned across the line (by some cross division), and the offsets on each side of the station line are pricked off. At 0, or ⊙ 1, the field book shows that on the left hand, at 10 links, is the boundary line of that side, where there is likewise a small road branching off. The offset on the right hand is 30, which, with + 40, goes to the extent of a small corner, also 40 links in breadth. At 300 on the left there is an offset of 20, and on the right another of 25, where there is also a gate to be noticed. At 760 there is an offset on the left of 15; and on the right, one of 35, where a small roadway branches off. All these offsets are to be pricked off as the surveyor proceeds. The boundary lines are drawn through these offset points, and in this manner the first station is completed.

The parallel ruler is then laid from the centre to the angular point of ⊙ 2; the limb of it is moved till it touches the end of the last station line, from which another obscure line is drawn, from the north-easterly, as noted in the field book.

The edge of the scale is then applied as before, and the numbers 30, 200, and 265 are pricked off. There is a toll gate at 30 links, and a lane of 30 links broad, going off at an acute angle. At 265, the end of this station, the offsets are 30 and 10.

The line from ⊙ 3 is then laid off, as before directed, north-easterly, and the numbers 20 and 293 are pricked off. Opposite to 20 is a hedge branching off to the left, and at 293 the offsets are 35 and 5.

The line north easterly is laid off from ⊙ 4, and the numbers on that line are pricked off as they appear in the field book, and the offsets are made as follows. At 120, 15 and 20 are set off; at 410 are 30 and 15, where two hedges branch off nearly in the direction of the side sketches. At 480 the offsets are 25 and 5, where there is a cross hedge on the left. At 750 on the left, is 30 + 15 with a cross hedge, and on the right 10. At 1050 on the left, is 20 with a cross hedge, and 20 on the right. At 1150 on the right, is 20 + 20, where stands a house. At 1300 on the left, is 5 with a cross hedge; on the right is 30, with a road branching from it; 1350 completes this line.

At ⊙ 5 the work takes another direction, and goes backward towards the west. The ruler is laid from the centre to this station, and an obscure line drawn in the direction mentioned. The distances and offsets are pricked off as in the field book. Here are offsets on one side only, not being in a road way.

At ⊙ 6 set off the line south-westerly, pricking off the distances and offsets as in the field-book.

This specimen is sufficient to give a complete idea of the practice of plotting; and more would be only a tedious repetition. It must, however, be observed, that the accuracy and facility of the work greatly depend on the judgment and care exercised in keeping a correct and clear field-book.

Surveying

When a circuit is plotted off, the measurer must fill up the interior, by separately completing the measure of each field with the chain, so that they may be laid down on the plan in their proper situations and dimensions. The lines taken with the theodolite will here be of great service, as the base lines of a number of interior angles.

The surveyor having thus on paper, a representation of the estate, must draw such measuring lines on it, as will enable him to calculate the content of each field separately. Having made out a fair plot of his work, another line must be drawn for the true meridian, to the eastward of the former, according to the variation of the magnetic needle, where the estate lies. On this true meridian line may be placed any device whatever, as a north point. A title must also be given to the map, a scale drawn of the proportion used in the plotting, and a border to the whole *.

* See Crocker's Elements, p. 240.

Having thus explained the general practice of surveying according to the latest improvements, we shall shew how a surveyor is to proceed in measuring and planning counties and towns.

11 Method of surveying counties or districts.

To survey a County or large Tract of Land.—1. Chuse two, three, or four eminent places for stations, such as the tops of high hills or mountains, towers, or church steeples, which may be seen from one another, and from which most of the towns, and other places of note, may also be seen. And let them be as far distant from each other as possible. On these places raise beacons, or long poles, with flags of different colours flying at them, so as to be visible from all the other stations.

2. At all the places which are to be set down in the map, plant long poles with flags at them of several colours, to distinguish the places from each other, fixing them on the tops of church steeples, or the tops of houses, or in the centres of smaller towns.

It is not necessary to have these marks at many places at once, as suppose ten at a time. For when the angles have been taken at the two stations, to all these places, the marks may be removed to new ones, and so successively to all the places required. These marks being set up at a convenient number of places, and such as may be seen from both stations, go to one of these stations, and with an instrument for taking angles, standing at that station, take all the angles between the other station, and each of these marks, observing which is blue, which red, &c. and on which hand they lie; and set all down with their colours. Next go to the other station, and take all the angles between the first station, and each of the former marks, and set them down with the rest, each against those corresponding with the same colour. If practicable, the angles may also be taken at some third station, which may serve to prove the work, if the three lines intersect in that point where any mark stands. The marks must be allowed to remain till the observations are finished at both stations, and then they must be taken down, and set up at fresh places. The same operations must be performed at both stations, for these fresh places, and the like for others. The instrument for taking angles must be exceedingly accurate, made on purpose with telescopic sights,

Surveying. sights, and of three, four, or five feet radius. A circumferentor is reckoned a good instrument for this purpose.

3. Though it be not absolutely necessary to measure any distance; because a stationary line being laid down from any scale, all the other lines will be proportional to it; yet it is better to measure some of the lines, to ascertain the distances of places in miles: and to know how many geometrical miles there are in any length; and from thence to make a scale for measuring any distance in miles. In measuring any distance, it will not be exact enough to go along the high roads, on account of their turnings and windings, and scarcely ever lying in a right line between the stations, which would cause endless reductions, and create trouble to make it a right line, for which reason it can never be exact. But a better way is to measure in a right line with a chain, between station and station, over hills and dales, or level fields, and all obstacles. Only in cases of water, woods, towns, rocks, banks, &c. where one cannot pass, such parts of the line must be measured by the method of inaccessible distances; and besides, allowing for ascents and descents, when we meet with them. A good compass that shews the bearing of two stations, will always direct to go straight, when the two stations are not seen; but when a straight progress can be made, offsets may be taken to any remarkable places, likewise noting the intersection of the stationary line, with all roads, rivers, &c.

4. From all the stations, and in the whole progress, care must be taken to observe sea coasts, the mouths of rivers, towns, castles, houses, churches, windmills, watermills, trees, rocks, sands, roads, bridges, fords, ferries, woods, hills, mountains, rills, brooks, parks, beacons, sluices, floodgates, locks, &c. and in general every thing remarkable.

5. When the first and main station lines are done, which command the whole country, inner stations are then to be taken at some places already determined, which will divide the whole into several partitions, and from these stations may be determined the places of as many of the remaining towns as possible. If any remain in that part, more stations may be taken at some places already determined, from which the rest may be determined. Proceeding thus through all parts of the country, station may be taken after station, till all that are required be determined. In general, the station distances must always pass through such remarkable points as have been formerly determined by the preceding stations.

6. The position of the station line measured, or the point of the compass on which it lies, must be determined by astronomical observation. Hang up a thread and plummet in the sun over some part in the station line, observing when the shadow runs along that line, and at that moment take the sun's altitude; then having his declination, and the latitude, the azimuth will be found by spherical trigonometry. The azimuth is the angle which the station line makes with the meridian, and therefore a meridian may easily be drawn through the map; or a meridian may be drawn through it by hanging up two threads in a line with the pole star, when due north, which may be known from astronomical tables. Or thus: Observe the star Alioth, or that in the rump of the Great Bear, being that next the square; or else Cassiopeia's hip; observing by a line and plummet when either of these stars and the pole star comes into a perpendicular; and at that time they are due north. Therefore two perpendicular lines being fixed at that moment, towards these two stars, will give the position of the meridian.

13 Method of surveying towns.

A Town or City may be surveyed with any of the instruments for taking angles, but best of all with the plane table, where every minute part is drawn while in sight. It is also proper to have a chain of 50 feet long, divided into 50 links, and an offset-staff of 10 feet long.

Begin at the meeting of two or more of the principal streets through which the longest prospect may be had, to get the longest station lines. Having there fixed the instrument, draw lines of direction along those streets, using two men as marks, or poles set in wooden pedestals, or perhaps some remarkable places in the houses at the farther ends, as windows, doors, corners, &c. Measure these lines with the chain, taking offsets with the staff, at all corners of streets, bendings, or windings, and to all remarkable objects, as churches, markets, halls, colleges, eminent houses, &c. Then remove the instrument to another station along one of these lines, and there repeat the same process as before, and so on till the whole be completed.

Thus, in fig. 13. (part of the New Town of Edinburgh) fix the instrument at A, and draw lines in the direction of all the streets meeting in that place, and measure AB, noting the street on the left at *m*. At the second station B, draw the directions of the streets meeting there, and measure CD. Do the same at D, and measure DE, noting the place at the cross streets at *p*. In this manner go through all the principal streets. This being done, proceed to the smaller and intermediate streets; and lastly to the lanes, alleys, courts, yards, and every part which it may be deemed expedient to represent *.

* See *Hutton's Math. Dict.* art. *Surveying.*

14 Subterraneous surveying.

We shall conclude this article with a few practical remarks on *subterraneous surveying*, or the method of surveying mines, and other works below ground, taken chiefly from Mr Fenwick's work on *subterraneous surveying*, lately published.

The instruments employed in surveying under ground, are the circumferentor, the chain (in coal mines) containing 100 links, and an instrument for taking the angles of elevation or depression, to reduce the measurements to horizontal distances, where the lines are not level. In lead mines, they sometimes employ a cord, divided into 10 feet, instead of a chain.

In conducting a subterraneous survey, the instrument used is placed where the survey is intended to commence, and a person goes forward in the direction of the line to be surveyed, holding a lighted candle in his hand, to the remotest point at which his light can be seen through the sights of the instrument; its bearing is then taken by the circumferentor, and noted down in the survey book. The surveyor then proceeds to take the distance of the light, or object, from the instrument, which is afterwards removed, and a person stands on the spot where it stood, holding one end of the chain in his hand, while another, going towards the object, holds the other end, together with a lighted candle, in the same hand, and being directed by the former, till the hand holding the candle

To tang, $\angle d$ 15° 45′	9.4505117

From 90°—15° 45′=74° 15′, $\angle$ N *d* D.

And $\sqrt{\overline{6.45}^2+\overline{1.82}^2}=6.7$ *d*D, or 6 chains 70 links.

Ib. p. 155. Therefore, the amount of the error, or the bearing and distance of D from *d*, will be north, 74° 15′ east 6 chains 70 links with the true meridian.

SURVEYOR, a person who has the oversight and care of considerable works, lands, or the like.

Surveyor, likewise denotes a gauger; as also a person who surveys lands, and makes maps of them.

SURVIVOR, in *Law*, signifies the longest liver of joint tenants, or of any two persons jointly interested in a thing.

SURVIVORSHIP, is that branch of mathematics which treats of reversions payable provided one or more particular persons survive certain others. By reversions are meant payments not to take place till some future period. Survivorship forms one of the most difficult and complicated parts of the doctrine of reversions and life-annuities. It has been very fully treated of by Mr Thomas Simpson in his Select Exercises, and considerably improved by Dr Price and Mr Morgan, who have bestowed a great deal of attention on this subject; though some parts of their principles are erroneous.

The calculations are founded on the expectation of lives at different ages, deduced from tables formed from bills of mortality, of which see several examples under the article *Bills of Mortality*. By the expectation of life is meant the mean time that any single or joint lives at a given age is found to continue; that is, the number of years which, taking one with another, they actually enjoy, and may be considered as sure of enjoying; those who survive that period enjoying as much more time in proportion to their number as those who fall short of it enjoy less. Thus, supposing 46 persons alive all 40 years of age, and that one will die every year till they are all dead in 46 years, half 46 or 23 will be the *expectation* of each of them. If M. de Moivre's hypothesis were true, that men always decrease in an arithmetical progression, the expectation of a single life is always half its complement (A), and the expectation of two joint lives one-third of their common complement. Thus, supposing a man 40, his expectation would be 23, the half of 46, his complement; the expectation of two joint lives, each 40, would be 15 years 4 months, or the third part of 46.

The number expressing the expectation, multiplied by the number of single or joint lives (of which it is the expectation), added annually to a society, gives the whole number living together, to which such an annual addition would in time grow. Thus, since 19, or the third of 57, is the expectation of two joint lives, whose common age is 29, twenty marriages every year between persons of this age would in 57 years grow to 20 times 19,

(A) By the complement of a life is meant what it wants of 86, which M. de Moivre makes the boundary of human life. Thus if a man be 30, the complement of his life is 56.

Survivorship.

19, or 380 marriages, always existing together. And since the expectation of a single life is always half its complement, in 57 years 20 single persons added annually to a town will increase to 20 times 28.5, or 570; and when arrived at this number, the deaths every year will just equal the accessions, and no farther increase be possible. It appears from hence, that the particular proportion that becomes extinct every year, out of the whole number constantly existing together of single or joint lives, must, wherever this number undergoes no variation, be exactly the same with the expectation of those lives, at the time when their existence commenced. Thus, was it found that a 19th part of all the marriages among any bodies of men, whose numbers do not vary, are dissolved every year by the deaths of either the husband or wife, it would appear that 19 was, at the time they were contracted, the expectation of these marriages. In like manner, was it found in a society, limited to a fixed number of members, that a 28th part dies annually out of the whole number of members, it would appear that 28 was their common expectation of life at the time they entered. So likewise, were it found in any town or district, where the number of births and burials are equal, that a 20th or 30th part of the inhabitants die annually, it would appear that 20 or 30 was the expectation of a child just born in that town or district. These expectations, therefore, for all single lives, are easily found by a table of observations, showing the number that die annually at all ages out of a given number alive at those ages; and the general rule for this purpose is, to divide the sum of all the living in the table, at the age whose expectation is required, and at all greater ages, by the sum of all that die annually at that age and above it; or, which is the same, by the number (in the Table) of the living at that age; and half unity subtracted from the quotient will be the required expectation. Thus, in Dr Halley's table, given in the article ANNUITY, the sum of all the living at 20 and upwards is 20,724, which, divided by 598, the number living at the age of 20, and half unity subtracted from the quotient, gives 34.15 for the expectation of 20.

In calculating the value or expectation of joint lives, M. de Moivre had recourse to the hypothesis, that the probabilities of life decrease in a geometrical progression; believing that the values of joint lives, obtained by rules derived from it, would not deviate much from the truth. But in this he was greatly mistaken; they generally give results which are near a quarter of the true value too great in finding the present value of one life after it has survived another in a single payment, and about two-fifths too great when the value is sought in annual payments during the joint lives. They ought therefore to be calculated on the hypothesis (if they are calculated on hypothesis at all), that the probabilities of life decrease in arithmetical progression, which is not very far from the truth. Even this hypothesis never corresponds with the fact in the first and last periods of life, and in some situations not in any period of life. Dr Price and Mr Morgan therefore have given tables of the value of lives, not founded on any hypothesis, but deduced from bills of mortality themselves. Some of these we shall give at the end of this article. Mr Morgan has likewise given rules for calculating values of lives in this manner.

M. de Moivre has also fallen into mistakes in his rules for calculating the value of reversions depending on survivorship: these have been pointed out by Dr Price in the third essay in the first volume of his Treatise on Reversionary Payments; who has also given proper rules for calculating these values, the most important of which are comprehended in the following paragraphs.

1 Method of finding the number of annuitants that will come on a society.

Suppose a set of married men to enter into a society in order to provide annuities for their widows, and that it is limited to a certain number of members, and constantly kept up to that number by the admission of new members as the old ones are lost; it is of importance, in the first place, to know the number of annuitants that after some time will come upon the establishment. Now, since every marriage produces either a widow or widower; and since all marriages taken together would produce as many widows as widowers, were every man and his wife of the same age, and the chance equal which shall die first; it is evident, that the number of widows that have ever existed in the world, would in this case be equal to half the number of marriages. And what would take place in the world must also, on the same suppositions, take place in this society. In other words, every other person in such a society leaving a widow, there must arise from it a number of widows equal to half its own number. But this does not determine what number, all living at one and the same time, the society may expect will come to be constantly on it. It is, therefore, necessary to determine how long the duration of survivorship between persons of equal ages will be, compared with the duration of marriage. And the truth is, that, supposing the probabilities of life to decrease uniformly, the former is equal to the latter; and, consequently that the number of survivors, or (which is the same, supposing no second marriages) of widows and widowers alive together, which will arise from any given set of such marriages constantly kept up, will be equal to the whole number of marriages; or half of them (the number of widows in particular) equal to half the number of marriages. Now it appears that in most towns the decrease in the probabilities of life is in fact nearly uniform. According to the Breslaw Table of Observations (see ANNUITY), almost the same numbers die every year from 20 years of age to 77. After this, indeed, fewer die, and the rate of decrease in the probabilities of life is retarded. But this deviation from the hypothesis is inconsiderable; and its effect, in the present case, is to render the duration of survivorship longer than it would otherwise be. According to the London Table of Observations, the numbers dying every year begin to grow less at 50 years of age; and from hence to extreme old age there is a constant retardation in the decrease of the probabilities of life. Upon the whole, therefore, it appears that, according to the Breslaw Table, and supposing no widows to marry, the number inquired after is somewhat greater than half the number of the society: but, according to the London Table, a good deal greater. This, however, has been determined on the supposition that the husbands and wives are of equal ages, and that then there is an equal chance who shall die first. But in reality husbands are generally older than wives, and males have been found to die sooner than females, as appears incontestably from several of the tables in Dr Price's Treatise on Reversions. It is therefore more than an equal chance that the husband will die before his wife. This will increase considerably the duration of

Survivorship.

of survivorship on the part of the women, and consequently the number which we have been inquiring after. The marriage of widows will diminish this number, but not so much as the other causes will increase it.

2 When the number of annuitants arrives at its maximum.

If the society comprehends in it from the first all the married people of all ages in any town, or among any class of people where the numbers always continue the same, the whole collective body of members will be at their greatest age at the time of the establishment of the society; and the number of widows left every year will at a medium be always the same. The number of widows will increase continually on the society, till as many die every year as are added. This will not be till the whole collective body of widows are at their greatest age, or till there are among them the greatest possible number of the oldest widows; and therefore not till there has been time for an accession to the oldest widows from the youngest part.

Let us, for the sake of greater precision, divide the whole medium of widows that come on every year into different classes according to their different ages, and suppose some to be left at 56 years of age, some at 46, some at 36, and some at 26. The widows, constantly in life together, derived from the first class, will come to their greatest age, and to a *maximum*, in 30 years, supposing, with M. de Moivre, 86 to be the utmost extent of life. The same will happen to the second class in 40 years, and to the third in 50 years. But the whole body composed of these classes will not come to a *maximum* till the same happens to the fourth or youngest class; that is, not till the end of 60 years. After this the affairs of the society will become stationary, and the number of annuitants on it of all ages will keep always nearly the same.

If a society begins with its complete number of members, but at the same time admits none above a particular age: If, for instance, it begins with 200 members all under 50, and afterwards limits itself to this number, and keeps it up by admitting every year, at all ages between 26 and 50, new members as old ones drop off; in this case, the period necessary for bringing on the *maximum* of annuitants will be just doubled.

3 What a man ought to pay in a single payment to entitle his widow to a certain annuity.

To determine the sum that every individual ought to pay in a single present payment, in order to intitle his widow to a certain annuity for her life, let us suppose the annuity 3l. per annum, and the rate of interest four per cent. It is evident, that the value of such an expectation is different, according to the different ages of the purchasers, and the proportion of the age of the wife to that of the husband. Let us then suppose that every person in such a society is of the same age with his wife, and that one with another all the members when they enter may be reckoned 40 years of age, as many entering above this age as below it. It has been demonstrated by M. de Moivre and Mr Simpson, that the value of an annuity on the joint continuance of any two lives, subtracted from the value of an annuity on the life in expectation, gives the true present value of annuity on what may happen to remain of the latter of the two lives after the other.

In the present case, the value of an annuity to be enjoyed during the joint continuance of two lives, each 40, is, by Table II. 9.826, according to the probabilities of life in the Table of Observations formed by Dr Halley from the bills of mortality of Breslaw in Silesia.

The value of a single life 40 years of age, as given by M. de Moivre, agreeably to the same table, is 13.20; and the former subtracted from the latter, leaves 3.37, or the true number of years purchase, which ought to be paid for any given annuity, to be enjoyed by a person 40 years of age, provided he survives another person of the same age, interest being reckoned at four per cent. per annum. The annuity, therefore, being 30l. the present value of it is 30 multiplied by 3.37, or 101l. 2s.

4 What he ought to pay in annual payments.

If, instead of a single present payment, it is thought preferable to make annual payments during the marriage; what these annual payments ought to be is easily determined by finding what annual payments during two joint lives of given ages are equivalent to the value of the reversionary annuity in present money. Suppose, as before, that the joint lives are each 40, and the reversionary annuity 30l. per annum. An annual payment during the continuance of two such lives is worth (according to Table II.) 9.82 years purchase. The annual payment ought to be such as, being multiplied by 9.82, will produce 101.1l. the present value of the annuity in one payment. Divide then 101.1 by 9.82, and 10.3 the quotient will be the annual payment. This method of calculation supposes that the first annual payment is not to be made till the end of a year. If it is to be made immediately, the value of the joint lives will be increased one year's purchase; and therefore, in order to find the annual payments required, the value of a present single payment must be divided by the value of the joint lives increased by unity. If the society prefer paying part of the value in a present single payment on admission, and the rest in annual payments; and if they fix these annual payments at a particular sum, the present single payment paid on admission is found by subtracting the value of the annual payment during the joint lives from the whole present value of the annuity in one payment. Suppose, for instance, the annual payments to be fixed at five guineas, the annuity to be 30l. the rate of interest four per cent. and the joint lives each 40; the value of the annuity in one present single payment is 101.1l. The value of five guineas or 5.25 per annum, is (5.25 multiplied by 9.82 the value of the joint lives) 51.55; which, subtracted from 101.1l. gives 49.5l. the answer.

If a society takes in all the marriages among persons of a particular profession within a given district, and subjects them for perpetuity to a certain equal and common tax or annual payment, in order to provide life annuities for all the widows that shall result from these marriages; since, at the commencement of such an establishment, all the oldest, as well as the youngest, marriages are to be intitled equally to the proposed benefit, a much greater number of annuitants will come immediately on it than would come on any similar establishment which limited itself in the admission of members to persons not exceeding a given age. This will check that accumulation of money which should take place at first, in order to produce an income equal to the disbursements at the time when the number of annuitants comes to a *maximum*; and therefore will be a particular burden upon the establishment in its infancy. For this some compensation must be provided; and the equitable method of providing it is, by levying fines at the beginning of the establishment on every member exceeding

Survivorship.

ceeding a given age, proportioned to the number of years which he has lived beyond that age. But if such fines cannot be levied, and if every payment must be equal and common, whatever disparity there may be in the value of the expectations of different members, the fines must be reduced to one common one, answering as nearly as possible to the disadvantage, and payable by every member at the time when the establishment begins. After this, the establishment will be the same with one that takes upon it all at the time they marry; and the tax or annual payment of every member adequate to its support will be the annual payment during marriage due from persons who marry at the mean age at which, upon an average, all marriages may be considered as commencing. The fines to be paid at first are, for every particular member, the same with the difference between the value of the expectation to him at his present age, and what would have been its value to him had the scheme begun at the time he married. Or, they are, for the whole body of members, the difference between the value of the common expectation, to persons at the mean age of all married persons taken together as they exist in the world, and to persons at that age which is to be deemed their mean age when they marry.

5

Method of finding the present value of an annuity to be enjoyed by one life after the expiration of another.

Suppose we wish to know the present value of an annuity to be enjoyed by one life, for what may happen to remain of it beyond another life, after a given term; that is, provided both lives continue from the present time to the end of a given term of years; the method of calculating is this: Find the value of the annuity for two lives, greater by the given term of years than the given lives; discount this value for the given term; and then multiply by the probability, that the two given lives shall both continue the given term; and the product will be the answer. Thus, let the two lives be each 30, the term seven years, the annuity 10l. interest four per cent. The given lives, increased by seven years, become each 37. The value of two joint lives, each 37, is (by Table II.) 10.25. The value of a single life at 37 is (by the table under the article ANNUITY) 13.67. The former subtracted from the latter is 3.42, or the value of an annuity for the life of a person 37 years of age, after another of the same age, as has been shown above. 3.42 discounted for seven years (that is, multiplied by 0.76 the value of 1l. due at the end of seven years) is 2.6. The probability that a single life at 30 shall continue seven years is $\frac{49}{56}$ (B). The probability, therefore, that two such lives shall continue seven years, is $\frac{2401}{3136}$, or in decimals 0.765; and 2.6 multiplied by 0.765 is 1.989, the number of years purchase which ought to be given for an annuity to be enjoyed by a life now 30 years of age, after a life of the same age, provided both continue seven years. The annuity then being 10l. its present value is 19.89l.

6

Method of finding the value of an annuity for what may happen to remain of one life after another, provided the life in expectation continues a given time.

Suppose the value is required of an annuity to be enjoyed for what may happen to remain of one life after another, provided the life in expectation continues a given time. 1. Find the present value of the annuity for the remainder of the life in expectation after the given time, which is done in this manner: Multiply the present value of the life at the given time by the present value of 1l. to be received at that time, and multiply the product again by the probability that the life in expectation will continue so long. Let the given time which the life in expectation is to continue be 15 years, and let the person then be arrived at 50 years of age. A life at fifty, according to M. de Moivre's valuation of lives, and reckoning interest at four per cent. is worth 11.34 years purchase. The present value of 1l. to be received at the end of 15 years, is 0,5553, and the probability that a life at 35 will continue 15 years is $\frac{146}{490}$. These three values multiplied into one another give 4.44l. for the present value of the life in expectation. 2. Find the value of the reversion, provided both lives continue the given time, by the rule given in parag. 5th. 3. Add these values together, and the sum will be the answer in a single present payment. We shall now illustrate this rule by an example.

An annuity of 10l. for the life of a person now 30, is to commence at the end of 11 years, if another person now 40 should be then dead; or, if this should not happen at the end of any year beyond 11 years in which the former shall happen to survive the latter: What is the present value of such an annuity, reckoning interest at four per cent, and taking the probabilities of life as they are in Dr Halley's table, given in the article MORTALITY?

The value of 10l. per annum, for the remainder of the life of a person now 30, after 11 years is 69.43l. The probability that a person 40 years of age shall live 11 years, is, by Dr Halley's table $\frac{315}{445}$. The probability, therefore, that he will die in 11 years, is $\frac{315}{445}$ subtracted from unity (C), or $\frac{110}{445}$; which multiplied by 69.43l. gives 17.16l.—The value of the reversion, provided both live 11 years, is 17l. and this value added to the former, makes 34.16l. the value required in a single present payment; which payment divided by 11.43l. the value of two joint lives, aged 30 and 40, with unity added, gives 3l.; or the value required in annual payments during the joint lives, the first payment to be made immediately.

TABLE

(B) The probability that a given life shall continue any number of years, or reach a given age, is (as is well known) the fraction, whose numerator is the number of the living in any table of observations opposite to the given age, and denominator, the number opposite to the present age of the given life.

(C) For the difference between unity and the fraction expressing the probability that an event will happen, gives the probability that it will not happen.

Surviver-ship.

Table I. *Showing the Present Values of an Annuity of* 1l. *on a Single Life, according to M. de Moivre's Hypothesis.*

Survivorship.

The values of joint lives in these tables have been computed for only one rate of interest; and of single lives in Table III. for only two rates of interest. The following rules will show, that it would be a needless labour to compute these values (in strict conformity to the observations) for any other rates of interest.

Account of a method of deducing, from the correct values (according to any observations) of any single or joint Lives at one rate of Interest, the same values at other rates of Interest.

Preliminary Problems.

Prob. I. The expectation given of a single life by any table of observations, to find its value, supposing the decrements of life equal, at any given rate of interest.

Solution. Find the value of an annuity certain for a number of years equal to twice the expectation. Multiply this value by the perpetuity increased by unity, and divide the product by twice the expectation: The quotient subtracted from the perpetuity will be the value required.

Example. The expectation of a male life aged 10, by the Sweden observations, is 43.94. Twice this expectation is 87.88. The value of an annuity certain for 87.88 years is (reckoning interest at 4 per cent.) 24.200. The product of 24.200 into 26 (the perpetuity increased by unity) is 629.2, which, divided by 87.88, gives 7.159. And this quotient subtracted from 25 (the perpetuity) gives 17.84 years purchase, the value of a life aged ten, deduced from the expectation of life at that age, according to the Sweden observations. (See the Tables in Dr Price on Reversions, vol. ii.).

Prob. II. Having the expectations given of any two lives by any table of observations, to deduce from thence the value of the joint lives at any rate of interest, supposing an equal decrement of life.

Solution. Find the difference between twice the expectation of the youngest life and twice the expectation of the oldest life increased by unity and twice the perpetuity. Multiply this difference by the value of an annuity certain for a time equal to twice the expectation of the oldest life; and by twice the same expectation divide the product, reserving the quotient.

From twice the perpetuity subtract the reserved quotient, and multiply the remainder by the perpetuity increased by unity. This last product divided by twice the expectation of the youngest life, and then subtracted from the perpetuity, will be the required value.

When twice the expectation of the youngest life is greater than twice the expectation of the oldest life increased by unity and twice the perpetuity, the reserved quotient, instead of being subtracted from twice the perpetuity, must be added to it, and the sum, not the difference, multiplied by the perpetuity increased by unity.

Example. Let the joint lives proposed be a female life aged 10, and a male life aged 15; and let the table of observations be the Sweden table for lives in general, and the rate of interest 4 per cent. Twice the expectations of the two lives are 90.14 and 83.28.

Twice the expectation of the oldest life, increased by unity and twice the perpetuity, is 134.28, which lessened by 90.14 (twice the expectation of the youngest life), leaves 44.14 for the reserved remainder. This remainder multiplied by 24.045 (the value of an annuity certain for 83.28 years, and the product divided by 83.28 (twice the expectation of the oldest life), gives 12.744, the quotient to be reserved; which subtracted from double the perpetuity, and the remainder (or 37.255) multiplied by the perpetuity increased by unity (or by 26) gives 968.630, which divided by 90.14 (twice the expectation of the youngest life) and the quotient subtracted from the perpetuity, we have 14.254 for the required value.

The value of an annuity certain, when the number of years is a whole number with a fraction added (as will be commonly the case) may be best computed in the following manner. In this example the number of years is 83.28. The value of an annuity certain for 83 years is 24.035. The same value for 84 years is 24.072. The difference between these two values is 0.37; which difference multiplied by .28 (the fractional part of the number of years), and the product (.0103) added to the least of the two values, will give 24.045 the value for 83.28 years.

General Rule. Call the correct value (supposed to be computed for any rate of interest) the first value. Call the value deduced (by the preceding problems) from the expectations at the same rate of interest, the second value. Call the value deduced from the expectations for any other rate of interest the third value.

Then the difference between the first and second values added to or subtracted from the third value, just as the first is greater or less than the second, will be the value at the rate of interest for which the third value has been deduced from the expectations.

The following examples will make this perfectly plain.

Example I. In the two last tables the correct values are given of two joint lives among mankind at large, without distinguishing between males and females, according to the Sweden observations, reckoning interest at 4 per cent. Let it be required to find from these values the values at 3 per cent. and let the ages of the joint lives be supposed 10 and 10.

The correct value by Table IV. (reckoning interest at 4 per cent.) is 16.141. The expectation of a life aged 10 is 45.07. The value deduced from this expectation at 4 per cent. by Prob. II. is 14.539. The value deduced by the same problem from the same expectation at 3 per cent. is 16.808. The difference between the first and second values is 1.602, which, added to the third value (the first being greater than the second), makes 18.410, the value required.

Example II. Let the value be required of a single male life aged 10, at 3 per cent. interest, from the correct value at 4 per cent. according to the Sweden observations.

First, or correct value at 4 per cent. (by Table III.) is 18.674. The expectation of a male life aged 10 is 43.94.

The second value (or the value deduced from this expectation by Prob. I.) is 17.838.

The third value (or the value deduced from the same expectation at 3 per cent.) is 21.277.

The difference between the first and second is .836; which (since the first is greater than the second) must be added to the third; and the sum (that is, 22.113) will be the value required.

The

Survivorship, Surya.

The third value at 5 per cent. is 15.286; and the difference added to 15.286 makes 16.122 the value of a male life aged 10 at 5 per cent. according to the Sweden observations. The exact value at 5 per cent. is (by Table III.) 16.014.

Again: the difference between 16.014 (the correct value at 5 per cent.). and 15.286 (the value at the same interest deduced from the expectation), is .728; which, added (because the first value is greater than the second) to 13.335 (the value deduced at 6 per cent. from the expectation) gives 14.063, the value of the same life, reckoning interest at 6 per cent.

These deductions, in the case of single lives particularly, are so easy, and give the true values so nearly, that it will be scarcely ever necessary to calculate the exact values (according to any given observations) for more than one rate of interest.

If, for instance, the correct values are computed at 4 per cent. according to any observations, the values at 3, $3\frac{1}{2}$, $4\frac{1}{2}$, 5, 6, 7, or 8 per cent. may be deduced from them by the preceding rules as occasion may require, without much labour or any danger of considerable errors. The values thus deduced will seldom differ from the true values so much as a tenth of a year's purchase. They will not generally differ more than a 20th or 30th of a year's purchase. In joint lives they will differ less than in single lives, and they will come equally near to one another whatever the rates of interest are.

The preceding tables furnish the means of determining the exact differences between the values of annuities, as they are made to depend on the survivorship of any male or female lives; which hitherto has been a *desideratum* of considerable consequence in the doctrine of life annuities. What has made this of consequence is chiefly the multitude of societies lately established in this and foreign countries for providing annuities for widows. The general rule for calculating from these tables the value of such annuites is the following.

Rule. "Find in Table III. the value of a female life at the age of the wife. From this value substract the value in Table IV. of the joint continuance of two lives at the ages of the husband and wife. The remainder will be the value in a single present payment of an annuity for the life of the wife, should she be left a widow. And this last value divided by the value of the joint lives increased by unity, will be the value of the same annuity in annual payments during the joint lives, and to commence immediately."

Example. Let the age of the wife be 24, and of the husband 30. The value in Table III. (reckoning interest at 4 per cet.) of a female life aged 24, is 17.252. The value in Table IV. of two joint lives aged 24 and 30, is 13.455, which substracted from 17.252 leaves 3.797, the value in a single present payment of an annuity of 1l. for the life of the wife after the husband; that is, for the life of the widow. The annuity, therefore, being supposed 20l. its value in a single payment is 20 multiplied by 3.797, that is, 75.94l. And this last value divided by 14.455 (that is, by the value of the joint lives increased by unity), gives 5.25, the value in annual payments beginning immediately, and to be continued during the joint lives of an annuity of 20l. to a wife aged 24 for her life, after her husband aged 30.

Surya ‖ Sussex.

SURYA, the orb of the sun personified and adored by a sect of Hindoos as a god. He seems to be the same divinity with the Phœbus of Greece and Rome; and the sect who pay him particular adoration are called *Sauras*. Their poets and painters describe his car as drawn by seven green horses, preceded by Arun, or the *Dawn*, who acts as his charioteer, and followed by thousands of genii worshipping him and modulating his praises. He has a multitude of names, and among them twelve epithets which denote his distinct powers in each of the twelve months; and he is believed to have descended frequently from his car in a human shape, and to have left a race on earth, who are equally renowned in the Indian stories with the Heliadai of Greece: it is singular, that his two sons called *Aswinau* or *Aswinicumarau*, in the dual, should be considered as twin-brothers, and painted like Castor and Pollux.

Asiatic Researches, vol. i. p. 262. and 263.

SUS, the Hog, a genus of quadrupeds. See Mammalia *Index*.

SUSA, the ancient royal residence of the kings of Persia, built by Darius Hystaspis, according to Pliny; though he probably only restored it, being a very ancient city, founded by Tithonus father of Memnon. Its compass was said by ancient authors to be 120 stadia; but the ruins give us the idea of a still greater extent. They are situated on the east side of the river Kerah, in the latitude of 32°, stretching not less than twelve miles from one extremity to the other. These ruins consist of hillocks of earth and rubbish, covered with broken pieces of brick and coloured tile. One of these hillocks is a mile in circumference, and 100 feet high. Another, though not quite so high, has double the circuit. Large blocks of marble covered with hieroglyphics are frequently discovered by the Arabs. There is a building, apparently modern, called the tomb of Daniel. The whole place is now a gloomy wilderness, inhabited by beasts of prey. See Kinneir's *Geographical Memoir of Persia*.

SUSPENSION, in *Scots Law*. See Law, N° clxxxv. 5, 6, and 7.

SUSSEX, a county of England, deriving its name from its situation in respect of the other Saxons, and called *Sussex*, i. e. the country of the South Saxons, has Hampshire on the west, the British channel on the south, Surrey on the north, and Kent on the east. Its length is 65 miles, its breadth 30, and its circumference 170. It is divided into 6 rapes, and these into 65 hundreds, in which are 342 parishes, of which 123 are vicarages, one city, 16 market towns, 1,140,000 acres, and in 1811 it contained 190,083 inhabitants. It has few good ports, though it lies along the channel for 65 miles, the coast being encumbered in many places with rocks; and where it is more open, such quantities of sand are thrown upon it by the south-west winds, and the harbours so choked up, that they will not admit vessels of any great draught or burden. The county is well watered by the rivers Arun, Adar, Ouse, Rother, Lavant, Cuckmeer, Ashburn, and Aften, by which it is well supplied with fish, as well as from the sea. Hence different places of the county are famed for different sorts of fish, as the Arun for mullets, which enter it from the sea in summer in shoals, and by feeding upon a particular kind of herb become extremely delicious: Chichester for lobsters, Selsey for cockles, Amberly for trout, Pulborough for eels, Rye for herrings, and

Gough's edition of Camden's Britannia, vol. i. p. 192.

Sussex, Sutherland.

and the county in general for carp. It is remarkable, that all the rivers above mentioned rise and fall into the sea, within the county.

The air, as well as the soil, is various in different parts of the county. Upon the coast the air is aguish, upon the hills and downs pleasant and wholesome; but somewhat moist and foggy in the valleys, the soil being deep and rich, and the vegetation in summer very vigorous. The downs in some places are very fertile in corn and grass; in others they feed great flocks of sheep, whose flesh and wool are very fine; but of the latter no inconsiderable quantity is clandestinely exported to France. In the Weald and the valleys the roads are very deep, especially in winter. In the north quarter are many woods, and some forests in other places; whence the king's yards are supplied with the largest and best timber in England, beside what is made into charcoal and consumed in the iron-works; for on the east side is plenty of iron ore, with furnaces, forges, and mills for manufacturing it. Those delicious birds called *wheat-ears* are bred in this shire; they are not bigger than a lark, but very fat. That part now called the *Wild* or *Weald* of Sussex, was anciently a mere desert for hogs and deer, of great extent, taking in a part of Kent and Surry; and was called *Andcrida Silva*, *Coid Andred*, and *Andradswald*, from Anderida an adjoining city. This county is in the home circuit and diocese of Chichester, giving the title of earl to the family of Yelverton, and sends 28 members to parliament, viz. two for the county, two for the city of Chichester, and two for each of the following towns, Horsham, Lewes, Bramber, East-Grinstead, Midhurst, Shoreham, Staining, Arundel, Hastings, Rye, Winchelsea, and Seaford; of which the four last are cinque ports. See SUSSEX, SUPPLEMENT.

SUTHERLAND, one of the most northerly counties of Scotland, bordering on Caithness to the east, and bounded by the ocean on the north, the country of Assynt on the west, Ross-shire on the south, and by the German sea on the south-east. It stretches about 70 miles in length, and 40 in breadth; it is generally hilly, though in many parts arable; well watered with small rivers and streams replete with fish, and containing about 60 lakes, the habitation of various fish, swans, ducks, geese, &c. One of the largest of these is Lochshin, extending 18 miles in length. Some of them are interspersed with small verdant islands, which in summer yield a very agreeable prospect. On the coast are many commodious harbours, and all the bays swarm with fish. Sutherland affords iron stone, freestone, limestone, marble and slate, in abundance. Turf and peat are the common fuel. Lead ore, and some copper ore, have been met with in some parts of the county.

The air is so temperate, and the soil so good, that saffron has here been brought to perfection. Many parts of the country are remarkably fruitful in corn, and the pasturage is everywhere excellent. Deer and some other game are abundant in Sutherland. On the hills are fed numerous flocks of sheep and black cattle. The northern part, called *Strathnaver*, and separated from the rest by a ridge of mountains, is bounded on the north by the Deucaledonian sea, on the west by the channel called the *Minch*, on the east by Caithness, and on the south by Assynt. The length from east to west, is 34 miles; but the breadth from north to south does not exceed 12 in some places. It is very hilly; and the mountains are so high, that the snow remains on the tops of them till midsummer. It is watered by the Naver, from whence it derives its name: this district gives a title to the eldest son of the earl of Sutherland. Strathnaver has many fresh-water lakes or lochs; the chief of which are Loch Naver and Loch Lyel: there are several islands on the northern coast. In various parts of the country there are monuments of victories obtained over the Danes or other foreign invaders. The inhabitants are hardy, bold, and enterprising; courteous to strangers; cheerful, open, frugal, and industrious. The salmon-fishery in this county is considerable, as well as the trade in black cattle, sheep, and horses, at the neighbouring fairs; corn, barley, salmon, butter, cheese, wool, hides, and tallow, are exported. Dornoch is the capital of the county. The population of Sutherland in 1811 amounted to 23,629. The following table shews the population at two different periods *.

Sutherland | Sutton.

* Statist. Hist. vol. xx.

	Parishes.	Population in 1755.	Population in 1790—798.

See SUTHERLAND, SUPPLEMENT.

SUTLER, in *War*, one who follows the army, and furnishes the troops with provision. Sutlers pitch their tents, or build their huts, in the rear of each regiment, and about head-quarters.

SUTRIUM, in *Ancient Geography*, a famous city, and an ancient colony of the Romans, the key of Etruria; founded about seven years after the taking of Rome by the Gauls (Velleius). Now *Sutri* in St Peter's patrimony, on the river Pozzolo; surrounded on every side with rocks, 24 miles to the north-west of Rome.

SUTTON, SAMUEL, was born at Alfreton in Derbyshire, and going into the army served under the duke of Marlborough in Queen Anne's wars with great credit. He afterwards came to London, commenced brewer, and kept a coffee-house in Aldersgate street, which was well frequented by the learned men of that time, by whom Mr Sutton was much respected, as a man of strong natural parts and uncultivated genius. About the year 1740 he schemed a very simple and natural method for extracting the foul air from the wells of ships, by pipes communicating with the fire-places of the coppers; which operated as long as any fire was kept burning for the ship's use. He took out a patent in 1744, to secure the profits of his invention; and died about the year 1752.

SWABIA. See SUABIA.

SWALLOW, a genus of birds. See HIRUNDO, ORNITHOLOGY *Index*. See also MIGRATION.

Swallow-Wort. See ASCLEPIAS, BOTANY *Index*.

SWAMMERDAM, JOHN, a celebrated and learned natural philosopher, was the son of John James Swammerdam, an apothecary and famous naturalist of Amsterdam, and was born in 1637. His father intended him for the church, and with this view had him instructed in Latin and Greek; but he, thinking himself unequal to so important a task, prevailed with his father to consent to his applying himself to physic. As he was kept at home till he should be properly qualified to engage in that study, he was frequently employed in cleaning his father's curiosities, and putting every thing in its proper place. This inspired our author with an early taste for natural history; so that, not content with the survey of the curiosities which his father had purchased, he soon began to make a collection of his own, which he compared with the accounts given of them by the best writers. When grown up, he seriously attended to his anatomical and medical studies; yet spent part of the day and the night in discovering, catching, and examining the flying insects proper to those times, not only in the province of Holland, but in those of Guelderland and Utrecht. Thus initiated in natural history, he went to the university of Leyden in 1651; and in 1653 was admitted a candidate of physic in that university. His attention being now engaged by anatomy, he began to consider how the parts of the body, prepared by dissection, could be preserved, and kept in constant order for anatomical demonstration; and herein he succeeded, as he had done before in his nice contrivances for dissecting and managing the minutest insects. Our author afterwards made a journey into France, where he spent some time at Saumur, and where he became acquainted with several learned men. In 1667 he returned to Leyden, and took his degree of Doctor of Physic. The next year the grand duke of Tuscany being in Holland in order to see the curiosities of the country, came to view those of our author and his father; and on this occasion Swammerdam made some anatomical dissections of insects in the presence of that prince, who was struck with admiration at our author's great skill in managing them, especially at his proving that the future butterfly lay with all its parts neatly folded up in a caterpillar, by actually removing the integuments that covered the former, and extricating and exhibiting all its parts, however minute, with incredible ingenuity, by means of instruments of inconceivable fineness. On this occasion the duke offered our author 12,000 florins for his share of the collection, on condition of his removing them himself into Tuscany, and coming to live at the court of Florence; but Swammerdam, who hated a court life, declined his highness's proposal. In 1663, he published a General History of Insects. About this time, his father began to take offence at his inconsiderately neglecting the practice of physic, which might have supported him in affluence; and would neither supply him with money nor clothes. This reduced him to some difficulties. In 1675 he published his History of the Ephemeras; and his father dying the same year, left him a fortune sufficient for his support; but he did not long survive him, for he died in 1682. Gaubius gave a translation of all his works from the original Dutch into Latin, from which they were translated into English, in folio, in 1758. The celebrated Boerhaave wrote his life.

SWEATING SICKNESS, a disorder which appeared in England about the year 1481, and was by foreigners called the *English sweat*. See MEDICINE, N° 51.

SWEDEN,

1 Situation and extent.

ONE of the northern states of Europe, now occupies the whole of the north-western corner of that portion of the globe, lying between the gulf of Bothnia and the Atlantic. Before the treaty concluded in 1809, between Sweden and Russia, the Swedish territory extended over a considerable tract of country on the east of the gulf of Bothnia; but by that treaty the whole of these provinces were ceded to Russia. But on the other hand, Sweden, by a treaty signed at Kiel in January 1814, compelled Denmark to cede Norway to her; in return for which Denmark received Pomerania. Thus enlarged, Sweden possesses nearly the whole Scandinavian peninsula. Her territories are bounded on all sides by the sea, except the north-east, where they are bounded by the rivers Tornea and Tana. They extend from 55° 20′ to 71° of North latitude, and from 5° to 31° of East longitude. Their greatest length is 1180 English miles, their greatest breadth 500, and they embrace an area of 340,000 square miles, which is about one-tenth of the surface of Europe. She has now also the greatest extent of sea coast of any European power. But Sweden proper, apart from Norway, includes only an area of 195,000 square miles; and as the latter country is described in a separate article, our observations here shall be confined to the former. The following shows the present divisions of Sweden.

Stockholm,

2 Division.

	Extent in German sq. miles.	Arable Land in Tunnas.	Population in 1805.

	8,963	1,445,395	2,424,874
Lakes,	180		
	(A) 9,143 equal to 195,000 square English miles.		

Population in 1818	2,615,400
Population of Norway (in 1803)	910,000
	3,525,400

The only colonial territory belonging to Sweden is the island of St Bartholomew, in the West Indies.

3 Face of the country. Sweden is diversified in a most picturesque manner, with extensive lakes, large rivers, winding streams, cataracts, gloomy forests, fertile vales, and stupendous rocks. But the most striking feature in the appearance of the country is the vast forests that cover its surface. "If the reader, says Dr Clarke *, cast his eyes upon the map of Sweden, and imagine the gulf of Bothnia to be surrounded by one unbroken forest, as ancient as the world, consisting principally of pine trees, with a few mingling birch and juniper trees, he will have a general and tolerably correct idea of the real appearance of the country. The population is yet small, because the whole country is covered with wood. The only region with which Sweden can properly be compared is North America; a land of wood and iron, with very few inhabitants."

* *Travels in Scandinavia, published in* 1815.

4 Soil. Sweden is by no means remarkable for the fertility of its soil, as appears from the above table. The land capable of tillage, it will be seen, amounts only to about 1,800,000 acres, or one acre in sixty of the whole surface of the country. But a great extent of land besides this ministers to the support of man, by affording pasturage for cattle and sheep; and probably much of what is now covered with wood is capable of cultivation if cleared.

The principal mountains belonging to Sweden are those of the elevated chain which divides it from Norway, and which branch off in a south-easterly direction. One of the highest of these Swucku. 5 Mountains.

The chief rivers are the Gotha connecting Lake Wener with the Categat; the Motala, forming the outlet of Lake Weter; the Dahl rising in the Norwegian mountains, and flowing through Dalecarlia into the gulf of Bothnia, and the Tornea forming the north-eastern boundary, and empting itself into the gulf of Bothnia at the town of the same name. 6 Rivers.

There are a vast number of lakes in all the provinces of Sweden. The most remarkable are Wener, Weter, and Maela, on the banks of which last stands the city of Stockholm. 7 Lakes.

The climate and seasons of Sweden nearly resemble those of the same latitudes in Russia. The winters are in most places extremely severe, and the summers short and sudden. The gulf of Bothnia is generally frozen over during winter, so as to admit of travellers passing over into Finland, and East Bothnia. The summer, though 8 Climate and seasons.

(A) The map of Sweden is united with that of Denmark and Norway, in Plate CLXX. The square German mile used in this table is equal to $21\frac{4}{10}$ square English miles. The tunna of land is equal $1\frac{1}{4}$ English acres nearly. The table is taken from Crome's View of the Powers of Europe, published in German at Leipzig, in 1818.

Sweden. though short, is generally hot, and seldom cloudy or inconstant. In the higher latitudes the sun of course is seen in the middle of summer for several days together, and the nights of winter are proportionably long. See LAPLAND.

9 Natural History. Much of the natural history of Sweden has been already given under the article LAPLAND. In the more southern provinces there are found in the forests the bear, lynx, wolf, beaver, otter, glutton, and flying squirrel. The Swedish horses are commonly small, but spirited, and are considered as superior to those of Germany for cavalry. The cattle and sheep are also small; goats are scarce, but swine are very numerous. Seals are found in the gulf of Bothnia; and the lakes and rivers of Sweden produce pike that are remarkably large, and which are salted and pickled for exportation. The forests produce a great variety of game, especially the large black cock, called in Scotland the cock of the forest. Among the reptiles the *rana bombina*, and the *coluber chersea*, are considered as almost peculiar to Sweden.

The chief vegetable productions of Sweden are its immense forests of pine and fir trees, though the country is not destitute of a great variety of shrubs and plants common to it with Denmark and Russia.

The principal riches of the natural history of Sweden are to be found in the mineral kingdom. It produces crystals, amethysts, topazes, porphyry, lapis lazuli, agate, cornelian, marble, and other fossils. The wealth of the country, however, arises chiefly from her mines of silver, copper, lead, and iron. According to Dr Thomson, who travelled in 1812, there were in Sweden 176 iron mines, which yielded annually about 1,200,000 hundred weights of metal. The annual produce of copper is about 1000 tons. The mines employ about 50,000 persons, exclusive of the artists who afterwards work up the metal into various manufactured articles.

There are likewise in Sweden some silver mines, of which that of Sahlberg is the richest, as well as the most ancient. It existed so early as 1188, and during the whole of the 14th century, it yielded 24,000 marks of silver per annum. In the 15th century the quantity was diminished to 20,000. In the reign of Charles X. it gave only 2000; and it furnishes at present still less, the ore yielding only one ounce of pure metal per quintal. The chief gallery, where the purest silver was obtained, having fallen in, is not yet cleared, notwithstanding their incessant labour. They are also digging pits in a perpendicular direction, in order to arrive at the principal vein, which extends itself from the north to the south-east. Formerly lead employed in separating the metal was imported from England; but the mine furnishes at present a sufficient quantity for the purpose. The most remarkable mineral waters in Sweden are those of Medewi in East Gothland.

10 Early history uncertain. The early history of Sweden is not less involved in fable than that of most other nations. Some historians have pretended to give regular catalogues of the princes who reigned in Sweden in very early times; but they differ so much that no credit can be given to them. All indeed agree that ancient Scandinavia was first governed by judges elected for a certain time by the voice of the people. Among these temporary princes the country was divided, until, in the year of the world 2054, according to some, or 1951, according to others, Eric, or, if we believe Puffendorf, Sueno, was raised to the supreme power, with the prerogatives of all the temporary magistrates united in his person for life, or until his conduct should merit deposition. Sweden.

From this very early period till the year 1366 of the Christian era, the histories of Sweden present us with nothing but what is common to all nations in their early periods, viz. the endless combats of barbarians, tending to no other purpose than the effusion of blood. At the time just mentioned, however, Albert of Mecklenburg, having concluded a peace between Sweden and Denmark, which had been at violent war for some time before, was proclaimed king of Sweden. The peace was of short duration, being broken in 1368; on which Albert entered into an offensive and defensive league with the earl of Holstein, the Jutland nobility, the dukes of Sleswick, Mecklenburg, and the Hanse-towns, against the kings of Denmark and Norway. Albert proved very successful against Waldemar king of Denmark at that time, driving him entirely out of his dominions; but he himself was defeated by the king of Norway, who laid siege to his capital. Soon after this, a new treaty was concluded, by which Albert was allowed to enjoy the crown of Sweden in peace. Having formed a design however of rendering himself absolute, he so displeased his subjects that Margaret of Norway was proclaimed queen of Sweden by the malecontents. A war immediately ensued, in which Albert was defeated and taken prisoner; but as the princes of Mecklenburg, the earls of Holstein, and the Hanse-towns, entered into a league in his favour, the war raged with more fury than ever. An. 1366. 11 Albert of Mecklenburg declared king. 12 War with Denmark and Norway. 13 Is defeated and taken prisoner by Margaret of Norway.

At length, in 1394, the contending parties were reconciled. Albert was set at liberty, on condition that he should in three years give up to Margaret all pretensions to the city of Stockholm; and the Hanse-towns engaged to pay the sum of 60,000 marks of silver if Albert should break that treaty. Not long after this, Eric the son of Albert died; and he, having no other child, did not think it worth his while to contend for the kingdom of Sweden: he therefore acquiesced in the pretensions of Margaret, and passed the remainder of his days at Mecklenburg. 14 Set at liberty. An. 1394.

Margaret died in 1415, and was succeeded by Eric of Pomerania. This prince's reign was cruel and oppressive. The consequence of this was a revolt; and Charles Canutson, grand mareschal of Sweden and governor of Finland, having joined the malecontents, was declared commander in chief of their army. Eric was now formally deposed: Canutson was chosen regent; but beginning to oppress the people, and aspiring openly to the crown, the Swedes and Danes revolted; in consequence of which a revolution took place, and Christopher duke of Bavaria, nephew to Eric, was chosen king of Denmark, Sweden, and Norway, in 1442. 15 Margaret is succeeded by Eric, a cruel tyrant. An. 1415.

On the accession of the new prince, complaints against Canutson were brought from all quarters; but through the interest of his friends, he escaped punishment; and in 1448, Christopher having died after a tyrannical reign of about five years, he was raised to the throne to which he had so long aspired. The kingdoms of Denmark and Norway however refused allegiance to him; on which a war immediately commenced. In 1454 peace was concluded, and Denmark for the present freed from the Swedish yoke. Nor did Canutson long enjoy even the crown of Sweden. Having quarrelled with the magistrates 16 Charles Canutson. An. 1448.

Sweden.

magistrates and the archbishop of Upsal, the latter formed such a strong party that the king could not resist him. Canutson died in 1470 after a long and turbulent reign.

An. 1520.

The Swedish affairs continued to be involved in dreadful confusion till the year 1520, when a great revolution was effected by Gustavus Ericson, a nobleman of the first rank, who restored the kingdom to its liberty, and laid the foundation of its future grandeur. The occasion of this great revolution was as follows: In 1518, Christiern king of Denmark invaded Sweden, with a design to subdue the whole country; but being defeated with great loss by young Steen Sture, at that time regent, he set sail for Denmark. But meeting with contrary winds, he made several descents on the Swedish coast, which he ravaged with all the fury of an incensed barbarian. The inhabitants, however, bravely defended themselves, and Christiern was reduced to the utmost distress; one half of his forces having perished with hunger, and the rest being in the most imminent danger by the approach of a rigorous winter. He then thought of a stratagem, which had almost proved fatal to the regent; for having invited him to a conference, at which he designed either to assassinate or take him prisoner, Sture was about to comply, had not the senate, who suspected the plot, interposed and prevented him. Christiern then offered to go in person to Stockholm in order to confer with Sture, on condition that six hostages should be sent in his room. This was accordingly done; but the wind happening then to prove favourable, he set sail for Denmark with the hostages, of whom Gustavus Ericson was one. Next year he returned; and having drawn Sture into an ambush, the regent received a wound of which he died some time after. The kingdom being thus left without a head, matters soon came to the most desperate crisis. The army disbanded itself; and the senate, instead of taking proper measures to oppose the enemy, spent their time in idle debates. Christiern in the mean time advanced into the heart of the kingdom, destroying every thing with fire and sword; but on his arrival at Stragnez, he granted a suspension of arms, on condition that they would elect him king. This they accordingly did; and Christiern proved one of the most bloody tyrants that ever sat on the throne of any kingdom. Immediately after his coronation, he gave grand entertainments for three days; during which time he projected the diabolical design of extirpating at once all the Swedish nobility, and thus for ever preventing the people from revolting, by depriving them of their proper leaders. As the tyrant had signed articles, by which he promised indemnity to all who had borne arms against him, it became necessary to invent some cause of offence against those whom he intended to destroy. To accomplish his purpose, Gustavus Trolle, formerly archbishop of Upsal, but who had been degraded from that dignity, in an oration before his majesty, lamented the demolition of Stecka, his place of residence, and the losses sustained by the see of Upsal, amounting to near a million of money. He then proceeded in a bitter accusation against the widow and the son-in-law of Sture the late regent, comprehending in the same accusation about 15 of the principal nobility, the whole senate, and the burghers of Stockholm. In consequence of this, about 60 of the principal nobility and people of first rank in Sweden were hanged as traitors. Innumerable other cruelties were committed; part of which are owned by the Danish historians, and minutely related by those of Sweden. At last he departed for Denmark, ordering gibbets to be erected, and causing the peasants to be hanged on them for the slightest offences.

17 Christiern king of Denmark invades Sweden, but is defeated and driven out.

18 He treacherously carries off six hostages, of whom Gustavus Ericson is one.

An. 1519.

19 Is chosen king, and proves a most bloody tyrant.

20 Massacres the nobility, and causes gibbets to be erected as he passes along.

This monstrous cruelty, instead of securing him on the throne, exasperated the whole nation against him. It has already been mentioned, that Gustavus Ericson, or, as he is commonly called, *Gustavus Vasa*, was among the number of the hostages whom Christiern had perfidiously carried to Denmark in 1519. Large promises had been made in order to reconcile him to Christiern, and all means had been employed, but in vain. Secret orders were given to strangle him in prison; but the officer to whom the assassination was committed remonstrated to the king about the consequences of it, and prevailed on him to change the sentence of death into close confinement in the castle of Copenhagen. Some of the hostages perished in consequence of the rigorous treatment they met with; but Gustavus withstood all hardships. At last one Banner, a Danish nobleman, prevailed on the king to put him into his hands, in order to try whether or not he could prevail on him to change his sentiments. The king, however, told Banner, that he must pay 6000 crowns if the prisoner should make his escape. Banner generously consented; and having brought the noble prisoner to his fortress of Calo in Jutland, soon allowed him all the liberty he could desire, and otherwise heaped favours on him. All this, however, could not extinguish his remembrance of the cruelties of Christiern, and the desire he had of being serviceable to his country. He therefore determined to make his escape; and the liberty he enjoyed soon put him in a capacity of effecting it. Having one day mounted his horse, under pretence of hunting as usual in the forest, when he got at a proper distance, he changed his dress to the habit of a peasant: and quitting his horse, travelled for two days on foot through by-paths, and over mountains almost impassable, arriving on the third at Flensburgh. Here no one was admitted without a passport: and Gustavus dreaded presenting himself to the governor or the officer on guard, for fear of being discovered. Gustavus hired himself to a cattle merchant; and in this disguise escaped out of the Danish territories, and arrived at Lubec.

21 Adventures of Gustavus Vasa or Ericson.

22 He escapes from Denmark.

23 Arrives at Lubec.

Banner was no sooner acquainted with his escape, than he set out after him with the utmost diligence, found him at Lubec, and reproached him with great warmth as ungrateful and treacherous; but he was soon appeased by the arguments urged by Gustavus, and especially by a promise of indemnifying him in the loss of his ransom. On this Banner returned, giving out that he could not find his prisoner. Christiern was enraged at his escape, apprehending that he might reverse all his designs in Sweden; and gave orders to Otho his general to make the strictest search, and leave no means untried to arrest him. Gustavus applied to the regency for a ship to convey him to Sweden, where he hoped he should be able to form a party against the Danes. He likewise endeavoured to draw the regency of Lubec into his measures; and reasoned with so much zeal and ability, that Nicholas Gemins, first consul, was entirely gained; but the regency could never be prevailed on to declare for a party without friends, arms, money, or credit. Before his departure, however, the consul gave him

24 Attempts in vain to draw the regency of Lubec over to his side.

Sweden. him assurances, that if he could raise a force sufficient to make head against the enemy in the field, he might depend on the services of the republic, and that the regency would immediately declare for him. Gustavus desired to be landed at Stockholm; but the captain of the ship, either having secret orders to the contrary, or business elsewhere, steered a different course, and put him on shore near Calmar; a city then garrisoned by the troops of Christiana widow of the regent. In fact, the governor held this place for his own purposes, and only waited to make the best terms he could with the Danes. When Gustavus arrived, he made himself known to him and the principal officers of the garrison, who were mostly Germans, and his fellow-soldiers in the late administrator's army; but the mercenary band, seeing him without troops and without attendants, regarded him as a desperate person devoted to destruction, refused to embrace his proposals, and even threatened to kill or betray him, if he did not instantly quit the city.

25 He arrives at Calmar, but meets with an unfavourable reception.

Disappointed in his expectations, Gustavus departed; and his arrival being now publicly known, he was again forced to have recourse to his peasant's disguise to conceal him from the Danish emissaries dispersed over the country to search for him. In a waggon loaded with hay he passed through the Danish army, and at last repaired to an old family castle in Sudermania. Hence he wrote to his friends, intimating his return to Sweden, and beseeching them to assemble all their forces in order to break through the enemy's army into Stockholm, at that time besieged; but they refused to embark in so hazardous and desperate an attempt.

26 His friends refuse to assist him.

Gustavus next applied himself to the peasants; but they answered, that they enjoyed salt and herrings under the government of the king of Denmark; and that any attempts to bring about a revolution would be attended with certain ruin, without the prospect of bettering their condition; for peasants they were, and peasants they should remain, whoever was king. At length, after several attempts to throw himself into Stockholm, after that city was surrendered to the king, after the horrid massacre of the senate, and after running a thousand dangers, and undergoing hardships and fatigues scarcely to be supported by human nature, he formed the resolution of trying the courage and affection of the Dalecarlians. While he was in the deepest obscurity, and plunged in almost insurmountable adversity, he never relinquished his designs nor his hopes. The news of the massacre had, however, nearly sunk him into despondency, as by it he lost all his friends, relations, and connections, and indeed almost every prospect of safety to himself or deliverance to his country. This suggested the thought of going to Dalecarlia, where he might live with more security in the high mountains and thick woods of that country, if he should fail in the attempt of exciting the inhabitants to revolt.

27 Applies in vain to the peasants.

Attended by a peasant, to whom he was known, he travelled in disguise through Sudermania, Nericia, and Westermania, and, after a laborious and painful journey, arrived in the mountains of Dalecarlia. Scarcely had he finished his journey, when he found himself deserted by his companion and guide, who carried off with him all the money which he had provided for his subsistence. Thus forlorn and destitute, he entered among the miners, without relinquishing his hopes of one day ascending the throne of Sweden. His whole object for the present was to live concealed, and gain a maintenance, till fortune should effect something in his favour: nor was it long before this happened. A woman in the mines perceived, under the habit of a peasant, that the collar of his shirt was embroidered. This circumstance excited curiosity; and the graces of his person and conversation, which had something in them to attract the notice of the meanest of the vulgar, afforded room for suspicion that he was some person of quality in disguise, forced by the tyranny of the government to seek shelter in these remote parts. The story came to the ears of a neighbouring gentleman, who immediately went to the mines to offer his protection to the unfortunate stranger; and was astonished on recognizing the features of Gustavus, to whom he had been known at the university of Upsal. Touched with compassion at the deplorable situation of so distinguished a nobleman, he could scarcely refrain from tears. At night he sent for Gustavus, made him an offer of his house, and gave him the strongest assurances of his friendship and protection. He told him, he would there meet with better accommodations, and as much security as in the mines; and that, should he chance to be discovered, he would, with all his friends and vassals, take arms in his defence.

28 Arrives in Dalecarlia, is robbed by his guide, and obliged to work in the mines.

Sweden.

29 Is discovered and relieved.

This offer was embraced by Gustavus with joy, and he remained for some time at his friend's house; but finding it impossible to induce him to take part in his designs, he quitted him, and fled to one Peterson, a gentleman whom he had formerly known in the service. This man received Gustavus with all the appearance of kindness; and on the very first proposal, offered to raise his vassals. He even named the lords and peasants whom he pretended to have engaged in his service; but in a few days, he went secretly to a Danish officer, and gave him information of what had passed. The officer immediately caused the house to be surrounded with soldiers, in such a manner that it seemed impossible for Gustavus to escape. Being warned, by Peterson's wife of the treachery of her husband, he, by her direction, contrived to flee to the house of a clergyman, her friend, by whom he was received with all the respect due to his birth and merit; and lest the domestic who conducted him should follow the treacherous example of his master, he removed him to the church, and conducted him to a small closet, of which he kept the key. Having lived for some time in this manner, Gustavus began to consult with his friend concerning the most proper method of putting their schemes in execution. The priest advised him to apply directly to the peasants themselves; told him that it would be proper to spread a report, that the Danes were to enter Dalecarlia in order to establish new taxes by force of arms; and as the annual feast of all the neighbouring villages was to be held in a few days, he could not have a more favourable opportunity: he also promised to engage the principal persons of the diocese in his interest.

30 Has a very narrow escape from the Danes.

In compliance with this advice, Gustavus set out for Mora, where the feast was to be held. He found the peasants already informed of his designs, and impatient to see him. Being already prepossessed in his favour, they were soon excited to an enthusiasm in his cause, and

31 His cause espoused by the peasants of Dalecarlia.

Sweden. and instantly resolved to throw off the Danish yoke. In this design they were more confirmed by their superstition; some of their old men having observed that the wind had blown from the north while Gustavus was speaking, which among them was reckoned an infallible omen of success. Gustavus did not allow their ardour to cool, but instantly led them against the governor's castle: which he took by assault, and put the garrison to the sword. This inconsiderable enterprise was attended with the most happy consequences. Great numbers of the peasants flocked to his standard; some of the gentry openly espoused his cause, and others supplied him with money. Christiern was soon informed of what had passed; but despising such an inconsiderable enemy, he sent only a slender detachment to assist his adherents in Dalecarlia. Gustavus advanced with 5000 men, and defeated a body of Danes; but he was strenuously opposed by the archbishop of Upsal, who raised numerous forces for Christiern. The fortune of Gustavus, however, still prevailed, and the archbishop was defeated with great loss. Gustavus then laid siege to Stockholm; but his force being unequal to such an undertaking, he was forced to abandon it with loss.

32 The Danes defeated.

This check did not prove in any considerable degree detrimental to the affairs of Gustavus; the peasants from all parts of the kingdom flocked to his camp, and he was joined by a reinforcement from Lubec. Christiern, unable to suppress the revolt, wreaked his vengeance on the mother and sisters of Gustavus, whom he put to death. His barbarities served only to make his enemies more resolute. Gustavus having assembled the states at Wadstena, he was unanimously chosen regent, the diet taking an oath of fidelity to him, and promising to assist him to the utmost. Having thus obtained the sanction of legal authority, he pursued his advantages against the Danes. A body of troops appointed to throw succours into Stockholm were cut in pieces; and the regent sending some troops into Finland, struck the Danes there with such terror, that the archbishop of Upsal, together with the Danish governors, fled to Denmark. Christiern then sent express orders to all his governors and officers in Finland and Sweden to massacre the Swedish gentry without distinction. The Swedes made reprisals by massacring all the Danes they could find; so that the whole country was filled with slaughter.

33 Horrid cruelty of King Christiern.

34 Success of Gustavus.

In the mean time Gustavus had laid siege to the towns of Calmar, Abo, and Stockholm; but Norby found means to oblige him to raise them with loss. Gustavus, in revenge, laid siege to the capital a third time, and applied to the regency of Lubec for a squadron of ships and other succours for carrying on the siege. This was granted on condition that Gustavus should oblige himself, in the name of the states, to pay 60,000 merks of silver as the expence of the armament; that, until the kingdom should be in a condition to pay that sum, the Lubec merchants trading to Sweden should be exempted from all duties on imports or exports; that all other nations should be prohibited from trading with Sweden, and that such traffic should be deemed illicit; that Gustavus should neither conclude a peace, nor even agree to a truce, with Denmark, without the concurrence of the regency of Lubec; and that if the republic should be attacked by Christiern, he should enter Denmark at the head of 20,000 men. On these hard terms Gustavus obtained assistance from the regency of Lubec; nor did his dear-bought allies prove very faithful. They did not indeed go over to the enemy; but in a sea-fight, where the Danes were entirely in the power of their enemies, they suffered them to escape, when their whole force might have been entirely destroyed. This treachery had nearly ruined the affairs of Gustavus; for Norby was now making preparations effectually to relieve Stockholm; in which he would probably have succeeded: but at this critical period news arrived that the Danes had unanimously revolted, and driven Christiern from the throne; and that the king had retired into Germany, in hopes of being restored by the arms of his brother-in-law the emperor. On hearing this news, Norby retired with his whole fleet to the island of Gothland, leaving but a slender garrison in Calmar. Gustavus did not fail to improve this opportunity to his own advantage, and quickly made himself master of Calmar. Mean time Stockholm continued closely invested; but Gustavus thought proper to protract the siege till he should get himself elected king. Having for this purpose called a general diet, he first filled up the vacancy in the senate occasioned by the massacres of Christiern. Gustavus had the address to get such nominated as were in his interest. The assembly was no sooner met, than a speech was made, containing the highest encomiums on Gustavus, setting forth in the strongest light the many eminent services he had done for his country, and concluded that the states would show themselves equally ungrateful and blind to their own interest if they did not immediately elect him king. This proposal was acceded to by such tumultuous acclamations that it was impossible to collect the votes; so that Gustavus himself acknowledged, that their affection exceeded his merit, and was more agreeable to him than the effects of their gratitude. He was urged to have the ceremony of his coronation immediately performed: but this he delayed, in consequence of some designs which he had formed to reduce the exorbitant power of the clergy. Gustavus had himself embraced the doctrines of the reformed religion, and did all in his power to establish the reformation in his new kingdom. His design could not fail to raise against him the enmity of the clergy, and of all the more supertitious part of his subjects. Accordingly, the first years of his reign were embittered by internal disturbances and revolts, which were aided and fomented by the deposed Christiern, who was at one time very near regaining possession of the Swedish dominions.

35 He is chosen king of Sweden. An. 1523.

Christiern having established a powerful interest in Norway, once more made an attempt to recover his kingdoms, and was joined by the Dalecarlians; but being defeated by the Swedish forces, he was forced to return to Norway, where, being obliged to capitulate with the Danish generals, he was kept prisoner all his life.

36 Unsuccessful attempt of Christiern.

In 1542, Gustavus having happily extricated himself out of all his troubles, prevailed on the states to make the crown hereditary in his family; after which he applied himself to the encouragement of learning and commerce. A treaty was set on foot for a marriage between his eldest son Eric and Elizabeth queen of England; but this negotiation failed of success.

37 Unsuccessful negotiation for a marriage with Queen Elizabeth. An. 1542.

Gustavus Vasa died in 1560, and was succeeded by his

Sweden.

his son Eric XIV. The new king was possessed of all the exterior ornaments which gave an air of dignity to the person; but he had neither the prudence nor the penetration of his father. He created the first nobility that were ever known in Sweden; but this he had no sooner done than he quarrelled with them, by passing some act, which they thought derogatory to their honour and dignity. The whole course of his reign was disturbed by wars with Denmark, and disputes with his own subjects. In the former he was unfortunate, and towards the latter he behaved with the greatest cruelty. At last, he is said to have become mad. He afterwards recovered his senses, but was soon dethroned by his brothers: of whom Duke John succeeded him in the kingdom.

38 Gustavus dies, and is succeeded by Eric, a weak and imprudent prince. An. 1560.

39 Eric deposed, and succeeded by his brother John.

This revolution took place in the year 1568, but with no great advantage to Sweden. Disputes about religion between the king and his brothers, and wars with Russia, threw matters into the utmost confusion. At last Prince Sigismund, the king's son, was chosen king of Poland, which proved the source of much trouble to the kingdom. In 1590 King John died; and as Sigismund was at a distance, every thing fell into the utmost confusion: the treasury was plundered, and the royal wardrobe quite spoiled, before even Duke Charles could come to Stockholm to take on himself the administration until King Sigismund should return. This, however, was far from being the greatest disaster which befel the nation at this time. It was known that the king had embraced the Popish religion, and it was with good reason suspected that he would attempt to restore it upon his arrival in Sweden. Sigismund was also obliged, on leaving Poland, to promise that he would stay no longer in Sweden than was necessary to regulate his affairs. These circumstances served to alienate the minds of the Swedes from their sovereign even before they saw him; and the universal dissatisfaction was increased, by seeing him attended on his arrival in Sweden in 1593, by the pope's nuncio, to whom he made a present of 30,000 ducats to defray the expences of his journey to Sweden.

40 Prince Sigismund chosen king of Poland. An. 1568.

41 Succeeds to the crown of Sweden. An. 1590.

What the people had foreseen was too well verified: the king refused to confirm the Protestants in their religious privileges, and showed such partiality on all occasions to the Papists, that a party was formed against him; at the head of which was Duke Charles his uncle. Remonstrances, accompanied with threats, took place on both sides. Sigismund was apparently reconciled to his brother, and promised to comply with the inclinations of the people, though without any inclination to perform what he had promised. The agreement, indeed, was scarcely made, before Sigismund conceived the horrid design of murdering his uncle at the Italian comedy acted the night after his coronation. The duke, however, having notice of the plot, found means to avoid it. This enraged the king so much, that he had resolved to accomplish his designs by force; and therefore commanded a Polish army to march towards the frontiers of Sweden, where they committed all the ravages that could be expected from an enraged and cruel enemy. Complaints were made by the Protestant clergy to the senate: but no other reply was made them, than that they should abstain from those bitter invectives and reproaches, which had provoked the Catholics, till the king's departure; at which time they would be at more liberty.

42 A party formed against him.

43 Forms a design of murdering his uncle.

In 1595 Sigismund set sail for Dantzic, leaving the administration in the hands of Duke Charles. The consequence of this was, that the dissensions which had already taken place being continually increased by the obstinacy of the king, Duke Charles assumed the sovereign power; and in 1604 Sigismund was formally deposed, and his uncle Charles IX. raised to the throne. He proved a wise and brave prince, restoring the tranquillity of the kingdom, and carrying on a war with vigour against Poland and Denmark. He died in 1611, leaving the kingdom to his son, the celebrated Gustavus Adolphus.

44 Sigismund deposed, and is succeeded by Charles IX. Ann. 1604.

Though Charles IX. by his wise and vigorous conduct had in a great measure retrieved the affairs of Sweden, they were still in a very bad situation. The finances of the kingdom were entirely drained by a series of wars and revolutions; powerful armies were preparing in Denmark, Poland, and Russia, while not only the Swedish troops were inferior in number to their enemies, but the government was destitute of resources for their payment.

45 State of Sweden on the accession of Gustavus Adolphus. An. 1611.

Though the Swedish laws required that the prince should have attained his 18th year before he was of age, yet such striking marks of the great qualities of Gustavus appeared, that he was allowed by the states to take on him the administration even before this early period. His first act was to resume all the crown-grants, that he might be the better able to carry on the wars in which he was engaged; and to fill all places, both civil and military, with persons of merit. At the head of domestic and foreign affairs was placed Chancellor Oxenstiern, a person every way equal to the important trust, and the choosing of whom impressed Europe with the highest opinion of the young monarch's penetration and capacity.

46 He is allowed to assume the administration while yet a minor.

Soon after his accession, Gustavus received an embassy from James I. of Britain, exhorting him to make peace with his neighbours. This was seconded by another from Holland. But as the king perceived that the Danish monarch intended to take every opportunity of crushing him, he resolved to act with such vigour, as might convince him that he was not easily to be overcome. Accordingly he invaded Denmark with three different armies at once; and though the enemy's superiority at sea gave them great advantages, and the number of the king's enemies distracted his attention, he carried on the war with such spirit, that in 1613 a peace was concluded on good terms. This war being finished, the king applied himself to civil polity, and made some reformation in the laws of Sweden. In 1615, hostilities were commenced against Russia, on account of the refusal of that court to restore some money which had been formerly lent them. The king entered Ingria, took Kexholm by storm, and was laying siege to Plescov, when, by the mediation of James I. peace was concluded, on condition of the Russians repaying the money, and yielding to Sweden some part of their territory. In this and the former war, notwithstanding the shortness of their duration, Gustavus learned the rudiments of the military art for which he soon became so famous. He is said, indeed, to have taken every opportunity of improvement with a quickness of understanding seemingly more than human. In one campaign, he not only learned, but improved all the military maxims of La Gardie, a celebrated general, brought the Swedish army to a more steady and regular disciple, and formed an invincible

47 He invades Denmark and obliges the king to conclude a peace.

48 Russia invaded with success.

49 Extraordinary military genius of the king.

invincible body of Finlanders, who had afterwards a very considerable share in the victories of Sweden.

Peace was no sooner concluded with Russia, than Gustavus was crowned with great solemnity at Upsal. Soon after this he ordered his general La Gardie to acquaint the Polish commander Codekowitz, that as the truce between the two kingdoms, which had been concluded for two years, was now expired, he desired to be certainly informed whether he was to expect peace or war from his master. In the mean time, having borrowed money of the Dutch for the redemption of a town from Denmark, he had an interview on the frontiers with Christiern the king of that country. At this interview, the two monarchs conceived the utmost esteem and friendship for each other; and Gustavus obtained a promise, that Christiern would not assist Sigismund in any design he might have against Sweden. In the mean time, receiving no satisfactory answer from Poland, Gustavus began to prepare for war. Sigismund entered into a negociation, and made some pretended concessions, with a view to seize Gustavus by treachery; but the latter having intimation of his design, the whole negociation was changed into reproaches and threats on the part of Gustavus.

50 Has a friendly interview with the king of Denmark, and prepares for war with Poland.

51 Marries Eleonora, daughter of the elector of Brandenburg.

Immediately after this, Gustavus made a tour in disguise through Germany, and married Eleonora the daughter of the elector of Brandenburg. He then resolved to enter heartily into a war with Poland; and with this view set sail for Riga with a great fleet, which carried 20,000 men. The place was well fortified, and defended by a body of veterans enthusiastically attached to Sigismund; but after a vigorous siege, the garrison being reduced to extremity, were obliged to capitulate, and were treated with great clemency.

52 Riga besieged and taken.

After the reduction of Riga, the Swedish monarch entered Courland, where he reduced Mittau; but ceded it again on the conclusion of a truce for one year. Sigismund, however, no sooner had time to recover himself, than he began to form new enterprises against the Swedes in Prussia; but Gustavus setting sail with his whole fleet for Dantzic, where the king of Poland then resided, so defeated his measures, that he was obliged to prolong the truce for another year. Sigismund, however, was not yet apprised of his danger, and refused to listen to any terms of accommodation: on which Gustavus entering Livonia, defeated the Polish general, and took Derpt, Hockenhausen, and several other places of less importance; after which, entering Lithuania, he took the city of Birsen.

53 The Poles defeated, and several places taken.

Notwithstanding this success, Gustavus proposed peace on the same equitable terms as before; but Sigismund was still infatuated with the hopes that, by means of the emperor of Germany, he should be able to conquer Sweden. Gustavus finding him inflexible, resolved to push his good fortune. His generals Horn and Thurn defeated the Poles in Semigallia. Gustavus himself with 150 ships set sail for Prussia, where he landed at Pillaw. This place was immediately delivered up to him; as were several other places. Sigismund, alarmed at the great progress of Gustavus, sent a body of forces to oppose him, and to prevent Dantzic from falling into his hands. In this he was attended with as little success as before; and in May 1627, Gustavus arrived with fresh forces before Dantzic, which he would probably have carried, had he not been wounded in the belly by a cannon-shot. The States of Holland sent ambassadors to mediate a peace between the two crowns; but Sigismund, depending on the assistance of the emperor of Germany and king of Spain, determined to hearken to no terms, and resolved to make a winter campaign. Gustavus, however, was so well intrenched, and all his forts were so strongly garrisoned, that the utmost efforts of the Poles were to no purpose. The city of Dantzic in the mean time made such a desperate resistance as greatly irritated Gustavus. In a sea engagement the Swedish fleet defeated that of the enemy; after which Gustavus, having blocked up the harbour with his fleet, pushed his advances on the land side with incredible vigour. He made a surprising march over a morass 15 miles broad, assisted by bridges of a peculiar construction, over which he carried a species of light cannon invented by himself. By this unexpected manœuvre he got the command of the city in such a manner, that the garrison were on the point of surrendering, when, by a sudden swell of the Vistula, the Swedish works were ruined, and the king was obliged to raise the siege. In other respects, however, the affairs of Gustavus went on with their usual good fortune. His general Wrangel defeated the Poles before Brodnitz. At Stum the king gained another and more considerable victory in person. The emperor had sent 5000 foot and 2000 horse under Arnheim, who joined the main army commanded by the Polish general Coniecspolski, in order to attack the Swedish army encamped at Quidzin. The enemy were so much superior in number, that the friends of Gustavus warmly dissuaded him from attacking them. But the king being determined, the engagement began. The Swedish cavalry charged with such impetuosity, contrary to their sovereign's express order, that they were almost surrounded by the enemy; but Gustavus, coming up to their assistance, pushed the enemy's infantry with so much vigour, that they gave way, and retreated to a bridge that had been thrown over the Werder. But here they were disappointed; for the Swedes had already taken possession of the bridge. On this a new action ensued more bloody than the former, in which the king was exposed to great danger, and thrice narrowly escaped being taken prisoner; but at last the Poles were totally defeated, with immense loss. The slaughter of the German auxiliaries was so great, that Arnheim scarcely carried off one half of the troops which he brought into the field. This defeat did not hinder the Polish general from attempting the siege of Stum; but here again he was attended by his usual bad fortune. Arnheim was recalled, and succeeded by Henry of Saxe Lawenburg and Philip Count Mansfeldt. The change of general officers, however, produced no good consequences to the Poles; a famine and plague raged in their camp, so that they were at last obliged to consent to a truce for six years, to expire in the month of June 1635. Gustavus kept the port and citadel of Memel, the harbour of Pillau, the town of Elbing, Brunsberg, and all that he had conquered in Livonia.

54 The Poles again defeated, and a great number of towns reduced by Gustavus.

55 The Poles defeated a third time. An. 1627.

56 The Poles defeated by sea, and Dantzic invested.

57 The king obliged by an inundation of the Vistula to raise the siege.

58 The Poles and Germans defeated with great slaughter in two engagements.

59 They are again defeated, and obliged to consent to a truce of six years.

60 Gustavus resolves on a war with the emperor.

Gustavus having thus brought the war with Poland to an honourable conclusion, began to think of resenting the conduct of the emperor in assisting his enemies and oppressing the Protestant states. Before embarking in such an important undertaking, it was necessary that he should consult the diet. In this the propriety of engaging

ging in a war with Germany was warmly debated; but, after much altercation, Gustavus in a very noble speech determined the matter, and set forth in such strong terms the virtuous motives by which he was actuated, that the whole assembly wept, and every thing was granted which he could require.

It was not difficult for Gustavus to begin his expedition. His troops amounted to 60,000 men, hardened by a succession of severe campaigns in Russia, Finland, Livonia, and Prussia. His fleet exceeded 70 sail, carrying from 20 to 40 guns, and manned with 6000 seamen. Embarking his troops, he landed at Usedom on

61 Reduces Wolgast, Stetin, &c. An. 1630.

the 24th of June 1630, the Imperialists having evacuated all the fortresses which they possessed there; and the isle of Rugen had been before reduced by General Lesly, in order to secure a retreat if fortune should prove unfavourable. Passing the frith, Gustavus stormed Wolgast and another strong fortress in the neighbourhood, leaving a garrison for the defence of these conquests. He then proceeded to Stetin; which consented to receive a Swedish garrison, and the king persuaded the duke of Pomerania to enter into an alliance with him. In consequence of this the Swedish troops were received into several towns of Pomerania; and the most bitter enmity took place between the Imperialists and Pomeranians.

These successes of Gustavus struck the empire with consternation; for being already overwhelmed with civil dissensions, they were in no condition to resist so impetuous an enemy.

62 Count Tilly chosen general by the emperor.

At last Count Tilly was invested with the dignity of veldt mareschal. In the mean time the king being reinforced by a considerable body of troops in Finland and Livonia under the conduct of Gustavus Horn, defeated the Imperialists before Griffenhagen; taking the place soon after by assault. By this and some other conquests he opened a passage into Lusatia and Silesia; but in the mean time Count Tilly

63 Cuts off 2000 Swedes.

cut off 2000 Swedes at New Brandenburg. This advantage, however, was soon overbalanced by the conquest of Franckfort on the Oder, which Gustavus took

64 Franckfort and Landberg taken by Gustavus.

by assault, making the whole garrison prisoners. Thus he commanded the rivers Elbe and Oder on both sides, and had a fair passage not only to the countries already mentioned, but also to Saxony and the hereditary dominions of the house of Austria. Soon after this, Gustavus laid siege to Landsberg, which he took by assault.

About this time the Protestant princes held a diet at Leipsic; to which Gustavus sent deputies, and conducted his negociations with such address, as tended greatly to promote his interests.

65 He reduces Pomerania, and restores the dukes of Mecklenburg.

Immediately after this he reduced Gripswald, and with it all Pomerania. Then marching to Gustrow, he restored the dukes of Mecklenburg to their dominions.

All this time Count Tilly was employed in the siege of Magdeburg; but now, being alarmed at the repeated successes of the Swedes, he left Pappenheim with part of the army before that city, while he marched with the rest into Thuringia, to attack the landgrave of

66 Magdeburg taken by the Imperialists, and the inhabitants cruelly used.

Hesse Cassel and the elector of Saxony. After a most obstinate defence, Magdeburg fell into the hands of Pappenheim, who committed there all imaginable cruelties. Gustavus formed a plan of recovering the city; but was obliged to abandon it, by Pappenheim's throwing himself into the place with his whole army, and by the progress which Tilly was making in Thuringia. Relinquishing this enterprise, therefore, he ordered an

67 Havelsberg and Werben reduced, and the cavalry of the Imperialists defeated by the Swedes.

attack on Havelsburg; which was done with such resolution, that the place was forced in a few hours, and all the garrison made prisoners. Werben was next obliged to submit after an obstinate conflict, in which many fell on both sides.—These successes obliged Count Tilly to attempt in person to check the progress of the Swedes. He detached the vanguard of his army, composed of the flower of the Imperial cavalry, within a few miles of the Swedish camp. An action ensued, in which Bernstein the Imperial general was defeated and killed, with 1500 of his men. Gustavus, after this advantage, placed himself in a situation so much superior to his enemies, that Count Tilly was fired with indignation, and marched up to the Swedish lines to give him battle. Gustavus kept within his works, and Tilly attacked his camp, though almost impregnably fortified, keeping up a most terrible fire from a battery of 32 pieces of cannon; which, however, produced no other effect, than obliging the Swedish monarch to draw up his army be-

68 Count Tilly defeated by Gustavus.

hind the walls of Werben. Tilly had placed his chief hopes in being able to spike the enemy's cannon, or set fire to their camp; after which he proposed making his grand attack. With this view he bribed some prisoners; but they betrayed him, and told his design to Gustavus. The king ordered fires to be lighted in different parts of his camp, and his soldiers to imitate the noise of a tumultuous disorderly rabble. This had the desired effect. The count led his army to the breach made by the cannon; where he was received with such a volley of grape shot as cut off the first line, and put the whole body in disorder, so that they could never be brought back to the charge. In this confusion the Imperial army was attacked, and after an obstinate conflict obliged to quit the field.

Soon after this action the queen arrived at the camp with a reinforcement of 8000 men; at the same time a

69 A body of British soldiers comes to the assistance of the Swedes.

treaty was concluded with Charles I. of England, by which that monarch allowed the marquis of Hamilton to raise 6000 men for the service of Gustavus. These auxiliaries were to be conducted to the main army by a body of 4000 Swedes; and were in every thing to obey the king while he was personally present, but in his absence were to be subject to the orders of the marquis. With these troops the king had resolved to make a diversion in Bremen: but the marquis finding it impossible to effect a junction with the Swedish army, resolved, without debarking his troops, to steer his course for the Oder, and land at Usedom. Gustavus was very much displeased at finding his project thus disconcerted; but, making the best of the present circumstances, he commanded the British troops to act on the Oder instead of the Weser. The number of this little army was magnified exceedingly by report, insomuch that Count Tilly had some thoughts of marching against them with his whole force; but on the departure of the marquis for Silesia, he reinforced the army in that country with a large detachment, which was thought to contribute not a little to the defeat he soon after received.

Since the late action Gustavus had kept within his intrenchments, where his army was well provided with every thing. Tilly made several attempts to surprise or draw him to an engagement; but finding all his endeavours fruitless, he marched into Saxony, and laid siege to

Sweden. to Leipsic. This precipitate measure proved highly advantageous to the Swedish monarch. A treaty offensive and defensive was immediately concluded with Gustavus: and the elector willingly promised every thing that was required of him. Tilly, in the mean time, carried fire and sword into the electorate. At the head of an army of 44,000 veterans, he summoned the city of Leipsic to surrender; denouncing the same vengeance against it as had been executed on Madgeburg, in case of a refusal. By this the governor was so much intimidated, that he instantly submitted; and also surrendered the castle of Passenberg, which was in a condition to have stood out till the arrival of the Swedish army. The elector, enraged at the loss of these valuable places, ordered his army to join the Swedes with all expedition, and pressed the king so warmly to engage, that at last he yielded to his desire. On the 7th of September 1631, Gustavus led out his army in the finest order, the Swedes forming one column on the right, and the Saxons another on the left; each amounting to 15,000 men. Tilly drew up his men in one vast column, probably with a view of surrounding the flanks of the king's army. Gustavus led on his troops against that wing of the Imperialists commanded by Pappenheim, whom he drove back to a considerable distance. General Bannier in the mean time cut in pieces the troops of Holstein, and mortally wounded the duke who commanded them. Pappenheim led on his troops seven times to the charge, but was as often repulsed by the Swedes. Tilly all this while was engaged with the Saxons; but having at last driven them off the field, the whole strength of the Imperial army was turned against the Swedish left wing. The Swedes sustained the attack with the greatest firmness, until the king detached the centre to assist them. The imperialists then were no longer able to stand their ground; but gave way everywhere except in the centre, which was composed of 18 regiments of veterans accustomed to victory, and deemed invincible. They made incredible efforts to maintain their reputation; and, though swept off in great numbers by the Swedish artillery, never shrunk or fell into confusion. Four regiments, after their officers had been killed, formed themselves, and retired to the skirt of a wood. Tilly retired at the head of 600 men, and escaped by the coming on of the night. Seven thousand Imperialists lay dead on the field of battle; 4000 were taken prisoners; a fine train of artillery was lost, with upwards of 100 standards, ensigns, and other military trophies.

70 Saxony ravaged by Count Tilly, who takes Leipsic.

71 Battle of Leipsic. An. 1631.

72 The Imperialist defeated with great slaughter.

Gustavus now determined to penetrate into Franconia, where he reduced several places, especially the fortress of Workburg. Tilly having collected his scattered troops, which formed an army still superior in number to that of Gustavus, marched to the relief of this place; but came too late. He then directed his march towards Rottenberg, where four regiments were cut in pieces by a Swedish detachment. After this the king reduced Hanau, Frankfort on the Maine, and Mentz; destroying a body of Spaniards, who had attempted to obstruct his passage.

73 The Swedes take a number of towns, and cut off four regiments of the enemy.

The court of Vienna was now thrown into the utmost confusion; and sent everywhere begging assistance, and soliciting the Catholic princes to arm in defence of their religion. The emperor was most embarrassed in finding out a general capable of opposing Gustavus in the field; for the late misfortunes of Count Tilly had entirely sunk his reputation. Wallestein, an old experienced officer, was selected; but as he had formerly been disgraced, it was apprehended that he would not accept of the command of which he had once been deprived. This objection, however, was got ever; and Wallestein not only accepted of the command, but, at his own expence, augmented the army to 40,000 men.

74 Wallestein chosen general by the emperor.

During the whole winter the Swedish army kept the field; and before the approach of summer had reduced a great number of places, while the landgrave William made great progress in Westphalia. Gustavus Horn was repulsed before Bamberg; but soon had his revenge, by entirely destroying two regiments of Imperialists. To prevent the troops from being affected by the loss before Bamberg the king resolved to give battle to Tilly, who was marching into Bavaria to prevent the Swedes from gaining a footing in that electorate. He pursued the Imperial general through a vast tract of country, defeated his rear-guard, and, having reduced a variety of towns and fortresses on the Danube, penetrated as far as Ulm. Advancing to the river Leck, Count Tilly posted himself in a wood on the opposite side, to dispute his passage. Gustavus endeavoured to dislodge him by a regular fire from 70 pieces of cannon. The slaughter was dreadful; and Tilly himself, being wounded by a cannon ball in the knee, died a few days before he was to have been superseded by Wallestein. The following night the Imperial army evacuated the post. Gustavus immediately crossed the river, and seized the towns of Rain and Newburg, which the enemy had abandoned, and Augsburg next submitted.

75 A great number of towns taken by the Swedes.

76 Count Tilly defeated and killed.

From Augsburg the Swedes advanced towards Ratisbon; but were disappointed in their design of getting possession of that city, as the Bavarians had thrown a numerous garrison into the place.—In the mean time, ambassadors arrived from Denmark, offering the mediation of that crown for obtaining a lasting peace between the contending parties. This negociation, however, failed of success, as the ambassadors had not been instructed to offer terms favourable to the Protestants. Gustavus now resolving to retort on themselves the cruelties which the Bavarians had inflicted on the Protestants, laid the towns of Morzbourg, Friesengen, and Landshut, in ashes. The inhabitants of Munich saved themselves by submission; Gustavus also defeated the forces of the elector, who had been joined by a considerable body of militia.

77 Three towns laid in ashes by the Swedes.

While Gustavus was thus employed, Wallestein had assembled a vast army. He was strongly solicited by the elector of Bavaria to come to his assistance; but, in revenge of the elector's having formerly obtained the command for Count Tilly in preference to himself, he drew off towards Bohemia to encounter the Saxons. Arnheim, who commanded the Saxon forces in that place, was an enemy to Gustavus, who had formerly rallied him for his cowardice. He therefore permitted Wallestein to gain an easy victory, in hopes that his master, the elector of Saxony, a prince entirely devoted to his pleasures, might be induced to relinquish the friendship of such a restless and warlike ally as Gustavus; and indeed he used all the eloquence of which he was master to detach him from the Swedish cause. Several advantages in the mean time, were gained by the Imperialists. Pappenheim defeated the archbishop of Bremen's cavalry at Werden; and three Swedish regiments were

78 The Saxon troops defeated by Wallestein.

were cut off near Kadingen. Pappenheim, however, was forced to retire, and withdraw his forces from Stade; of which the Swedes took possession. Wallestein and the elector of Bavaria, who had now joined their forces, threatened Gustavus with greatly superior numbers. At last, however, the king, being reinforced with 15,000 men, no longer declined the engagement; but Wallestein was too wise to trust the fate of the empire to a single battle against such an enemy as the king of Sweden.

79 Gustavus attacks his camp, and is repulsed with loss.

Gustavus attacked his camp, but was repulsed with the loss of 2000 men. Several other misfortunes happened to the Swedes; and at last, after various manœuvres, Wallestein bent his course towards Misnia, in order to oblige the elector of Saxony to declare against the Swedes, and to draw them out of Bavaria. Gustavus, notwithstanding the inconstancy of Augustus, immediately set out to assist him. With incredible diligence he marched to Misnia, where the Imperialists were assembling their whole strength. Hearing that the enemy were encamped at Wesenfells, and that Pappenheim had been detached with a strong corps, Gustavus resolved to engage them before they could effect a

80 Battle of Lutzen.

junction. With this view he marched to Lutzen, where he attacked Wallestein with incredible fury. The Swedish infantry broke the Imperialists in spite of their utmost efforts, and took all their artillery. The cavalry not being able to pass the river so expeditiously as the king thought necessary, he led the way, attended only by a single regiment and the duke of Saxe Lauwenburg.

81 Gustavus killed.

Here, after charging impetuously, he was killed. The news of his death was in an instant spread over both armies. The courage of the Imperialists revived, and they now made themselves sure of victory. But the Swedes, eager to revenge the death of their beloved monarch, charged with such fury that nothing could resist them. The Imperialists were defeated a second time, just as

82 The Imperialists totally defeated.

Pappenheim, with his fresh corps, came up to their assistance. On this the battle was renewed, but the Swedes were still irresistible. Pappenheim was mortally wounded, and his army finally routed, with the loss of 9000 killed in the field and in the pursuit.

83 Christina, an infant, proclaimed queen of Sweden.

This victory proved more unfortunate to Sweden than the greatest defeat. The crown devolved on Christina the daughter of Gustavus, an infant of six years old; the nation was engaged in an expensive foreign war, without any person equal to the arduous task of commanding the armies, or regulating domestic affairs, as Gustavus had done. Christina was immediately proclaimed queen. The regency devolved on the grand bailiff, the marischal, the high admiral, the chancellor, and the treasurer of the crown. Oxenstiern was invested with the chief management of affairs, and conducted himself with the greatest prudence. The reign and character of Christina have been fully detailed under the article CHRISTINA, to which we may refer our readers.

84 Charles Gustavus appointed heir to the crown of Sweden.

From the treaty of Westphalia, Sweden enjoyed some years of repose. Charles Gustavus, Count Palatine, having gained the favour of Christina, was appointed generalissimo of the forces, and heir-apparent to the crown. A marriage was proposed between them; but the queen would never listen to this or any other proposal of the kind. In 1650, the ceremony of the queen's coronation was performed; but in four years after, she

An. 1654.

resigned the crown in favour of Gustavus. (See the article CHRISTINA).

85 State of Sweden on the accession of Charles X.

The new king found himself involved in considerable difficulties on his accession to the throne. The treasury was quite exhausted; great part of the revenue was appointed for the support of Christina's household; the people were oppressed with taxes; and the nation having been disarmed for several years, began to lose its reputation among foreigners. To remedy these evils, Charles proposed to resume all the crown-lands which had been alienated by grants to favourites during the late reign; to repeal a duty which had been laid on salt; to put the kingdom in a posture of defence; and to enter on a war

86 War with Poland resolved on.

with some neighbouring state. Under a pretence that Casimir king of Poland had questioned his title to the throne, he prepared to invade that kingdom. Several embassies were sent from Poland to Stockholm; but some point of ceremony always disappointed them of an audience of the king; so that they were obliged to return without their errand. As soon as matters were in readiness, General Wittemberg made an irruption into Poland from the side of Pomerania. The Poles opposed him with an army of 15,000 men; but instead of fighting, they began to negociate, and in a short time entirely dispersed. Charles himself soon followed with a powerful army, and pursued his march without obstruction, all the cities throwing open their gates to him as he approached. As he advanced to Cracow, Casimir

87 The Poles defeated, and the kingdom reduced.

resolved to make one effort to save his capital. His army amounted only to 10,000 men; and these were unfortunately such as had never stood fire. After a feeble resistance, they fled with precipitation, having lost 1000 men killed and taken prisoners. A few days after this Charles defeated the Poles a second time, about eight leagues from Cracow; on which Casimir fled with his family to Oppelen in Silesia. The capital was then invested; and though defended with the utmost valour, was in a short time obliged to capitulate. Thus in less than three months Charles apparently became master of Poland; but it was soon evident that the Poles had no intention of abandoning their former sovereign.

88 War with the elector of Brandenburg. An. 1656.

In 1656, a war took place with the elector of Brandenburg. While Charles was employed in the conquest of Poland, that prince had invaded Royal and Ducal Prussia, and reduced the most considerable towns with little opposition. The king of Sweden took umbrage at his progress; and having marched against him, defeated his forces in several slight encounters, and obliged him to acknowledge himself a vassal of Sweden. These rapid conquests alarmed all Europe; and the different powers sought for means of driving the Swedes out of Poland, which they had so unexpectedly and unjustly seized.

89 The Poles revolt.

The Poles were no sooner assured that they should be assisted, than they every where revolted and massacred the Swedes. Casimir returned from Silesia; and those very troops and generals who had before submitted to Charles without opposition, now ranged

90 Charles gains a victory, but is obliged to retire.

themselves under the banners of his antagonist. Charles immediately marched from Prussia to chastise the insolence of the Poles, and totally defeated a body of 12,000 men. This did not hinder all the Poles incorporated with his troops to desert; which considerably reduced his army; and the campaign being performed in the depth of winter, he was at last obliged to retreat to Prussia. In his march he was harassed by the Poles; and a body of 4000 Swedes was surprised and defeated by them at Warka. This loss, however, was soon after

Sweden

recompensed by a complete victory gained by Adolphus the king's brother and General Wrangel. In the mean time the king was taking measures for laying siege to Dantzic; but was prevented by the Dutch, who threat-

91 Concludes a treaty with the Dutch and the elector of Brandenburg.

ened to oppose him, unless a proper regard was paid to their interest. Charles accordingly granted them advantageous terms; and afterwards gained over the elector of Brandenburg, by ceding to him the sovereignty of Prussia, that he might be at liberty to turn his whole strength against Poland.

By the treaty just concluded with the elector, the latter was to assist Charles in his war with Poland; but the elector had so procrastinated matters, that the Poles, having obtained assistance from the Tartars, had reduced the city of Warsaw. The two princes, however, now marched in concert against their enemies, who were encamped in a strong situation in the neighbourhood of the city above mentioned, their camp being fronted by the Vistula. The Poles were driven from their en-

92 The Poles and Tartars defeated with great slaughter.

trenchments with prodigious slaughter. The Poles and Tartars then laboured to break the alliance; with which view they entered Ducal Prussia, and defeated the electoral army, taking many prisoners. The Swedes soon had their revenge. General Steinboek attacked the same Polish army at Philippowa, and overthrew it with such slaughter as obliged the Poles for that season to quit the field. A more formidable enemy than the Poles now began to make their appearance. The Russians invaded the provinces of Carelia, Ingermania, and

93 The Russians invade the Swedish dominions.

Livonia; while the elector of Brandenburg, began to waver in his fidelity. To preserve this only ally at such a critical juncture, Charles was obliged to give him more advantageous terms than those already mentioned; while the Russians were repulsed in the provinces of Carelia and Ingermania. But in Livonia they had better success. See Russia. For seven months, however, they battered the walls of Riga, without venturing to pass the ditch or storm the practicable breaches.

Charles, notwithstanding the number of his enemies, was now become so formidable by the valour and discipline of his troops, that whole armies often fled on his

An. 1657.

approach. At last, in 1657, the Poles, finding they could not resist him in the field, contented themselves

94 Charles enters into an alliance with Ragotski prince of Transylvania.

with harassing the Swedes on their march, and cutting off the foragers and convoys. This proved much more destructive to the Swedes than their former method; so that Charles was obliged to enter into an alliance with Ragotski prince of Transylvania, by assigning him certain provinces in his neighbourhood, in order to furnish himself with irregular troops, who might fight the Poles in their own way. This, however, proved of no real advantage; for the confederates, after wasting a whole campaign in Lithuania, were obliged to return without accomplishing more than the reduction of a single for-

95 Leopold king of Hungary declares against Sweden.

tress; on which Charles returned with the Swedish army to Prussia.

Leopold, the young king of Hungary, having long beheld the Swedes with a jealous eye, now resolved to declare for Poland. The more effectually to curb the ambition of the Swedish monarch, he solicited the king

96 Ragotski's army destroyed by the Poles and Tartars.

of Denmark to come to a rupture with him. This was instantly complied with, and the Danes invaded Bremen. Charles hastened to oppose this new enemy; which gave such offence to Ragotski, that he neglected to take the proper measures for his own defence in the absence of the Swedes, and suffered his army to be destroyed by the Poles and Tartars. At the same time the Turks invaded Transylvania, under pretence that Ragotski, being a vassal of the Grand Signior, had no right to invade Poland without his leave. Ragotski opposed them in the field; where he was defeated and killed, leaving Charles destitute of the only ally on whom he could depend.

97 He is defeated and killed by the Turks.

The king, however, not dismayed by this misfortune, traversed Pomerania and the duchy of Mecklenburg; after which he attacked Holstein, while General Wrangel with another corps entered the duchy of Bremen. The latter executed his measures with the utmost vigour. In 15 days he retook all the towns which the enemy had reduced; defeated and drove the Danish army out of the country, killing 3000 of their best soldiers. In Holstein the king reduced several fortresses, laid Itzehoe in ashes, defeated a body of Danes, and laid siege to Frederic Udda, into which the Danes had thrown a strong garrison. The conduct of this siege he left to Wrangel, he himself retiring to Wismar in order to observe the situation of affairs in Poland; but no sooner was he gone than Wrangel attaked the place with such fury, that he became master of it in two hours. In the province of Halland the Swedes were defeated; but the enemy derived no advantage from their victory: at sea the fleets met, and maintained an engagement for two days, without any considerable advantage on either side. In Poland affairs were not better conducted. The house of Austria had now declared for Casimir; a German army entered Poland, and reduced Cracow, though not without great loss to themselves.

98 Bravery and success of General Wrangel.

99 The house of Austria declares against Sweden.

The king of Sweden was now surrounded by enemies. The elector of Brandenburg had declared against him; and he had besides to engage the armies of Austria, Poland, Russia, and Denmark. In this dangerous situation he resolved to attack Denmark, so as to oblige that power to come to a speedy accommodation. His designs were forwarded by a very early frost, which enabled him to transport his troops without shipping. Having passed over on the ice to the island of Funen, he cut in pieces a body of 4000 Danish soldiers and 500 peasants. The whole island was reduced in a few days; after which he passed to Langland, then to Laaland, after that to Falstre, and lastly to Zealand. The Danes were terrified at this unexpected invasion, and were giving themselves up to despair, when Charles offered to conclude a peace on equitable terms. The king of Denmark gladly consented; intending to renew the war as soon as he thought it could be done with safety.

100 Charles invades Denmark with great success.

101 Peace concluded. An. 1658.

Charles was no sooner retired, than the king of Denmark began to act secretly against him; on which, resolving to anticipate him in his designs, he appeared unexpectedly with a fleet before Copenhagen. The Swedish monarch laid siege to the capital, but with so little prudence that he made no progress, and was at length compelled to turn the siege into a blockade, which continued to the end of the war. Charles X. died of an epidemic fever, and was succeeded by his son Charles XI.

102 The war renewed, and Copenhagen besieged.

103 Charles XI. An. 1660.

The new king Charles XI. was a minor at the time of his father's death; and as the kingdom was involved in a dangerous war with so many enemies, the regency determined to conclude a peace, if it could be obtained on

Sweden.

on reasonable terms. A treaty was accordingly concluded at Olivia; by which Casimir renounced his pretensions to the crown of Poland, and that republic gave

104 Treaty of Olivia.

up all pretensions to Livonia. Bornholm and Drontheim were ceded to Denmark; and an equivalent in Schonen remained with Sweden. During the minority of the king, nothing remarkable occurs in the history of Sweden. In 1672 he entered into alliance with Louis

105 War with Brandenburg.

XIV. which two years after involved him in a war with the elector of Brandenburg. At first the Swedes carried all before them. Almost all the towns in Brandenburg were reduced, when the elector arrived with

106 The Swedes defeated by land and sea.

an army to the relief of his distressed subjects. He retook several towns, defeated the Swedes in a general engagement, and soon after forced them to abandon all their conquests. In conjunction with the Danes, he then invaded the Swedish dominions: many places of

An. 1676.

importance were reduced; and, in 1676, Sweden received a most destructive blow by the defeat of her fleet in an engagement with the combined fleets of Denmark and Holland. Soon after this the king took the government into his own hands, and in some degree restored the fortune of Sweden; but though matters went on in a more prosperous way where the king command-

107 Their affairs every-where go to wreck.

ed in person, the same losses and disgrace attended the Swedish arms in every other quarter. In 1678, the Swedish fleet was defeated in two engagements. At Landscroon a most obstinate battle was fought from ten in the morning till six at night; when both parties were obliged, by fatigue, to retire to their respective camps. At Oldeval in Norway, the Swedes were defeated; and the Danes laid desolate the islands of Oeland, Smaaland, Unno, and Kuno; while the electoral troops and Imperialists reduced Count Konigsmark to the utmost distress in the neighbourhood of Stralsund.

In this deplorable situation of affairs Count Konigsmark found an opportunity of attacking his enemies to such advantage, that he obtained a complete victory; after which he ravaged the duchy of Mecklenburg. Notwithstanding this success, he could not prevent the elector from reducing Stralsund; after which he was obliged to evacuate Pomerania; and, to complete his distress, the fleet which transported the Swedish army from Pomerania was wrecked on the coast of Bornholm.

In this unprosperous situation of affairs a peace was concluded at St Germain's between France and her enemies, by which the Swedes and Danes were left to decide their quarrel by themselves. Denmark was by no

108 Peace concluded.

means a match for Sweden, even in the distressed situation to which she was reduced; and therefore a treaty was concluded, on terms much more favourable to Sweden than could have been expected; and the peace was confirmed by a marriage between Charles and Ulrica Eleonora, daughter to the king of Denmark. From this time the Swedish monarch applied himself to the reformation of the state; and by artfully managing the disputes between the nobility and peasants, he ob-

109 Charles becomes absolute.

tained a decree empowering him to alter the constitution as he pleased. The proceedings of the king after this decree were such as to exasperate the nobility, and produce violent commotions. See PATKUL.

On the 15th of April 1697, died Charles XI. leaving his crown to his son, the celebrated Charles XII. at that time a minor. On his accession he found himself under the tuition of his grandmother Eleonora, who had governed the kingdom during the minority of the late

110 Charles XI. dies, and is succeeded by his son Charles XII.

king. Though Charles was at that time only 15 years of age, he showed a desire of taking the government into his own hands. His counsellors, Count Piper and Axel Sparre, signified his desire to the queen-regent. They were by her referred to the states; and there all

111 He takes the government into his own hands at the age of 15.

were unanimous: so that the queen, finding that opposition would be vain, resigned her power with a good grace; and Charles was invested with absolute authority, in three days after he had expressed his desire of reigning alone. He was scarcely seated on the throne when a powerful combination was formed against him. Augustus king of Poland formed designs on Livonia; the king

112 A powerful combination formed against him.

of Denmark revived the disputes he had with the duke of Holstein, as a prelude to a war with Sweden; and Peter the Great of Russia began to form designs on Ingria, formerly a province of Russia. In 1699 the king of Denmark marched an army into Holstein. Charles sent a considerable body of troops to the duke's assist-

113 Holstein ravaged by the Danes. An. 1699.

ance; but before their arrival the Danes had ravaged the country, taken the castle of Gottorp, and laid close siege to Tonningen. Here the king of Denmark commanded in person; and was assisted by the troops of Saxony, Brandenburg, Wolfenbuttle, and Hesse Cassel. England and Holland, as guarantees of the last treaty with Denmark, in concert with Sweden, joined Charles against this confederacy, and sent fleets to the Baltic. They proposed a termination of the war on equitable terms; but these were haughtily refused by the Danish monarch, who despised the youth and inexperience of Charles, and relied too much on the alliance he had formed with Saxony, Brandenburg, Poland, and Russia.

114 They are repulsed at Tonningen.

Tonningen, however, resisted all his efforts; and when he ordered the place to be stormed, he had the mortification to see his troops driven headlong from the walls by a handful of Swedes.

115 Charles sets out from Stockholm, and defeats the fleet of the allies. An. 1700.

In the year 1700, Charles, having entrusted the affairs of the nation with a council chosen out of the senate, set out on the 8th May from his capital, to which he never afterwards returned. He embarked at Carlscroon, and defeated the fleet of the allies. Having made a descent on the island of Zealand, he defeated a body of cavalry that opposed his march, and then proceeded to invest Copenhagen by sea and land. The king of Denmark then saw the necessity of either having his capital destroyed, or of doing justice to the duke of Holstein.

116 Obliges the Danes to make peace.

He chose the latter; and a treaty was concluded on much the same terms as formerly. Charles, being thus at liberty to turn his arms against the other princes who had conspired his destruction, resolved to lead his army

117 Marches against the Russians.

against Augustus king of Poland. On the road, however, he received intelligence that the tzar of Russia was on his march to oppose him, and had laid siege to Narva with an army of 100,000 men. The contest that ensued between Charles and Peter, with the celebrated battles of Narva and Pultava, have been already related under RUSSIA, so that we shall here confine ourselves chiefly to those events in which Peter the Great was not immediately concerned.

The tzar Peter was the chief support of Augustus, and he took the most active measures to oppose the progress of the Swedish monarch. His want of success, and the subsequent

Sweden. frequent contests between him and Charles, till the decisive battle of Pultava, are related in the article Russia.

118 Charles marches against the Saxons, An. 1701. In 1701, as early as the season permitted, Charles, having received a reinforcement from Sweden, took the field, and appeared suddenly on the banks of the Duna, along which the Saxon army was posted to receive him. The king of Poland being at that time sick, the army was commanded by Ferdinand duke of Courland, Marischal Stenau, and General Paykel, all officers of valour and experience. They had fortified certain islands in the mouth of the river, and taken every other precaution against an attack; the soldiers were hardy, well disciplined, and nearly equal to the Swedes in number;

119 and entirely defeats them. yet Charles, having passed the river in boats with high sides, to screen the men from the fire of the enemy, attacked them with such fury, that they were entirely defeated with great loss.

This victory was followed by the surrender of all the towns and fortresses in the duchy of Courland. Charles then passed into Lithuania, where every town opened its gates to him. At Birsen, an army of 20,000 Russians retired with the utmost precipitation on the news of his approach.

120 Forms a scheme for dethroning Augustus. Here Charles, perceiving that the kingdom of Poland was greatly disaffected to Augustus, began to project the scheme of dethroning him by means of his own subjects. This scheme he executed with more policy than he ever showed on any other occasion.

121 Makes a second application to no purpose. Augustus, in the mean time, finding his scheme of peace frustrated, had recourse to the senate; but met with such a rough answer from them, that he determined to apply to Charles. To him therefore he sent his

122 Warsaw taken. chamberlain; but a passport being forgotten, the ambassador was arrested. Charles continued his march to Warsaw, which surrendered on the first summons: but the citadel held out for some days. Augustus, finding at last that no dependence was to be placed on the Poles, determined to trust his fortune wholly to the Saxon army and the nobility of the palatinate of Cracow, who offered to support him to the utmost of their power. The Saxon army was now advanced to the frontiers, and Augustus immediately put himself at its head. Being joined by the nobility of Cracow, he found his forces to amount to 30,000 men, all brave and well disciplined. With these he marched in quest of his enemy; who did not

123 The Saxons entirely defeated. decline the combat, though he had with him only 12,000 men. Though the Saxons were strongly posted, having their front covered by a morass, besides being fortified

124 Cracow taken. with pallisadoes and chevaux de frise, they were attacked with irresistible impetuosity, and entirely defeated. This victory was followed by the loss of Cracow: after which Charles set out in pursuit of the flying army, with a design of preventing them from re-assembling; but his horse falling under him, he had the misfortune to break his thigh, by which he was confined six weeks; and thus Augustus obtained some respite. He improved this interval. Having convoked a diet first at Marienburg, and then at Lublin, he obtained the following resolutions; that an army of 50,000 men should be raised by the republic for the service of the prince; that six weeks should be allowed the Swedes to determine whether they were for war or peace; and that the same time should be granted to the turbulent and discontented nobles of Poland to make their concessions. To counteract the effects of these resolutions, Charles assembled another diet at Warsaw; and while the two assemblies disputed concerning their rights and privileges, he recovered from his wound, received a strong reinforcement from Pomerania, and utterly defeated and dispersed the remains of the Saxon army. Sweden. 125 Remains of the Saxon army entirely defeated.

The ill fortune of Augustus continued still to prevail. In 1704 he was formally deposed by the diet, and the crown conferred by Charles on Stanislaus Lecsinsky palatine of Posnania. An. 1704. 126 Augustus formally deposed, and Stanislaus raised to the throne. Augustus, however, did not yet tamely give up his kingdom. His adherents daily skirmished with the Swedes; and Augustus himself, being reinforced by 9000 Russians, retook Warsaw, and was near surprising the new king, who lived in perfect security in the city while Charles fought in his cause. Count Horn, with 1500 Swedes, vigorously defended the citadel; but at last, finding it no longer tenable, he was obliged to surrender at discretion. 127 Warsaw retaken by Augustus. The reduction of Warsaw was among the last advantages gained by Augustus in the course of this war. His troops were now composed of Saxon recruits and undisciplined Poles, who had no attachment to his person, and were ready on all occasions to forsake him. Charles and Stanislaus advanced with the victorious army; the Saxons fled before them, and the towns several miles round sent him their submissions. 128 Excellent conduct of his general Schullemberg. The Poles and Saxons were under the command of Schullemberg, a most sagacious and experienced general, who used every expedient to check the progress of the Swedes. With all his conduct and caution he found himself outwitted, and Charles in the neighbourhood of his camp ready to fall on him, while he thought him at 50 leagues distance. 129 His engagement with the Swedes. The Swedish monarch attacked him with a superior army, but entirely composed of horse. Schullemberg had posted his men in such a manner as rendered it impossible to surround them. His first rank being armed with pikes and fusees, presented a kind of rampart of bayonets; the second line stooping over the first who kneeled, fired over their heads, while the third rank, who stood upon their feet, kept up an incessant fire, by which the Swedish horse were exceedingly galled and put in disorder. Charles lost the opportunity of cutting off the whole Saxon army, by omitting to order his men to dismount. This was almost the first time that infantry had been regularly opposed to cavalry, and the superiority of the former was evident. 130 His fine retreat. After the engagement had continued about three hours, the Saxons retreated in good order; which no enemy had ever done before in any engagement with Charles. The Swedes pursued their enemies towards the Oder, and forced them to retreat through thick woods, almost impervious even to infantry. The Swedish horse, however, pushed their way, and at last inclosed Schullemberg between a wood and the river, where Charles had no doubt of obliging him to surrender at discretion, or die sword in hand, as having neither boats nor bridges; but the genius of Schullemberg supplied every defect. In the night he ordered planks and floats of trees to be fastened together; on which he carried over his troops, while the Swedes were employed in dislodging 300 men, whom he had placed in a windmill, for the purpose of defending his flank and keeping the enemy in play. Charles spoke of this retreat with admiration, and said he had been conquered by Schullemberg.

131 Augustus leaves Poland. No material advantage, however, resulted from this to Augustus; who was again obliged to leave Poland, and fortify

Sweden. fortify the capital of his hereditary dominions, which he expected every moment to see invested. In the mean

132 The Russians take several towns in Livonia, and invade Poland.

time the Russians having recovered their spirits, attacked the Swedes in Livonia with the utmost fury. Narva, Dorpt, and several other towns, were taken, and the inhabitants and garrisons treated with great barbarity. Soon after, an army of 100,000 Russians entered Poland. Sixty thousand Cossacks under Mazeppa entered the country at the same time, and ravaged every thing with the fury of barbarians. Schullenberg, too, perhaps more formidable than either, advanced with 14,000 Saxons and 7000 Russians, disciplined in Germany, and reputed excellent soldiers. Could numbers have determined the event of war, the Swedes must certainly have been at this time overpowered. Instead of this, however, Charles seemed to triumph over his enemies with more ease the more numerous they were. The Russians were defeated so fast, that they were all dispersed before

133 Astonishing success of Charles against them.

one party had notice of the misfortunes of another. The defeating an army of 40,000 men scarcely obstructed the march of the Swedes, while their astonished enemies looked on these actions as the effects of witchcraft, and imagined that the king of Sweden had dealings with infernal spirits. With these apprehensions they fled beyond the Dniepr, leaving the unhappy Augustus to his fate. Schullemberg, with all his skill and experience,

134 Schullemberg entirely defeated by Renschild.

succeeded no better. The Swedish general Renschild engaged and defeated him in half an hour, though the Swedes were vastly inferior in number, and their enemies posted in a most advantageous situation. Nothing could be more complete than this victory. This extraordinary victory, indeed, is said to have been owing to a panic which seized the troops of Schullemberg: but it was regarded with admiration, and thought to make the renown of Renschild equal to that of his sovereign. Charles himself was jealous, and could not help exclaiming, "Surely Renschild will not compare himself with me!"

135 Charles invades Saxony.

Soon after this victory, which was gained on the 12th of February, 1706, Charles entered Saxony at the head of 24,000 men. The diet at Ratisbon declared him an enemy to the empire if he crossed the Oder. But to this declaration no regard was paid. Charles pursued his march; while Augustus was reduced to the condition of a vagrant in Poland, where he possessed not a single town except Cracow. Into this city he threw himself with a few Saxon, Polish, and Russian regiments, and began to erect some fortifications for its defence; but the approach of the Swedish general Meyerfeldt, and the news of the invasion of Saxony, disconcerted all his measures, and threw him into despair. The Russians indeed were his faithful allies; but he dreaded them al-

136 Augustus begs for peace on any terms.

most as much as the Swedes: so that he was reduced to the necessity of writing a letter to Charles with his own hand, begging for peace on whatever terms he thought proper to grant. However, as he was then at the mercy of the Russians, this transaction was concealed with the greatest care. His emissaries were introduced to the Swedish court in the night-time; and being presented

137 Charles's answer.

to Charles, received the following answer: That King Augustus should for ever renounce the crown of Poland, acknowledge Stanislaus, and promise never to reascend the throne, should an opportunity offer; that he should release the princes Sobieski, and all the Swedish prisoners made in the course of the war; surrender Patkul, at that time resident at his court as ambassador for the tzar of Russia, and stop proceedings against all who had passed from his into the Swedish service. These articles, Charles wrote with his own hand, and delivered to Count Piper, ordering him to finish them with the Saxon ambassadors.

After his defeat at Pultava by the Russians, Charles fled in a mean calash, attended by a little troop inviolably attached to his person, some on foot, and some on horseback. They were obliged to cross a sandy desert, where neither herb nor tree was to be seen, and where the burning heat and want of water were more intolerable than the extremities of cold they had formerly suffered. The whole had almost perished for

138 Charles arrives in Turkey after his defeat at Pultava.

want of water, when a spring was fortunately discovered; after which they reached Otchakoff, a town in the Turkish dominions, the bashaw of which supplied the king with every necessary. It was some time, however, before boats could be got ready for transporting the whole of the king's attendants; by which accident 500 Swedes and Cossacks fell into the hands of the enemy. This loss affected him more than all his other misfortunes. He shed tears at seeing, across the river Bog, the greater part of his few remaining friends carried into captivity, without having it in his power to assist them. The bashaw waited on him to apologise for the delay, and was severely reprimanded by Charles, as if he had been his own subject.

The king remained but a few days at Otchakoff, when the serasquier of Bender sent an aga to compliment him on his arrival in the Turkish dominions, and

139 Is kindly received, and his hopes of conquering Russia begin to revive.

to invite him to that city. Here he was treated with hospitality: the Turks practised to its full extent their generous maxim of regarding as sacred the persons of unfortunate princes who had taken shelter in their dominions: and perhaps regarded him, notwithstanding his misfortunes, as an ally that might be useful to themselves against the Russians. Every one, indeed, regarded him in his distress. The French king offered him a safe passage from the Levant to Marseilles, from whence he might easily return to his own dominions. But Charles was too obstinate to receive advice. Puffed up with the notion of imitating Alexander the Great, he disdained to return except at the head of a numerous army; and he yet expected, by means of the Turks, to dethrone his adversary the tzar. Negociations for this purpose were carried on in the Turkish divan; and it was proposed to escort Charles with a numerous army to the frontiers of Poland: but the revolution which took

140 Augustus recovers the kingdom of Poland.

place there, put an end to all such projects. Augustus thought himself no longer bound to observe the treaty which he had made, than while Charles was at hand to compel him. After the battle of Pultava, he entered Poland, and took every measure, in concert with the tzar, for the recovery of his kingdom. Stanislaus was not able to stand before such enemies, but was obliged to leave his dominions and fly to Bender, in the disguise of a Swedish officer, in order to share the fortune of Charles.—It was not in Poland alone that the Swedish affairs began to suffer in consequence of the defeat at

141 The Danes invade Sweden;

Pultava. The Danes invaded the province of Schonen with an army of 13,000 foot and 2500 horse. Only 13,000 Swedish forces remained to defend all the territories possessed by Charles in Germany; and of these only a small part was allotted for the defence of Schonen.

nen. The regency of Sweden, however, exerted themselves to the utmost to repel this ungenerous invasion; and having collected an army of 12,000 militia and 8000 regulars, dispatched them under General Steenboek into Schonen. Some Saxon troops were incorporated in this army; and among these a prodigious desertion took place, which the general found it impossible to prevent; and thus the Danes gained several advantages, and at last took Christianstadt. Their insolence on this success was so great, that the Swedes demanded to be instantly led against them. Here the good fortune of Sweden seemed once more to revive. The Danes were driven from a very strong situation, with the loss of 8000 killed and taken prisoners, besides a vast number wounded. The king received the intelligence of this victory with the greatest exultation; and could not help exclaiming, "My brave Swedes, should it please God that I once more join you, we shall conquer them all!"

142 but are utterly defeated.

In the mean time, Charles, by means of his agents the count Poniatoffski and the sieur Neugebar, used his utmost efforts to procure a rupture between the Porte and Russia. For a long time the money bestowed by Peter on the vizirs and janisaries prevailed; but at last, in 1711, the grand signior, influenced by his mother, who was strongly in the interest of Charles, and had been used to call him *her lion*, determined to support his quarrel with Peter. He therefore gave orders to the vizir to fall on the Russians with an army of 200,000 men. The vizir promised obedience; but at the same time professed his ignorance in the art of war, and dislike to the present expedition. The khan of Crim Tartary, who had been gained over by the reputation and presents of the king of Sweden, had orders to take the field with 40,000 of his men, and had the liberty of assembling his army at Bender, that Charles might see that the war was undertaken on his account. See Russia, N° 119.

143 The Turks declare war against the Russians.

The treaty of the Pruth was most violently opposed by Count Poniatoffski and the khan of Tartary. The former had made the king acquainted with the situation of both armies; on which he instantly set out from Bender, filled with the hopes of fighting the Russians, and taking ample vengeance. Having ridden 50 leagues post, he arrived at the camp just as the tzar was drawing off his half-famished troops. He alighted at Poniatoffski's tent; and being informed of particulars, instantly flew in a rage to the vizir, whom he loaded with reproaches, and accused of treachery. Recollecting himself, however, he proposed a method by which the fault might be remedied; but finding his proposal rejected, he posted back to Bender, after having by the grossest insults showed his contempt of the vizir.

The violent behaviour of Charles did not promote his interest. The vizir perceived that his stay in Turkey might prove fatal to himself; and therefore determined to get him out of the country as soon as possible. Succeeding vizirs adopted the same plan; and at last the grand signior himself wrote a letter to Charles, in which he desired him to depart by next winter, promising to supply him with a sufficient guard, with money, and every thing else necessary for his journey. Charles gave an evasive answer, and determined to procrastinate his journey, as well to gratify his own stubborn temper, as because he discovered a correspondence between Augustus and the khan of Tartary, the object of which, he had reason to believe, was to betray him to the Saxons. When he was again pressed to fix the day of his departure, he replied, that he could not think of going before his debts were paid. Being asked how much was necessary for this purpose, he replied 1000 purses (A). Twelve hundred purses were instantly sent to the serasquier at Bender, with orders to deliver them to the king of Sweden, but not before he should have begun his journey. By fair promises, Charles persuaded him to part with the money; after which, instead of setting out, he squandered away his treasure in presents and gratifications, and then demanded 1000 purses more before he would set out. The serasquier was astonished at this behaviour. He shed tears; and turning to the king, told him, that his head would be the forfeit of having obliged him with the money. The grand signior, on being acquainted with the shameful behaviour of Charles, flew into a rage, and called an extraordinary divan, where he himself spoke, a thing very unusual for the Turkish monarchs. It was unanimously agreed that such a troublesome guest ought to be removed by force, should other means fail. Positive orders were therefore sent to Charles to depart; and, in case of refusal, to attack him in his quarters. Nothing could equal his obstinacy on this occasion: in spite of the menaces of his enemies, in spite of the intreaties of his friends, he persisted in his resolution; and at last determined to resist, with 300 Swedes, being all the attendants he had, an army of 20,000 janisaries well armed and furnished with cannon. At length he was attacked in good earnest; though it must be owned, that even in this extremity, the Turks showed their regard to him, and were tender of his life, which the king did not return at all in a similar manner. Most of the Swedes surrendered at once, perhaps as thinking it the only method of saving the king's life. This misconduct, however, had a quite contrary effect. Charles became the more obstinate, the more desperate his affairs seemed to be. With 40 menial servants only, and the generals Hord and Dardorff, he determined to defend himself to the last extremity. Seeing his soldiers lay down their arms, he told the generals, "We must now defend the house. Come, (adds he with a smile), let us fight *pro aris et focis*." The house had been already forced by the Tartars, all but a hall which was near the door, and where his domestics had assembled. Charles forced his way through the janisaries, attended by the generals Hord and Dardorff, joined his people, and then barricaded the door. The moment he entered, the enemy who were in the house, threw down their booty, and endeavoured to escape at the windows. Charles pursued them from room to room with much bloodshed, and cleared the house in a few minutes. He then fired furiously from the windows, killed 200 of the Turks in a quarter of an hour, so that the bashaw who commanded them was at length forced to set the house on fire. This

144 The grand signior desires him to depart.

145 Mean and unjust behaviour of Charles.

146 The Turks resolve to force him to depart.

147 His desperate resolution to resist.

148 Is abandoned by all his followers except 40.

149 Fights like a madman, but is taken prisoner with all his followers.

(A) Each purse contained 30 sequins.

This was done by arrows with lighted matches shot into the roof; but Charles, instead of quitting it, gave orders for extinguishing the fire, in which he himself assisted with great diligence. All efforts, however, were vain: the roof fell in; and Charles, with his few faithful companions, was ready to be buried in the ruins. In this extremity one called out, that there was a necessity for surrendering. "What a strange fellow! (cries the king), who would rather be a prisoner with the Turks than mix his ashes with those of his sovereign." Another had the presence of mind to cry out, that the chancery was but 50 paces off, had a stone roof, and was proof against fire. Pleased with the thoughts of again coming to blows, the king exclaimed, "A true Swede! Let us take all the powder and ball we can carry." He then put himself at the head of his troops, and sallied out with such fury, that the Turks retreated 50 paces; but falling down in the hurry, they rushed in upon him, and carried him by the legs and arms to the bashaw's tent.

This extraordinary adventure, which savours not a little of insanity, happened on the 12th of February 1713. He was now kept prisoner with all his retinue; and in this situation he was visited by the unfortunate Stanislaus.

150 Begins to think of returning to his dominions.

Charles at last seemed inclined to submit to his fate, and began seriously to think of returning to his kingdom, now reduced to the most deplorable situation. His habitation was now fixed at Demotica, a small town about six leagues from Adrianople. Here he was allowed provisions for his own table and those of his retinue; but only 25 crowns a-day in money, instead of 500 which he had received at Bender. During his residence here he received a deputation from Hesse Cassel, soliciting his consent to the marriage of the landgrave with Eleonora, princess royal of Sweden; to which he readily agreed: a deputation was also sent him by the regency of Sweden, requesting that he would prepare for returning to his own dominions, which were ready to sink under a ruinous war in his absence.

151 Sets out for Sweden. An. 1714.

On the 14th of October 1714, Charles set out for Sweden. All the princes through whose territories he was to pass, had given orders for his entertainment in the most magnificent manner; but the king, perceiving that these compliments only rendered his imprisonment and other misfortunes more conspicuous, suddenly dismissed his Turkish attendants, and assembling his own people, bid them take no care about him, but make the best of their way to Stralsund. After this he set out post, in the habit of a German officer, attended only by Colonel During. Keeping the bye-roads through Hungary, Moravia, Austria, Bavaria, Wirtemberg, the Palatinate, Westphalia, and Mecklenburgh, he arrived on the 21st of November at midnight before the gates of Stralsund. Being unknown, he was admitted with difficulty; but being soon recognised by the governor, the greatest tokens of joy were shown all over the town. In the midst of the tumult Charles went to bed.

152 Dismisses his retinue, and proceeds with only one attendant.

153 Arrives at Stralsund, and is received with the utmost joy.

154 Distressed situation of Sweden.

Sweden was now in the greatest distress. On the news of the defeat at Pultava, the Danes had invaded Schonen, but were defeated by General Steenboek. This vistory, however, did not put an end to the war. On the contrary, the kings of Denmark and Poland, with the tzar of Russia, entered into stricter bonds of amity than ever. They dreaded the return of Charles to his own dominions, and apprehended that numberless victories would soon efface the remembrance of Pultava. They determined, therefore, to make the best use of their time; and perhaps Charles never took a more imprudent resolution than obstinately to remain so long in the Turkish dominions. The return of Charles seemed to give new life to the whole nation. Though the number of inhabitants was visibly diminished, the levies he had ordered were completed in a few weeks: but the hands left to cultivate the earth consisted of the infirm, aged, and decrepid; so that a famine was threatened in consequence of the military rage which had seized all the youth of the kingdom.

155 The king is unable to retrieve the Swedish affairs. An. 1715.

The presence of Charles did not now produce those consequences which the allies had feared. The kingdom was too much reduced to furnish the necessary supplies of men and money; and though the king's courage and military skill were not in the least diminished, the efforts he made, instead of restoring Sweden to its splendour, served more completely to ruin it. In 1715, Prussia declared against him, on account of his demanding back the town of Stetin, which that monarch had seized. To complete his embarrassment, the elector of Hanover, George I. of Britain, also became his enemy.

156 Is encompassed on all sides by enemies.

The forces of Denmark, Prussia, Saxony, and Hanover, joined to invest Wismar, while a body of 36,000 men formed the siege of Stralsund; at the same time that the tzar, with a fleet of 20 large ships of war, and 150 transports, carrying 30,000 men, threw every part of the Swedish coast into the greatest consternation. The heroism of Charles could not prevail against so many enemies; yet he was still so much dreaded, that the prince of Anhalt, with 12,000 brave troops, did not think himself a match for this furious enemy when at the head of only 2000, till he had entrenched his army behind a ditch, defended by chevaux de frize. It appeared, indeed, that his precaution was not unnecessary: for in the night Charles with his men clambered up the ditch, and attacked the enemy in his usual manner. Numbers, however, at last prevailed; and Charles was obliged to retire, after having seen his favourite Grothusen, General Dardorff and During, the companions of his exile, killed by his side, he himself being wounded in the breast.

157 His desperate valour.

158 Stralsund besieged,

This rash attempt was made in order to save Rugen, whence the town of Stralsund was supplied with provisions. The place was well fortified, and garrisoned with 9000 men, with Charles himself at their head; but nothing could resist the efforts of the enemy. By the 17th of December it was proposed to give the assault. The attack on the horn-work was desperate: the enemy was twice repulsed; but at last, by dint of numbers, effected a lodgment. The next day, Charles headed a sally, in which he dealt terrible destruction among the besiegers, but was at length overpowered and obliged to retreat into the town. At last his officers, apprehending that he must either fall into the hands of the enemy, or be buried in the ruins of the place, intreated him to retire. A retreat, however, was now almost as dangerous as to remain in the town, on account of the fleets of the enemy with which the sea was covered; and it is thought that this very circumstance induced the king to consent to it. Setting out, therefore,

159 and taken, in spite of the utmost efforts of the king.

therefore, in a small boat with sails and oars, he passed all the enemy's ships and batteries, and arrived safe at Ystedt in Schonen.

160

Charles invades Norway to no purpose.

To revenge himself for these losses, Charles invaded Norway with an army of 25,000 men. The Danes were everywhere defeated and pursued with that vigour for which the king of Sweden was so remarkable; but strong reinforcements arriving from Denmark, and provisions failing, he was at last obliged to retire. Soon after this the Swedes lost Wismar; but when every thing seemed hopeless, Baron Goertz the chief minister and favourite of Charles contrived to set on foot a treaty with the tzar of Russia, by which the most formidable of all Charles's enemies was taken off. The minister found means to work on the inflexible temper of Charles, by representing to him that the cession of certain provinces to Peter would induce him to assist him in his projects of again dethroning Augustus, and of replacing James on the throne of Britain; which last scheme he had projected out of revenge for the elector of Hanover having seized on the duchies of Bremen and Verden. In consequence of the conferences between the tzar and Goertz, the former engaged to send into Poland an army of 80,000 men, in order to dethrone that prince whom he had so long defended. He engaged also to furnish ships for transporting 30,000 Swedes to Germany and 10,000 into Denmark. This treaty, however, was not ratified, and the king's death, which happened in 1718, put a final stop to all the great prospects of Sweden.

Charles invades Norway again, and lays siege to Fredericks-hall.

The king had resolved on the conquest of Norway before he dethroned Augustus; and as no difficulties ever deterred him, he marched his army into that cold and barren country in the month of October, when the ground was covered with frost and snow. With 18,000 men he formed the siege of Frederickshall, though the severity of the frost rendered it almost impossible to break ground. Charles resolved to form trenches; and his soldiers cheerfully obeyed, digging into the ground with the same labour as if they had been piercing a rock. On the 11th of December the king visited the trenches in the midst of a terrible fire from the enemy, imagining that his men might be animated by his presence. He took his post in the most dangerous station he could choose, standing on a gabion and leaning with his arm over the parapet, while the enemy were firing chain shot at the very spot where he stood. He was intreated to change his station; but he remained obstinate. At last he was seen to fall on the parapet with a deep groan, and soon afterwards expired, having been mortally wounded, as is supposed, by a cannon ball. See CHARLES XII.

164

Account of the Swedish affairs from the death of Chas. XII. to the year 1771.

Charles XII. was succeeded by his sister the princess Ulrica Eleonora, wife to the hereditary prince of Hesse. On this occasion the states took care to make a previous stipulation for the preservation of their liberties, and obliged the princess to sign a paper to this purpose before entering on the government. Their first care was to make a peace with Great Britain, which the late king intended to have invaded. The Swedes then, to prevent their farther losses by the progress of the Russian, the Danish, the Saxon, and other arms, made many great sacrifices to obtain peace from those powers. The French, however, about the year 1738, formed a dangerous party in the kingdom, which not only broke its internal quiet, but led it into a ruinous war with Russia, by which it lost the province of Finland. Their Swedish majesties having no children, it was necessary to settle the succession; especially as the duke of Holstein was descended from the queen's eldest sister, and was, at the same time, the presumptive heir to the empire of Russia. Four competitors appeared; the duke of Holstein Gottorp, Prince Frederic of Hesse-Cassel nephew to the king, the prince of Denmark, and the duke of Deux-Ponts. The duke of Holstein would have carried the election, had he not embraced the Greek religion, that he might mount the throne of Russia. The tzarina interposed, and offered to restore all the conquests she had made from Sweden, excepting a small district in Finland, if the Swedes would receive the duke of Holstein's uncle, Adolphus Frederic bishop of Lubec, as their hereditary prince and successor to their crown. This was agreed to; and a peace concluded at Abo, under the mediation of his Britannic majesty. This peace was so firmly adhered to by the empress of Russia, that his Danish majesty thought proper to drop all resentment for the indignity done his son. The prince-successor married the princess Ulrica, third sister to the king of Prussia; and in 1751 entered into the possession of his new dignity, which proved to him a crown of thorns. The French had acquired vast influence in all the deliberations of the Swedish senate, who of late had been little better than pensioners to that crown. The intrigues of the senators forced Adolphus to take part in the war against Prussia: but as that war was disagreeable not only to the people, but also to the king of Sweden, the nation never made so mean an appearance; and on Russia's making peace with the king of Prussia, the Swedes likewise made peace. Adolphus died dispirited in 1771, after a turbulent reign of twenty years; and was succeeded by his son Gustavus. The most remarkable transaction of this reign is the revolution which took place in the government in the year 1772, by which the king, from being the most limited became one of the most despotic monarchs in Europe. Ever since the death of Charles XII. the whole power of the kingdom had been lodged in the states; and this power they had much abused. Gustavus therefore determined either to seize on that power of which they made such a bad use, or perish in the attempt. The revolution was effected in the following manner. On the morning of the 19th of August 1772, a considerable number of officers, as well as other persons known to be attached to the royal cause, had been summoned to attend his majesty. Before ten he was on horseback, and visited the regiment of artillery. As he passed through the streets he was more than usually courteous to all he met, bowing familiarly to the lowest of the people. On the king's return to his palace, the detachment which was to mount guard that day being drawn up together with that which was to be relieved, his majesty retired with the officers into the guard-room. He then addressed them with all that eloquence of which he is said to have been a perfect master; and after insinuating to them that his life was in danger, he exposed to them in the strongest colours the wretched state of the kingdom, the shackles in which it was held by means of foreign gold, and the dissensions and troubles arising from the same cause which had distracted the diet during the course of fourteen

Account of the revolution 1772, by which he became despotic.

Sweden.

teen months. He assured them that his only design was to put an end to these disorders; to banish corruption, restore true liberty, and revive the ancient lustre of the Swedish name, which had been long tarnished by a venality as notorious as it was disgraceful. Then assuring them in the strongest terms that he disclaimed for ever all absolute power, or what the Swedes call *sovereignty*, he concluded with these words: "I am obliged to defend my own liberty and that of the kingdom, against the aristocracy which reigns. Will you be faithful to me, as your forefathers were to Gustavus Vasa and Gustavus Adolphus? I will then risk my life for your welfare and that of my country."

The officers, most of them young men, of whose attachment the king had been long secure, who did not thoroughly perhaps see into nature of his majesty's request, were allowed no time to reflect, immediately consented to every thing, and took an oath of fidelity to him.

168 Resolution of a Swedish officer.

Only three refused. One of these, Frederic Cederstrom, captain of a company of the guards, alleged he had already, and very lately, taken an oath to be faithful to the states, and consequently could not take that which his majesty then exacted of him. The king, looking at him sternly, answered, "Think of what you are doing." "I do, (replied Cederstrom); and what I think to day, I shall think to-morrow: and were I capable of breaking the oath by which I am already bound to the states, I should be likewise capable of breaking that which your majesty now requires me to take."

The king then ordered Cederstrom to deliver up his sword, and put him in arrest.

His majesty, however, apprehensive of the impression which the proper and resolute conduct of Cederstrom might make on the minds of the other officers, shortly afterwards softened his tone; and again addressing himself to Cederstrom, told him, that as a proof of the opinion he entertained of him, and the confidence he placed in him, he would return him his sword without insisting on his taking the oath, and would only desire his attendance that day. Cederstrom continued firm; he answered, that his majesty could place no confidence in him that day, and that he begged to be excused from the service.

While the king was shut up with the officers, Senator Ralling, to whom the command of the troops in the town had been given two days before, came to the door of the guard-room, and was told that he could not be admitted. The senator insisted on being present at the distribution of the orders, and sent to the king to desire it; but was answered, he must go to the senate, where his majesty would speak to him.

The officers then received their orders from the king; the first of which was, that the two regiments of guards and of artillery should be immediately assembled, and that a detachment of 36 grenadiers should be posted at the door of the council-chamber to prevent any of the senators from coming out.

But before the orders could be carried into execution, it was necessary that the king should address himself to the soldiers: men wholly unacquainted with his designs, and accustomed to pay obedience only to the orders of the senate, whom they had been taught to hold in the highest reverence.

As his majesty, followed by the officers, was advancing from the guard room to the parade for this purpose, some of them more cautious, or perhaps more timid than the rest, became, on a short reflection, apprehensive of the consequences of the measure in which they were engaged: they began to express their fears to the king, that unless some persons of greater weight and influence than themselves were to take a part in the same cause, he could scarcely hope to succeed in his enterprise. The king stopped a while, and appeared to hesitate. A serjeant of the guards overheard their discourse, and cried aloud,—"It shall succeed—Long live Gustavus!" His majesty immediately said, "Then I will venture;"—and stepping forward to the soldiers, he addressed them in terms nearly similar to those which he had expressed to the officers, and with the same success. They answered him with loud acclamations: one voice only said, No; but it was not attended to.

169 The king gains over the soldiers.

In the mean time some of the king's emissaries had spread a report about the town that the king was arrested. This drew the populace to the palace in great numbers, where they arrived as his majesty had concluded his harangue to the guards. They testified by reiterated shouts their joy at seeing him safe; a joy which promised the happiest conclusion to the business of the day.

170 Secures the senators, and becomes master of the whole power in the kingdom.

The senators were now immediately secured. They had from the window of the council-chamber beheld what was going forward on the parade before the palace; and, at a loss to know the meaning of the shouts they heard, were coming down to inquire into the cause of them, when 30 grenadiers, with their bayonets fixed, informed them it was his majesty's pleasure they should continue where they were. They began to talk in a high tone, but were answered only by having the door shut and locked on them.

The moment the secret committee heard that the senate was arrested, they separated of themselves, each individual providing for his own safety. The king then mounting his horse, followed by his officers with their swords drawn, a large body of soldiers, and numbers of the populace, went to the other quarters of the town where the soldiers he had ordered to be assembled were posted. He found them all equally willing to support his cause, and to take to him an oath of fidelity. As he passed through the streets, he declared to the people, that he only meant to defend them, and save his country; and that if they would not confide in him, he would lay down his sceptre, and surrender up his kingdom. So much was the king beloved, that the people (some of whom even fell down on their knees) with tears in their eyes implored his majesty not to abandon them.

171 Summons an assembly of the states;

The king proceeded in his course, and in less than an hour made himself master of all the military force in Stockholm. In the mean time the heralds, by proclamation in the several quarters of the city, summoned an assembly of the States for the ensuing morning, and declared all members traitors to their country who should not appear. Thither his majesty repaired in all the pomp of royalty, surrounded by his guards, and holding in his hand the silver sceptre of Gustavus Adolphus. In a very forcible speech, he lamented the unhappy state to which the country was reduced by the conduct of a party

Sweden.

party ready to sacrifice every thing to its ambition, and reproached the states with adapting their actions to the views of foreign courts, from which they received the wages of perfidy. "If any one dare contradict this, let him rise and speak."—Conviction, or fear, kept the assembly silent, and the secretary read the new form of government, which the king submitted to the approbation of the states. It consisted of fifty-seven articles; of which the five following were the chief.

172 which accepts a new form of government.

1. The king has the entire power of convoking and dissolving the assembly of the states as often as he thinks proper. 2. His majesty alone has the command of the army, fleet, and finances, and the disposal of all offices civil and military. 3. In case of an invasion, or of any pressing necessity, the king may impose taxes, without waiting for the assembly of the states. 4. The diet can deliberate on no other subjects than those proposed by the king. 5. The king shall not carry on an offensive war without the consent of the states. When all the articles were gone through, the king demanded if the states approved of them, and was answered by a general acclamation. He then dismissed all the senators from their employments, adding, that in a few days he would appoint others; and concluded this extraordinary scene by drawing out of his pocket a small book of psalms, from which, after taking off the crown, he gave out Te Deum. All the members very devoutly added their voices to his, and the hall resounded with thanksgiving.

173 The king makes a good use of his power.

The power thus obtained was employed by the king for the good of his subjects. He took care that the law should be administered with impartiality to the richest noble and the poorest peasant, making a severe example of such judges as were proved to have made justice venal. He gave particular attention and encouragement to commerce, was a liberal and enlightened patron of learning and science, and laboured strenuously to introduce into his kingdom the most valuable improvements in agriculture that had been made in foreign countries.

174 Reforms the army and navy.

But while thus active in promoting the arts of peace, he was not inattentive to those of war. The fleet, which he found decayed and feeble, he in a few years restored to a respectable footing, and, besides changing the regulations of the navy, he raised a new corps of sailors, and formed them to the service by continual exercise. The army, which, as well as the navy, had been neglected during the aristocracy, was next to be reformed. The king began by giving cloaks, tents, and new arms to all the regiments. Afterwards, under the direction of Field Marshal Count de Hessenstein, a new exercise was introduced, and several camps were formed, in which the soldiery were manœuvred by the king himself. The sale of military offices, which had been permitted for many years, was entirely suppressed; and the king provided not only for the re-establishment of discipline and good order in the army, but for the future welfare of the individuals which composed it. These warlike preparations were necessary to a plan which he had formed for entirely abolishing the power of the aristocracy, and freeing Sweden from the factions which had long been formed in it by the court of St Petersburgh. The change which he had introduced was very inimical to the intrigues of that court; and the Russian ambassador exerted himself openly to bring about a rupture between the king and the discontented nobles. Gustavus ordered him to quit the kingdom in eight days, and immediately prepared for war with Russia. To this apparently rash enterprise he was incited by the Ottoman Porte, at that time unable to oppose the armies of the two empires; and his own ambition, together with the internal state of his kingdom, powerfully concurred to make him lend every assistance to his ancient ally. It is needless for us to enter into a detail of the particulars of that war, the principal circumstances of which have already been noticed under RUSSIA, N° 157. Suffice it to say, that neither Gustavus Adolphus nor Charles XII. gave greater proofs of undaunted courage and military conduct in their long and bloody wars than were given by Gustavus the III. from the end of the year 1787 to 1790, when peace was restored between the courts of St Petersburgh and Stockholm. When the court of Copenhagen was compelled, by the means of England and Prussia, to withdraw its troops from the territories of Sweden, the king attacked Russia with such vigour both by sea and land, displayed such address in retrieving his affairs when apparently reduced to the last extremity, and renewed his attacks with such pertinacious courage, that the empress lowered the haughtiness of her tone, and was glad to treat with Gustavus as an equal and independent sovereign.

175 His conduct in the war with Russia.

176 Produces a conspiracy against the king's life. An. 1792.

Sweden now enjoyed peace, but the nobles continued discontented, and a conspiracy was planned against Gustavus under his own roof. He had entered into the alliance that was formed against the revolutionary government of France; and to raise an army, which he was to lead in person to co-operate with the emperor and the king of Prussia, he was obliged to negociate large loans, and to impose on his subjects heavy taxes. The nobles took advantage of that circumstance to prejudice the minds of many of the people against the sovereign who had laboured so long for their good. On the 16th of March 1792 he received an anonymous letter, warning him of his immediate danger from a plot that was laid to take away his life, requesting him to remain at home, and avoid balls for a year; and assuring him that, if he should go to the masquerade for which he was preparing, he would be assassinated that very night. The king read the note with contempt, and at a late hour entered the ball room. After some time he sat down in a box with the compte d'Essen, and observed that he was not deceived in his contempt for the letter, since, had there been any design against his life, no time could be more favourable than that moment. He then mingled, without apprehension, among the crowd; and just as he was preparing to retire in company with the Prussian ambassador, he was surrounded by several persons in masks, one of whom fired a pistol at the back of the king, and lodged the contents in his body. A scene of dreadful confusion immediately ensued. The conspirators, amidst the general tumult and alarm, had time to retire to other parts of the room; but one of them had previously dropped his pistols and a dagger close by the wounded king. A general order was given to all the company to unmask, and the doors were immediately closed; but no person appeared with any particular distinguishing marks of guilt. The king was immediately conveyed to his apartment; and the surgeon, after extracting a ball and some slugs, gave favourable hopes of his recovery.

177 The king dangerously wounded.

178 Death of Gustavus III. An. 1792.

The favourable reports of his medical attendants soon appeared to be fallacious, and on the 28th of March a mortification

Sweden. mortification was found to have taken place. He expired on the following day, and on opening his body there were found within the ribs a square piece of lead and two rusty nails.

The king had by his will appointed a council of regency; but convinced by recent experience how little dependence was to be placed on the attachment of his nobles, and aware of the necessity of a vigorous government in times of such difficulty and danger, he appointed his brother, the duke of Sudermania, sole regent, till his son, then a minor, should attain the age of 18 years. In his dying moments he desired that all the conspirators, except the perpetrator of his murder, might be pardoned.

179 Accession of Gustavus IV.

The young king, who was about 14 at his father's death, was proclaimed by the name of Gustavus IV. The regent soon took the most vigorous and active measures to apprehend and punish the projectors and perpetrators of the murder of his brother. A nobleman of the name of Ankerstrom confessed himself the assassin, and gloried in the action, which he called liberating his country from a monster and a tyrant. He was executed in a most cruel manner on the 17th of May. Two other noblemen, and two officers, also suffered death; but the rest of the conspirators were either pardoned, or punished only by fine and imprisonment.

From the accession of Gustavus IV. till the revolution which has been recently effected in Sweden, few transactions of any importance have occurred. Soon after the king had taken on himself the administration of affairs, he engaged warmly in the war against France, and till the time of his deposition, continued a most faithful ally of Britain. The efforts of the Swedish monarch towards humbling the power of Bonaparte, have been already noticed under the articles BRITAIN and FRANCE; and the war with Russia, in which his alliance with Britain had involved him, has been sufficiently touched in the article RUSSIA. This prince seems to have been endowed with great and amiable qualities, but he was certainly rash and imprudent, and perhaps in some degree tinctured with insanity. He thus materially injured his kingdom, and alienated the affections of his principal nobles, especially of his uncle the duke of Sudermania.

180 Revolution in favour of the duke Sudermania. An. 1809.

In the beginning of March 1809, the plan which appears to have been concerted between the duke of Sudermania and the principal nobility, was carried into effect. The king was arrested; the duke assumed the reins of government, and issued a proclamation, announcing that under existing circumstances, the king was incapable of conducting the affairs of the nation.

Gustavus, now in close custody, was easily prevailed upon to abdicate the government. The diet was assembled; the duke of Sudermania was declared king of Sweden, under the title of Charles XIII.; Prince Augustenberg was chosen crown prince; and various changes were introduced into the constitution, confirming the powers of the diet, and doing away what the prevailing party held to be incroachments of the crown, during the late and preceding reigns. The people, wearied or disgusted by the late king's folly and rashness, readily acquiesced in all the alterations. Peace was then made with Russia, a measure become absolutely necessary, as the military force of the kingdom was completely broken, and no means existed to check the progress of the enemy. By this peace Sweden lost Finland, a country of peculiar importance to her on account of the supplies of grain she was accustomed to draw from it; but in the treaty she reserved the right of importing a certain quantity of grain yearly, duty free. Swedish Finland with Lapmark, now annexed to Russia, was estimated to contain about 120,000 square English miles, with 895,000 inhabitants. Peace was also concluded with France (6th January 1810), who gave up Pomerania.

Sweden was now enjoying tranquillity, when the sudden and unexpected death of the crown prince (Augustenberg) in April 1810, became a new source of perplexity. The duke of Sudermania was old and in a feeble state of health, and as there was no person within the kingdom who had any title by blood to the throne, it was necessary for the security of the new order of things to choose a successor. The threatening position which the acquisition of Finland gave to Russia, induced the noblemen who in concert with the court took a lead in this business, to look out for some man of military talents. It so happened that Bernadotte, prince of Ponte Corvo, who had lately commanded in the north of Germany, had gained the peculiar esteem of the Swedish officers and soldiers he had made prisoners in Gustavus's ill concerted operations in Pomerania, by his liberal and kind treatment. He was besides highly respected for his military skill; and had been still farther raised in general estimation, in consequence of Napoleon having removed him from his command for his lenity and humanity in exercising his power. Some of the Swedish officers, to whom his character was known, first conceived the idea of offering him the succession to the crown. The scheme was for some time kept extremely private; but received so much countenance from the most considerable men, that it was at length opened to Bernadotte himself in Paris. He received it as might be expected; and his friends redoubled their intrigues. The prince of Denmark had been proposed, but the ancient enmity against that country was an invincible obstacle to his success. At length, when every thing was prepared, the diet was called, and Bernadotte was elected crown prince, with acclamations, by all the four orders, on the 21st of July. Of all the changes in the fortune and station of individuals which arose out of the French revolution, this is perhaps the most singular. Bonaparte seized the royal power and dignity for himself, and by force of arms he compelled some of the weaker states to accept his relations and followers as kings. But it does not appear that he was ever consulted as to Bernadotte's elevation, or had the smallest influence in it, except that the example given in his own person and that of his followers, had contributed to destroy some of the old illusions as to birth and hereditary honours, and had prepared men's minds for great innovations. It was thus that the son of a French peasant was raised to the Swedish throne, by the spontaneous choice of a body of nobles, proud of their birth and ancestry.

The appearance of Bernadotte in the Swedish capital was followed by numerous feasts and spectacles. He received congratulations from all the public bodies; and though not immediately called to the throne, was, from the king's infirmities, entrusted with the entire conduct of the government. One of his first acts was to recommend to the diet the introduction of a conscription law like that of France, a measure which certainly hazarded his popularity. It passed however; and on this occasion he prevailed with the nobles, to make a voluntary surrender of their ancient privilege of exemption from military service, and from taxation. Pressed by France and Russia, Sweden in November 1810, professed her adherence to the continental system, and declared war against Britain. The war, however, was only nominal, and the British cruisers returned in most cases their captures untouched. This state of things continued till Bonaparte was preparing for his great Russian campaign, when the Swedish government, solicited by both parties, and tempted by great offers, at length signed treaties of alliance with Russia and Britain in 1812 and 1813. By these treaties, the two powers mentioned engaged to assist the king in conquering Norway from Denmark. The French, for the purpose of intimidation, had previously seized Pomerania. Bernadotte carried over an army of 30,000 Swedes to Germany in 1813, and being joined by several large bodies of Prussian and German troops, he was encountered by Marshal Ney between Berlin and Leipsic on the 6th September, and after an obstinate engagement, drove back the French army with the loss of 16,000 men. In the battle of Leipzic also, fought the 18th October, he bore a conspicuous share. After the victory, he continued to act against Marshal Davoust's corps, and against the Danes, till he made the latter to capitulate. He lost no time in improving this advantage; and by a treaty concluded at Kiel on the 14th January 1814, compelled Denmark to cede Norway, giving her the trifling possession of Pomerania in return. He now advanced to the Rhine; but satisfied with reducing Napoleon's power, and, from views of interest, most probably adverse to ruining him, he was thought to be rather dilatory in pushing his advantages. The success of the allies at length left him at liberty to secure Norway, the prize for which he had fought. As the Norwegians announced their intention to resist, he crossed the frontier with an army in July, and, by judicious manœuvres, which placed the Norwegian force in his power, he obliged them to capitulate, and obtained possession of the country almost without bloodshed; Norway preserving its ancient constitution, and having states of its own. On the death of Charles XIII. in 1818, Bernadotte mounted the throne; and, being on good terms with most of the surrounding powers, has every chance to preserve his situation, and transmit the crown to his posterity.

181 Government.

We have seen, that from the reign of Charles XII. to the revolution under Gustavus III. in 1772, the government of Sweden was a limited monarchy, and that since that time, till the accession of the present king (Charles XIII.) the power of the monarchs was absolute. In 1811, however, the power of the diet was re-established by new regulations. The four estates of nobles, clergy, burghers, and peasants, sit in separate houses, and meet necessarily at the end of five years, or oftener, if convoked by the king. The consent of three of these houses, with that of the king, gives a proposition the form of law. No taxes can be raised without the authority of the diet; and the persons of the members are inviolable during the session. The session lasts three months or longer. The law declares the press to be free; but this provision has not been enforced. The nobles consist of about 1200 families, the heads of which sit in the diet. (See James's Travels, 1817.)

182 Revenues.

The revenue of Sweden and Norway united, is estimated at no more than 1,500,000l. sterling since the peace in 1815. The debt of Sweden in 1816 was 10,209,611 dollars banco, or about 1,480,000l.; and Norway also owes a considerable sum.

183 Military strength.

The army, which amounted to 53,560 men in 1817, is chiefly supported by lands which are assigned to the soldiers to cultivate. The navy is stated to consist of 20 ships of the line, and 16 frigates. The conscription places all the young men from 20 to 25, who are estimated to amount to 80,000, at the disposal of the government for military duty.

184 Religion.

Christianity was introduced into Sweden in the 9th century. Their religion is Lutheran, which was propagated among them by Gustavus Vasa about the year 1523. The Swedes are surprisingly uniform and unremitting in religious matters; and have such an aversion to Popery, that if a Roman Catholic priest be discovered in the country, he is treated with the greatest indignity. The archbishop of Upsal had a revenue of 400l. a-year, and had under him 13 suffragans with moderate stipends. No clergyman had the least direction in the affairs of state. Their morals, and the sanctity of their lives, were such as to endear them to the people. Their churches are neat, and often ornamented. A body of ecclesiastical laws and canons direct their religious economy. A conversion to Popery, or a long continuance under excommunication, which cannot pass without the king's permission, was punishment and exile.

185 Language and literature.

The language of Sweden is a dialect of the Gothic, and nearly allied to those of Denmark, Norway, and Iceland. In the two grand divisions of the Gothic, consisting of the German and Scandinavian dialects, the latter is distinguished by greater brevity and force of expression. In the south of Sweden, which contains the chief mass of population, some German and French words have been adopted; while the Dalecarlian, in the north-west, is esteemed a peculiar dialect, perhaps only because it contains more of the ancient terms and idiom.

In the antiquity of literature, Sweden cannot pretend to vie with Denmark, Norway, or Iceland; the most nearly native chronicle, or perhaps literary composition, being not more ancient than the 14th century. In return, while the Danes seem occupied with internal policy and public regulation, the Swedes have, in modern times, borne the palm of genius in many departments of literature and philosophy.

But Swedish literature can scarcely be said to have dawned till the middle of the 17th century, when Queen Christina, finding the country immersed in ignorance, invited Grotius, Descartes, and other celebrated men, who though they did not reside long in the kingdom, sowed the seed of letters, which gradually began to prosper in the wise and beneficent reign of Charles XI. In the succeeding or 18th century, the name of Linné alone might distinguish the national literature; and it is joined in natural history with those of Scheele, Bergman, Tilas, Wallerius, Quist, Cronstedt, and others. In history, Dalin and Lagerbring have distinguished themselves by a precision and force, which the Danes seem to sacrifice to antiquarian discussions. Sweden also boasts of native poets and orators; and the progress of the sciences

Sweden. ences is supported by the institution of numerous academies.

186 Produce and agriculture. The Swedes, since the days of Charles XII. have been at incredible pains to correct the barrenness of their country, by encouraging agriculture. Wheat is raised only in the southern provinces; rye, oats, barley, and potatoes, are raised in the rest of the kingdom. The whole annual produce of grain, however, was estimated to amount only to 5,700,000 spans, or 1,482,000 quarters in 1810; a quantity not sufficient for the consumption of the country. Potatoes are in general use. The farms are commonly small, and the return of the crops is computed to be 5 for 1. For some years previous to 1812, there had been a progressive rise of prices, and agriculture had considerably improved. But since this period a revulsion seems to have taken place. The common people know, as yet, little of the cultivation of apricots, peaches, nectarines, pine-apples, and other high-flavoured fruits; but melons are brought to the greatest perfection in dry seasons.

187 Manufactures and commerce. The Swedish commonalty subsists by agriculture, mining, hunting, grazing, and fishing. Their materials for traffic are the bulky and useful commodities of masts, beams, and other kinds of timber for shipping; tar, pitch, bark of trees, potash, wooden utensils, hides, flax, hemp, peltry, furs, copper, lead, iron, cordage, and fish.

Even the manufacturing of iron was introduced into Sweden so late as the 16th century; for till then they sold their own crude ore to the Hanse towns, and bought it back again manufactured into utensils. About the middle of the 17th century they set up some manufactures of glass, starch, tin, woollen, silk, soap, leather-dressing, and saw mills. Bookselling was at that time unknown in Sweden. They have since had sugar making, tobacco plantations, and manufactures of sail cloth, cotton, fustian, and other stuffs; also of linen, alum, brimstone, paper mills, and gunpowder-mills. The iron mine of Dannemora is said to yield 60lbs. of metal in 100lbs. of ore, and others about 30lbs. The iron extracted from this is known in Europe by the name of *Oregrund*, which name is derived from a seaport on the Baltic. A large portion of it is employed by different nations for making the best steel. The wood of Sweden is highly valued for some purposes; and Norway has a very considerable trade in timber of various kinds. The Swedes have also founderies for cannon, manufactories for fire-arms and anchors, armories, wire and flatting mills, also mills for fulling, and for boring and stamping; and of late they have built many ships for sale.

According to the tables drawn up by Mr Coxe, the Swedish exports amounted, about 30 years ago, to 1,368,830l. while the imports amounted to 1,008,391l. In 1816 the exports were stated to be about seven millions of dollars (exclusive of Norway), and the imports twenty millions. This real or supposed inequality, accompanied by considerable commercial distress, created a great alarm in the country, and led the government to issue edicts of the nature of sumptuary laws. Wine, rum, and various manufactured articles were prohibited to be imported; and injunctions were issued to the people to lay aside the use of costly articles and every thing considered a luxury. We know not what the result has been, but the indubitable tendency of such measures is to increase the evils they are meant to cure. The imports are chiefly corn, hemp, tobacco, sugar, coffee, drugs, silk, wine, and brandy.

188 Character of the Swedes. The Swedish peasants seem to be a heavy plodding race of men, strong and hardy, but without any other ambition than that of subsisting themselves and their families as well as they can: they are honest, simple, and hospitable; and the mercantile classes are much of the same cast; but great application and perseverance is discovered among them all. The principal nobility and gentry of Sweden are naturally brave, polite, and hospitable; they have high and warm notions of honour, and are jealous of their national interests. The dress of the common people is almost the same with that of Denmark: the better sort are infatuated with French modes and fashions. The common diversions of the Swedes are skating, running races in sledges, and sailing in yachts upon the ice. The women go to plough, thresh out the corn, row upon the water, serve the bricklayers, carry burdens, and do all the common drudgeries in husbandry.

Swedenborg. SWEDENBORG, Emanuel, was born at Stockholm in Sweden, in January 1689. His father was bishop of West Gothland; member of a society for the propagation of the gospel, formed on the plan of that of England; and president of the Swedish church in Pennsylvania and London. To this last office he was appointed by Charles XII. who seems to have had a great regard for the bishop, and to have continued that regard to his son.

Of the course of young Swedenborg's education we have procured no account; but from the character of the father, it may be supposed to have been pious; and by his appearing with reputation as an author, when but 20 years of age, it is proved to have been successful. His first work was published in 1709; and the year following he sent into the world a collection of pieces on different subjects, in Latin verse, under the title of *Ludus Heliconius, sive Carmina Miscellanea quæ variis in locis cecinit.* The same year he began his travels,

S W E

first into England, afterwards into Holland, France, and Germany; and returning to Stockholm in 1714, he was two years afterwards appointed to the office of assessor in the Metallic College by Charles XII. who honoured him with frequent conversations, and bestowed upon him a large share of his favour. At this period of his life Swedenborg devoted his attention principally to physic and mathematical studies; and in 1718 he accompanied the king to the siege of Fredrickshall, where he gave an eminent proof that he had not studied in vain. Charles could not send his heavy artillery to Frederickshall from the badness of the roads, which were then rendered much worse than usual by being deeply covered with snow. In this extremity Swedenborg brought the sciences to the aid of valour. By the help of proper instruments he cut through the mountains, and raised the valleys which separated Sweden from Norway, and then sent to his master two galleys, five large boats, and a sloop, loaded with battering pieces, Swedenborg. pieces, to be employed in the siege. The length of this canal was about two miles and a half. The execution of this great work, however, did not occupy all his time. In 1716 he had begun to publish essays and observations on the mathematical and physical sciences, under the title of *Dædalus Hyperboreus;* and he found leisure during the siege to complete his intended collection, and also in the same year to publish an introduction to algebra, under the whimsical title of *The Art of the Rules.*

At the siege of Frederickshall he lost his patron Charles; but found another in Ulrica Eleonora, the sister and successor of that hero, by whom in 1719 he was ennobled, and took of course his seat among the senators of the equestrian order in the triennial assemblies of the states. His promotion did not lessen his ardour for the sciences; for he published in the same year *A Method to fix the Value of Money, and to determine the Swedish Measures in such a way as to suppress all the Fractions and facilitate the Calculations.* About the same time he gave the public a treatise on *the Position and Course of the Planets;* with another on *the Height of the Tides, and Flux and Reflux of the Sea;* which, from information gathered in different parts of Sweden, appeared to have been greater formerly than when he wrote.

As Swedenborg continued, under the new sovereign, to hold the office of assessor to the Metallic College, he thought it necessary, for the discharge of his duty, to make a second journey into foreign countries, that he might himself examine their mines, particularly those of Saxony and Harts. During these travels, which were undertaken for the improvement of the manufactures of his native country, he printed at Amsterdam, 1. *Prodromus principiorum Naturalium, sive novorum tentaminum, Chemiam et Physicam experimentalem geometricè explicandi.* 2. *Nova observata et inventa circa Ferrum et Ignem, præcipue naturam Ignis Elementarum, una cum nova Camini inventione.* 3. *Methodus nova inveniendi Longitudines locorum terræ marique ope Lunæ.* 4. *Modus construendi receptacula navalia, vulgo en Suedois, Dockybynadder.* 5. *Nova constructio aggeris aquatici.* 6. *Modus explorandi virtutes Navigiorum.* And at Leipsic and Hamburg, 7. *Miscellanea observata circa res naturales, præsertim Mineralia, Ignem, et Montium strata.* (European Magazine, 1787, July.)

This journey was made, and these tracts published, in the compass of a year and a half; and perhaps there has not been another man, Linnæus excepted, who has done so much in so short a time. After his return in 1722, Swedenborg divided his time so equally between the duties of his office and his private studies, that in 1733 he finished his grand work, entitled *Opera Philosophica et Mineralia*, and had it printed under his own direction in 1734, part at Dresden and part at Leipsic; in which year he also went to inspect the mines of Austria and Hungary. This work is divided into three volumes folio; the title of the first is *Principia rerum Naturalium sive novorum tentaminum, Phænomena Mundi elementaris philosophicè explicandi.* The second, *Regnum Subterraneum sive Minerale de Ferro;* and the third, *Regnum Subterraneum sive Minerale de Cupro, et Orichalco;* all of them written with great strength of judgment, and ornamented with plates, to facilitate the comprehension of the text.

In the year 1729 he was enrolled among the members of the Society of Sciences at Upsal, and was, probably about the same time, made a Fellow of the Royal Academy of Sciences at Stockholm; nor were strangers less willing than his own countrymen to acknowledge the greatness of his merit. Wolfius, with many other learned foreigners, was eager to court his correspondence. The Academy of St Petersburg sent him, on the 17th of December 1734, a diploma of association as a correspondent member; and soon afterwards the editors of the *Acta Eruditorum* at Leipsic found in his works a valuable supplement to their own collection. Swedenborg.

By many persons the approbation of learned academies would have been highly valued; but by Baron Swedenborg it was considered as of very little importance. "Whatever of worldly honour and advantage may appear to be in the things before mentioned, I hold them (says he) but as matters of low estimation, when compared to the honour of that holy office to which the Lord himself hath called me, who was graciously pleased to manifest himself to me, his unworthy servant, in a personal appearance, in the year 1743, to open in me a sight of the spiritual world, and to enable me to converse with spirits and angels; and this privilege has continued with me to this day. From that time I began to print and publish various unknown *Arcana*, which have been either seen by me or revealed to me, concerning heaven and hell, the state of men after death, the true worship of God, the spiritual sense of the Scriptures, and many other important truths tending to salvation and true wisdom." (*Short Account of the Honourable E. Swedenborg.*)

We shall not affront the understandings of our readers by making upon this account of the Baron's *call* such reflections as every person of a sound mind will make for himself; but it is rather remarkable, that a man who had devoted the better part of his life to the study of such sciences as generally fortify the mind against the delusions of fanaticism, and who had even excelled in these sciences, should have fallen into such a reverie as this. After this extraordinary call, the Baron dedicated himself wholy to the great work which, he supposed, was assigned him, studying diligently the word of God, and from time to time publishing to his fellow-creatures such important information as was made known to him concerning another world. Among his various discoveries concerning the spiritual world, one is, that it exists not in space. "Of this (says he) I was convinced, because I could there see Africans and Indians very near me, although they are so many miles distant here on earth; nay, that I could be made present with the inhabitants of other planets in our system, and also with the inhabitants of planets that are in other worlds, and revolve about other suns. By virtue of such presence (i. e. without real space), not of place, I have conversed with apostles, departed popes, emperors, and kings; with the late reformers of the church, Luther, Calvin, and Melancthon, and with others from distant countries." (*Swedenborg's Universal Theology*, vol. i. p. 87.)

Notwithstanding the want of space in the spiritual world, he tells us, "that after death a man is so little changed that he even does not know but he is living in the present world; that he eats and drinks, and even enjoys conjugal delight as in this world; that the resemblance between the two worlds is so great, that in the spiritual world there are cities, with palaces and houses, (*Ibid.* N° 734.)

Swedenborg.

houses, and also writings and books, employments and merchandises; that there is gold, silver, and precious stones there. In a word (he says), there is in the spiritual world all and every thing that there is in the natural world, but that in heaven such things are in an infinitely more perfect state."

Such was his zeal in the propagation of these whimsical and sometimes sensual doctrines, that he frequently left his native country to visit distant cities, particularly London and Amsterdam, where all his theological works were printed at a great expence, and with little prospect or probability of a reimbursement. "Where-ever he resided when on his travels, he was (says one of his admirers) a mere solitary, and almost inaccessible, though in his own country of a free and open behaviour. He affected no honour, but declined it; pursued no worldly interest, but spent his time in travelling and printing, in order to communicate instruction and benefit to mankind. He had nothing of the precise in his manner, nothing of melancholy in his temper, and nothing in the least bordering on enthusiasm in his conversation or writings." This is too much. We believe he was an inoffensive visionary; of his conversation we cannot judge; but the specimens that we have given of his writings are frantic enthusiasm. He died at London, March 29th, in the year 1772; and after lying in state, his remains were deposited in a vault at the Swedish church, near Radcliff-Highway.

Short Account, &c. p. 11. and *Harley's Preface to the Treatise on Influx.*

Though Baron Swedenborg's followers appear not to have been numerous during his life, they have increased since his death; and a sect subsists at present in England which derives its origin from him, and is called *the New Jerusalem Church*. The discriminating tenets of this sect seem to be the following: "Holding the doctrine of one God, they maintain that this one God is no other than Jesus Christ, and that he always existed in a human form; that for the sake of redeeming the world, he took upon himself a proper human or material body, but not a human soul; that this redemption consists in bringing the hells or evil spirits into subjection, and the heavens into order and regulation, and thereby preparing the way for a new spiritual church; that without such redemption no man could be saved, nor could the angels retain their state of integrity; that their redemption was effected by means of trials, temptations, or conflicts with evil spirits; and that the last of them, by which Christ glorified his humanity, perfecting the union of his divine with his human nature, was the passion of the cross. Though they maintain that there is but one God, and one divine person, they hold that in this person there is a real Trinity; consisting of the divinity, the humanity, and the operation of them both in the Lord Jesus; a Trinity which did not exist from all eternity, but commenced at the incarnation. They believe that the Scriptures are to be interpreted not only in a literal but in a spiritual sense, not known to the world till it was revealed to B. Swedenborg; and that this spiritual sense extends to every part of Scripture, except the Acts of the Apostles. They believe that there are angels attending upon men, residing, as B. Swedenborg says, in their affections; that temptation consists in a struggle between good and bad angels within men; and that by this means God assists men in these temptations, since of themselves they could do nothing. Indeed B. Swedenborg maintains, that there is an universal influx from God into the souls of men, inspiring them especially with the belief of the divine unity. This efflux of divine light on the spiritual world he compares to the efflux of the light from the sun in the natural world.

Priestley's Letters to the New Jerusalem Church, p. 4, &c.

Swedenborg ‖ Swift.

"There are (says B. Swedenborg) two worlds, the natural and the spiritual, entirely distinct, though perfectly corresponding to each other; that at death a man enters into the spiritual world, when his soul is clothed with a body, which he terms *substantial*, in opposition to the present *material* body, which, he says, is never to rise out of the grave."

SWEEP, in the sea-language, is that part of the mould of a ship where she begins to compass in the rung-heads; also when the hauser is dragged along the bottom of the sea to recover any thing that is sunk, they call this action *sweeping for it*.

SWEET, in the wine trade, denotes any vegetable juice, whether obtained by means of sugar, raisins, or other foreign or domestic fruit, which is added to wines with a design to improve them.

SWEIN-MOT. See *Forest Courts*.

SWERTIA, Marsh Gentian, a genus of plants belonging to the class pentandria, and in the natural system ranging under the 20th order, *rotaceæ*. See Botany *Index*.

SWIETENIA, Mahogany, a genus of plants belonging to the class decandria, and in the natural system arranged under the 54th order, *miscellaneæ*. See Botany and Materia Medica *Index*.

The first use to which mahogany was applied in England, was to make a box for holding candles. Dr Gibbons, an eminent physician in the latter end of the 17th and beginning of the 18th century, had a brother, a West India captain, who brought over some planks of this wood as ballast. As the Doctor was then building a house in King-street, Covent Garden, his brother thought they might be of service to him. But the carpenters, finding the wood too hard for their tools, they were laid aside for a time as useless. Soon after, Mrs Gibbons, wanting a candle-box, the Doctor called on his cabinet-maker to make him one of some wood that lay in his garden. Wollaston, the cabinet-maker also complained that it was too hard. The Doctor said he must get stronger tools. The candle-box was made and approved; insomuch, that the Docter then insisted on having a bureau made of the same wood, which was accordingly done; and the fine colour, polish, &c. were so pleasing, that he invited all his friends to come and see it. Among them was the duchess of Buckingham. Her Grace begged some of the same wood of Dr Gibbons, and employed Wollaston to make her a bureau also; on which the fame of mahogany and Mr Wollaston was much raised, and things of this sort became general.

SWIFT, Dr Jonathan, so universally admired as a wit and classical writer of the English language, was born in Dublin on November 30th 1667. His father was an attorney, and of a good family; but dying poor, the expence of his son's education was defrayed by his friends. At the age of six young Swift was sent to the school of Kilkenny, whence he was removed in his 15th year to Trinity College, Dublin.

In his academical studies (says Dr Johnson) he was either not diligent or not happy. The truth appears to be,

Swift.

be, that he despised them as intricate and useless. He told Mr Sheridan, his last biographer, that he had made many efforts, upon his entering the college, to read some of the old treatises on logic writ by Smeglesius, Keckermannus, Burgersdicius, &c. and that he never had patience to go through three pages of any of them, he was so disgusted at the stupidity of the work. When he was urged by his tutor to make himself master of this branch, then in high estimation, and held essentially necessary to the taking of a degree, Swift asked him, What it was he was to learn from those books? His tutor told him, The art of reasoning. Swift said, That he found no want of any such art; that he could reason very well without it; and that, as far as he could observe, they who had made the greatest proficiency in logic had, instead of the art of reasoning, acquired the art of wrangling; and instead of clearing up obscurities, had learned how to perplex matters that were clear enough before. For his own part, he was contented with that portion of reason which God had given him; and he would leave it to time and experience to strengthen and direct it properly; nor would he run the risk of having it warped or falsely biassed by any system of rules laid down by such stupid writers, of the bad effects of which he had but too many examples before his eyes in those reckoned the most acute logicians. Accordingly, he made a firm resolution, that he never would read any of those books; which he so pertinaciously adhered to, that though his degree was refused him the first time of sitting for it, on account of his not answering in that branch, he went into the hall a second time as ill prepared as before; and would also have been stopped a second time, on the same account, if the interest of his friends, who well knew the inflexibility of his temper, had not stepped in, and obtained it for him; though in a manner little to his credit, as it was inserted in the College Registry, that he obtained it *speciali gratia*, "by special favour;" where it remains upon record. But this circumstance is explained by others, that the favour was in consequence of Swift's distinguished talents.

"He remained in the college near three years after this, not through choice, but necessity, little known or regarded. By scholars he was reckoned a blockhead; and as the lowness of his circumstances would not permit him to keep company with persons of an equal rank with himself, upon an equal footing, he scorned to take up with those of a lower class, or be obliged to those of a higher. He lived therefore much alone, and his time was employed in pursuing his course of reading in history and poetry, then very unfashionable studies for an academic; or in gloomy meditations on his unhappy circumstances. Yet, under this heavy pressure, the force of his genius broke out, in the first rude draught of the Tale of a Tub, written by him at the age of 19, though communicated to nobody but his chamber-fellow Mr Waryng; who, after the publication of the book, made no scruple to declare, that he had read the first sketch of it in Swift's hand-writing when he was of that age."

In 1688, being, by the death of Godwin Swift his uncle, who had chiefly supported him, left without subsistence, he went to consult his mother, who then lived at Leicester, about the future course of his life; and, by her direction, solicited the advice and patronage of Sir William Temple, whose father had lived in great friendship with Godwin Swift. Temple received him with great kindness, and was so much pleased with his conversation, that he detained him two years in his house, and recommended him to King William, who offered to make him a captain of horse. This not suiting his disposition, and Temple not having it quickly in his power to provide for him otherwise, Swift left his patron (1694) in discontent; having previously taken his master's degree at Oxford, by means of a testimonial from Dublin, in which the words of disgrace were omitted. He was resolved to enter into the church, where his first preferment was only 100l. a-year, being the prebend of *Kilroot* in *Conner;* which some time afterwards, upon Sir William Temple's earnestly inviting him back to his house at Moorpark, he resigned in favour of a clergyman far advanced in years and burdened with a numerous family. For this man he solicited the prebend, to which he himself inducted him.

In 1699 Swift lost his patron Sir William Temple, who left him a legacy in money, with the property of his manuscripts; and, on his death-bed, obtained for him a promise from the king of the first prebend that should become vacant at Westminster or Canterbury. That this promise might not be forgotten, Swift dedicated to the king the posthumous works with which he was entrusted, and for a while attended the court; but soon found his solicitations hopeless. He was then invited by the earl of Berkeley to accompany him into Ireland, where, after suffering some cruel disappointments, he obtained the livings of Laracor and Rathbeggin in the diocese of Meath; and soon afterwards invited over the unfortunate Stella, a young woman of the name of Johnson, whose life he contrived to embitter, and whose days, though he certainly loved her, we may confidently affirm, he shortened by his caprice.

This lady is generally believed to have been the daughter of Sir William Temple's steward; but her niece, a Mrs Hearn, assured Mr Berkeley, the editor of a volume of letters intitled *Literary Relics*, that her father was a merchant, and the youngest brother of a good family in Nottingham-shire; that her mother was the intimate friend of Lady Gifford, Sir William's sister; and that she herself was educated in the family with his niece, the late Mr Temple of Moorpark by Farnham *. This story would be intitled to the fullest credit, had not Mrs Hearn affirmed, in the same letter, that before the death of Sir William Temple, Mrs Johnson's little fortune had been greatly injured by the South sea bubbles, which are known to have injured no person till the year 1720: (See COMPANY, II. 1.). When one part of a narrative is so palpably false, the remainder will always be received with hesitation. But whether Miss Johnson was the daughter of Temple's steward or of the friend of Lady Gifford, it is certain that Sir William left her 1000l.; and that, accompanied by Mrs Dingley, whose whole fortune amounted to an annuity of 27l. for life, she went, in consequence of Swift's invitation, to Laracor. With these two ladies he passed his hours of relaxation, and to them he opened his bosom; but they never resided in the same house, nor did he see either without a witness.

* See *Inquiry into the life of Dean Swift, prefixed to Literary Relics*, printed in 1789 for Elliot and Kay.

In 1701, Swift published *A Discourse of the Contests and Dissensions in Athens and Rome*. It was his first work, and indeed the only which he ever expressly acknowledged.

knowledged. According to his constant practice he had concealed his name; but after its appearance, paying a visit to some Irish bishop, he was asked by him if he had read that pamphlet, and what its reputation was in London. Upon his replying that he believed it was very well liked in London; "Very well liked!" said the bishop with some emotion. "Yes, Sir, it is one of the finest tracts that ever was written, and Bishop Burnet is one of the best writers in the world." Swift, who always hated Burnet with something more than political rancour, immediately questioned his right to the work when he was told by the bishop that he was "a young man;" and still persisting to doubt of the justice of Burnet's claim on account of the dissimilarity of the style of the pamphlet from that of his other works, he was told that he was "a very positive young man," as no person in England but Bishop Burnet was capable of writing it. Upon which Swift replied, with some indignation, I am to assure your lordship, however, that Bishop Burnet did *not* write the pamphlet, for I wrote it myself. And thus was he forced in the heat of argument to avow what otherwise he would have for ever concealed.

Early in the ensuing spring King William died; and Swift, on his next visit to London, found Queen Anne upon the throne. It was generally thought, upon this event, that the Tory party would have had the ascendant; but, contrary to all expectation, the Whigs had managed matters so well as to get entirely into the queen's confidence, and to have the whole administration of affairs in their hands. Swift's friends were now in power; and the Whigs in general, knowing him to be the author of the Discourse on the Contests, &c. which was written in defence of King William and his ministers against the violent proceedings of the house of commons, considered themselves as much obliged to him, and looked upon him as fast to their party. But Swift thought with the Whigs only in the state; for with respect to the church his principles were always those of a Tory. He therefore declined any intimate connection with the leaders of the party, who at that time professed what was called *low church principles*. But what above all shocked him, says Mr Sheridan, was their inviting Deists, Freethinkers, Atheists, Jews, and Infidels, to be of their party, under pretence of moderation, and allowing a general liberty of conscience. As Swift was in his heart a man of true religion, he could not have borne, even in his private character, to have mixed with such a motley crew. But when we consider his principles in his political capacity, that he looked upon the church of England, as by law established, to be the main pillar of our newly erected constitution, he could not, consistently with the character of a good citizen, join with those who considered it more as an ornament than a support to the edifice; and could therefore look on with composure while it was undermining, or could even open the gate to a blind multitude, to try, like Sampson, their strength against it, and consider it only as sport. With such a party, neither his religious nor political principles would suffer him to join; and with regard to the Tories, as is usual in the violence of factions, they had run into opposite extremes, equally dangerous to the state. He was therefore during the earlier part of the queen's reign of no party, but employed himself in discharging the duties of his function, and in publishing from time to time such tracts as he thought might be useful. In the year 1704 he published the *Tale of a Tub*, which, considered merely as a work of genius, is unquestionably the greatest which he ever produced; but the levity with which religion was thought to be there treated, raised up enemies to him among all parties, and eventually precluded him from a bishopric. From that period till the year 1708, he seems to have employed himself in solitary study; but he then gave successively to the public *The Sentiments of a Church of England man*, the ridicule of astrology under the name of *Bickerstaff*, the *Argument against abolishing Christianity*, and the defence of the *Sacramental Test*.

Soon after began the busy and important part of Swift's life. He was employed (1710) by the primate of Ireland to solicit the queen for a remission of the first fruits and twentieth parts to the Irish clergy. This introduced him to Mr Harley, afterwards earl of Oxford, who, though a Whig himself, was at the head of the Tory ministry, and in great need of an auxiliary so able as Swift, by whose pen he and the other ministers might be supported in pamphlets, poems, and periodical papers. In the year 1710 was commenced the *Examiner;* of which Swift wrote 33 papers, beginning his first part of it on the 10th of November 1711. The next year he published *the Conduct of the Allies* ten days before the parliament assembled; and soon afterwards, *Reflections on the Barrier Treaty*. The purpose of these pamphlets was to persuade the nation to a peace, by showing that "mines had been exhausted and millions destroyed" to secure the Dutch and aggrandize the emperor, without any advantage whatever to Great Britain. Though these two publications, together with his *Remarks on the Bishop of Sarum's Introduction to the third Volume of his History of the Reformation*, certainly turned the tide of popular opinion, and effectually promoted the designs of the ministry, the best preferment which his friends could venture to give him was the deanery of St Patrick's, which he accepted in 1713. In the midst of his power and his politics he kept a journal of his visits, his walks, his interviews with ministers, and quarrels with his servant, and transmitted to Mrs Johnson and Mrs Dingley, to whom he knew that whatever befel him was interesting: but in 1714 an end was put to his power by the death of the queen, which broke down at once the whole system of Tory politics, and nothing remained for him but to withdraw from persecution to his deanery.

In the triumph of the Whigs, Swift met with every mortification that a spirit like his could possibly be exposed to. The people of Ireland were irritated against him beyond measure; and every indignity was offered him as he walked the streets of Dublin. Nor was he insulted by the rabble only; for persons of distinguished rank and character forgot the decorum of common civility to give him a personal affront. While his pride was hurt by such indignities, his more tender feelings were also often wounded by base ingratitude. In such a situation he found it in vain to struggle against the tide that opposed him. He silently yielded to it, and retired from the world to discharge his duties as a clergyman, and attend to the care of his deanery. That no part of his time might lie heavy on his hands, he employed his leisure hours on some historical attempts relating to the change of the ministers and the conduct of the ministry;

Swift.

and completed the history of the four last years of the queen, which had been begun in her lifetime, but which he never published. Of the work which bears that title, and is said to be his, Dr Johnson doubts the genuineness; and it certainly is not such as we should have expected from a man of Swift's sagacity and opportunities of information.

In the year 1716 he was privately married to Mrs Johnson by Dr Ashe bishop of Clogher; but the marriage made no change in their situation, and it would be difficult to prove (says Lord Orrery) that they were ever afterwards together but in the presence of a third person. The dean of St Patrick's lived in a private manner, known and regarded only by his friends, till about the year 1720 that he published his first political pamphlet relative to Ireland, intitled *A Proposal for the Universal Use of Irish Manufactures;* which so roused the indignation of the ministry that they commenced a prosecution against the printer, and thus drew the attention of the public to the pamphlet, and at once made its author popular.

Whilst he was enjoying the laurels which this work had wreathed for him, his felicity, as well as that of his wife, was interrupted by the death of Mrs Van Homrigh, and the publication of his poem called *Cadenus and Vanessa*, which brought upon him much merited obloquy. With Mrs Van Homrigh he became acquainted in London during his attendance at court; and finding her possessed of genius and fond of literature, he took delight in directing her studies, till he got insensibly possession of her heart. From being proud of his praise, she grew fond of his person; and despising vulgar restraints, she made him sensible that she was ready to receive him as a husband. She had wit, youth, beauty, and a competent fortune to recommend her; and for a while Swift seems to have been undetermined whether or not he should comply with her wish. She had followed him to Ireland, where she lived in a house about twelve miles distant from Dublin; and he continued to visit her occasionally, and to direct her studies as he had done in London; but with these attentions she was not satisfied, and at last sent to him a letter written with great ardour and tenderness, insisting that he should immediately accept or refuse her as a wife. His answer, which probably contained the secret of his marriage, he carried himself; and having indignantly thrown it on the lady's table, instantly quitted the house, we believe without speaking to her, and returned to Dublin to reflect on the consequences of his own conduct. These were dreadful. Mrs Van Homrigh survived her disappointment but a few weeks; during which time she cancelled a will that she had made in his favour, and ordered the poem to be published in which Cadenus had proclaimed her excellence and confessed his love.

His patriotism again burst forth in 1724 to obstruct the currency of Wood's halfpence; and his zeal was crowned with success. Wood had obtained a patent to coin 180,000l. in halfpence and farthings for the kingdom of Ireland; and was about to turn his brass into gold, when Swift, finding that the metal was debased to an enormous degree, wrote letters under the name of *M. B. Drapier* to show the folly of giving gold and silver for coin not worth a third part of its nominal value. A prosecution was carried on against the printer; and Lord Carteret, then lord-lieutenant, issued a proclamation, offering 300l. for discovering the author of the fourth letter. The day after it was published there was a full levee at the castle. The lord-lieutenant was going round the circle, when Swift abruptly entered the chamber, and pushing his way through the crowd, never stopped till he got within the circle; where, with marks of the highest indignation in his countenance, he addressed the lord-lieutenant with the voice of a Stentor, that re-echoed through the room, "So, my lord-lieutenant, this is a glorious exploit that you performed yesterday, in issuing a proclamation against a poor shopkeeper, whose only crime is an honest endeavour to save his country from ruin. You have given a noble specimen of what this devoted nation is to hope for from your government. I suppose you expect a statue of copper will be erected to you for this service done to Wood." He then went on for a long time, inveighing in the bitterest terms against the patent, and displaying in the strongest colours all the fatal consequences of introducing that execrable coin. The whole assembly were struck mute with wonder at this unprecedented scene. For some time a profound silence ensued. When Lord Carteret, who had listened with great composure to the whole speech, made this fine reply, in a line of Virgil's:

Res dura, et regni novitas me talia cogunt
Moliri.

From this time Swift was known by the name of *the Dean*, and was acknowledged by the populace as the champion, patron, and instructor of Ireland.

In 1727 he returned to England; where, in conjunction with Pope, he collected three volumes of miscellanies; and the same year he sent into the world his *Gulliver's Travels*, a production which was read by the high and the low, and filled every reader with a mingled emotion of merriment and amazement. Whilst he was enjoying the reputation of this work, he was suddenly called to a home of sorrow. Poor Stella was sinking into the grave; and after a languishing decay of about two months, died in her 44th year, on January 28. 1728. How much he wished her life is shown by his papers; nor can it be doubted that he dreaded the death of her whom he loved most, aggravated by the consciousness that himself had hastened it. With her vanished all his domestic enjoyments, and of course he turned his thoughts more to public affairs; in the contemplation of which he could see nothing but what served to increase the malady. The advances of old age, with all its attendant infirmities; the death of almost all his old friends; the frequent returns of his most dispiriting maladies, deafness and giddiness; and, above all, the dreadful apprehensions that he should outlive his understanding, made life such a burden to him, that he had no hope left but a speedy dissolution, which was the object of his daily prayer to the Almighty.

The severity of his temper increasing, he drove his acquaintance from his table, and wondered why he was deserted. In 1732, he complains, in a letter to Mr Gay, that "he had a large house, and should hardly find one visitor if he was not able to hire him with a bottle of wine:" and, in another to Mr Pope, "that he was in danger of dying poor and friendless, even his female friends having forsaken him; which," as he says, "vexed

Swift.

ed him most." These complaints were afterwards repeated in a strain of yet greater sensibility: "All my friends have forsaken me.

"*Vertiginosus, inops, surdus, male gratus amicis.*

"Deaf, giddy, helpless, left alone,
"To all my friends a burden grown."

The fits of giddiness and deafness to which he had been subjected from his boyish years, and for which he thought walking or riding the best remedy, became more frequent and violent as he grew old; and the presentiment which he had long entertained of that wretchedness which would inevitably overtake him towards the close of life, clouded his mind with melancholy and tinged every object around him. How miserable he was rendered by that gloomy prospect, we may learn from the following remarkable anecdote mentioned by Mr Faulkner in his letter to Lord Chesterfield. "One time, in a journey from Drogheda to Navan, the dean rode before the company, made a sudden stop, dismounted from his horse, fell on his knees, lifted up his hands, and prayed in the most devout manner. When his friends came up, he desired and insisted on their alighting; which they did, and asked him the meaning. "Gentlemen," said he, "pray join your hearts in fervent prayers with mine, that I may never be like this oak-tree, which is decayed and withered at top, while the other parts are sound." In 1736, while he was writing a satire called the *Legion Club* against the Irish parliament, he was seized with so dreadful a fit of his malady, that he left the poem unfinished; and never after attempted a composition that required a course of thinking. From this time his memory gradually declined, his passions perverted his understanding, and, in 1741, he became utterly incapable of conversation; and it was found necessary to appoint legal guardians to his person and his fortune. He now lost all sense of distinction. His meat was brought to him cut into mouthfuls; and he would never touch it while the servant staid; and at last, after it stood perhaps an hour, would eat it walking; for he continued his old habit, and was on his feet ten hours a day. During next year a short interval of reason ensuing, gave hopes of his recovery; but in a few days he sunk into lethargic stupidity, motionless, heedless, and speechless. After a year of total silence, however, when his housekeeper told him that the usual illuminations were preparing to celebrate his birth, he answered, "It is all folly; they had better let it alone." He at last sunk into a perfect silence, which continued till the 29th of October 1745, when he expired without a struggle, in his 78th year. The behaviour of the citizens on this occasion gave the strongest proof of the deep impression he had made on their minds. Though he had been so many years to all intents and purposes dead to the world, and his departure from that state seemed a thing rather to be wished than deplored, yet no sooner was his death announced, than they gathered from all quarters, and forced their way in crowds into the house, to pay the last tribute of grief to their departed benefactor. Nothing but lamentations were heard all around the quarter where he lived, as if he had been cut off in the vigour of his years. Happy were they who first got into the chamber where he lay, to procure, by bribes to the servants, locks of his hair, to be handed down as sacred relics to their posterity; and so eager were numbers to obtain at any price this precious memorial, that in less than an hour, his venerable head was entirely stripped of all its silver ornaments, so that not a hair remained. By his will, which was dated in May 1740, just before he ceased to be a reasonable being, he left about 1200l. in specific legacies; and the rest of his fortune, which amounted to about 11,000l. to erect and endow an hospital for lunatics and idiots. He was buried in the most private manner, according to directions in his will, in the great aisle of St Patrick's cathedral, and, by way of monument, a slab of black marble was placed against the wall, on which was engraved the following Latin epitaph, written by himself:

Hic depositum est corpus
JONATHAN SWIFT, S. T. P.
Hujus Ecclesiæ Cathedralis
Decani:
Ubi sæva indignatio
Ulterius cor lacerare nequit.
Abi, viator,
Et imitare, si poteris,
Strenuum pro virili libertatis vindicem.
Obiit anno (1745)
Mensis (Octobris) die (29.)
Ætatis anno 78.

Swift undoubtedly was a man of native genius. His fancy was inexhaustible; his conceptions were lively and comprehensive; and he had the peculiar felicity of conveying them in language equally correct, free, and perspicuous. His penetration was as quick as intuition; he was indeed the critic of nature; and no man ever wrote so much and borrowed so little.

As his genius was of the first class, so were some of his virtues. The following anecdote will illustrate his filial piety. His mother died in 1710, as appears by a memorandum in one of the account-books which Dr Swift always made up yearly, and on each page entered minutely all his receipts and expences in every month, beginning his year from November 1. He observed the same method all his lifetime till his last illness. At the foot of that page which includes his expences of the month of May 1710, at the glebe house of Laracor in the county of Meath, where he was then resident, are these remarkable words, which show at the same time his filial piety, and the religious use which he thought it his duty to make of that melancholy event. "*Mem.* On Wednesday, between seven and eight in the evening, May 10. 1710. I received a letter in my chamber at Laracor (Mr Percival and Jo. Beaumont being by) from Mrs F—, dated May 9, with one inclosed, sent by Mrs Worral at Leicester to Mrs F—, giving an account that my dear mother, Mrs Abigail Swift, died that morning, Monday April 24. 1710, about ten o'clock, after a long sickness: being ill all winter, and lame; and extremely ill about a month or six weeks before her death. I have now lost my barrier between me and death. God grant I may live to be as well prepared for it as I confidently believe her to have been! If the way to heaven be through piety, truth, justice, and charity, she is there. J. S." He always treated his mother, during her life, with the utmost duty and affection; and she sometimes came to Ireland to visit him after his settlement at Laracor.

The liberality of the dean hath been a topic of just

Swift. encomium with all his admirers; nor could his enemies deny him this praise. In his domestic affairs, he always acted with strict economy. He kept the most regular accounts; and he seems to have done this chiefly with a view to increase his power of being useful. "His income, which was little more than 700l. per annum, he endeavoured to divide into three parts, for the following purposes. First, to live upon one-third of it. Secondly, to give another third in pensions and charities, according to the manner in which persons who received them had lived: and the other third he laid by, to build an hospital for the reception of idiots and lunatics." "What is remarkable in this generous man, is this (says Mr F.), that when he lent money upon bond or mortgage, he would not take the legal interest, but one per cent. below it."

His charity appears to have been a settled principle of duty more than an instinctive effort of good nature: but as it was thus founded and supported, it had extraordinary merit, and seldom failed to exert itself in a manner that contributed most to render it beneficial. He did not lavish his money on the idle and the worthless. He nicely discriminated characters, and was seldom the dupe of imposition. Hence his generosity always turned to an useful account; while it relieved distress, it encouraged industry, and rewarded virtue. We dwell with great pleasure on this truly excellent and distinguishing part of the dean's character: and for the sake of his charity we can overlook his oddities, and almost forgive his faults. He was a very peculiar man in every respect. Some have said, "What a man he would have been, had he been without those whims and infirmities which shaded both his genius and his character!" But perhaps the peculiarities complained of were inseparable from his genius. The vigour and fertility of the root could not fail now and then of throwing out superfluous suckers. What produced these, produced also the more beautiful branches, and gave the fruit all its richness.

It must be acknowledged, that the dean's fancy hurried him into great absurdities and inconsistencies, for which nothing but his extraordinary talents and noble virtues, discovered in other instances, could have atoned. The rancour he discovered on all occasions towards the dissenters is totally unjustifiable. No sect could have merited it in the degree in which he always showed it to them; for, in some instances, it bordered on downright persecution. He doubtless had his reasons for exposing their principles to ridicule, and might perhaps have sufficient grounds for some of his accusations against their principal leaders in Ireland; but nothing could justify his virulence against the whole body. In a short poem on one class of dissenters he bestowed a stricture upon Bettesworth, a lawyer eminent for his insolence to the clergy, which, from a very considerable reputation, brought him into immediate and universal contempt. Bettesworth, enraged at his disgrace and loss, went to the dean, and demanded whether he was the author of that poem? "Mr Bettesworth (answered he), I was in my youth acquainted with great lawyers, who, knowing my disposition to satire, advised me, if any *scoundrel* or *blockhead* whom I had lampooned should ask, 'Are you the author of this paper?', to tell him that I was not the author; and therefore, I tell *you*, Mr Bettesworth, that I am not the author of these lines."

Swift has been accused of irreligion and misanthropy, on account of his Tale of a Tub, and his Yahoos in Gulliver's Travels; but both charges seem to be ill-founded, or at least not supported by that evidence. The *Tale of a Tub* holds up to ridicule superstitious and fanatical absurdities; but it never attacks the essentials of religion: and in the story of the *Yahoos*, disgusting we confess, there appears to us as little evidence that the author hated his own species, as in the poems of *Strephon and Chloe*, and the *Ladies Dressing room*, that he approved of grossness and filth in the female sex. We do not indeed, with his fondest admirers, perceive the moral tendency of the Voyage to the Houyhnhnms, or consider it as a satire admirably calculated to reform mankind; but neither do we think that it can possibly corrupt them, or lead them to think meanly of their rational nature. According to Sheridan, "the design of this apologue is to place before the eyes of man a picture of the two different parts of his frame, detached from each other, in order that he may the better estimate the true value of each, and see the necessity there is that the one should have an absolute command over the other. In your merely animal capacity, says he to man, without reason to guide you, and actuated only by a blind instinct, I will show you that you would be degraded below the beasts of the field. That very form, that very body, you are now so proud of, as giving you such a superiority over all other animals, I will show you, owe all their beauty, and all their greatest powers, to their being actuated by a rational soul. Let that be withdrawn, let the body be inhabited by the mind of a brute, let it be prone as theirs are, and suffered like theirs to take its natural course, without any assistance from art, you would in that case be the most deformed, as to your external appearance, the most detestable of all creatures. And with regard to your internal frame, filled with all the evil dispositions and malignant passions of mankind, you would be the most miserable of beings, living in a continued state of internal vexation, and of hatred and warfare with each other.

"On the other hand, I will show another picture of an animal endowed with a rational soul, and acting uniformly up to the dictates of right reason. Here you may see collected all the virtues, all the great qualities, which dignify man's nature and constitute the happiness of his life. What is the natural inference to be drawn from these two different representations? Is it not evidently a lesson to mankind, warning them not to suffer the animal part to be predominant in them, lest they resemble the vile Yahoo, and fall into vice and misery; but to emulate the noble and generous Houyhnhnm, by cultivating the rational faculty to the utmost; which will lead them to a life of virtue and happiness."

Such *may* have been the author's intention; but it is not sufficiently obvious to produce the proper effect, and is indeed hardly consistent with that incapability under which he represents the Yahoos of ever acquiring, by any culture, the virtues of the noble Houyhnhnms.

With respect to his religon, it is a fact unquestionable, that while the power of speech remained, he continued constant in the performance of his private devotions; and in proportion as his memory failed, they were

Swift.

were gradually shortened, till at last he could only repeat the Lord's prayer, which he continued to do till the power of utterance for ever ceased. Such a habit as this could not have been formed but by a man deeply impressed with a conviction of the truth and importance of revelation.

The most inexcusable part of Swift's conduct is his treatment of Stella and Vanessa, for which no proper apology can be made, and which the vain attempts of his friends have only tended to aggravate. One attributes his singular conduct to a peculiarity in his constitution; but if he knew that he was incapable of fulfilling the duties of the married state, how came he to tie one of the ladies to himself by the marriage ceremony, and in the most explicit terms to declare his passion to the other? And what are we to think of the sensibility of a man who, strongly attached as he seems to have been to both, could, without speaking, fling a paper on the table of the one, which "proved (as our author expresses it) her death-warrant," and could throw the other, his beloved Stella, in her last illness, into unspeakable agonies, and "never see her more, for only adjuring him, by their friendship, to let her have the satisfaction of dying at least, though she had not lived, his acknowledged wife?" Another apologist insinuates, upon something like evidence, that Stella bore a son to Swift, and yet labours to excuse him for not declaring her his wife, because she had agreed at the marriage that it should remain a secret from all the world unless the discovery should be called for by *urgent necessity;* but what could be meant by the term *urgent necessity*, unless it alluded to the birth of children, he confesses that it would be hard to say. The truth we believe to be what has been said by Johnson, that the man whom Stella had the misfortune to love was fond of singularity, and desirous to make a mode of happiness for himself different from the general course of things and the order of Providence; he wished for all the pleasures of perfect friendship, without the uneasiness of conjugal restraint. But with this state poor Stella was not satisfied; she never was treated as a wife, and to the world she had the appearance of a mistress. She lived sullenly on, hoping that in time he would own and receive her. This, we believe, he offered at last to do, but not till the change of his manners and the depravation of his mind made her tell him, that "it was too late."

The natural acrimony of Swift's temper had been increased by repeated disappointments. This gave a splenetic tincture to his writings, and amidst the duties of private and domestic life it too frequently appeared to shade the lustre of his more eminent virtues.—The dean hath been accused of avarice, but with the same truth as he hath been accused of infidelity. In detached views, no man was more liable to be mistaken. Even his genius and good sense might be questioned, if we were only to read some passages of his writings. To judge fairly and pronounce justly of him as a man and as an author, we should examine the uniform tenor of his disposition and conduct, and the general nature and design of his productions. In the latter he will appear great, and in the former good; notwithstanding the puns and puerilities of the one, and the absurdities and inconsistencies of the other.

SWIFT, a species of swallow. See HIRUNDO, ORNITHOLOGY *Index*.

Swimming.

SWIMMING, the art of suspending one's self on water, and at the same time making a progressive motion through it.

1
Swimming not natural to man.

As swimming is not natural to man, it is evident that at some period it must have been unknown among the human race. Nevertheless there are no accounts of its origin to be found in the history of any nation; nor are there any nations so barbarous but that the art of swimming is known among them, and that in greater perfection than among civilized people. It is probable, therefore, that the art, though not absolutely natural, will always be acquired by people in a savage state from imitating the brute animals, most of whom swim naturally. Indeed so much does this appear to be the case, that very expert swimmers have recommended it to those who wished to learn the art, to keep some frogs in a tub of water constantly beside them, and to imitate the motions by which they move through that element.

2
Depends on a simple principle.

The theory of swimming depends upon one very simple principle; namely, that if a force be applied to any body, it will always move towards that side where there is the least resistance. Thus, if a person standing in a boat pushes with a pole against the side or any other part of the vessel in which he stands, no motion will ensue; for as much as he presses in one direction with the pole, just so much does the action of his feet, on which the pressure of the pole must ultimately rest, push the vessel the other way: but if, instead of the side of the vessel, he pushes the pole against the shore, then only one force acts upon it, namely, that of the feet; which being resisted only by the fluid water, the boat begins to move from the shore. Now the very same thing takes place in swimming, whether the animal be man, quadruped, bird, or fish. If we consider the matter simply, we may suppose an animal in such a situation that it could not possibly swim: thus, if we cut off the fins and tail of a fish, it will indeed float in consequence of being specifically lighter than the water, but cannot make any progressive motion, or at least but very little, in consequence of wriggling its body; but if we allow it to keep any of its fins, by striking them against the water in any direction, the body moves the contrary way, just as a boat moves the contrary way to that in which the oars strike the water. It is true, that as the boat is but partly immerged in the water, the resistance is comparatively less than when a frog or even any other quadruped swims; but a boat could certainly be rowed with oars though it was totally immerged in water, only with less velocity than when it is not. When a man swims, he in like manner strikes the water with his hands, arms, and feet; in consequence of which the body moves in a direction contrary to the stroke. Upon this principle, and on this only, a man may either ascend, descend, or move obliquely in any possible direction, in the water. One would think, indeed, that as the strength of a man's arms and legs is but small, he could make but very little way by any stroke he could give the water, considering the fluidity of that element. Nevertheless it is incredible what expert swimmers will perform in this way; of which Mr Forster gives a most remarkable instance in the inhabitants of Otaheite; whose agility, he tells us, was such, that when a nail was thrown overboard, they would jump after it into the sea, and never fail to catch it before it reached to the bottom.

As to the practice of swimming, there are but few directions

Swimming directions which can be given. The great obstacle is the natural dread which people have of being drowned; and this it is impossible to overcome by any thing but accustoming ourselves to go into the water. With regard to the real danger of being drowned, it is but little; and on innumerable occasions arises entirely from the terror above mentioned, as will appear from the following observations by Dr Franklin.

3 Observations by Dr Franklin.

"1st, That though the legs, arms, and head, of a human body, being solid parts, are specifically somewhat heavier than fresh water, yet the trunk, particularly the upper part, from its hollowness, is so much lighter than water, as that the whole of the body, taken together, is too light to sink wholly under water, but some part will remain above until the lungs become filled with water; which happens from drawing water into them instead of air, when a person in the fright attempts breathing while the mouth and nostrils are under water.

"2dly, That the legs and arms are specifically lighter than salt water, and will be supported by it; so that a human body would not sink in salt water though the lungs were filled as above, but from the greater specific gravity of the head.

"3dly, That therefore a person throwing himself on his back in salt water, and extending his arms, may easily lie so as to keep his mouth and nostrils free from breathing; and by a small motion of his hands may prevent turning, if he should perceive any tendency to it.

"4thly, That in fresh water, if a man throws himself on his back near the surface, he cannot long continue in that situation, but by a proper action of his hands on the water. If he uses no such action, the legs and lower part of the body will gradually sink till he comes into an upright position; in which he will continue suspended, the hollow of the breast keeping the head uppermost.

"5thly, But if in this erect position the head is kept upright above the shoulders, as when we stand on the ground, the immersion will, by the weight of that part of the head that is out of the water, reach above the mouth and nostrils, perhaps a little above the eyes; so that a man cannot long remain suspended in water with his head in that position.

"6thly, The body continued suspended as before, and upright, if the head be leaned quite back, so that the face looks upwards, all the back part of the head being then under water, and its weight consequently in a great measure supported by it, the face will remain above water quite free for breathing, will rise an inch higher every inspiration, and sink as much every expiration, but never so low as that the water may come over the mouth.

"7thly, If therefore a person unacquainted with swimming, and falling accidentally into the water, could have presence of mind sufficient to avoid struggling and plunging, and let the body take this natural position, he might continue long safe from drowning, till perhaps help would come; for as to the clothes, their additional weight while immersed is very inconsiderable, the water supporting it; though when he comes out of the water, he would find them very heavy indeed."

4 His method of learning to swim.

The method of learning to swim is as follows: The person must walk into water so deep that it will reach to the breast. He is then to lie down gently on the belly, keeping the head and neck perfectly upright, the breast advancing forward, the thorax inflated, and the back bent; then withdrawing the legs from the bottom, and stretching them out, strike the arms forwards in unison with the legs. Swimming on the back is somewhat similar to that on the belly; but with this difference, that although the legs are employed to move the body forwards, the arms are generally unemployed, and the progressive motion is derived from the movement of the legs. In diving, a person must close his hands together, and, pressing his chin upon his breast, make an exertion to bend with force forwards. While in that position, he must continue to move with rapidity under the surface; and whenever he chooses to return to his former situation, he has nothing to do but bend back his head, and he will immediately return to the surface.

It is very common for novices in the art of swimming to make use of corks or bladders to assist in keeping the body above water. Some have utterly condemned the use of these; however, Dr Franklin allows that they may be of service for supporting the body while one is learning what is called the *stroke*, or that manner of drawing in and striking out the hands and feet that is necessary to produce progressive motion. "But (says he) you will be no swimmer till you can place confidence in the power of the water to support you: I would therefore advise the acquiring that confidence in the first place, especially as I have known several who, by a little of the practice necessary for that purpose, have insensibly acquired the stroke, taught as it were by nature.

5 and of acquiring confidence.

"The practice I mean is this: Choosing a place where the water deepens gradually, walk coolly into it till it is up to your breast: then turn round your face to the shore, and throw an egg into the water, between you and the shore; it will sink to the bottom, and be easily seen there, if the water is clear. It must lie in the water so deep as that you cannot reach it to take it up but by diving for it. To encourage yourself in order to do this, reflect that your progress will be from deeper to shallower water; and that at any time you may, by bringing your legs under you, and standing on the bottom, raise your head far above the water: then plunge under it with your eyes open, throwing yourself towards the egg, and endeavouring, by the action of your hands and feet against the water, to get forward till within reach of it. In this attempt you will find that the water buoys you up against your inclination; and it is not so easy a thing to sink as you imagined; that you cannot but by active force get down to the egg. Thus you feel the power of the water to support you, and learn to confide in that power; while your endeavours to overcome it, and to reach the egg, teach you the manner of acting on the water with your feet and hands; which action is afterwards used in swimming to support your head higher above water, or to go forward through it."

6 Swimming a pleasant and useful exercise.

As swimming is a healthy exercise and a pleasant amusement, and as a dexterity in it may frequently put it in a man's power to save his own life and the lives of his fellow-creatures, perhaps of his dearest friends, it can neither be useless nor uninteresting to consider a few of the evolutions which a swimmer must be master of, that he move in any direction without difficulty, without danger, and without being unnecessarily fatigued.

These

Swimming. 7 How to turn to the right or left.

There are several different ways of turning one's self in swimming. You may do it in this way: Turn the palm of the right hand outwards, extend the arm in the same manner, and make a contrary movement with the left hand and left arm; then, by a gradual motion, incline your head and whole body to the left side, and the evolution will be finished. There is another way which is easier still: Bend your head and body toward that side to which you are going to turn. If you wish to turn to the left, incline the thumb and the right hand toward the bottom, bend the fingers of the right hand, stretch it out, and use it for driving away the water sidewise, or, which is the same thing, for pushing yourself the contrary way. At the same time, with your left hand, the fingers being close, push the water behind you, and all at once turn your body and your face to the left, and the manœuvre will be accomplished. If you wish to turn to the right, you must do with your right hand what you did with your left, and with your left what you did with your right. You must be careful when turning yourself never to stretch out your legs, and be sure that the water be so deep that you be in no danger of hurting yourself.

8 How to turn from the belly to the back.

When you are swimming on your belly, and wish to turn on your back, draw your feet in quickly, and throw them before you; stretch out your hands behind you, and keep your body firm and steady. When you wish to turn from swimming on your back, fold your feet at once under your body as if you were throwing them to the bottom, and at the same instant dart your body forwards, that you may fall upon your belly.

9 The eyes ought to be turned towards heaven.

In swimming, the eyes ought to be turned towards heaven. This is a most important rule, and to the neglect of it many of the accidents which befal swimmers are owing. For when they bend their eyes downwards, they insensibly bend their head too, and thus the mouth being too deep in the water, may admit a quantity of it in breaking; besides, the more the body is stretched, it covers a greater part of the surface of the water, and consequently its specific gravity is less. Any person who will make the experiment will find it impossible to dive while he keeps his head erect and his eyes fixed on the heavens (A).

10 How to swim on the back,

The easiest posture in swimming is lying on the back. When you wish to swim in this posture, lay yourself softly on your back, and raise your breast to the surface of the water, keeping your body extended in the same line. Put your hands easily over the upper part of your thighs, and throw out your legs and draw them in alternately keeping them within two feet of the surface. In this way you may advance in any direction you please. You may perhaps not like having so much of your head under water; there is, however, no way of swimming so easy, so safe, and so little fatiguing. If you wish to swim with great rapidity, you may use your arms as well as your feet; and you will find this the easiest way of breaking the force of the waves.

11 and advance forward.

In swimming on the back, one may advance forward as well as backward. For this purpose the body must be kept straight and extended; the breast inflated, so that the hollow of the back may assume a semicircular form. The hands must recline over the upper parts of the thighs. It is also necessary to raise the legs one after another, and draw them in strongly towards the hams, and then leave them suspended in the water. This way of swimming is not only pleasant, but may serve to rest you when fatigued.

12 How to swim on one side.

When you are tired with swimming on your back and belly, you may swim on one side. When you wish to do this, sink a little your left side and raise your right; you will immediately find yourself on your left side. Move then your left hand without either raising or sinking it; you have only to stretch it and draw it back, as in a straight line, on the surface of the water. Independent of the pleasure which this kind of motion will give you, you will have the satisfaction of seeing both sides of the river.

13 How to swim on the belly without the assistance of the hands.

It is possible to swim on the belly without the assistance of the hands. For this purpose you must keep your breast erect, your neck straight, and fix your hands behind your head, or upon your back, while you move forward by employing your feet. This way is not without its advantages. It is an excellent resource when the arms are seized with a cramp, or with any indisposition which makes it painful to exert them. This in some cases may be preferable to swimming on the back; for while in that attitude, one cannot see before them without turning every instant. If one of your legs be seized with a cramp, take hold of it with the hand opposite to it, and use the other hand and leg to advance or support yourself.

14 How to swim with the hands joined.

A very ancient and graceful mode of swimming, is that of swimming with the hands joined. When you wish to put this in practice, join your hands, keeping the thumbs and fingers towards heaven, so that they may appear above the water; then draw them back and push them forwards alternately from your breast. This method of swimming may be useful in several circumstances, but above all if you are entangled with grass or weeds. Your hands will then open a passage for you.

15 With the hands elevated.

As a person may sometimes have occasion to carry something in his hand in swimming, which he is anxious to preserve from the water, he may swim easily with one hand and hold a parcel in the other, as Cæsar swam with his Commentaries at Alexandria; or one may swim with both hands elevated. To perform this well, the swimmer must raise his breast, and keep it as much inflated as

(A) An interesting question occurs here, which deserves to be considered. Since the body, when spread upon the surface, can be supported with so little exertion, and frequently without any at all, as in swimming on the back, how comes it to pass that a person when drowned sinks and frequently rises again some time afterwards? The reason is this: In the act of drowning, the lungs are filled with water, and consequently the body, being specifically heavier, sinks. It is well known that the human body contains a great quantity of air: this air is at first compressed by the water; and while this is the case the body remains at the bottom: but as soon as the air by its elasticity endeavours to disengage itself from the compression, they body is swelled and expanded, becomes specifically lighter than the water, and consequently rises to the top.

Swimming || Switzerland. as he can, at the same time that he supports the arms above the water. It must not be concealed, that this method of swimming is attended with some danger to one who is not dexterous at the art; for if one should imprudently draw in his breast, when his arms are raised, he would immediately sink to the bottom.

16 How to rise to the surface after diving. When a man plunges into the water, and has reached the bottom, he has only to give a small stroke which his foot against the ground, in order to rise; but an experienced swimmer, if he misses the ground, has recourse to another expedient, which is very pretty, and which has not been much considered. Suppose him at a considerable depth, when he perceives that he cannot reach the bottom. In such a case, he first puts his hands before his face, at the height of his forehead, with the palms turned outwardly; then holding the fore part of his arm vertically, he makes them move backwards and forwards from right to left; that is to say, these two parts of his arms, having the elbow as a kind of pivot, describe very quickly, both the hands being open, and the fingers joined, two small portions of a circle before the forehead, as if he would make the water retire, which he in fact does; and from these strokes given to the water, there results an oblique force, one part of which carries the swimmer upwards.

There are many artificial methods of supporting one's self in water, but we have not room to describe them.—Those who wish to see a full account of them may consult the *Encyclopédie Methodique*.

Swimming of Fish. A great proportion of the inhabitants of the waters have an air-bladder, by which they poise themselves. Their movements chiefly depend upon their tail. See ANATOMY, Part II.; and ICHTHYOLOGY.

SWINDLER, a word which has been lately adopted into the English language, derived from the German word *schwindel*, "to cheat." Swindling has now become so common in several of the great towns of this country, that it is unfortunately too well known to require any description.

SWINE. See SUS, MAMMALIA *Index*.

Swine-Stone. See MINERALOGY *Index*.

SWINGING, a kind of exercise strongly recommended to persons in consumption by some physicians, and disapproved of by others. See MEDICINE *Index*.

SWING-TREE of a waggon, is the bar fastened across the fore-guide, to which the traces of the horses are fastened.

Swing-Wheel, in a royal pendulum, that wheel which drives the pendulum. In a watch or balance clock it is called the crown-wheel.

SWINGLE, in the fireworks in England, the wooden spoke which is fixed to the barrel that draws the wire, and which, by its being forced back by the cogs of the wheel, is the occasion of the force with which the barrel is pulled.

SWITZ, or SCHWEITS, the capital of one of the cantons of Switzerland, to which it gives name, seated on the east side of the lake Lucerne, in N. Lat. 46. 55. E. Long. 8. 30.

1 Situation. SWISSERLAND, or SWITZERLAND, a mountainous district of the south of Europe, forming a republic composed of several independent states or cantons, each governed by its own council and laws, but united into one body by a federal constitution.

2 Boundaries and extent. Switzerland is bounded on the north and east by Germany, on the south by Italy, and on the west by the departments of the Higher and Lower Alps, and the mouths of the Rhone. Its extent from east to west is computed at about 200 British miles, and its breadth from north to south at about 130 British miles. Its area in square English miles is estimated at 23,000.

3 Divisions. Before the French revolution, Switzerland contained 13 independent cantons, and a number of small districts, which were dependent on the cantons. The independent cantons were, 1. BERNE, including the *Pays de Vaud*; 2. FRIBURG; 3. BASIL; 4. SOLEURE; 5. SCHAFFHAUSEN; 6. ZURICH; 7. APPENZEL; 8. LUCERNE; 9. ZUG; 10. SCHWEITZ; 11. UNDERWALDEN; 12. URI; 13. GLARIS.

After the conquest of the country by the French, it was divided into 21 cantons, which were reduced to 19 by the annexation of some districts to France; and since the peace in 1815 they have been increased to 22 by the restitution of the ceded districts, and the addition of Geneva to the number. The following table, from Crowe's *View of the Powers of Europe* (1818), shews the extent and population of each.

	Extent in square German miles.	Population.
Zurich,	51	182,080
Berne,	184	291,600
Lucern,	41	99,972

Switzerland is the most mountainous country in Europe. Both on the mountains and in the valleys the air is extremely cold in winter; but in summer it is very pleasant, cool, and refreshing in the former, but excessively hot in the latter. Prodigious masses of ice and snow often fall from the mountains in winter, and do a great deal of damage; and most of the streams and rivers take their rise from the thawing of the ice and snow on their sides and tops.

The lower parts of Switzerland are very pleasant and fertile, being diversified with vineyards, corn-fields, meadows, and pasture-grounds. Many petrifactions are found

Switzerland. found both among these and the others, with a variety of fossils. The sands of the rivers yield gold dust, particularly those of the Rhine, the Emmet, and the Aar, the Reuss, the Arve, and the Inn.

The metals of this country being generally found to be brittle, the only mines that are worked are a few of iron. In the lower parts of Switzerland they sow rye, oats, barley, spelt, flax, hemp. Wines of various sorts are also produced by some of them, with a variety of fruits. Of wood for fuel and other uses there is generally plenty; in some places, however, they are obliged to burn sheep's dung, and in others a kind of heath and small shrubs. In the valleys they cultivate saffron with success. The Swiss derive their principal subsistence from their flocks and herds of cattle, which in summer graze on the mountains. Their cheese is much esteemed, especially that of Berne and Griers in the canton of Friburg. Great numbers of horses are also bred here, and bought up for the French cavalry.

5 Lakes. Besides the above-mentioned rivers, the Rhone and the Tesin have their sources in this country. The lakes are very numerous; but the chief are those of Geneva, Neufchatel, Biel, Zurich, Thun, Brien, Constance, and Lucerne. Both rivers and lakes abound with fish, and afford a cheap water-carriage. Switzerland is not so populous as many countries in Europe, but is more so than Spain, Sweden, or Denmark, and is really well peopled considering the great proportion of useless soil it contains.

6 Language, religion, &c. The language generally spoken here is the German, in which also public affairs are transacted; but in those parts of the country that border on Italy or France, a corrupt French or Italian prevails. The two predominant religions are Calvinism and Popery. Of the former are the cantons of Zurich and Berne, the towns of St Gal, Geneva, Muhlhausen, and Biel, the principality of Neufchatel, the greater part of Basle, Schaffhausen, the country of the Grisons, the Thurgau, Toggenburg, Glaris, and the Rhine valley; the frontiers of Appenzel, with a small part of Solothurn, and some places in the mountains of Baden and Sargans. The rest of the Swiss cantons, allies, and dependents, are Popish. For the education of youth there is an university at Basle, and academies at Zurich, Berne, Lausanne, and Geneva; besides gymnasiums and scholæ illustres, both in the Popish and Protestant cantons. There are also societies among them for the improvement of the German language, and the sciences.

7 Manufactures and trade. The principal manufactures are snuff and tobacco, linen of several sorts, lace, thread, silk, and worsted stockings, neckcloths, cotton stuffs, gloves, handkerchiefs, silks of several sorts, gold and silver brocades, a variety of woollen manufactures, hats, paper, leather of all sorts, earthen wares, porcelain, toys, watches, clocks, and other hardwares, &c. The trade of Switzerland is generally promoted by many navigable lakes and rivers. In some of the above manufactures, and in cheese, butter, sheep, horses, black cattle, hides, and skins, the exports are considerable; and as the imports are chiefly grain and salt, with some American and Asiatic goods, there is probably a large balance in their favour. In some parts of Switzerland dress is restrained by sumptuary laws.

8 Character of the Swiss. The Swiss are a brave, honest, hospitable, hardy people; very true to their engagements, friendly and humane. In short, there is not a people in Europe whose national character is better. In their persons they are generally tall, robust, and well-made; but their complexions are none of the best, and those that live in the neighbourhood of the mountains are subject to wens. The women are said to be generally handsome and well-shaped, sensible and modest; yet frank, easy, and agreeable in conversation. Few of the peasants are miserably poor; many of them are rich, especially in the Protestant cantons, and that of Berne in particular.

9 Outline of the history of Switzerland. In the very confined limits to which we are now reduced, we cannot give more than a faint outline of the history of Switzerland. In the first century before the Christian era, we find the natives involved in frequent wars with the Romans, by whom the Helvetii and the Rhætii, two of the most powerful tribes, were entirely subjugated. In the beginning of the 4th century of the Christian era, the Allemanni, a German tribe, made an irruption into Switzerland, occupied the country, and, as is supposed, extirpated the Helvetii. Soon after we find the western part of Switzerland, as far as the Reuss, occupied by the Franks, by whom it was annexed to Burgundy, while the eastern part, or the Grisons, was subject to Theodoric the Goth, and other Italian princes. In the beginning of the 7th century, Christianity was introduced, chiefly by two Irish monks, Columbanus and Gallus. In the beginning of the 10th century, that part of Switzerland which was occupied by the Allemanni, was invaded by the Huns or Ugurs, who in particular ravaged the abbey of St Gal, at that time famous for its power and its literature. The Huns were defeated by Conrad king of Burgundy, about the year 928. Soon after the commencement of the 11th century, the districts of Switzerland began to be regarded as a part of the German empire, and in the two following centuries they gradually became subject to the house of Hapsburgh. In 1307 commenced the struggles of the Swiss with the house of Austria, those glorious struggles which finally terminated in the complete emancipation of that brave people, and in the formation of a confederacy which continued to be the admiration of Europe for nearly five centuries. The transactions which mark this contest between the inhabitants of a small district and a mighty monarch, and in particular the heroism of their great champion William Tell, are familiar to most of our readers. We shall therefore only give a short account of the government and institutions of the Swiss cantons, as they existed previous to the late revolution, and shall conclude this article with a brief narrative of the proceedings of the French, when they entered Switzerland in 1797.

10 Constitution of the Swiss cantons before the late revolution. With respect to the government and constitution of the Swiss cantons, it must be remarked that some of them were aristocracies and some democracies. In the former, both the legislative and executive power were lodged in the burghers or citizens of the capital of each canton; and of those there were seven, viz. Zurich, Berne, Basle, Friburg, Soleure, and Schaffhausen; an account of the most important of which may be seen under their respective names. In the others, the legislative power was lodged in the whole body of the people, and every male above 16, whether master or servant, had a vote in making laws and in the choice of magistrates. For what concerned the whole Helvetic body, there were diets ordinary and extraordinary; the former were held

Switzerland.

held annually, and the others on particular emergencies; and both were summoned by the city of Zurich, which appointed the time and place of their meetings. Besides the general diets, since the Reformation there were particular diets of the two religions, at which all public affairs of consequence that regarded the two parties were treated separately; for though a sense of their common interest obliged them to study the maintaining the league and union, yet it is certain that the mutual confidence between the cantons was in some measure lost through the zeal of each party for their particular opinions, especially of the Roman Catholics. The annual general diets were held always at Frauenfield or Baden, principally to regulate the affairs of the common baillages. Lucerne took the lead of the Roman Catholic cantons, being the most powerful of that denomination; but Zurich, though less powerful than that of Berne, took the precedence of all the other cantons, both Protestant and Popish. These cantons did not make one commonwealth, but were so many independent states, united together by strict alliances for their mutual defence. The extraordinary diets or congresses were held at Aldorf. Each canton usually deputed two envoys, both to the ordinary and extraordinary, to which also the abbot and the town of St Gal, and the town of Biel, sent representatives. To the 13 cantons belonged in common 21 baillages, 2 towns, and 2 lordships. The allies, as they were called, were the abbot and town of St Gal, the three Grison leagues, the republic of the Valais, the towns of Muhlhausen and Biel, the principality of Neuenburgh, Geneva, and the bishop of Basle. Of these, the abbot and town of St Gal, and the town of Biel, were regarded as members of the Helvetic body, but the rest only as allies.

The public revenues were in general very inconsiderable, and since the peace in 1815 have been computed at 430,000l sterling, arising chiefly from the usual regalia, appropriated every where to the sovereign, the demesnes, and public granaries, voluntary contributions, the sale of salt, and a land-tax; in the Protestant cantons, from the church lands also that were seized at the reformation. Except in Zurich, Bern, Basle, and Schaffhausen, where the people are more industrious, have a greater trade, and are richer than in the others, they defrayed only the ordinary charges.

The cantons never kept any standing troops except for a few garrisons; but their militia was reckoned to be the best regulated of any in Europe. Every male from 16 to 60 was enrolled, and about one-third of them formed into regiments. They were all obliged to provide themselves with arms, clothing, accoutrements, and to appear on the stated days for exercise; and the several cantons and districts were obliged to furnish themselves with a sufficient train of artillery, and all the other implements of war. The Swiss of the several cantons were allowed to engage in the service of such foreign princes and states as were in alliance with those cantons, or with whom they had made a previous agreement. Such states paying an annual subsidy to the respective cantons, were allowed to make levies. Every man enlisted voluntarily, for what number of years he pleased, at the expiration of which he was at liberty to return home. Many thus always returning from foreign service, Switzerland was never unprovided with able and experienced officers and soldiers.

11
Origin of the disputes between the cantons and the French republic.

It was scarcely to be expected that a country so long and so intimately connected with France, by its position, by perpetual alliance, by commerce, and partly by language, should escape the influence of the principles of its revolution, when states far more remote and distinct were strongly imbued with their spirit. But previous to the epoch of the French revolution, various parts of the Swiss confederation had been the seat of civil discord, and popular murmurs. In some cantons the indignant spirit of the subject had led him to revolt against what he deemed the oppresive administration of the ruler; in others, the distinctions which exist in society, and which form the different classes of privileged and unprivileged individuals, were strangely and inversely distributed. The French revolution, declaring the principle of equality, found a wide predisposition among the subjects of the Swiss confederacy to embrace the cause, and as strong a resistance on the part of the governors, who were deeply interested in opposing the progress of opinions so immediately subversive of authority. Conscious that with such a system no brotherhood could be cherished, many of the leading cantons kept themselves in a state of watchfulness, bordering on hostility, against the principles established by the French national assembly. But with so powerful a sanction, the frowns of power were ineffectual to calm the murmurs of discontent; and claims, which fear or policy had hitherto shut up in silence, were now produced, with confidence that they would be admitted from the sentiment of fear, if not of justice.

Among those who were most active in demanding a review of their grievances were the inhabitants of the French part of the canton of Berne, known by the name of the Pays-de-Vaud. The nobles and the higher classes of this province had long transmitted to their children a hereditary hatred of the government of Berne. This disaffection was not concealed; nor is it singular that the desire of change should operate on the titled and the rich, while they saw their political existence depending on the will of a self-elected sovereign, and their provinces subjected to the administration of an emissary of those whom they considered as usurpers of their rights.

But however strongly the sensibility of the subject inhabitants of the Pays-de-Vaud was excited by this political degradation, they were compelled to submit, or brood over their grievances in silence. They were incapable of procuring redress by force; and the sovereign burghers of Berne were too firmly seated to regard the remonstrances of impotent claimants, or to listen to the murmurs of discontent. Partial insurrections against the governments of certain cantons had often taken place in Switzerland. These disorders had sometimes been suppressed and punished with the interposition of the neighbouring cantons, where the danger was not excessive; but when these insurrections wore the serious characters of rebellion or revolt, the whole confederation marched against the conspirators. France before the revolution had even lent its aid to the suppression of those domestic quarrels, and had become the instrument of vengeance to the insulted sovereign; so that, whatever was the degree of oppression, or whatever the desire of resistance, redress was become hopeless, and change impossible.

It was chiefly among the classes of burghers and artizans who inhabited the towns, that discontent against the

2

Switzerland.

the ruling power prevailed. The peasants, less oppressed, because more ignorant of their rights and privileges, not only did not themselves oppose the aggressions of the chief men in power, but even assisted them in quelling insurrections which arose among their rival classes.

All writers agree in the existence of vexatious and oppressive abuses among all the governments of the Swiss cantons, at the time of which we are now writing. The despotism of their institutions; the abuses of election to sovereign councils; the daily and encroaching spirit of authority; the overgrown influence of patrician families; the striking inequality which prevailed, even on this basis, of aristocratical power; the monopoly of places of profit to the exclusion of worth and talent; the undefined limits of proconsular administration; the want of encouragement to the arts and sciences; the neglect of education among those who were destined to rule, the void of which was filled up by idleness, arrogance, ignorance, and dissipation,—are so many features presented by writers of different characters and discordant sentiments, to fill up the picture of this vaunted region of happiness and liberty.

The severity exercised by the government of Berne over those inhabitants of the Pays-de-Vaud who had assembled on the 14th of July 1791, to commemorate the taking of the Bastile at Paris, and express their approbation of the French revolution, had created in the minds of the French people sensations of jealousy towards their Swiss neighbours; while the disbanding and dismissal of the Swiss regiments in the service of France, had contributed to exasperate the government of the cantons against the new republic.

All the cantons, except that of Berne, appeared for a long time disposed to preserve a neutrality towards revolutionary France; but that canton, under pretence of supporting the people of Geneva against the aggressions of the French, first displayed an avowed hostility, and marched a body of 15,000 troops towards the frontiers of the French republic. The true cause of this movement in the canton of Berne, has been by others stated to be the hopes entertained by some individuals of that government, of sharing in the plans of emolument and preferment which were expected to arise on the re-establishment of monarchy in France. The mutual jealousy subsisting between the Swiss cantons and the ruling power in France, was heightened by the protection given by some of the cantons to the French emigrants, and by the correspondence which others of the cantons had held with the bloody tribunal of Robespierre. After the retreat of the allied armies from the frontiers of France, the Swiss found it politic to make at least a show of amity towards the victorious republic; and accordingly recognised the existing government of the republic, and openly received M. Barthelemy as its *charge d'affaires*. Still, however, the sincerity of the cantons was justly doubted by the French directory, who appear to have long formed designs against the independence of Switzerland.

12 The Pays-de-Vaud occupied by the French, anno 1798.

The directory, confirmed in power, and relieved from the controul of a popular legislature, hastened, towards the close of the year 1797, to put in force their project of subjugating the Swiss republics. The first hostile movement on the part of the French, was to take possession of the Helvetic part of the bishopric of Basle, under some frivolous pretence, and contrary to an express treaty concluded with the Swiss in the year 1792. Either too weak or too prudent to resent this infraction of their rights, the Helvetic body still flattered themselves with an amicable termination of their difference with France; when an insurrection, which broke out in the *Pays-de-Vaud*, probably through French instigation, or at least through the influence of French principles, afforded a fuller pretext for the overthrow of the government. In the month of December, the French directory thought proper to interfere in this domestic dispute, and demanded from the government of Berne, what they termed the restoration of the rights of that people, and the assembling of the states of the Pays-de-Vaud in their ancient form. This demand they immediately prepared to enforce by arms; and General Menard was ordered to march, with a body of 15,000 men, to support the claims of the petitioning party in the Pays-de-Vaud. The designs of the French were for the moment frustrated by the timidity or generosity of the supreme council of Berne. On the 5th of January, 1798, they issued a proclamation, enjoining the citizens of the Pays-de-Vaud to assemble in arms, to renew the oath of allegiance, to proceed immediately to the reform of every abuse in the government, and to assert and re-establish all their ancient rights. A commission had been previously appointed at Lausanne, for determining on the claims of the petitioners, and for reinstating the conntry in its former tranquillity. From what causes it happened, we have not as yet been correctly informed, but the proceedings of the commission seemed involved altogether in embarrassment and delay. The people became impatient, and the insurrection at once broke out into actual hostility. The castle of Chillon was seized by the insurgents; and the commotions which took place in the southern districts of the province appeared no less formidable. The government of Berne now determined to reduce the insurgents by force; and a body of 20,000 troops, under the command of Colonel Weiss, was dispatched to disperse them. Whether the lenient measures pursued by this general, were consistent with sound policy or not, it is impossible, from the materials which have hitherto fallen under our inspection, to determine, Suffice it to say, that though it is not certain that more precipitate movements would have saved the country, yet his inactivity undoubtedly served to increase at once the power and the audacity of the insurgents. Thus situated, the approach of the French decided the contest. On passing the boundary, Menard dispatched an aide-de-camp, attended by two hussars, to General Weiss, at Yverdun; on their return, a fatal affray took place at the village of Thierens, in which one of the hussars was killed. Who were the aggressors in this unfortunate business is not correctly ascertained, but it was regarded by Menard as a declaration of war. His troops immediately advanced, while those of Weiss retreated, and the whole of the Pays-de-Vaud was, by the beginning of February, in the possession of the French.

The government of Berne still hoped, it appears, to avert the destruction which now seemed to await them; the centinels who had killed the hussar at Thierens were delivered up, and fresh negotiations were entered on. In the mean time, however, new insurrections were planned in different parts, and the revolutionary mania appeared to increase. In the seditious assemblages

Switzerland. on these occasions, the French envoy, Mengaud, was observed to take a decided part; and, on the 2d of January, he formally reclaimed some persons who had been arrested for treasonable practices by the government of Berne, as the friends and allies of the French republic. To this reclamation the government of Berne paid little attention; and the standard of revolt having been erected at Arau, they determined on effective measures for its suppression and their own defence. The Argovian militia marched to Arau; the town and province were immediately reduced, and the leaders of the insurrection were taken into custody.

13
Preparations for war on the part of the cantons.

War now appeared inevitable. To conciliate the minds of the people, and induce them more freely to lend their assistance, the government of Berne decreed, that 52 deputies from the principal towns and communes should be added to the supreme council; and, on the 2d of February, these new deputies took their seats. A general reform of all the abuses of the government was the first resolution agreed on in their deliberations; and the example of Berne was followed by the cantons of Lucerne, Fribourg, Soleure, Schaffhausen, and Zurich.

While, in this state of things, fresh negotiations were commenced with the French directory, a defensive force of about 20,000 men was collected. The other Swiss cantons dispatched their quotas to the defence of Berne, which amounted to about 5500 men. A truce had been concluded with the French general in the Pays-de-Vaud, where an officer of the name of Brune had succeeded Menard in the command. The truce was to have expired on the 1st of March; but General d'Erlach, fearful lest the spirit of his troops should slacken, demanded, on the 26th of February, positive orders to put his army in motion, and the council immediately made a decree to that effect. The plan of the campaign was now arranged by M. d'Erlach, and notice had been given to the posts that hostilities were to commence on the evening of the 1st of March; when the movements of the Swiss general were frustrated by the repeal of the decree which had been so hastily passed, and the negotiation was renewed with the French commander.

M. Mallet du Pan asserts, that the French general Brune, had agreed to prolong the truce for 30 hours; but, on the 2d March, the castle of Dornach, at the northern extremity of the canton of Soleure, was attacked and carried by the French; and at the same time, 13,000 men were marched under the walls of Soleure, which capitulated to General Schawenbourg on the first summons. Friburg was immediately after reduced by General Brune, and the Swiss army was forced to retreat.

While disaffection prevailed in the army of General d'Erlach, the inhabitants of Berne saw the rapid approach of the victorious army. On the 3d of March, the levy of the *Landsthurm*, or the rising of the people in a mass, was proclaimed. The expedient did not succeed in favour of the magistrates; the people were no sooner assembled in arms, than they of themselves dissolved the government; a provisional regency was elected for the occasion; the event was notified to General Brune; and to facilitate a pacification, an order was issued to dismiss the army, on condition that the French would keep the posts they at present occupied.

Unsatisfied with this concession, the French general insisted on the town receiving a French garrison. In the mean time all was confusion, both in Berne and in the army; the left division of which had mutinied, deserted their posts, and put to death some of their officers. By desertion, the Swiss army was now reduced to 14,000, to which might be added the undisciplined rabble which the Landsthurm had called forth. About 8000 of the regular forces were stationed at Neweneg, and 6400 held the position of Frauenbrun, against which General Schawenbourg advanced from Soleure, at the head of 18,000 men On the morning of the 5th March, both posts were attacked by the French, and a momentary success seemed to crown the valorous efforts of the division at Neweneg; but those stationed at Frauenbrun were, after a vigorous resistance, obliged to retreat; M. d'Erlach rallied his men at Uteren, where a second engagement took place, but with no better success on the part of the Swiss. At Grouholtz, however, they again made a stand, whence they were driven to the gates of the capital, where they were completely routed. The Swiss, in this engagement, lost 2000 in killed and wounded; while the loss of the French was about 1800. 14

Berne entered by the French.

On the evening of the 5th, General Brune entered the city of Berne by capitulation. The divisions of the Swiss army stationed at Neweneg and Guminen retreated; the soldiers of this last column, in despair, put their officers to death; and the unfortunate d'Erlach, in flying from the field of battle, was murdered by his countrymen and soldiers.

The submission of nearly the whole of Switzerland followed the defeat of the Bernese. The democratic republics, however, still made a glorious stand, defeated General Schawenbourg, and forced him to retire with the loss of 3000 men. 15

Helvetic republic formed.

The Swiss confederacy, after this revolution, changed its constitution, and even its name. Provisional governments, under the direction of the French generals, were established in the different districts, and the whole assumed the name of the Helvetic republic. Contributions were levied as usual, by the French commissioners; and some shocking enormities are reported to have been committed, chiefly by the army of the Rhine; for the divisions which belonged to the army of Italy are said to have conducted themselves with superior humanity and justice *. 16

Constitution of 1802.

In the beginning of 1802, a new constitution was framed for the Helvetic republic, under the direction of Bonaparte. Its leading features are as follows.

The Helvetic republic is one. Every citizen has a right of settling in any canton of the republic, and of exercising all the civil and political rights in the same manner as the citizens of the canton.

Berne is the capital of Helvetia. The Helvetic territory is divided into 21 cantons. The ecclesiastical property, in general, can be employed only for establishments of religious instruction, or of charity.

There is a central administration of the republic for the exercise of the national sovereignty, and an administration of the cantons. The administration of the cantons is composed of a diet and a senate. The diet is formed by the union of representatives from all the cantons, in the following proportions,—Berne, six; Zurich, two; Lucerne, five; Uri, one; Schweitz, three; Underwalden,

* See *New Annual Register* for 1798 and 1799.

Underwalden, one; Zug, one; Glaris, one; Soleure, two; Fribourg, three; Basle, two; Schaffhausen, one; Appenzel, one; St Gal, four; Turgovia, two; Argovia, two; Baden, two; Vaud, four; Grisons, one; Tessin, three; Valais, two. The members of the diet remain five years in office. The diet is to assemble regularly every year on the 1st of March. It shall be extraordinarily convoked by the senate when the majority of the cantons require it, or when itself shall judge that measure necessary. The president of the diet shall be the landamtman who is not in office. He has a casting vote, in case the votes shall be equally divided. A deputation of four members from the senate shall assist at the diet, but without having a right to vote.

The senate is composed of two landamtmans, two stadtholders or lieutenants, and 26 counsellors. Each canton must have at least one member in it. The senate forms the projects of laws and regulations, and submits them to the sanction of the cantons. The two landamtmans and their lieutenants have the direction of foreign affairs. The senate names and recalls diplomatic agents, on a proposition from the landamtmans.

Though France had not formally abolished the independent government of Switzerland, she exercised an influence in the affairs of the cantons, which left the diet little substantial power. From this influence Switzerland was delivered on the overthrow of the French power in 1814. The territories forced from her were restored, and Geneva was added to the list of cantons. Whether any change has subsequently been made in the internal or federative government we have not yet learned.

SWIVELS, a kind of ring made to turn round in a staple, or other ring. These are used when a ship lies at her moorings; also in tedders for cattle, that they may turn round without unwarping the tedder.

Swivel-Cannon, is a small piece of artillery belonging to a ship of war, which carries a shot of half a pound, and is fixed in a socket on the top of the ship's side, stern, or bow, and also in her tops. The trunnions of this piece are contained in a sort of iron crotch, of which the lower end terminates in a cylindrical pivot resting in the socket, so as to support the weight of the cannon. The socket is bored in a strong piece of oak, reinforced with iron hoops, in order to enable it to sustain the recoil. By means of this frame, which is called the *swivel*, and an iron handle on its cascable, the gun may be directed by the hand to any object. It is therefore very necessary in the tops, particularly when loaded with musket-balls, to fire down on the upper decks of the adversary in action.

SWOONING. See Medicine, N° 274.

SWORD, an offensive weapon worn at the side, and serving either to cut or stab. Its parts are, the handle, guard, and blade; to which may be added the bow, scabbard, pummel, &c.

Sword of State, which is borne before the king, lords, and governors of counties, cities, or boroughs, &c. For or before the king, it ought to be carried upright; the hilt as low as the bearer's waist, the blade up between his eyes. For or before a duke, the blade must decline from the head, and be carried between the neck and the right shoulder. For or before an earl, the blade is to be carried between the point of the shoulder and the elbow; and for or before a baron, the blade is to be borne in the bend of the arm. This ceremonial form no less denotes the dignity of a governor than the coronet set on his coat of arms.

Sword-Fish. See Xiphias, Ichthyology *Index*.

SWORN brothers (*fratres jurati*), persons who, by mutual oath, covenanted to share each other's fortune. Formerly, in any notable expedition to invade and conquer an enemy's country, it was the custom for the more eminent soldiers to engage themselves by reciprocal oaths to share the rewards of their service. This practice gave occasion to the proverb of *sworn brothers* or *brethren in iniquity*, because of their dividing plunder and spoil.

SYCAMORE-tree. See Acer, Botany *Index*.

SYCOPHANT, an appellation given by the ancient Athenians to those who informed of the exportation of figs contrary to law; and hence it is still used in general for all informers, parasites, flatterers, cheats, &c.

SYDENHAM, Dr Thomas, an excellent English physician, was the son of William Sydenham of Winford Eagle in Dorsetshire, and was born there about the year 1624. He studied at Magdalen-hall, Oxford; but left that university when Oxford was garrisoned for King Charles I. and went to London: where, becoming acquainted with Dr Thomas Cox, an eminent physician, that gentleman persuaded him to apply himself to the study of physic; accordingly, after the garrison was delivered up to the parliament, he retired again to Magdalene-hall, entered on the study of medicine, and in 1648 was created bachelor of physic. Soon after, he was made a fellow of All-Souls college, and continued there several years: when leaving the university, he settled at Westminster, became doctor of his faculty at Cambridge; grew famous for his practice; and was the chief physician in London from the year 1660 to 1670; at which period he began to be disabled by the gout. He died in 1689. His works are highly esteemed both at home and abroad. He was famous for his cool regimen in the small pox; for giving the bark after the paroxysm in agues; and for his use of laudanum. He regulated his practice more by his own observations and inquiries, than by the method either of his predecessors or contemporaries.

SYENE, an ancient city of Egypt, situated, according to Mr Bruce, in north latitude 24° 0′ 45″. Pliny and Strabo both say, that it lay directly under the tropic of Cancer. Whether Mr Bruce's authority be sufficient to overturn the evidence of Pliny and Strabo, we shall leave to others to determine.

Syene is remarkable for being the place where the first attempt was made to measure the circumference of the earth. This was done by Eratosthenes, whom Ptolemy Euergetes had invited from Athens to Alexandria. In this attempt two positions were assumed, viz. that Alexandria and Syene were exactly 5000 stadia distant from each other, and that they were precisely under the same meridian; but both these are denied by Mr Bruce, who has made many observations on the subject which our limits will not allow us to take notice of at present. He tells us, that there is at Asum an obelisk erected by Ptolemy Euergetes, the patron of Eratosthenes, without hieroglyphics, directly facing the south, with its top first cut into a narrow neck, then spread out like a fan into a semicircular form, with

Syene, Sylla. with pavements curiously levelled to receive the shade, and make the separation of the true shadow from the penumbra as distinct as possible. This is supposed by Mr Bruce to have been constructed with a design to vary the experiment of Eratosthenes with a larger radius; and the inquiry concerning the dimensions of the earth, in our author's opinion, was the occasion of many obelisks being erected in this kingdom; a demonstration of which is, that the figure of the top is varied; being sometimes very sharp, and sometimes a portion of a circle, in order to get rid of the great impediment arising from the penumbra, which makes it difficult to determine the length of the shadow with precision. It is now called *Assouan*.

SYLLA, Lucius Cornelius, was descended from the illustrious family of the Scipios. His behaviour in his younger years by no means corresponded with the excellent education which he had received. But debauchery, instead of bringing along with it infamy and ruin, its usual attendants, served only to increase the wealth of this fortunate Roman; for Nicopolis, a rich courtezan, whose affections he had gained, left him heir to her great estate.—He learned the art of war under Marius, whom he attended to Numidia in quality of questor. Though hitherto unaccustomed to arms, he became in a short time the most skilful soldier in the army, while by his polite and obliging behaviour he gained the love and esteem of every body. His courage and dexterity contributed a great deal towards the success of the war; it was his eloquence in particular that persuaded Bocchus to deliver up Jugurtha. He served afterwards in the Social war, where his actions entirely eclipsed those of every other commander. As a reward for this conduct he was raised to the prætorship. It is pretended by some that Sylla purchased this dignity; and that when he threatened one day to make use of the powers of *his* office against Strabo the father of Pompey, that Roman replied with a smile, "You are in the right to say so; your office is certainly *yours*, since you purchased it." Be this as it may, after the conclusion of the Social war he was made consul, and soon after declared general of the army which was to be sent against Mithridates king of Pontus. Marius, at that time the most renowned of the Roman generals, expected that the management of this war would have been committed to him, and was therefore much exasperated at the disappointment. The people were persuaded by his intrigues to reverse the former decree, and substitute him in place of Sylla. Upon this he sent down officers to take the command of the army; but Sylla by this time had gained over the soldiers; who, instead of obeying the decree of the people, slew Marius's officers, and intreated Sylla to lead them instantly to Rome. Accordingly he entered the city sword in hand, slew Sulpicius the consul, obliged Marius to flee, new-modelled the laws, and afterwards marched into the East, and immediately laid siege to Athens; for that city, together with the rest of Greece, had fallen into the power of Mithridates. He wrote to the Amphictyons, who were assembled at Delphi, to send him all the gold which was deposited in the temple of Apollo, because he stood in need of money; promising, at the same time, to restore it again at the end of the war. When he received this treasure, he observed, with an air of raillery, that he now no longer despaired of victory, since the gods themselves furnished him with money to pay his troops. Famine soon obliged the Athenians to think of a surrender. Their ambassadors waited on Sylla, and began to harangue about Theseus and Codrus, and Marathon and Salamis,—when he interrupted them, and exclaimed, "Go, repeat these fine orations in your schools; I have come hither, not to learn your history, but to chastise rebels." Athens was at last taken by assault, and Sylla was upon the point of destroying it, when he recollected its ancient glory, and spared (as he said) the living for the sake of the dead. After burning the Piræus, he gained two decisive victories over the generals of Mithridates. In the second battle, which was fought at Orchomenus, he was almost defeated; his troops began to flee, when, leaping from his horse, he snatched up a standard, and advanced against the enemy, crying out, "I will die here gloriously; and, soldiers, when you are asked where you abandoned your general, answer, At Orchomenus." This reproach recalled the courage of the Romans; they followed him to the charge, and gained a complete victory. Mithridates, humbled by these disasters, sent ambassadors to sue for peace.

Mean time Cinna had declared against Sylla in Italy; and Marius returning from banishment, had taken the most severe vengeance on all his enemies. Sylla was declared a traitor; his laws were reversed, his friends murdered, and the government new-modelled. The news of these transactions induced Sylla to conclude a treaty with Mithridates, and march directly to Rome. His approach terrified the Romans. Marius and Cinna were both dead; but the consuls made vigorous preparations to oppose him. A civil war was begun; but Sylla in the end subdued all his enemies, and entirely ruined the Marian faction. He entered Rome at the head of his victorious army, and publicly assumed the surname of *Happy*. Happy, indeed, had he ceased to live when he ceased to conquer. The remainder of his life contains nothing else but a catalogue of the most abominable cruelties. He declared that every one who expected a pardon for their late offences, must gain it by destroying the enemies of the state. The sword of the assassin was thus unsheathed, and murder encouraged as the path to power and distinction. The noblest of the Romans were everywhere massacred; slaves were rewarded for cutting off their masters; children were seen dragging their parents to execution; and brothers claiming a recompense for the murder of brothers. Sylla ordered 8000 wretches, who had thrown themselves upon his clemency, to be butchered in the Campus Martius. In the mean time he entered the senate-house, and began to talk with great coolness about his exploits. The senate, alarmed at the horrid outcries of the sufferers, at first thought that the city was given up to be plundered; but Sylla informed them, with an unembarrassed air, that it was only some criminals punishing by his orders, and that they needed not be apprehensive about their own fate.

To carry on these cruelties with the appearance of justice, he commanded the people to elect him dictator. He kept this office for more than two years; and then, to the amazement of all, laid it down, and offered to stand his trial before the people. Soon afterwards he retired into the country, and plunged headlong into every kind of debauchery. Nor did he relinquish his cruelty

cruelty together with his power: His wife falling ill in the midst of a sumptuous feast, he divorced her immediately; and ordered her to be carried away, lest her death should interrupt the festivity of his house.

He died of the morbus pedicularis, in the 60th year of his age. His body, according to his orders, was burnt. A little before his death he wrote his epitaph; the tenor of which was, that no man had ever exceeded him in doing good to his friends or injury to his enemies.

His person was elegant, his air noble, his manners easy and apparently sincere. He was fond of pleasure, but fonder of glory; indulging without scruple in sensual delights, but never suffering them to interrupt his serious business: He was eloquent, liberal, crafty, insinuating; a profound master of dissimulation; he spoke of himself with modesty, while he lavished praises on every other person: he stooped even to an acquaintance with the meanest soldier, and constantly adapted himself to the humours, pursuits, and opinions, of those with whom he conversed. Such was his character during the earlier part of his life; but when success had raised him above the necessity of dissimulation, he displayed a hideous train of vices, which his ambition had formerly taught him to conceal.—It was Sylla who recovered the works of Aristotle at the taking of Athens.

SYLLABLE, in *Grammar*, one or more letters pronounced by a single impulse of the voice, forming a complete sound, and constituting a word or a part of a word. No single letter can form a syllable except a vowel. The longest syllable in the English language is the word *strength*.

The most natural way of dividing words into syllables is, to separate all the simple sounds of which any word consists, so as not to divide those letters which are joined close together according to the most accurate pronunciation.

SYLLABUB, a kind of compound drink, most used in the summer season; ordinarily made of white wine, sugar, and nutmeg, into which is milked a quantity of new milk from the cow. Sometimes it is made of canary in place of white wine; in which case the sugar is spared, and a little lemon and nutmeg are added instead of it. To prepare it the best way, the wine and other ingredients, except the milk, are to be mixed over night, and the milk or cream added in the morning. The proportion, is a pint of wine to three of milk. For

SYLLABUB, *Whipt*. To half a pint of white wine or Rhenish is put a pint of cream, with the whites of three eggs. This they season with sugar, and beat with birchen rods, or work with a syringe. The froth is taken off as it rises, and put into a pot; where, after standing to settle two or three hours, it is fit to eat.

SYLLABUS, in matters of literature, denotes a table of contents, or an index of the chief heads of a book or discourse.

SYLLOGISM, in *Logic*, an argument or term of reasoning, consisting of three propositions; the two first of which are called *premises;* the last, the *conclusion*. See LOGIC, Part III.

SYLVIA, a genus of birds, belonging to the order of passeres, formed by Dr Latham by limiting the motacilla to the wagtail, and arranging the other species, formerly classed under that genus, under the sylvia. He making 13 species of the motacilla, and 175 species of the sylvia. See MOTACILLA, ORNITHOLOGY *Index*.

SYMBOL, a sign or representation of something moral, by the figures or properties of natural things. Hence symbols are of various kinds; as hieroglyphics, types, enigmas, parables, fables, &c.

SYMMACHUS, a citizen and senator of ancient Rome, and consul in the year 391, has left us ten books of epistles; from which, as well as from other things, we collect, that he was a warm opposer of the Christian religion. He was banished from Rome by Valentinian on some account or other, but afterwards recalled and received into favour by Theodosius. Ammianus Marcellinus speaks of him as a man of great learning and modesty. Scioppius, Pareus, and other learned men, have written notes upon the epistles of Symmachus: we know of no later edition of them than that of Frankfort, 1642, 8vo. Ambrose bishop of Milan wrote against Symmachus, and so did the Christian poet Prudentius.

SYMMETRY, the just proportion of the several parts of any thing, so as to compose a beautiful whole.

SYMMETRY, in *Painting*. See PAINTING, Part I. Sect. III.

SYMONDSBOROUGH, a remarkable large barrow of flints, near Wellington in Devonshire, in the northern extremity of Hemyock. The common people have a notion that a king called *Symon* was buried here. The tradition of the country plainly shows that it was the burial-place of some person or persons of eminence.

SYMPATHETIC, something that acts or is acted upon by sympathy. Thus we say, sympathetic diseases, inks, &c.

SYMPATHETIC Inks. See *Sympathetic* INK.

SYMPATHY, an agreement of affections and inclinations, or a conformity of natural qualities, humours, temperaments, which make two persons delighted and pleased with each other.

SYMPATHY, also denotes the quality of being affected by the affection of another; and may subsist either between different persons or bodies, or between different parts of the same body. It is either similar or dissimilar; similar, when the affection or action in the sympathiser is similar to the affection or action in the sympathant; and dissimilar, when those are different.—Sympathy too, is often an imitative faculty, sometimes involuntarily, frequently without consciousness: thus we yawn when we see others yawn, and are made to laugh by the laughing of another.

Sympathy, according to Dr Jackson *, relates to the operations of the affections of the mind, to the operations of the imagination, and to the affections of the external senses.

* *Treatise on Sympathy*.

1. The passions and affections of the mind produce in the body different sensations and impressions, and, as sympathies of consciousness, determine in general the spirits to those parts which labour most, or are most apt to be affected. Thus fear and anger determine to the heart; lust to the eyes, &c.; joy, pity, wonder, and the like to the head. See PASSION, page 14.

The affections of the mind of one person will often work upon the spirits of many. Thus whole companies are sometimes disposed to be sad and melancholy, or merry and jovial, when any one is present much inclined to either of those states of mind; and it has been observed, Sympathy. observed, that old people, who have loved the company of the young, and have been conversant continually with them, have generally lived long. But young people must not conclude from this, that the company and conversation of the grave and old will operate upon the living and sensitive principle, through the affections of their mind, and dispose them to be short-lived. On the contrary, by thus improving their understanding, they will be more enabled to fortify their constitution and resist the ravages of youthful indulgence.

It may also be further observed, that those tender sympathetic affections which lay hold of the mind, at the representation of theatrical performances, originate from the same principle, while they are to be considered as the surest test of just execution in the actor, and of the expressive language of the author. Indeed all stage effect depends on sympathy.

It has been said, that the passions of the mind are occasionally infectious, particularly some of them. Thus *fear* and *shame* are sometimes very suddenly so. We frequently may have occasion to see, that the starting of one will make another ready to start. Again, when one man is out of countenance in company, others will often blush in his behalf. However, the serious passions may surely be so under the controul of reason as to resist infection, whatever may be the case of temporary, muscular, or nervous attraction.

2. Our author is inclined to think, that a connection between the affections and sensations of the female mind and uterus, is very materially concerned in the process of generation, and probably can alone give efficacy to those actions and impressions subservient to conception, through the sympathizing affections of the mind. But this is a subject of which we know so little, that the speculations of even the most distinguished philosophers respecting it have been nothing but the wild ravings of imagination.

With respect to the depravity and force of the imagination in the production of sympathies, they always operate most upon "weak minds and spirits, and therefore most on women, superstitious and fearful persons, sick people, children, and young creatures." Their effects, however, sometimes fail to appear, because they are encountered and overcome by the mind and spirit before they work any manifest effects.

Such effects are obviated upon the same principle which establishes the prevention of bodily disease: "for in infection and contagion from body to body (as, for example, during the plague), the miasma may be received; but from the strength and good disposition of the body, it is expelled and wrought out before it has had sufficient time to form the disease."

It has been said, and many are of the opinion, that the force of imagination doth often forward the end proposed. Thus, for instance, it has been put as a question, "Whether a man, when he constantly and strongly believes that such a thing shall be (as that such a one will love him, and the like), helps any thing to the effecting the thing desired?" Certainly not in the manner which has been advanced, namely, "by a secret operation on the spirit of another." If he succeeds, it is either because he persevered, or because his perseverance and earnestness (and not any occult operation) makes him at length be attended to.

There is not a doubt but the force of imagination often gives energy to our actions. It may, however, unless we are much on our guard, easily delude us aside from reason. It has been the tree which has yielded the fruits of superstition in former times, and which has often fed the human mind with the most extravagant notions of sympathy. Sympathies of this kind, such as the power of charms, and the like, are now pretty generally exploded.

3. The five senses, *hearing*, *tasting*, *smelling*, *feeling*, and *seeing*, are conscious of a sympathetic impression from odious objects. "1. A disagreeable sound will set the teeth on edge, and make all the body shiver. 2. The swallowing of a nauseous medicine will be attended with a shaking of the head and neck. 3. Disagreeable smells produce nearly the same effect, which are less perceived, because there is a remedy at hand by stopping the nose. 4. If you come suddenly out of the sun into the shade, the sense of feeling is disturbed by a chillness or shivering of the whole body. 5. And even sudden darkness produces a propensity to shivering.

There is a very apparent reason why a sympathy should take place between the eyes. Hence their motions are synchronous. It may be said, that custom and habit dispose the eyes to move one and the same way; "for when one moveth towards the nose, the other eye moveth from the nose."

Though the eyes are by nature prone to move in concert, custom will, however, destroy this natural concert, and produce the contrary effect. Thus some people can squint when they will. Our author therefore gives this caution to mothers and nurses: "Let them not suffer infants to sit with a candle placed behind them; for both their eyes will be disposed to move outwards, as affecting to see the light of the candle, which may bring on the habit of squinting.

It appears as a quality in the senses of hearing and seeing, "that the instrument of each separate sense has a sympathy and similitude to that which giveth the reflection." Thus it has been observed, "that the eye will sympathize with a crystal glass or water, and the ear with caves and such hollow places as are suited to report echo."

Sympathies have been compared to unisons of sound in music. Unisons of sound produce agreeable sympathetic feelings; the reverse produce disagreeable feelings. "All concords and discords of music are (no doubt) sympathies and antipathies of sound." Moreover, "they are said to work as well by report of sound as by motion."

The most agreeable as well as odious objects operate in a secondary way, in producing those sympathetic impressions and actions which they commonly give rise to. An increased secretion of saliva often takes place at the sight of a favourite dish; and the running of water from a bottle, or otherwise, will sometimes affect individuals of a particular temperature, with an involuntary propensity to void urine.

Many have attempted to account for the remarkable sympathy which takes place between parts of the body seemingly unconnected with each other; but as these attempts are merely conjectures, without any solid principles to rest on, we pass them over as the dreams of ingenious men. It would be fortunate for science, if men would confine themselves to those subjects which can be known, Sympathy || Synagogue.

known, and never draw conclusions till they have established principles. See PHYSIOLOGY, chap. ii.

SYMPHONIA, a genus of plants belonging to the class of monadelphia. See BOTANY *Index*.

SYMPHONY, in *Music*, properly denotes a consonance or concert of several sounds agreeable to the ear, whether vocal or instrumental, called also *harmony*. See HARMONY.

SYMPHYSIS, in *Anatomy*, one of the kinds of junctures or articulations of the bones. See ANATOMY, N° 2.

Cutting the SYMPHYSIS of the Pubes. See MIDWIFERY, N° 136.

SYMPHYTUM, COMFREY, a genus of plants belonging to the class pentandria; and in the natural system ranging under the 41st order, *asperifoliæ*. See BOTANY *Index*.

SYMPLOCE, συμπλοκη, in *Rhetoric*, a figure, where the same word is repeated several times in the beginning and end of a sentence, including the ANAPHORA and EPITROPHE: thus, *Quis legem tulit? Rullus. Quis majorem populi partem suffragiis privavit? Rullus. Quis comitiis præfuit? Idem Rullus.*

SYMPLOCOS, a genus of plants belonging to the class polydelphia. See BOTANY *Index*.

SYMPOSIARCH, in antiquity, the director or manager of an entertainment. This office was sometimes performed by the person at whose charge the entertainment was provided; sometimes by another named by him; and at other times, especially in entertainments provided at the common expence, he was elected by lot, or by the suffrages of the guests.

SYMPTOM, in *Medicine*, any circumstance which indicates the existence, nature, or stage of a disease. Pain, waking, drowsiness, convulsions, suppression of urine, difficulty of breathing and swallowing, coughs, distastes, nauseas, thirsts, swoonings, faintings, looseness, costiveness, dryness and blackness of the tongue, are the principal *symptoms* of diseases. See MEDICINE, N° 41. and 58.

SYMPTOMATICAL, in *Medicine*, is a term often used to denote the difference between the primary and secondary causes in diseases: thus a fever from pain is said to be symptomatical, because it rises from pain only.

SYNÆRESIS, CONTRACTION, in *Grammar*, a figure whereby two syllables are united in one; as *vemens* for *vehemens*.

SYNAGOGUE, among the Jews, is a place where that people met to worship God. Authors are not agreed about the time when the Jews first began to have synagogues:—Some suppose them as old as the ceremonial law, and others fix their beginning to the times after the Babylonish captivity. They erected synagogues not only in towns and cities, but also in the country, especially near rivers, that they might have water for their purifications and ceremonious washings. No synagogue was built in any town unless there were ten persons of leisure in it; but there might be many in one town, or in one quarter of a town, provided it was very populous. Jerusalem is said to have contained 480. The chief things belonging to a synagogue were, 1. The ark or chest, made after the model of the ark of the covenant, containing the Pentateuch. 2. The pulpit and desk in the middle of the synagogue, in which he that was to read or expound the law stood. 3. The seats or pews for the people. 4. The lamps to give light at evening service, and the feast of dedication. 5. Rooms or apartments for the utensils and alms chest. The synagogue was governed by a council or assembly, over whom was a president, called *The Ruler of the Synagogue*. These are sometimes called *Chiefs of the Jews*, *The Rulers*, *The Priests* or *Elders*, *The Governors*, *The Overseers*, *The Fathers of the Synagogue*. Their business was to punish the disobedient, by censures, by excommunication, or by penalties, such as fines and scourging; to take care of the alms, which are frequently called by the name of righteousness. The chief ruler, or one of the rulers, gave leave to have the law read and expounded, and appointed who should do it. In every synagogue, there were several ministers who had different offices assigned to them. Service was performed three times a-day, viz. in the morning, in the afternoon, and at night; at the time of morning sacrifice, evening sacrifice, and after the evening sacrifice on Mondays, Thursdays, and Saturdays, there was a more forcible obligation upon the people to attend than upon the other days. There are synagogues at London, Amsterdam, Rotterdam, Avignon, Metz, &c.

Wilson's Archæological Dictionary.

Synagogue || Syncopation.

SYNALOEPHA, in *Grammar*, a contraction of syllables, performed principally, by suppressing some vowel or diphthong at the end of a word, on account of another vowel or diphthong at the beginning of the next. As, *ill' ego*, for *ille ego*, &c.

Conticuer' omnes intentiqu' ora tenebant. VIRG.

It is called by the Latins *collisio*.

SYNARTHROSIS. } See ANATOMY, N° 2.
SYNCHONDROSIS. }

SYNCELLUS, or SINCELLUS, an ancient officer in the family of the patriarchs, and other prelates of the eastern church. The word, in the corrupt Greek, συγκηλλος, signifies a person who lies in the chamber with another; a *chamber-fellow*, or *chum*. The syncellus was an ecclesiastic, who lived with the patriarch of Constantinople, to be a witness of his conduct; whence it is, that the syncellus was also called the *patriarch's eye*, because his business was to observe and watch. The other prelates had also their syncelli, who were clerks living in the house with them, and even lying in the same chamber, to be witnesses of the purity of their manners. Afterwards the office degenerated into a mere dignity; and there were made syncelli of churches.—At last, it became a title of honour, and was bestowed by the emperor on the prelates themselves; whom they called *pontifical syncelli*, and *syncelli Augustales*.

SYNCHRONISM denotes the happening of several things at the same time. See CHRONOLOGY.

SYNCOPATION, in *Music*, denotes a striking or beating of time, whereby the distinction of the several times or parts of the measure is interrupted. However, it is more properly used for the connecting the last note of any measure, or bar, with the first of the following measure, so as only to make one note of both. A syncope is sometimes also made in the middle of a measure. Syncopation is also used when a note of one part ends or terminates on the middle of a note of the other part. This is otherwise denominated *binding*. It is likewise used for a driving note; that is, when some shorter note at the beginning of a measure, or half measure, is followed

lowed by two, three, or more longer notes before another short note occurs, equal to that which occasioned the driving, to make the number even, e. gr. when an odd crotchet comes before two or three minims, or an odd quaver before two, three, or more crotchets. In syncopated or driving notes, the hand or foot is taken up, or put down, while the note is sounding.

SYNCOPE, FAINTING; a deep and sudden swooning, during which the vital functions are suspended. See MEDICINE, N° 98. and 272.

SYNCOPE, in *Grammar*, an elision or retrenchment of a letter or syllable out of the middle of a word, as *caldus* for *calidus*.

SYNDIC, in government and commerce, an officer, in divers countries, intrusted with the affairs of a city or other community, who calls meetings, makes representations and solicitations to the ministry, magistracy, &c. according to the exigency of the case.

SYNECDOCHE, in *Rhetoric*, a kind of trope frequent among orators and poets. See ORATORY, N° 56.

SYNECPHONESIS, in *Grammar*, a coalition, whereby two syllables are pronounced as one; being much the same as SYNALOEPHA and SYNÆRESIS.

SYNEUROSIS. See ANATOMY, N° 2.

SYNGENESIA, (συν and γενεσις, "congeneration)," the name of the 19th class in Linnæus's artificial system. See *Classification*, BOTANY *Index*.

SYNGNATHUS, PIPE-FISH, a genus of fishes belonging to the cartilaginous order. See ICHTHYOLOGY, page 104.

SYNOCHA, and SYNOCHUS, in *Medicine*, the names of two species of continued fever. See MEDICINE, N° 164.

SYNOD, in *Astronomy*, a conjunction or concourse of two or more stars or planets, in the same optical place of the heavens.

SYNOD signifies also a meeting or assembly of ecclesiastical persons to consult on matters of religion.

Of these there are four kinds, viz. 1. *General*, or *œcumenical*, where bishops, &c. meet from all nations. These were first called by the emperors, afterwards by Christian princes; till in later ages the pope usurped to himself the greatest share in this business, and by his legates presided in them when called. 2. *National*, where those of one nation only come together, to determine any point of doctrine or discipline. The first of this sort which we read of in England, was that of Herudford or Hertford, in 673, and the last was that held by Cardinal Pole, in 1555. 3. *Provincial*, where those only of one province meet, now called the *convocation*. 4. *Diocesan*, where those of but one diocese meet, to enforce canons made by general councils, or national and provincial *synods*, and to consult and agree upon rules of discipline for themselves. These were not wholly laid aside, till by the act of submission, 25 Hen. VIII. c. 19. it was made unlawful for any *synod* to meet, but by royal authority. See COUNCIL and CONVOCATION.

SYNODS, *Provincial, in the Government of the Church of Scotland* See PRESBYTERIANS, N° 14.

SYNODALS, or SYNODIES, were pecuniary rents (commonly of two shillings), paid to the bishop, or archdeacon, at the time of their Easter visitation, by every parish priest. They were thus called, because usually paid in synods: because anciently bishops used to visit and hold their diocesan synods once.—For the same reason, they are sometimes also denominated *synodalica;* but more usually, *procurations*.

SYNODICAL, something belonging to a synod. Thus, synodical epistles are circular letters written by the synods to the absent prelates and churches; or even those general ones directed to all the faithful, to inform them of what had passed in the synod.

SYNOECIA, in Grecian antiquity, a feast celebrated at Athens in memory of Theseus's having united all the petty communities of Attica into one single commonwealth; the seat whereof was at Athens, where all the assemblies were to be held. This feast was dedicated to Minerva; and, according to the scholiast on Thucydides, it was held in the month *Metagitnion*.

SYNONYMOUS, is applied to a word or term that has the same import or signification with another.

Several works have been composed for the express purpose of explaining synonymous words. In 1777 a work was published on the Latin synonyma at Paris by M. Gardin Dumesnil. The abbé Girard published one on the synonymous terms of the French language many years ago. Another was published on the same subject in the year 1785 by the abbé Roubaud. An account of the English synonyma was published by an anonymous author in 1766; which is a close imitation, and in some parts a literal translation, of the abbé Girard's *Synonymes François*. Mrs Piozzi has written some essays on the same subject.

SYNOVIA, in *Medicine*, a term used by Paracelsus and his school for the nutritious juice proper and peculiar to each part. Thus they talk of the synovia of the joints, of the brain, &c.

SYNTAX, in *Grammar*, the proper construction or due disposition of the words of a language into sentences and phrases. See GRAMMAR and LANGUAGE.

SYNTHESIS, in *Logic*, denotes a branch of method, opposite to analysis.

In the synthesis or synthetic method, we pursue the truth by reasons drawn from principles before established or assumed, and propositions formerly proved: thus proceeding by a regular chain, till we come to the conclusion. Such is the method in Euclid's Elements, and most demonstrations of the ancient mathematicians, which proceed from definitions and axioms, to prove propositions, &c. and from those propositions proved to prove others. This method we also call *composition*, in opposition to *analysis* or *resolution*. See ANALYSIS.

SYPHILIS. See MEDICINE, N° 350.

SYPHON. See HYDRODYNAMICS. Some uncommon phenomena in nature may be accounted for upon the principles of the syphon; as, for instance, that of reciprocating springs. See PNEUMATICS, N° 373.

SYRACUSE, a celebrated city of Sicily, and once the capital of the island. It was built, according to Thucydides and Strabo, by Archias, one of the Heraclidæ, who came from Corinth into Sicily in the second year of the 11th Olympiad, and derived its name from a neighbouring marsh named *Syraco*. What form of government first prevailed in the city is not known. Many have supposed it originally to have been governed by kings: but if this were the case, the monarchical government continued only for a very short time; since Aristotle, Diodorus Siculus, and Justin, mention it as being very early subject to a democracy. The history is

1 At what time built.

Syracuse. is obscure and unimportant till the time of Gelon, when Syracuse first began to make a conspicuous figure.

2 Gelon seizes on the sovereignty. Gelon was born in the city of Gela in Sicily, of the family of Telines, who had been created priest of the infernal gods. He signalized himself in a war carried on against the Syracusans, by Hippocrates tyrant of Gela, whom he defeated in a pitched battle. Having thus become very powerful among his countrymen, he soon found means to seize on the sovereignty for himself. In a short time, having put himself at the head of some Syracusan exiles, he marched towards that place, where he was received with loud acclamations and obtained possession of the city.

Gelon, in order to people the capital of his new dominions, first demolished the neighbouring city of Camarina, and transplanted the inhabitants to Syracuse. Soon after, entering into a war with the Megareans, he defeated them, took and rased their cities, and in like manner transplanted the people. Syracuse thus became powerful, and full of inhabitants; and the friendship of Gelon was courted both by Athens and Lacedæmon at the time of the Persian invasion. In the mean time the Carthaginians had entered into a treaty with the Persians; by which it was agreed, that the former should attack those of the Greek name in Sicily and Italy, in order to divert them from assisting each other.

3 Defeats the Carthaginians, and takes the title of king. Sicily was accordingly invaded by the Carthaginians with a vast army; but they were utterly overthrown by Gelon, as is related under the article CARTHAGE, N° 7—9. After this victory, the people out of gratitude obliged him to assume the title of king; which till that time he had refused. A decree also passed by which the crown was settled on his two brothers Hiero and Thrasybulus after his death.

4 His excellent reign. The new king, instead of keeping his subjects in greater awe, studied to make them happy, and was the first man who became more virtuous by being raised to a throne. He was particularly famous for his honesty, truth, and sincerity; is said never to have wronged the meanest of his subjects, and never to have promised a thing which he did not perform.

5 Gelon dies, and is succeeded by Hiero. An. 471: B. C. Gelon died in the year 471 B. C. after having reigned three or four years; and was succeeded by his brother Hiero, whose character is differently drawn by different historians. He is highly celebrated in the odes of Pindar; and it is certain that his court was the resort of men of wit and learning, to whom he behaved in the most courteous manner and with the greatest liberality.

6 Thrasybulus, a tyrant. An. 459. In 459 B. C. Hiero was succeeded by Thrasybulus; who proving a tyrant, was in ten months driven out, and a popular government restored; which continued for the space of 55 years.

7 The Siculi subdued. About this time the Syracusans entered into a war with the Siculi, which terminated in the total subjection of the latter; after which Syracuse became so powerful, that it in a manner gave law to the whole island. The Greek cities indeed enjoyed a perfect liberty; but they all acknowledged Syracuse as their metropolis: by degrees, however, the latter began to assume such an authority over them as was totally inconsistent with liberty; and this occasioned many wars, which involved them in much distress and danger. They began with the Leontines, whose territory they laid waste, and reduced their city to great straits. Leontini was an Athenian colony: and this furnished the Athenians,

8 Syracuse invaded by the Athenians without success.

who had already meditated the conquest of Sicily, with a pretence to attack the Syracusans with their whole force. Under colour of assisting their countrymen, therefore, they sent a fleet of 250 sail to Sicily; but the Leontines, sensible that their pretended allies aimed at nothing less than the conquest of the whole island, concluded a peace with Syracuse; and the disappointed Athenians vented their rage on those who had advised and conducted the expedition.

During the continuance of the popular government, the Syracusans took part in the long war between Athens and Sparta. The circumstances which took place in this contest are sufficiently detailed under ATTICA, N° 126—150.

This war was scarcely ended, when a new and formidable invasion by the Carthaginians took place; but the event of that expedition was as unfortunate to the Carthaginians as the former had been, as has been particularly related under the article CARTHAGE, N° 12. *et seq.* 9 New invasion by the Carthaginians.

In the mean time, a considerable revolution had happened in Syracuse. The city of Agrigentum had been taken by the Carthaginians, and of the few inhabitants who escaped, some fled to Syracuse, where they accused the Syracusan commanders of having betrayed the city into the hands of the enemy. Dionysius, a man of great valour and address, but who had become very obnoxious to the populace, took this opportunity of attempting to retrieve his credit. He therefore supported the accusations brought against his countrymen by the Agrigentines, and even impeached the magistrates as having a secret intelligence with the enemy, and attempting to introduce an oligarchy. As his speech was entirely levelled against the more wealthy citizens, it was very agreeable to the lower class: the commanders were instantly degraded; and others, among whom was Dionysius, were appointed. Having once gained this point, he began to consider how he might get all his colleagues turned out. For this purpose he never joined in any council of war with the other commanders, nor imparted to them his resolutions, giving out that he could not trust them, and that they had more regard for their own interest than the welfare of their country. But while he was proceeding in this manner, the more prudent part of the citizens, perceiving what he aimed at, complained of him to the senate and magistrates, and fined him as a disturber of the public peace. According to the laws, the fine was to be paid before he could speak in public, and the circumstances of Dionysius did not allow him to discharge it. In this dilemma he was assisted by Philistus the historian, a man of great wealth, who not only paid this fine for him, but encouraged him to speak his mind freely, as it became a zealous citizen to do, promising to pay all the fines that should be laid upon him. 10 Rise of Dionysius.

Being extricated out of this difficulty, Dionysius next proceeded to inveigh, with all the eloquence of which he was master, against those who by means of their power or interest were able to oppose his designs, and by degrees brought them into discredit. His next scheme was to get those exiles recalled whom the nobility had banished at different times; as thinking that they would support him with all their power, as well out of gratitude as out of hatred to the opposite party. Having gained this point also, he next found means to ingratiate him-

Syracuse. self with the soldiery to such a degree, that, under pretence of taking proper measures for resisting the Carthaginians, he was chosen commander in chief, with absolute and unlimited power. This was no sooner done, than, pretending his life was in danger, he chose out 1000 men for his guard, whom he attached to his interest by great promises. As no person durst now oppose him, he possessed himself of the capital, where all the arms and provisions were kept; after which he publicly took the title of king of Syracuse in the year 404 B. C.

11 who becomes king of Syracuse. An. 404. B. C.

The Syracusans did not tamely submit to their new master: but Dionysius managed matters so well, that their frequent revolts answered no other purpose than more certainly to entail slavery on themselves; and he was allowed to possess the throne without much opposition till his death, which happened in the year 366 B. C.

12 Dionysius II. An. 366. B. C.

On the death of Dionysius, he was succeeded by his son, called also Dionysius. He was naturally of a mild and peaceable temper, averse to cruelty, and inclined to learning; but his father, to whom all merit, even in his own children, gave umbrage, stifled as far as possible his good qualities by a mean and obscure education. He no sooner ascended the throne, than Dion, brother to Aristomache the other wife of Dionysius the Elder, undertook to correct the faults of his education, and to inspire him with thoughts suitable to the high station in which he was placed. For this purpose he sent for the philosopher Plato, under whose care he immediately put the young king. This instantly produced a reformation on Dionysius; but the courtiers, dreading the effects of the philosopher's instructions, prevailed on him to banish Dion, and to keep Plato himself in a kind of imprisonment in the citadel. At last, however, he set him at liberty; upon which Plato returned to his own country.

13 Put under the care of Plato by his uncle Dion, whom he banishes.

Dion, in the mean time, visited several of the Grecian cities, and at last took up his residence in Athens; but the honours which were everywhere paid him, raised such jealousies in the breast of the tyrant, that he stopped his revenue, and caused it to be paid into his own treasury. In a short time Dionysius again sent for Plato; but finding it impossible to dissolve the friendship between him and Dion, disgraced, and placed him in a very dangerous situation, in the midst of assassins who hated him. Not daring, however, to offer him any violence, he allowed him soon after to depart; revenging himself on Dion, whose estate he sold, and gave his wife Arete in marriage to Timocrates one of his flatterers.

Dion now resolved to revenge himself on the tyrant for the many injuries he had sustained, and at once to deliver his country from the oppression under which it groaned. He began with raising foreign troops privately, by proper agents, for the better execution of his design. Many Syracusans of distinction entered into his scheme, and gave him intelligence of what passed in the city; but of the exiles, of whom there were upwards of 1000 dispersed up and down Greece, only 25 joined him; so much were they awed by the dread of the tyrant. The troops were assembled at the island of Zacynthus, in number only about 800; but who had all been tried on many occasions, were well disciplined, and capable of animating by their example the forces which Dion hoped to find in Sicily. When they were about to sail, Dion acquainted them with his design, the boldness of which at first occasioned among them no small consternation; but Dion soon removed their fears, by telling them that he did not lead them as soldiers, but as officers, to put them at the head of the Syracusans and all the people of Sicily, who were ready to receive them with open arms. Having then embarked in two small trading vessels, they arrived in 12 days at Cape Pachynum near Syracuse. At last they arrived at the port of Minoa, not far from Agrigentum. Here they received intelligence that Dionysius had set sail for Italy, attended by a fleet of 80 galleys. On this Dion resolved to take advantage of the tyrant's absence, and immediately set sail for Syracuse. On his march he prevailed on the inhabitants of Agrigentum, Gela, Camarina, and other cities, to join him. As soon as he entered the territories of Syracuse, multitudes flocked to him; and as nobody appeared to oppose him, he boldly entered the city, where he quickly found himself at the head of 50,000 men. As soon as he had landed in Sicily, Timocrates, to whom his wife Arete had been given by Dionysius, and to whom the care of the city had been left, dispatched a courier to let the tyrant know the danger in which he was. Dionysius was, however, accidentally prevented from receiving a timely account of Dion's arrival; so that when he entered the citadel by sea, seven days after Dion's arrival, he found his affairs in a desperate situation. Upon this he had recourse to artifice; and having amused the Syracusans by a feigned negociation, until he observed that they kept a negligent guard, he attacked them all at once with such fury, that he had almost taken the city. But Dion encouraged the soldiers by his example so much, that he at last obtained a complete victory; for which they presented him with a crown of gold.

14 Dion raises troops for dethroning the tyrant.

15 Enters Syracuse without opposition.

16 Dionysius arrives, but is totally defeated.

It was not long, however, before the ungrateful Syracusans began to think of conferring quite different rewards on their benefactor. Dionysius had the address to render him suspected by the multitude; at the same time that Heraclides, an excellent officer, but a secret enemy to Dion, did all that lay in his power to sink his credit. Dionysius was soon obliged to fly into Italy, but left Heraclides to oppose Dion.

17 Ingratitude of the Syracusans to Dion.

At length Dion got possesion of the city, Heraclides submitted to him, and was received into favour; but as his seditious and turbulent behaviour still continued, Dion at last gave orders to put him to death. This action, however necessary, so affected the mind of Dion, that he became melancholy; and ever after imagined himself haunted by a frightful spectre, resembling a woman of gigantic stature, with the haggard looks and air of a fury. In a short time after he lost his life, through the base treachery of Calippus, or Gylippus, who pretended to be his intimate friend, and who immediately after caused his wife and sister to be carried to prison.

18 Dion becomes melancholy, and is murdered.

Calippus having removed Dion, soon made himself master of Syracuse, where he committed all manner of cruelties; but was driven out, and forced to fly to Rhegium, where he was murdered by the same dagger which had killed Dion. In 350 B. C. Dionysius again made himself master of Syracuse; and being exasperated by his past misfortunes, tyrannized worse than ever. The Syracusans first had recourse to Icetas tyrant of Leontini; but as the Carthaginians took this opportunity to invade

19 Dionysius restored.

Syracuse. vade them with a powerful fleet and army, they were obliged to apply to the Corinthians. By them Timoleon, a celebrated commander, was sent to the assistance of the Syracusans, whom he found in a very distressed situation; Icetas being master of the city, the Carthaginians of the harbour, and Dionysius of the citadel.

20 Surrenders to Timoleon, and keeps a school at Corinth. As all parties were equally the enemies of Dionysius, he found it impossible to hold out, and therefore surrendered himself to Timoleon, by whom he was sent to Corinth; where at last he was reduced to the necessity of teaching a school for his support.

After the expulsion of the tyrant, Timoleon withdrew to Catana, leaving only 400 Corinthians, under the command of an experienced officer named *Leon*, to guard the citadel. These were immediately besieged by Icetas and the Carthaginians, but Timoleon found means to relieve them in spite of all opposition; and having dispersed emissaries through the army of Mago the Carthaginian general, exhorting the mercenary Greeks to forsake him, he was so much intimidated, that in spite of all the remonstrances Icetas could make, he set sail for Africa, leaving his colleague to carry on the war in the best manner he could.

21 Cowardice of the Carthaginians.

The day after the departure of Mago, Timoleon assaulted the city so briskly, that the troops of Icetas were driven from the walls, and the Corinthians became masters of the place. Timoleon, by sound of trumpet, invited the inhabitants to come and assist in demolishing the citadel and other castles, which he called the *nests of tyrants:* after which he caused edifices to be erected in the place where the citadel had stood, for the administration of justice. He found the city in a most miserable situation: for many having perished in the wars and seditions, and others having fled to avoid the oppression of tyrants, Syracuse, once so wealthy and populous, was now become almost a desert; insomuch that the horses were fed on the grass which grew on the market-place. Timoleon supplied the city with inhabitants from Corinth and other cities of Greece, at the same time that great multitudes from Italy and the other parts of Sicily resorted thither. Timoleon distributed the lands among them *gratis;* but sold the houses, and with the money arising from the sale established a fund for the support of the poor. Having thus restored Syracuse, he in like manner delivered all the Greek cities of Sicily from the tyrants who had taken possession of them, all of whom he put to death. After this he resigned his authority, and led a retired life, honoured in the highest degree by the Syracusans, and by all the cities in Sicily. After his death he was honoured as a god; the expence of his funeral was defrayed by the public; sports, with horse-races and gymnastic exercises, were held annually on the day of his death; and it was decreed, that whenever the Syracusans were at war with the barbarians, they should send to Corinth for a general.

22 Citadel of Syracuse and other forts demolished by Timoleon.

23 He repeoples the city.

24 Dies, and is honoured as a god.

25 Syracuse again falls under the power of tyrants.

For 20 years the Syracusans enjoyed the fruits of Timoleon's victories; but new disturbances arising, in a short time another tyrant started up, who exceeded all that had gone before him in cruelty and other vices. This was the celebrated Agathocles, of whose exploits against the Carthaginians a full account is given under the article CARTHAGE, N° 33—53. He was poisoned by one Mœnon in the year 289 B. C. after having reigned 28 years, and lived 95.—A succession of tyrants followed, till at last the city, being held by two rivals, Tœnion and Sosistratus, who made war within the very walls, Pyrrhus king of Epirus was invited into Sicily, in order to put an end to these distractions. He willingly complied with the invitation; and was everywhere received with loud acclamations, as the deliverer not only of Syracuse, but of all Sicily. As he had a fine army of 30,000 foot and 5000 horse, with a fleet of 200 sail, he drove the Carthaginians from place to place, till he left them only the two strong posts of Eryx and Lilybæum. The former of these he took by assault, and was himself the first man who mounted the walls, after having killed a great number of Africans with his own hand. The Mamertines likewise, who had conquered a considerable part of the island, were everywhere defeated and driven out, till at last they were shut up in the city of Messana. The Carthaginians, alarmed at the rapidity of his conquests, sent ambassadors with proposals of peace upon very advantageous terms; but Pyrrhus, puffed up with the expectation of reducing the whole island, refused to hearken to any terms unless they would instantly abandon it. So firm was he in the belief of this, that he caused his son to assume the title of *king of Sicily;* but in the mean time, having displeased the Sicilians by his arbitrary behaviour, they deserted from him in such numbers that he was glad to set out for Italy, for which retreat the embassies he received from the Samnites, Tarentines, and other Italians, furnished him with an honourable pretext. He embarked in the ships which he had brought with him from Italy; but was met at sea by the Carthaginians, who sunk 70 of his vessels, and dispersed or took the rest; so that he saved himself in Italy with only 12 vessels, the poor remains of a fleet of 200 sail. No sooner were the Mamertines apprised of his departure, than they dispatched a body of 18,000 men to harass him after his landing. These having passed the straits before him, posted themselves in the road which Pyrrhus must take in marching by land to Tarentum; and concealing themselves among woods and rocks, attacked him unexpectedly, and with great resolution. But Pyrrhus behaved on this occasion with his usual bravery. The attack being made on his rear, he hastened thither, and made a dreadful slaughter of the enemy, till a wound on his head obliged him to retire.

Syracuse.

26 Pyrrhus king of Epirus invited into Sicily.

27 Syracuse harassed by the Mamertines.

28 Hiero chosen general of the Syracusan forces.

After the departure of Pyrrhus, Hiero the son of Hierocles, a descendant of Gelon, the first king of Syracuse, was chosen general of the forces, along with another named *Artemidorus.* The two generals had nothing more at heart than to put an end to the confusion and disorder which reigned in the city; for which reason they entered it at the head of their forces. On this occasion Hiero discovered extraordinary talents for government. By mere dint of insinuation and address, without shedding blood, or hurting a single citizen, he calmed the minds of the people; reconciled the factions; and so gained the affections of all, that he was invested with the whole civil as well as military power in the state. Soon after this, he married the daughter of one of the first citizens; and having distinguished himself by his exploits against the Mamertines, was unanimously elected king of Syracuse, in the year 265 B. C.

29 Is elected king of Syracuse. An. 265. B. C.

Some time after Hiero's accession to the throne, he again defeated the Mamertines, and reduced them to such straits, that they were obliged to call in the Ro-

mans

Syracuse. mans to their assistance. The consequences of this have been fully related under the articles ROME and CARTHAGE. Hiero, who had allied himself with the Carthaginians, being himself defeated by the Romans, and finding his allies unable to protect him against the power of that republic, concluded an alliance with them; and continued faithful to them even in the time of the second Punic war, when they were in the greatest distress. In his reign flourished the celebrated mathematician Archimedes, whose genius he employed in fortifying the city of Syracuse, by innumerable machines, in such a manner as rendered it absolutely impregnable to every method of attack known at that time.

30 Hieronymus allies with the Carthaginians.

Hiero died about 211 B. C. and was succeeded by his grandson Hieronymus: but he imprudently forsook the counsels of his grandfather, and entered into an alliance with the Carthaginians. Soon after this he was murdered, in consequence of his tyranny and cruelty, and the greatest disorders took place in the city; which Hannibal, though then in Italy, found means to foment, in hopes of keeping the Syracusans in his interest. This indeed he effected; but as his own affairs in Italy began to decline*, he could not prevent Marcellus from landing in Sicily with a formidable army, which the Sicilians could by no means resist. Syracuse was soon invested; but the machines invented by Archimedes baffled all attempts to take it by assault. The immense preparations which the consul had made for taking the city by storm, could not have failed to accomplish his purpose, had the place been otherwise defended than by the contrivance of Archimedes. The Roman fleet consisted of 60 quinqueremes, besides a far greater number of other ships. The decks were covered with soldiers armed with darts, slings, and bows, to drive the besieged from the ramparts, which on one side were washed by the sea, and to facilitate the approach to the walls. But a machine of Marcellus's own invention, called a *sambuca*, was what he chiefly depended on. The consul's design was to bring his sambuca to the foot of the walls of Acradina; but, while it was at a considerable distance (and it advanced very slowly, being moved only by two ranks of rowers), Archimedes discharged from one of his engines a vast stone, weighing, according to Plutarch's account, 1250 pounds, then a second, and immediately after a third; all which, falling upon the sambuca with a dreadful noise, broke its supports, and gave the galleys upon which it stood such a violent shock that they parted, and the machine which Marcellus had raised upon them at a vast trouble and expence was battered to pieces. At the same time, several other machines, which were not visible without the walls, and consequently did not lessen the confidence of the Romans in the assault, played incessantly upon their ships, and overwhelmed them with showers of stones, rafters, and beams pointed with iron; insomuch that Marcellus, being at a loss what to do, retired with all possible haste, and sent orders to his land-forces to do the same; for the attack on the land-side was attended with no better success, the ranks being broken and thrown into the utmost confusion by the stones and darts, which flew with such noise, force, and rapidity, that they struck the Romans with terror, and dashed all to pieces before them.

* See *Carthage*, N° 123.

31 Syracuse invested.

32 Incredible effects of the machines of Archimedes.

Marcellus, surprised, though not discouraged, at this artificial storm, which he did not expect, held a council of war, in which it was resolved, the next day before sunrise, to come up close under the wall, and keep there. They were in hopes by this means to secure themselves against the terrible storm of stones and darts which fell on the ships when at a distance. But Archimedes had prepared engines which were adapted to all distances. When the Romans therefore had brought their ships close under the wall, and thought themselves well covered, they were unexpectedly overwhelmed with a new shower of darts and stones, which fell perpendicularly on their heads, and obliged them to retire with great precipitation. But they were no sooner got at some distance, than a new shower of darts overtook them, which made a dreadful havock of the men, while stones of an immense weight, discharged from other machines, either disabled or broke in pieces most of their galleys. This loss they sustained, without being able to revenge it in the least on the enemy. For Archimedes had placed most of his engines behind the walls, and not only out of the reach, but even out of the sight, of the enemy; so that the Romans were repulsed with a dreadful slaughter, without seeing the hand that occasioned it. What most harassed the Romans in the attack by sea, was a sort of crow with iron claws, fastened to a long chain, which was let down by a kind of lever. The weight of the iron made it fall with great violence, and drove it into the planks of the galleys. Then the besieged, by a great weight of lead at the other end of the lever, weighed it down, and consequently raised up the iron of the crow in proportion, and with it the prow of the galley to which it was fastened, sinking the poop at the same time into the water. After this the crow letting go its hold all of a sudden, the prow of the galley fell with such force into the sea, that the whole vessel was filled with water, and sunk. At other times, the machines, dragging ships to the shore by hooks, dashed them to pieces against the points of the rocks which projected under the walls. Other vessels were quite lifted up into the air, there whirled about with incredible rapidity, and then let fall into the sea, and sunk, with all that were in them. How these stupendous works were effected, few, if any, have hitherto been able to comprehend.

The troops under the command of Appius suffered no less in this second attack than the fleet. In the whole space of ground which the army, when formed, took up, the last files as well as the first were overwhelmed with showers of darts and flints, against which they could not possibly defend themselves. When they had with infinite trouble brought the mantlets and covered galleries, under which they were to work the rams, near the foot of the wall, Archimedes discharged such large beams and stones upon them as crushed them to pieces. If any brave Roman ventured to draw too near the wall, iron hooks were immediately let down from above, which, taking hold of his clothes or some part of his body, lifted him up in the air and dashed out his brains with the fall. Marcellus, though at a loss what to do, could not however forbear expressing himself with pleasantry: Shall we persist, said he to his workmen, in making war upon this Briareus, upon this giant with an hundred hands? But the soldiers were so terrified, that if they saw upon the walls only a small cord, or the least piece of wood, they immediately turned their backs and fled, crying out, that Archimedes was going to discharge some dreadful machine upon them.

The

Syracuse.

The consuls, finding themselves thus defeated in every attempt, turned the siege into a blockade, reduced most of the other places in the island, and defeated the forces which were sent against them; and at last Marcellus made himself master of Syracuse itself.

33 The siege turned into a blockade.

He took the opportunity of a festival, when the soldiers and citizens had drunk plentifully, to make a detachment scale the walls of Tyche, in that part of it which was nearest to Epipolæ, and which was ill guarded. He presently after possessed himself of Epipolæ; whereupon the inhabitants of Neapolis, as well as Tyche, sent deputies to him, and submitted.

34 Account of the taking of Syracuse.

35 The city plundered and Archimedes killed.

Marcellus granted life and liberty to all of free condition, but gave up those quarters of the city to be plundered. The soldiers had orders to spare the lives of the citizens; but they were cruel in their avarice, slew many of them, and among the rest the incomparable Archimedes. He was very intent on a demonstration in geometry, and calmly drawing his lines, when a soldier entered the room, and clapped a sword to his throat. "Hold! (said Archimedes) one moment, and my demonstration will be finished." But the soldier, equally regardless of his prayer and his demonstration, killed him instantly. There are different accounts of the manner of his death; but all agree that Marcellus regretted it extremely, and showed a singular favour to his relations for his sake.

36 Syracuse destroyed by the Saracens.

The city of Syracuse continued subject to the western empire till its declension, when the island of Sicily, being ravaged by different barbarians, the capital also underwent various revolutions; till at last, in the 9th century, it was so destroyed by the Saracens, that very few traces of its ancient grandeur are now to be seen. "The ancient city of Syracuse was of a triangular form, and consisted of five parts or towns. The circuit, according to Strabo, amounted to 180 stadia, or 22 English miles, and four furlongs. An account which Mr Swinburne once suspected of exaggeration; but, after spending two days in tracing the ruins, and making reasonable allowances for the encroachments of the sea, he was convinced of the exactness of Strabo's measurement.

At present it is fortified strongly toward the land, and the ditches of the bastions form the communications between the two havens. It is very weak towards the sea, but the shelves render it hazardous to debark on that side. The garrison is one of the best appointed in the kingdom, but the heights of Acradina command the works.

About eighteen thousand inhabitants are now contained in it. The dwellings are far from being memorials of ancient Syracusan architecture or opulence. In any other situation they might be thought tolerable; but to observers who reflect on the style of those buildings that probably once covered the same ground, the present edifices must have a mean appearance. The ancient temple of Minerva is now turned into a cathedral. The walls of the cella are thrown down, and only as much left in pillars as is necessary to support the roof; the intercolumniations of the peristyle are walled up. This temple is built in the old Doric proportions used in the rest of Sicily; its exterior dimensions are 185 feet in length and 75 in breadth. There are also some remains of Diana's temple, but now scarcely discernible. Besides these, there are few ruins in the island; and one is surprised that any should exist in a place which had been so often laid waste by enemies, and so often shaken by earthquakes. E. Long. 15. 27. N. Lat. 37. 3.

Syracuse, Syria.

SYRIA, a very ancient kingdom of Asia, lying between the Mediterranean on the west, the Euphrates on the east, and Arabia Deserta, Phœnicia, and Palestine, on the south.

1 Names, divisions, &c. of ancient Syria.

In ancient times this country was called *Aram*, probably from Aram the youngest son of Shem. At first it was parcelled out into several petty states; all of which seem afterwards to have been reduced under subjection to the four principal ones, Zobah, Damascus, Hamath, and Geshur. Afterwards the whole country was divided into two parts only, viz. Cœlesyria and Phœnicia; though the Phœnicians, Idumeans, Jews, Gazites, and Azotites, or the whole country of the Philistines, was included. After the death of Alexander, Syria in the great extent of the word, was divided, according to Strabo, into Comagene, Seleucis of Syria, Cœlesyria, Phœnice on the sea coast, and Judea in the midland. Ptolemy, however, subdivides these; and in the Proper Syria reckons only Comagene, Pieria, Cyrrhistica or Cyrrhestica, Seleucis, Cassiotis or Casiotis, Chalybonitis, Chalcidice or Chalcidene, Apamene, Laodicene, Phœnicia Mediterranea, Cœlesyria, and Palmyrene.

The history of the ancient Syrians, till the time of their being carried away by the kings of Assyria, is totally unknown, excepting a few particulars which may be gathered from Scripture, and which it is needless here to repeat. During the continuance of the Assyrian, Babylonian, and Persian monarchies, the history of this country affords nothing remarkable; but after the death of Alexander, it gave name to a very considerable empire, which makes a conspicuous figure in ancient history. At this time, however, it was not confined to Syria properly so called, but comprehended all those vast provinces of the Upper Asia which formed the Persian empire; being, in its full extent, bounded by the Mediterranean upon one side, and the river Indus on the other.

2 Seleucus the first king of Syria after Alexander the Great.

The first king was Seleucus, one of the generals of Alexander the Great; who, after the death of that conqueror, being made governor of Babylon, was tempted, by the example of Alexander's other captains, to set up for himself. Eumenes, who had sincerely at heart the interest of Alexander's family, solicited his assistance against Antigonus, who had openly revolted; but Seleucus not only refused his assistance, but attempted to destroy Eumenes himself with his whole army. Eumenes, however, found means to escape the danger without the loss of a man. On this Seleucus endeavoured to gain over his troops: but finding that impossible, he made a truce with Eumenes, and granted him a safe passage through his province; but at the same time sent an express to Antigonus, desiring him to fall upon him, before he was joined by the governors of Upper Asia. Antigonus did not fail to follow his advice; but having prevailed against Eumenes through treachery, he next thought of bringing Seleucus himself under subjection.

3 Obliged by Antigonus to fly into Egypt.

On his return to Babylon, therefore, after having been feasted with his whole army by Seleucus, he demanded of him an account of the revenues of his province. Receiving an unfavourable answer to this requisition, Antigonus was so much exasperated, that Seleucus, not thinking himself a match for him at that time, thought proper to fly into Egypt.

By

Syria.

By the flight of Seleucus, Antigonus was left master of all his provinces; but his son Demetrius being afterwards defeated by Ptolemy at Gaza, Seleucus began to think of recovering what he had lost. Having received from Ptolemy a very slender force, he set out towards Babylon, and procured reinforcements as he proceeded.

4 Becomes master of Babylon. An. 312. B. C.

As he approached the city, those who favoured Antigonus retired into the citadel, but were soon obliged to surrender; and in that fortress Seleucus found his children, friends, and domestics, whom Antigonus had kept prisoners ever since his flight into Egypt.

Seleucus having made himself master of Babylon, in the year 312 B. C. began to prepare for encountering Antigonus, who he knew would soon attack him with all his force.

5 Defeats Nicanor, and reduces Media and Susiana.

Nicanor, governor of Media under Antigonus, first advanced against him at the head of 10,000 foot and 7000 horse; but Seleucus, with only 3000 foot and 400 horse, having drawn him into an ambush, cut off almost the whole of his army, and such of the soldiers as had escaped the slaughter willingly enlisted under his banner.

The consequence of this victory was the submission of all Media and Susiana; but during his absence from the capital, Demetrius advanced towards it, and made himself master of it.

On the return of Seleucus to Babylon, he easily drove out the troops left by Demetrius, recovered the castle which he had garrisoned, and settled his authority on such a firm foundation, that it could never afterwards be moved. Having then marched again into Media, he defeated and killed with his own hand Nicanor or Nicator, whom Antigonus had sent against him; after which, having settled the affairs of Media, he reduced all Persia, Bactria, and Hyrcania, subjecting to his new empire these and all the other provinces on this side the Indus which had been conquered.

Seleucus being now master of all the countries which lie between the Euphrates and the Indus, took the title of king of Babylon and Media. But, not satisfied with these possessions, ample as they were, he crossed the Indus, in order to conquer those regions which had submitted to Alexander beyond that river. In this expedition, however, he was unsuccessful; but returning westward against his old enemy Antigonus, he defeated and killed him at Ipsus, and reduced his son Demetrius to a very dependent state. Seleucus now betook himself to the building of a city, which he called *Seleucia*, and which stood on the place where the city of Bagdad now stands. Besides these, he built a great many others; 16 of which he called *Antioch*, from the name of his brother Antiochus; nine *Seleucia*, from his own name; three *Apamea*, from Apama his first wife; one *Stratonicea*, from his second wife Stratonice; and six *Laodicea*, from his mother Laodice.

In 284 Seleucus entered into a war with Lysimachus, with whom he had hitherto lived in strict amity. Out of 36 general officers left by Alexander the Great, they two survived, and both were upwards of 70 years old. Nevertheless they were both filled with the ambition and animosity of young men.

6 Defeats and kills Lysimachus.

The two armies met at a place called *Curopedion* in Phrygia, where an obstinate engagement took place. Victory was long doubtful: but at last Lysimachus was run through with a spear, and died on the spot; on which his troops betook themselves to flight. This victory added to the possessions of Seleucus all those provinces which had formerly been subject to Lysimachus, and from this victory he is generally called *Nicator*, or *the conqueror*.

7 Is himself treacherously murdered.

His triumph, however, on this occasion, was but short-lived; for seven months after, as he was marching towards Macedon to take possession of that kingdom, he was treacherously murdered by Ptolemy Ceraunus, on whom he had conferred innumerable favours.

8 Antiochus Soter. An. 280. B. C.

Seleucus was succeeded by his son Antiochus Soter, who held the empire 19 years. He resigned to Antigonus Gonatus all pretensions to the crown of Macedon; and having engaged in a war with Eumenes king of Pergamus, he was defeated by him, and obliged to yield up part of his dominions.

9 Antiochus Theos. An. 261 B. C.

He died in 261 B. C. and was succeeded by his son Antiochus Theos; who having engaged in a war with Ptolemy Philadelphus king of Egypt, the Parthians and Bactrians took that opportunity to revolt, and could never afterwards be reduced. In 246 B. C. he was poisoned by his wife Laodice, who raised to the throne her own son, named *Seleucus Callinicus*.

10 Seleucus Callinicus. An. 246. B. C.

He was succeeded by his eldest son Seleucus Ceraunus, a weak prince, who was poisoned by a conspiracy of two of his officers, when he had reigned one year; after which his brother Antiochus, surnamed the *Great*, ascended the throne in 225 B. C.

11 Antiochus the Great. An. 225. B. C.

In the very beginning of his reign, two of his generals, Alexander and Molo, rebelled against him. The former had been appointed governor of Persia, and the latter of Media. Antiochus marched against the rebels, whom he defeated in a pitched battle; on which their chiefs laid violent hands on themselves.

12 Suppresses one rebellion, but is embarrassed by another.

On his return he received the submission of the Atropatii, a barbarous people in Media; and put to death his prime minister Hermias, whom he had found hatching treacherous designs against him. During his lifetime, however, the traitor, by accusing Achæus of treason, had obliged him to revolt in his own defence; so that the king had still two important wars on his hands, viz. one with Ptolemy king of Egypt, and the other against Achæus. After some deliberation, he resolved to march first against the king of Egypt; and was at first very successful, reducing many cities in Cœlesyria and Palestine, and defeating the Egyptians in a pitched battle; but in the year 217 B. C. being worsted in the battle of Raphia, he was obliged to abandon all his conquests; of which Ptolemy immediately took possession, and Antiochus was obliged to cede them to him, that he might be at leisure to pursue the war against Achæus.

Antiochus having made vast preparations for his expedition, soon reduced Achæus to such distress, that he was obliged to shut himself up in the city of Sardis, which he defended for some time with great bravery; till at last, being betrayed by two Cretans, he was delivered up to the king, and by his order put to death.

13 His successes in the east.

Antiochus then undertook an expedition against the Parthians, whom he obliged to conclude a peace on very advantageous terms. He then turned his arms against the king of Bactria, whom he also compelled to agree to his terms. He then crossed Mount Caucasus, and entered India; where he renewed his alliance with the king of that country. From India he marched into Arachosia, Drangiana, and Carmania, establishing order and discipline in all those countries: then passing through Persia, Babylonia, and Mesopotamia, he returned to Antioch, after an absence of seven years.

In

Syria.

14 Enters into a league with Philip of Macedon against the king of Egypt. An. 204. B. C.

In the year 204 B. C. Antiochus entered into a league with Philip of Macedon, on purpose to deprive Ptolemy Epiphanes, the infant king of Egypt, of all his dominions. He defeated the Egyptian general, recovered all Palestine and Cœlesyria; after which he invaded Asia Minor, in hopes of reducing it also, and restoring the Syrian empire to the same extent it had in the time of Seleucus Nicator. The free cities in Asia Minor immediately had recourse to the Romans, who sent an embassy to Antiochus on the occasion;

15 His conquests checked by the Romans.

but as both parties put on those haughty and imperious airs to which they thought the greatness of their power gave them a right, no satisfaction was given, but every thing tended to an open rupture. While matters were in this situation, Hannibal the Great, being obliged to leave

16 Hannibal flees to him for protection.

his own country, fled to Antiochus: from whom he met with a gracious reception. As Hannibal had, while a child, sworn perpetual enmity against the Romans, he used all his eloquence to persuade Antiochus to make war with them; and as the many victories which he had gained over them left no room to doubt of his capacity, Antiochus doubted nothing of being able, by his assistance, to conquer that haughty people. Several embassies passed between the two nations; but chiefly with a design, on the part of Antiochus, to gain time. Hannibal endeavoured to draw his countrymen into the confederacy against Rome, but without effect.

17 Antiochus neglects the advice of Hannibal

Antiochus having strengthened himself by several alliances, at last resolved to begin the war in earnest. The king imprudently became the aggressor, by falling on a body of 500 Romans before war had been declared. He also made King Philip his enemy, by entertaining the

18 His shameful behaviour.

regent of Athamania, who was a pretender to the crown of Macedon. To complete all, he himself fell in love, though above 50 years of age, with a beautiful young woman of Chalcis, whom he married; and became so great a slave to this passion, that he entirely neglected his affairs; the army gave themselves up entirely to dissipation and debauchery, and every trace of military discipline vanished.

19 Is defeated by the Romans at Thermopylæ. An. 191. B. C.

In the year 191 B. C. Antiochus was roused from his lethargy by a declaration of war against him at Rome, and set out for Ætolia. His army at this time amounted to no more than 10,000 foot and 500 horse. He had been made to believe that he would receive a vast reinforcement in Ætolia: but when he came to make the experiment, he soon found his mistake; all the troops he could raise there amounted to no more than 4000 men. With this force, so exceedingly inadequate to the purpose, he was obliged to oppose the Roman army, who were advancing in conjunction with the Macedonians, and had already made surprising progress. Antiochus seized the straits of Thermopylæ; but was driven from them by the Romans, the king himself being the first that fled. Almost his whole army was destroyed in the battle or in the pursuit, and Antiochus returned with disgrace into Asia.

Soon after his return, Antiochus equipped a fleet of 200 sail; on which he immediately embarked for the Thracian Chersonesus, now Crim Tartary. He fortified the cities of Lysimachia, Sestus, and Abydos, with others in that neighbourhood, to prevent the Romans from crossing the Hellespont. In the mean time Polyxenidas the Syrian admiral sent intelligence to the king that the Roman fleet had appeared off Delos; upon which he desired him to seek them out and engage them at all events. He did so, and was defeated with the loss of 40 ships taken or sunk in the engagement.

20 His fleet defeated by that of the Romans.

This was soon after revenged by the destruction of the Rhodian fleet by the artifice of Polyxenidas; but in the end the king's affairs went everywhere to wreck. Having laid siege to the city of Pergamus, he was obliged to raise it with loss; the Phœnician fleet commanded by

21 Meets with two other defeats, and becomes like one infatuated.

Hannibal was defeated by the Rhodians: and soon after the Syrian fleet under Polyxenidas was utterly defeated by the Romans. Antiochus was so much disheartened by these repeated defeats, that he appeared like one infatuated. Instead of fortifying more strongly those cities which lay on the frontiers of his kingdom, he entirely deserted them: and thus Lysimachia and Abydos, the two keys to Asia, fell into the hands of the Romans without the least resistance.

The arrival of the Romans in Asia struck Antiochus with such terror, that he instantly sued for peace. The terms he offered were indeed very advantageous, but by no means agreeable to the expectations of the Romans.

22 Sues for peace, but is refused.

They therefore gave him his final answer: 1. That since he had drawn upon himself the war, he should defray the whole expence of it; 2. That he should restore liberty in general to all the Greek cities in Asia; and, 3. That to prevent future hostilities, he should relinquish all Asia on this side Mount Taurus. These terms, however, still appeared to him so intolerable, that he resolved to continue the war; and determined also to take the most imprudent method of carrying it on, namely, by hazarding all on the event of a general engagement. The king encamped near Magnesia, and strongly fortified his camp. The Romans insulted him in his trenches, and proposed to attack his fortifications if he continued to decline an engagement. At last the king, thinking it would be shameful for him longer to refuse an engagement, being at the head of an army far more numerous than that of the enemy, in a friend's country, and in the midst of his allies, resolved at all events to accept the challenge, and accordingly prepared for a decisive battle.

23 Battle of Magnesia.

On the day of the battle the weather proved very favourable to the Romans; for a thick fog rising in the morning, the day was almost turned into night, so that the Syrian commanders could not have all the corps under their command in view, on account of their great extent, nor send them proper orders in time; whereas the fog was not thick enough to prevent the Roman generals from seeing their several bodies at the greatest distance, as they took up but little ground. Besides, the damp which was occasioned by the fog slackened the strings of the enemy's bows, so that the Asiatics who used them could shoot their darts and arrows but faintly. The whole dependence of Antiochus in the first attack was on his armed chariots, which were to cut their way into the Roman army. But Eumenes, king of Pergamus, undertook to render them useless, and even fatal, to the enemy. After this advantage, the Roman cavalry advanced, and fell on those whom the chariots

24 The Syrians defeated.

had put in disorder. The Syrians being already intimidated, after a faint resistance gave way; and the Romans made a great slaughter of their men and horses, both being borne down with the weight of their heavy armour. Eumenes charged the left wing, in which Seleucus commanded, with such vigour, that he put it to flight;

Syria. and the fugitives flying to the phalanx for protection, put that body likewise in disorder; which Domitius observing, advanced against it at the head of his legionaries, but could not break it till he ordered his men to attack the elephants which the Syrians had placed in the spaces between the companies. The Romans had learned, in their wars with Pyrrhus and Hannibal, not to fear those monsters which were once so terrible to them. They attacked them, therefore, with great resolution; and driving them against the phalanx, put that body into disorder, by means of those very animals which had been posted there for its defence.

After a long and bloody contest, the Syrians were totally routed, and the Romans walking over heaps of
25 And their camp taken. dead bodies, marched up to the Syrian camp, attacked, and plundered it. The riches they found in it are not to be described; but the taking of it cost the Romans a new battle, which proved more fatal to the Syrians than that in the field; for the Romans having, in spite of a most desperate resistance, forced the intrenchments, gave no quarter, but put all to the sword without distinction. There fell this day in the battle, in the pursuit, and in the plunder of the camp, 50,000 foot and 4000 horse; 1500 were taken prisoners, and 15 elephants. In the consular army there were but 300 foot killed and 35 horse. Eumenes had only 15 of his men killed; so that this victory, as we are told by the ancients, seemed a prodigy to all nations both of the east and west.

Antiochus retired to Sardis with as many of his forces that had escaped the slaughter as he could draw together. From Sardis he soon marched to rejoin his son Seleucus, who had fled to Apamea. As for the consul, he took advantage of the king's defeat and flight, making himself master of all the neighbouring countries. Deputies hastened to him from all parts; the cities of Thyatira, Magnesia, Trallis, Magnesia in Caria, all Lydia, and Ephesus itself, though highly favoured by Antiochus, declared for the Romans. Polyxenidas, upon the news of the king's defeat, left the port of Ephesus, and sailed to Patara, where he landed with a very small guard, and returned by land into Syria. The consul took the road to Sardis, which opened its gates to him.

Antiochus finding his affairs in a bad situation both by sea and land, and not daring to appear before the consular army in the field, sent Antipater his brother's son, and Zeuxis, who had been governor of Lydia and Phrygia, to sue for a peace. They were ordered to treat chiefly with the elder Scipio, of whose clemency and good nature Antiochus entertained a high opinion. Accordingly, on their arrival at Sardis, where the consul then was with his brother, they addressed the latter, and were by him presented to the consul. Their speech was very submissive, and such as became a vanquished people.

26 Antiochus obtains peace on very hard terms. Hereupon a council was summoned, and after long debates the ambassadors were called in; and Scipio Africanus proposed terms that were very humiliating.

The ambassadors of Antiochus had been ordered to refuse no terms; and therefore these were accepted and the whole affair concluded. So that the Syrian ambassadors now prepared to set out for Rome, to get the conditions of peace proposed by Scipio ratified there. L. Aurelius Cotta was sent with the ambassadors to Rome, to acquaint the senate with the particulars of the treaty. When they appeared before the conscript fathers, they spoke with great submission, and only desired them to ratify the articles which the Scipios had offered to their master. The senate, after examining them, ordered that a treaty of peace should be concluded with Antiochus, and the articles of it engraved on brass, and fixed up in the Capitol. They only added one clause, which was, That the Syrians should change every year all their hostages, except the son of King Antiochus, who should continue at Rome as long as the republic thought fit. The peace being thus ratified, and all Asia on this side Mount Taurus delivered into the hands of the Romans, the Greek cities were by them restored to their liberty, the provinces of Caria and Lydia given to the Rhodians, and all the rest that had belonged to Antiochus bestowed upon Eumenes.

Antiochus did not long survive his misfortune at Magnesia. He died in 187, and with him fell the glory of the Syrian empire. 27 His death. An. 187. B.C. The Romans now gave laws to the kings of Syria, insomuch, that when Antiochus Epiphanes the grandson of Antiochus the Great hesitated at obeying the command of the senate, one of the ambassadors drew a circle round him with a rod on the floor, and told him that he should not go out of that spot before he had told him what he was to do. The most remarkable transactions of this prince are his wars with the Jews, and persecutions of them; of which a full account is given under the article JEWS. After a variety of usurpers and tyrants, the kingdom of Syria fell under Tigranes king of Armenia in the year 83 B. C.; and upon his overthrow by the Romans, it became a province of the dominions of the republic. 28 Syria becomes a Roman province From them it was taken by the Saracens in the reign of the caliph Omar, and is now a province of Turkey in Asia. See ACRE.

Syria is in some measure only a chain of mountains, varying in their levels, situation, and appearances. 29 Climate, soil, &c. of the country. The part of the country, however, next the sea is in general low, and besides this there are several extensive valleys. The climate on the sea-coast and in these valleys is very hot, but in the higher parts of the country it bears a good deal of resemblance to that of France. Syria is exceedingly fertile, and the variety of its productions is very great. Besides wheat, rye, barley, beans, and the cotton plant, which is cultivated everywhere, Palestine abounds in sesamum, from which oil is procured, and doura as good as that of Egypt. Maize thrives in the light soil of Balbec, and even rice is cultivated with success on the borders of the marshy country of Havula. They have lately begun to plant sugarcanes in the gardens of Saide and of Bairout, and they find them equal to those of the Delta. Indigo grows without cultivating on the banks of the Jordan, in the country of Bisan, and only requires care to make it of an excellent quality. The hill-sides of Latakia produce tobacco. Gaza produces dates like Mecca, and pomegranates like Algiers; Tripoli affords oranges equal to those of Malta; Bairout figs like those of Marseilles, and bananas not inferior to those of St Domingo; Aleppo enjoys the exclusive advantage of producing pistachios; and Damascus justly boasts of possessing all the fruits known in France. Its stony soil suits equally the apples of Normandy, the plums of Touraine, and the peaches of Paris. Volney's Travels, vol. i.

Paris. Twenty sorts of apricots are reckoned there, the stone of one of which contains a kernel highly valued through all Turkey. The cochineal plant, which grows on all that coast, contains perhaps that precious insect in as high perfection as it is found in Mexico and St Domingo.

The inhabitants may be divided into three principal classes: the descendants of the Greeks of the Lower Empire; the Arabs, their conquerors; and the Turks, the present ruling power: and these again, the first into three, the second into four, classes; besides three wandering tribes of Turkomans, Curds, and Bedouin Arabs. The ancient inhabitants before the Greeks under Alexander are entirely lost. The inhabitants are in general of a middling stature, and the eyes of the women almost everywhere beautiful, and their shape correct and well proportioned. The general language is Arabic.

SYRINGA, the LILAC, a genus of plants belonging to the class diandria, and in the natural system ranging under the 44th order, *Sepiariæ*. See BOTANY *Index*.

SYRINGE, a well-known instrument, serving to imbibe or suck in a quantity of fluid, and to squirt or expel the same with violence. The word is formed from the Greek συριγξ, or the Latin *syrinx*, "a pipe." —A syringe is only a single pump, and the water ascends in it on the same principle as in the common sucking-pump. See HYDRODYNAMICS.

SYRUP, in *Pharmacy*, a saturated solution of sugar, made in vegetable decoctions or infusions. See MATERIA MEDICA.

SYSTEM, in general, denotes an assemblage or chain of principles and conclusions, or the whole of any doctrine, the several parts whereof are bound together, and follow or depend on each other; in which sense we say a *system of philosophy*, *system of divinity*, &c. The word is formed from the Greek συστημα, "composition, compages."

SYSTEM, in the animal economy, the *vascular*, the *nervous*, and the *cellular*. See ANATOMY.

SYSTEM, in *Music*, an assemblage of the rules for harmony, deduced from some common principle by which they are reunited; by which their connection one with another is formed; from whence, as from their genuine source, they natively flow; and to which, if we would account for them, we must have recourse. See the articles CHROMATIC, DIATONIC, ENHARMONIC, HARMONY, INTERVAL, and MUSIC.

SYSTEM, in *Botany*. See BOTANY.

SYSTEM, in *Astronomy*. See ASTRONOMY.

SYSTOLE, in *Anatomy*, the contraction of the heart, whereby the blood is drawn off its ventricles into the arteries; the opposite state to which is called the *diastole*, or *dilatation of the heart*. See ANATOMY *Index*.

SYSTYLE, in *Architecture*, that manner of placing columns where the space between the two shafts consists of two diameters or four modules.

SYZYGY, SYZYGIA, in *Astronomy*, a term equally used for the conjunction and opposition of a planet with the sun. The word is formed from the Greek συζυγια, which properly signifies *conjunctio*. On the phenomena and circumstances of the syzygies a great part of the lunar theory depends. See ASTRONOMY.

T.

T, or t, the 19th letter and 16th consonant of our alphabet; the sound whereof is formed by a strong expulsion of the breath through the mouth, upon a sudden drawing back of the tongue from the fore-part of the palate, with the lips at the same time open. The proper sound of *t* is expressed in most words beginning or ending with that letter; as in *take*, *tell*, *hot*, *put*. *Ti* before a vowel has the sound of *si*, or rather of *shi*, as in *creation*, except when *s* precedes, as in *question*; and in derivatives from words ending in *ty*, as *mighty*, *mightier*. *Th* has two sounds; the one soft, as *thou*, *father*; the other hard, as *thing*, *think*. The sound is soft in these words, *then*, *thence*, and *there*, with their derivatives and compounds; and in the words *that*, *this*, *thus*, *thy*, *they*, *though*; and in all words in which *th* comes between two vowels, as, *whether*, *rather*; and between *r* and a vowel, as *burthen*.

In abbreviations, amongst the Roman writers, T. stands for *Titus*, *Titius*, &c.; Tab. for *Tabularius*; Tab. P. H. C. *Tabularius Provinciæ Hispaniæ Citerioris*; Tar. *Tarquinius*; Ti. *Tiberius*: Ti. F. *Tiberii filius*; Ti. L. *Tiberii libertus*: Ti. N. *Tiberii Nepos*; T. J. A. V. P. V. D. *tempore judicem arbitrumve postulat ut det*; T. M. P. *terminum posuit*; T. M. D. D. *terminum dedicavit*; Tr. *trans*, *tribunus*; Tr. M. or Mil. *tribunus militum*; TR. PL. DES. *tribunus plebis designatus*; TR. AER. *tribunus ærarii*; TRV. CAP. *triumviri capitales*; T. P. or TRIB. POT. *tribunicia potestate*; Tul. H. *Tullus Hostilius*.

Amongst the ancients, T, as a numeral, stood for *one hundred and sixty*; and with a dash at top, thus $\bar{T}$, it signified *one hundred and sixty thousand*. In music, T stands for *tutti*, "all, or altogether."

TABANUS, the BREEZE-FLY; a genus of insects belonging to the order of diptera. See ENTOMOLOGY *Index*.

TABARCA, a small island lying opposite to a town of the same name, which divides the maritime coasts of Tunis and Algiers, in Africa. It is two miles from the land, and is in possession of the noble family of the Lamellini of Genoa, who have here a governor and a garrison of 200 men to protect the coral fishery. N. Lat. 36. 50. E. Long. 9. 16.

TABASHEER, a Persian word, signifying a hard substance found in the cavities of the bamboo or Indian reed, and highly valued as a medicine in the East Indies.

Though some account was given of the tabasheer by the Arabian physicians, no accurate knowledge of it was obtained till Dr Russel favoured the public with his observations on it.

The tabasheer is produced from the female bamboo, which is distinguished from the male by a larger cavity. The bamboos containing it make a rattling noise when shaken. Dr Russel having examined a bamboo brought from Vellore, consisting of six joints, found no tabasheer in two of them: all the rest contained some, but of various quality and quantity; the whole amounting to about 27 grains. The best was of a bluish white, resembling small fragments of shells, harder also than the rest, but which might be easily crumbled between the fingers into a gritty powder; and when applied to the tongue and palate, had a slight saline and testaceous taste; the weight not exceeding four grains. The colour of the rest was cinerititous, rough on the surface, and more friable; having some particles of a larger size intermixed, but light, spongy, and somewhat resembling pumice stones; which appearance, our author supposes, led the Arabians to think that fire was concerned in the production. The two middle joints were of a pure white colour within, and lined with a thin film. In these the tabasheer was principally found. The other joints, particularly the two upper ones, were discoloured within; and in some parts of the cavity was found a blackish substance in grains or in powder, adhering to the sides, the film being there obliterated. In two or three of the joints a small round hole was found at top and bottom, which seemed to have been perforated by some insect.

Garzius informs us, that it is not found in all bamboos, or in all the branches indiscriminately, but only in those growing about Bisnagur, Batecala, and one part of the Malabar coast. Dr Russel was informed by a letter from a medical gentleman attending the embassy to the Nizam, that though tabasheer bears a high price at Hydrabad, it is never brought thither from Bisnagur; and that some of what is sold in the markets comes from the pass of Atcour in Canoul; and some from Emnabad, at the distance of about 80 miles to the north-west; but that the most part comes from Masulipatam. That sold in the markets is of two kinds; one the rate of a rupee per dram, but the other only half that price; the latter, however, is supposed to be factitious, and made up mostly of burnt teeth and bones. Dr Russel himself also, is persuaded that the tabasheer met with in commerce is greatly adulterated. The above-mentioned gentleman likewise informed the doctor that tabasheer was produced in great quantities at Sylhat, where it is sold by the pound, from one rupee to one and a half; forming a considerable article of trade from Bengal to Persia and Arabia. There is, however, a third kind, much superior in quality, being whiter, purer, and also harder and heavier.

Dr Russel supposes that the tabasheer is the juice of the bamboo thickened and hardened. The following observations on its medical effects were taken from a Persian work, intitled the "Tofut ul Monein of Mahommed Monein Hoseiny," by Mr Williams a surgeon in the service of the East India company. The tabasheer puts a stop to bilious vomitings and to the bloody flux. It is also of service in cases of palpitation of the heart [illegible] and for strengthening those members of the body that are weakened by heat. It is useful also for the piles, and for acute or burning fevers, and for pustules in the mouth (thrush); and, given with oxymel, is of service against restlessness, melancholy, and hypochondriacal affections. The habitual internal use of it is prejudicial to the virile powers. It is also said to be prejudicial to the lungs. Its correctives are the gum of the pine and honey. The dose of it is to the weight of two d'herems, or seven mashás.

TABBY, in *Commerce*, a kind of rich silk which has undergone the operation of tabbying.

TABBYING, the passing a silk or stuff under a callender, the rolls of which are made of iron or copper variously engraven, which bearing unequally on the stuff renders the surface thereof unequal, so as to reflect the rays of light differently, making the representation of waves thereon.

TABELLIO, in the Roman law, an officer or scrivener, much the same with our notaries public, who are often called *tabelliones*.

TABERNACLE, among the Hebrews, a kind of building, in the form of a tent, set up, by express command of God, for the performance of religious worship, sacrifices, &c. during the journeying of the Israelites in the wilderness: and, after their settlement in the land of Canaan, made use of for the same purpose till the building of the temple of Jerusalem. It was divided into two parts; the one covered, and properly called the *tabernacle;* and the other open, called the *court*. The curtains which covered the tabernacle were made of linen, of several colours, embroidered. There were ten curtains, 28 cubits long and four in breadth. Five curtains fastened together made up two coverings, which covered up all the tabernacle. Over these there were two other coverings; the one of goat's hair, the other of sheep's skins. The holy of holies was parted from the rest of the tabernacle by a curtain made fast to four pillars, standing ten cubits from the end. The length of the whole tabernacle was 32 cubits, that is, about 50 feet; and the breadth 12 cubits or 19 feet. The court was a spot of ground 100 cubits long, and 50 in breadth, enclosed by 20 columns, each 20 cubits high and 10 in breadth, covered with silver, and standing on copper bases, five cubits distant from one another; between which there were curtains drawn, and fastened with hooks. At the east end was an entrance, 20 cubits wide, covered with a curtain hanging loose.

Feast of TABERNACLES, a solemn festival of the Hebrews, observed after harvest, on the 15th day of the month Tisri, instituted to commemorate the goodness of God, who protected the Israelites in the wilderness, and made them dwell in booths, when they came out of Egypt. On the first day of the feast they began to erect booths of the boughs of trees, and in these they were obliged to continue seven days. The boughs were placed in the open air, and were not to be covered with cloths, nor made too close by the thickness of the boughs; but so loose that the sun and the stars might be seen, and the rains descend through them. For further particulars of the celebration of this festival, see Levit. ch. xxiii.

TABERNÆ, in *Ancient Geography*. See *TRES Tabernæ*.

TABERNÆMONTANA, in *Botany*, a genus of plants belonging to the class of pentandria, and order of monogynia; and in the natural system arranged under the

the 30th order, *Contortæ*. There are two horizontal follicles, and the seeds are immersed in pulp. There are eight species, all of foreign growth.

TABLE, a moveable piece of furniture, usually made of wood or stone, and supported on pillars or the like, for the commodious reception of things placed thereon.

TABLE is also used for the fare or entertainment served up.

TABLE, in *Mathematics*, systems of numbers calculated to be ready at hand for the expediting astronomical, geometrical, and other operations.

TABLE-Book. See WRITING.

TABLE-Mountain, a mountain of Africa, being the most westerly cape or promontory in that part of the world, and near the Cape of Good Hope. The bay which is formed thereby is called the *Table-bay*.

Laws of the Twelve TABLES, were the first set of laws of the Romans: thus called either because the Romans then wrote with a style on thin wooden tablets covered with wax; or rather, because they were engraved on tables or plates of copper, to be exposed in the most noted part of the public forum. After the expulsion of the kings, as the Romans were then without any fixed or certain system of law, at least had none ample enough to take in the various cases that might fall between particular persons, it was resolved to adopt the best and wisest laws of the Greeks. One Hermodorus was first appointed to translate them, and the decemviri afterwards compiled and reduced them into ten tables. After a world of care and application, they were at length enacted and confirmed by the senate and an assembly of the people, in the year of Rome 303. The following year they found something wanting therein, which they supplied from the laws of the former kings of Rome, and from certain customs which long use had authorised: all these being engraven on two other tables, made the law of the twelve tables, so famous in the Roman jurisprudence, the source and foundation of the civil or Roman law.

TABLES of the Law, in Jewish antiquity, two tables on which were written the decalogue, or ten commandments, given by GOD to Moses on Mount Sinai.

TABOO, a word used by the South sea islanders, nearly of the same import as prohibited or interdicted. It applies equally to persons and things, and is also expressive of any thing sacred, devoted, or eminent.

TABOR, a mountain of Galilee, about 12 miles from the city of Tiberias. It rises in the form of a sugar loaf, in the midst of an extensive plain, to the height of 30 stadia, according to Josephus. The ascent is so easy, that one may ascend on horseback. On the top there is a plain two miles in circumference.

The situation of Mount Tabor is most delightful. Rising amidst the plains of Galilee, it exhibits to the enchanted eye a charming variety of prospects. On one side there are lakes, rivers, and a part of the Mediterranean; and on the other a chain of little hills, with small valleys, shaded by natural groves, and enriched by the hands of the husbandman with a great number of useful productions. Here you behold an immensity of plains interspered with hamlets, fortresses, and heaps of ruins; and there the eye delights to wander over the fields of Jezrael or Mageddon, named by the Arabs *Ebn-Aamer*, which signifies "the field of the sons of Aamer." A little farther you distinguish the mountains of Hermon, Gilboa, Samaria, and Arabia the Stony. In short, you experience all those sensations which are produced by a mixture and rapid succession of rural, gay, gloomy, and majestic objects.

Mariti's Travels, vol. ii.

It was upon this enchanting mount that the apostle Peter said to Christ, "It is good for us to be here: and let us make three tabernacles; one for thee, and one for Moses, and one for Elias."

Flavian Josephus, governor of Galilee, caused the summit of this mountain, for the space of two miles and a half, to be surrounded with walls. The inhabitants of Tabor long braved the power of the Roman armies; but being deprived of water in consequence of the great heats, they were forced to surrender at discretion to Placidus, the general of Vespasian.

Several churches were built upon this mountain by St Helen, who founded here also some monasteries. Of the two most remarkable, one was dedicated to Moses, and inhabited by Cenobites of the order of St Benedict, who followed the Latin rites: the other was dedicated to the prophet Elias by monks of the order of St Basil, attached to the Greek rites. The kings of Hungary erected here also a pretty spacious convent for some monks belonging to that nation, of the order of St Paul the first hermit. Tabor was also the seat of a bishop, dependant on the patriarchate of Jerusalem.

When Godfrey of Bouillon seized on this mountain, he repaired the ancient churches, which were beginning to fall into ruins. Under Baldwin I. in 1113, the Saracen troops retook Tabor; and their sanguinary fury gained as many victories as there were priests and Cenobites. This mountain again fell into the hands of the Christians; but the Catholic standard was not long displayed on it. Saladin pulled it down the year following, and destroyed all the churches. The Christians retook it once more in 1253; and their zeal made them rebuild all the sacred places. At this time Rome being accustomed to give away empires, Pope Alexander IV. granted Tabor to the Templars, who fortified it again. At length, in the course of the year 1290, the sultan of Egypt destroyed and laid waste the buildings of this mountain, which could never be repaired afterwards; so that at present it is uninhabited.

TACAMAHACA, in *Pharmacy*, a gum resin, obtained from the fagara octandra and populus balsamifera; and having a fragrant smell, a bitterish nauseous taste, and supposed to be stimulant and tonic in its effects.

TACCA, a genus of plants belonging to the class dodecandria. See BOTANY *Index*.

TACHYGRAPHY, from ταχυς, *short*, and γραφω, *I write*, or the art of writing short-hand. See STENOGRAPHY.

TACITUS, CAIUS CORNELIUS, a celebrated Roman historian, and one of the greatest men of his time, appears to have been born about the year of Rome 809 or 810, and applied himself early to the labours of the bar, in which he gained very considerable reputation. Having married the daughter of Agricola, the road to public honours was laid open to him in the reign of Vespasian; but during the sanguinary and capricious tyranny of Domitian, he, as well as his friend Pliny, appears to have retired from the theatre of public affairs. The reign of Nerva restored these luminaries of Roman literature to the metropolis, and we find Tacitus engaged, in A. U. C. 850, to pronounce the funeral oration

Murphy's Translation of Tacitus.

Tacitus. oration of the venerable Virginius Rufus, the colleague of the emperor in the consulship, and afterwards succeeding him as consul for the remainder of the year.

The time of his death is not mentioned by any ancient author, but it is probable that he died in the reign of Trajan.

His works which still remain are, 1. Five books of his History. 2. His Annals. 3. A Treatise on the different Nations which in his time inhabited Germany: and, 4. The Life of Agricola his father-in-law. There is also attributed to him a Treatise on Eloquence, which others have ascribed to Quintilian. The Treatise on the Manners of the Germans was published in 851.—In the year 853, Pliny and Tacitus were appointed by the senate to plead the cause of the oppressed Africans against Marius Priscus, a corrupt proconsul, who was convicted before the fathers; and the patriot orators were honoured with a declaration that they had executed their trust to the entire satisfaction of the house. The exact time when Tacitus published his history is uncertain, but it was in some period of Trajan's reign, who died suddenly, A. U. C. 870, A. D. 117.—The history comprises a period of 27 years, from the accession of Galba, 822, to the death of Domitian, 849. The history being finished, he did not think he had completed the tablature of slavery; he went back to the time of Tiberius: and the second work, which, however, comes first in the order of chronology, includes a period of 54 years, from the accession of Tiberius, 767, to the death of Nero, 821: this work is his "Annals."

Biographical Dictionary. It is remarkable, that princes and politicians have always held the works of Tacitus in the highest esteem; which looks as if they either found their account in reading them, or were pleased to find courts, and the people who live in them, so exactly described after the life as they are in his writings. Part of what is extant was found in Germany by a receiver of Pope Leo X. and published by Beroaldus at Rome in 1515. Leo was so much charmed with Tacitus, that he gave the receiver a reward of 500 crowns; and promised not only indulgences, but money also and honour, to any one who should find the other part; which it is said was afterwards brought to him. Pope Paul III. as Muretus relates, wore out his Tacitus by much reading it; and Cosmo de Medicis, who was the first great duke of Tuscany, and formed for governing, accounted the reading of him his greatest pleasure. Muretus adds, that several princes, and privy-counsellors to princes, read him with great application, and regarded him as a sort of oracle in politics. A certain author relates, that Queen Christina of Sweden, though extremely fond of the Greek tongue, which she made "the diversion of her leisure hours, was not restrained by that from her serious studies; so she called among others Tacitus's History, some pages of which she read constantly every day." Lastly, Lord Bolingbroke, an authority surely of no mean rank, calls him, "a favourite author," and gives him manifestly the preference to all the Greek and Roman historians.

Baillet Vie de Des Cartes, tom. ii. Study of History, Letter v.

No author has obtained a more splendid reputation than Tacitus. He has been accounted, and with good reason, the most cultivated genius of antiquity; and we must not seek for his parallel in modern times. It is impossible not to admire and recommend his intimate knowledge of the human heart, the spirit of liberty which he breathes, and the force and vivacity with which he perpetually expresses himself. The reader of taste is struck by the greatness of his thoughts and the dignity of his narration; the philosopher by the comprehensive powers of his mind; and the politician by the sagacity with which he unfolds the springs of the most secret transactions. Civil liberty and the rights of mankind never met with a bolder or a more able assertor: servitude, debasement, and tyranny, appear not in the writings of any other author in juster or more odious colours. He has been censured as obscure; and indeed nothing can be more certain than that he did not write for the common mass of men. But to those who are judges of his compositions, it is no matter of regret that his manner is his own, and peculiar. Never were description and sentiment so wonderfully and so beautifully blended; and never were the actions and characters of men delineated with so much strength and precision. He has all the merits of other historians, without their defects. He possesses the distinctness of Xenophon without his uniformity; he is more eloquent thon Livy, and is free from his superstition; and he has more knowledge and judgment than Polybius, without his affectation of reasoning on every occasion.

Tacitus, Tack.

One of the best editions of the works of Tacitus was published at Paris by Brotier, in 4 vols. 4to. There have been four translations of his works into English; the first by Greenway and Sir Henry Saville, in the reign of Elizabeth; the second by Dryden and others; the third by Gordon, which is remarkable for affectation of style, though some think it bears a striking resemblance to the original; and the fourth and best by Murphy, in 1793, in 4 vols. 4to.

TACK, a rope used to confine the foremost lower corners of the courses and stay-sails in a fixed position, when the wind crosses the ship's course obliquely. The same name is also given to the rope employed to pull out the lower corner of a studding-sail or driver to the extremity of its boom.

The main-sail and fore-sail of a ship are furnished with a tack on each side, which is formed of a thick rope tapering to the end, and having a knot wrought upon the largest end, by which it is firmly retained in the clue of the sail. By this means one tack is always fastened to windward, at the same time that the sheet extends the sail to the leeward.

TACK, is also applied, by analogy, to that part of any sail to which the tack is usually fastened.

A ship is said to be on the starboard or larboard tack, when she is close-hauled, with the wind upon the starboard or larboard side; and in this sense the distance which she sails in that position is considered as the length of the tack; although this is more frequently called *board*. See that article.

To TACK, to change the course from one board to another, or turn the ship about from the starboard to the larboard tack, in a contrary wind. Thus a ship being close-hauled on the larboard tack, and turning her prow suddenly to windward, receives the impression of the wind on her head sails, by which she falls off upon the line of the starboard tack. Tacking is also used in a more enlarged sense, to imply that manœuvre in navigation by which a ship makes an oblique progression to the windward, in a zig-zag direction. This, however, is more usually called *beating*, or *turning to windward*.

Falconer's Marine Dictionary.

ward. See NAVIGATION, SAILING, and *Naval Tactics*, under WAR.

TACK, in *Scots Law.* See LAW, N° clxvii.

TACKLE, among seamen, denotes all the ropes or cordage of a ship used in managing the sails, &c.

TACKSMAN. See TENURE.

TACTICS, in the art of war, is the method of disposing forces to the best advantage in order of battle, and of performing the several military motions and evolutions. See WAR.

TADCASTER, a town in the west riding of Yorkshire, noted for the great plenty of limestone dug up near it; and for being one of the first places in which a building was erected for Sunday schools. It is nine miles from York, and 188 from London.

TADMOR. See PALMYRA.

TADPOLE, a young frog before it has disengaged itself from the membranes that envelope it in its first stage of life. See ERPETOLOGY, p. 281.

TÆNIA, a genus of animals belonging to the class of *vermes*. See HELMINTHOLOGY, N° 29, 30.

TAFFETY, or TAFFETA, in *Commerce*, a fine smooth silken stuff, remarkably glossy. There are taffeties of all colours, some plain, and others striped with gold, silver, &c. others chequered, others flowered, &c. according to the fancy of the workmen.

TAGANROK, or TAGANROG, a sea-port town situated at the head of the sea of Azof, and forming one of the principal ports of the Russian empire. It stands on a small promontory, at the extremity of which is a fortress of considerable strength, and capable of accommodating a numerous garrison. The streets are wide but unpaved, and from the lightness of the soil, are either intolerably dusty, or ankle-deep in mud. The houses, which do not exceed a thousand, are small, built chiefly of wood, plaistered with mud, and roofed with bark. It is in north latitude 46°.

Taganrok is remarkable only as a place of trade, but in this view is highly respectable. When Mr M'Gill visited it in 1805, he found there upwards of 200 vessels of various sizes, waiting for cargoes. From its advantageous situation, at the head of the sea of Azof, and near the mouths of the rivers Don and Volga, and from its being in the vicinity of a very fertile country, it has become the centre of commerce for many staple articles. Hither are brought, for exportation, vast quantities of grain, wool, hides, butter, tallow, bees-wax, and honey from the southern provinces of Russia; iron, timber, pitch, and tar from Siberia; caviar to the amount of 50,000 puds annually from the Don and the Volga; hemp and flax from the neighbouring districts. Cordage and canvas are manufactured here, and form a considerable article of traffic. The trade is carried on chiefly by Ragusan and Greek supercargoes, who remain only till their commodities are collected and shipped. For the best accounts of this place, see Pallas's *Travels in the Russian Empire*, and M'Gill's *Travels in Turkey, Italy, and Russia*.

TAGARA, a city of ancient India, the metropolis of a large district called *Ariaca*, which comprehended the greatest part of the Subah of Aurungabad, and the southern part of Concan. Arrian says, that it was situated about ten days journey to the eastward of Pultanah; which, according to the rate of travelling in that country with loaded carts, might be about 100 British miles. This fixes its situation at Deoghir, a place of great antiquity, and famous through all India on account of the pagodas of Elousa. It is now called *Doulet-abad.*

TAGETES, MARYGOLD, a genus of plants belonging to the class syngenesia; and in the natural system ranking under the 49th order, *Compositæ*. See BOTANY *Index.*

TAGUS, the largest river of Spain; which, taking its rise on the confines of Arragon, runs south-west through the provinces of New Castile and Estremadura; and passing by the cities of Aranjuez, Toledo, and Alcantara, and then crossing Portugal, forms the harbour of Lisbon, at which city it is about three miles broad; and about eight or ten miles below this it falls into the Atlantic ocean.

TAHOEREWA, one of the Sandwich islands, is small, destitute of wood, the soil sandy and unfertile; is situated in north latitude 20° 38', in east longitude 203° 27'.

TAHOORA, one of the Sandwich islands in the South sea. It is uninhabited, and lies in north latitude 21° 43', and in east longitude 199° 36'. See SANDWICH-*Islands.*

TAJUCA, or PECCARY, in *Zoology*, a species of hog. See SUS, MAMMALIA *Index.*

TAI-OUAN, the Chinese name of the island of Formosa. See FORMOSA.—Tai-ouan is also the name of the capital of the island.

TAIL, the train of a beast, bird, or fish; which in land animals, it is said, serves to drive away flies, &c. and in birds and fishes to direct their course, and assist them in ascending or descending in the air or water. But the tail in all animals is of great use in directing their motions.

TAIL, or FEE-TAIL, in *Law*, is a conditional estate or fee, opposed to *fee-simple.* See FEE.

A conditional fee, at the common law, was a fee restrained to some particular heirs exclusive of others; as to the heirs of a man's body, by which only his lineal descendants were admitted, in exclusion of collateral heirs; or to the heirs male of his body, in exclusion both of collaterals and lineal females also. It was called a *conditional fee*, by reason of the condition expressed or implied in the donation of it, that if the donee died without such particular heirs, the land should revert to the donor. For this was a condition annexed by law to all grants whatsoever, that on failure of the heirs specified in the grant, the grant should be at an end, and the land return to its ancient proprietor. Such conditional fees were strictly agreeable to the nature of feuds, when they first ceased to be mere estates of life, and were not yet arrived to be absolute estates in fee-simple.

With regard to the condition annexed to these fees by the common law, it was held, that such a gift (to a man and the heirs of his body) was a gift upon condition that it should revert to the donor if the donee had no heirs of his body; but if he had, it should then remain to the donee. They therefore called it a *fee-simple* on condition that he had issue. Now we must observe, that when any condition is performed, it is thenceforth entirely gone; and the thing to which it was before annexed becomes absolute and wholly unconditional. So that as soon as the grantee had any issue born,

his

Tail. his estate was supposed to become absolute by the performance of the condition; at least for these three purposes: 1. To enable the tenant to alienate the land, and thereby to bar not only his own issue, but also the donor, of his interest in the reversion. 2. To subject him to forfeit it for treason: which he could not do till issue born longer than for his own life, lest thereby the inheritance of the issue and reversion of the donor might have been defeated. 3. To empower him to charge the land with rents, commons, and certain other encumbrances, so as to bind his issue. And this was thought the more reasonable, because, by the birth of issue, the possibility of the donor's reversion was rendered more distant and precarious: and his interest seems to have been the only one which the law, as it then stood, was solicitous to protect, without much regard to the right of succession intended to be vested in the issue. However, if the tenant did not in fact alienate the land, the course of descent was not altered by this performance of the condition; for if the issue had afterwards died, and then the tenant or original grantee had died, without making any alienation, the land, by the terms of the donation, could descend to none but the heirs of his body; and therefore, in default of them, must have reverted to the donor. For which reason, in order to subject the lands to the ordinary course of descent, the donees of these conditional fee-simples took care to alienate as soon as they had performed the condition by having issue; and afterwards repurchased the lands, which gave them a fee-simple absolute, that would descend to the heirs general, according to the course of the common law. And thus stood the old law with regard to conditional fees: which things, says Sir Edward Coke, though they seem ancient, are yet necessary to be known, as well for the declaring how the common law stood in such cases, as for the sake of annuities, and such-like inheritances, as are not within the statutes of entail, and therefore remain as the common law. The inconveniences which attended these limited and fettered inheritances were probably what induced the judges to give way to this subtle finesse (for such it undoubtedly was), in order to shorten the duration of these conditional estates. But, on the other hand, the nobility, who were willing to perpetuate their possessions in their own families, to put a stop to this practice, procured the statute of Westminster the second (commonly called the statute *de donis conditionalibus*) to be made; which paid a greater regard to the private will and intentions of the donor, than to the propriety of such intentions, or any public considerations whatsoever. This statute revived in some sort the ancient feodal restraints which were originally laid on alienations, by enacting, that from thenceforth the will of the donor be observed; and that the tenements so given (to a man and the heirs of his body) should at all events go to the issue, if there were any; or if none, should revert to the donor.

Upon the construction of this act of parliament, the judges determined that the donee had no longer a conditional fee-simple, which became absolute and at his own disposal the instant any issue was born; but they divided the estate into two parts, leaving the donee a new kind of particular estate, which they denominated a *fee-tail;* and vesting in the donor the ultimate fee-simple of the land, expectant on the failure of issue; which expectant estate is what we now call a *reversion.* And hence it is that Littleton tells us, that tenant in fee-tail is by virtue of the statute of Westminster the second. The expression *fee-tail*, or *feodum talliatum*, was borrowed from the feudists (see Crag. *l. s. t.* 10. § 24, 25.), among whom it signified any mutilated or truncated inheritance, from which the heirs general were cut off; being derived from the barbarous verb *taliare*, to cut; from which the French *tailler* and the Italian *tagliare* are formed, (Spelm. *Gloss.* 531.). Tail.

Having thus shown the original of estates tail, we now proceed to consider what things may or may not be entailed under the statute *de donis*. Tenements is the only word used in the statute: and this Sir Edward Coke expounds to comprehend all corporeal hereditaments whatsoever: and also all incorporeal hereditaments which savour of the reality, that is, which issue out of corporeal ones, or which concern or are annexed to or may be exercised within the same; as rents, estovers, commons, and the like. Also offices and dignities, which concern lands, or have relation to fixed and certain places, may be entailed. But mere personal chattels, which savour not at all of the reality, canno tbe entailed. Neither can an office, which merely relates to such personal chattels; nor an annuity, which charges only the person, and not the lands of the granter. But in these last, if granted to a man and the heirs of his body, the grantee hath still a fee conditional at common law as before the statute, and by his alienation may bar the heir or reversioner. An estate to a man and his heirs for another's life cannot be entailed; for this is strictly no estate of inheritance, and therefore not within the statute *de donis*. Neither can a copyhold estate be entailed by virtue of the statute; for that would tend to encroach upon and restrain the will of the lord; but, by the special custom of the manor, a copyhold may be limited to the heirs of the body; for here the custom ascertains and interprets the lord's will.

As to the several species of estates-tail, and how they are respectively created; they are either general or special. Tail-general is where lands and tenements are given to one, and the heirs of his body begotten: which is called *tail-general;* because, how often soever such donee in tail be married, his issue in general, by all and every such marriage, is, in successive order, capable of inheriting the estate-tail *per formam doni.* Tenant in *tail-special* is where the gift is restrained to certain heirs of the donee's body, and does not go to all of them in general. And this may happen several ways. We shall instance in only one; as where lands and tenements are given to a man and the heirs of his body, on Mary his now wife to be begotten. Here no issue can inherit but such special issue as is engendered between them two; not such as the husband may have by another wife; and therefore it is called *special tail.* And here we may observe, that the words of inheritance (to him and his heirs) give him an estate in fee; but they being heirs to be by him begotten, this makes it a fee tail; and the person being also limited, on whom such heirs shall be begotten (viz. Mary his present wife), this makes it a fee-tail special.

Estates in general and special tail are farther diversified by the distinction of sexes in such entails; for both of them may either be in tail male or tail female. As if

Tail. if lands be given to a man, and his heirs-male of his body begotten, this is an estate in tail male general; but if to a man, and the heirs-female of his body on his present wife begotten, this is an estate in tail female special. And in case of an entail male, the heirs-female shall never inherit, nor any derived from them; nor, *è converso*, the heirs-male in case of a gift in tail female. Thus, if the donee in tail male hath a daughter, who dies leaving a son, such grandson in this case cannot inherit the estate tail; for he cannot deduce his descent wholly by heirs-male. And as the heir-male must convey his descent wholly by males, so must the heir-female wholly by females. And therefore if a man hath two estates-tail, the one in tail male and the other in tail female, and he hath issue a daughter, which daughter hath issue a son; this grandson can succeed to neither of the estates, for he cannot convey his descent wholly either in the male or female line.

As the word *heirs* is necessary to create a fee, so, in farther imitation of the strictness of the feodal donation, the word *body*, or some other words of procreation, are necessary to make it a fee-tail, and ascertain to what heirs in particular the fee is limited. If, therefore, either the words of inheritance or words of procreation be omitted, albeit the others are inserted in the grant, this will not make an estate-tail. As if the grant be to a man and the issue of his body, to a man and his seed, to a man and his children or offspring; all these are only estates for life, there wanting the words of inheritance, "his heirs." So, on the other hand, a gift to a man, and his heirs male or female, is an estate in fee-simple and not in fee-tail; for there are no words to ascertain the body out of which they shall issue. Indeed, in last wills and testaments, wherein greater indulgence is allowed, an estate-tail may be created by a devise to a man and his seed, or to a man and his heirs male, or by other irregular modes of expression.

There is still another species of entailed estates, now indeed grown out of use, yet still capable of subsisting in law; which are estates *in libero maritagio*, or FRANK-MARRIAGE. See that article.

The incidents to a tenancy in tail, under the statute Wesminster 2. are chiefly these: 1. That a tenant in tail may commit waste on the estate-tail, by felling timber, pulling down houses, or the like, without being impeached or called to account for the same. 2. That the wife of the tenant in tail shall have her dower, or thirds, of the estate-tail. 3. That the husband of a female tenant in tail may be tenant by the curtesy of the estate-tail. 4. That an estate-tail may be barred, or destroyed, by a fine, by a common recovery, or by lineal warranty descending with assets to the heir. See ASSETS.

Thus much for the nature of estates-tail: the establishment of which family law (as it is properly styled by Pigott) occasioned infinite difficulties and disputes. Children grew disobedient when they knew they could not be set aside: farmers were ousted of their leases made by tenants in tail; for if such leases had been valid, then, under colour of long leases, the issue might have been virtually disinherited: creditors were defrauded of their debts; for, if a tenant in tail could have charged his estate with their payment, he might also have defeated his issue, by mortgaging it for as much as it was worth: innumerable latent entails were produced to deprive purchasers of the lands they had fairly brought; of suits in consequence of which, our ancient books are full: and treasons were encouraged, as estates-tail were not liable to forfeiture longer than for the tenant's life. So that they were justly branded as the source of new contentions and mischiefs unknown to the common law; and almost universally considered as the common grievance of the realm. But as the nobility were always fond of this statute, because it preserved their family estates from forfeiture, there was little hope of procuring a repeal by the legislature; and therefore, by the connivance of an active and politic prince, a method was devised to evade it.

About 200 years intervened between the making of the statute *de donis*, and the application of common recoveries to this intent, in the 12th year of Edward IV.; which were then openly declared by the judges to be a sufficient bar of an estate-tail. For though the courts had, so long before as the reign of Edward III. very frequently hinted their opinion that a bar might be effected upon these principles, yet it was never carried into execution; till Edward IV. observing (in the disputes between the houses of York and Lancaster) how little effect attainders for treason had on families whose estates were protected by the sanctuary of entails, gave his countenance to this proceeding, and suffered Taltarum's case to be brought before the court: wherein, in consequence of the principles then laid down, it was in effect determined, that a common recovery suffered by tenant in tail should be an effectual destruction thereof. These common recoveries are fictitious proceedings, introduced by a kind of *pia fraus*, to elude the statute *de donis*, which was found so intolerably mischievous, and which yet one branch of the legislature would not then consent to repeal; and that these recoveries, however clandestinely begun, are now become by long use and acquiescence a most common assurance of lands; and are looked upon as the legal mode of conveyance, by which a tenant in tail may dispose of his lands and tenements: so that no court will suffer them to be shaken or reflected on, and even acts of parliament have by a side-wind countenanced and established them.

This expedient having greatly abridged estates-tail with regard to their duration, others were soon invented to strip them of other privileges. The next that was attacked was their freedom from forfeitures for treason. For, notwithstanding the large advances made by recoveries, in the compass of about threescore years, towards unfettering these inheritances, and thereby subjecting the lands to forfeiture, the rapacious prince then reigning, finding them frequently resettled in a similar manner to suit the convenience of families, had address enough to procure a statute, whereby all estates of inheritance (under which general words estates-tail were covertly included) are declared to be forfeited to the king upon any conviction of high-treason.

The next attack which they suffered, in order of time, was by the statute 32 Hen. VIII. c. 28. whereby certain leases made by tenants in tail, which do not tend to the prejudice of the issue, were allowed to be good in law, and to bind the issue in tail. But they received a more violent blow in the same session of parliament, by the construction put upon the statute of fines, by the statute 32 Hen. VIII. c. 36. which declares a fine duly levied by tenant in tail to be a complete bar to him and his heirs, and all other persons claiming under such entail.

entail. This was evidently agreeable to the intention of Henry VII. whose policy it was (before common recoveries had obtained their full strength and authority) to lay the road as open as possible to the alienation of landed property, in order to weaken the overgrown power of his nobles. But as they, from the opposite reasons, were not easily brought to consent to such a provision, it was therefore couched, in his act, under covert and obscure expressions. And the judges, though willing to construe that statute as favourably as possible for the defeating of entailed estates, yet hesitated at giving fines so extensive a power by mere implication, when the statute *de donis* had expressly declared that they should not be a bar to estates-tail. But the statute of Henry VIII. when the doctrine of alienation was better received, and the will of the prince more implicitly obeyed than before, avowed and established that intention. Yet, in order to preserve the property of the crown from any danger of infringement, all estates-tail created by the crown, and of which the crown has the reversion, are excepted out of this statute. And the same was done with regard to common recoveries, by the statute 34 and 35 Hen. VIII. c. 28. which enacts, that no feigned recovery had against tenants in tail, where the estate was created by the crown, and the remainder or reversion continues still in the crown, shall be of any force and effect. Which is allowing, indirectly and collaterally, their full force and effect with respect to ordinary estates-tail, where the royal prerogative is not concerned.

Lastly, by a statute of the succeeding year, all estates-tail are rendered liable to be charged for payment of debts due to the king by record or special contract; as since, by the bankrupt laws, they are also subjected to be sold for the debts contracted by a bankrupt. And by the construction put on the statute 43 Eliz. c. 4. an appointment by tenant in tail of the lands entailed to a charitable use is good without fine or recovery.

Estates-tail being thus by degrees unfettered, are now reduced again to almost the same state, even before issue born, as conditional fees were in at common law, after the condition was performed by the birth of issue. For, first, the tenant in tail is now enabled to alienate his lands and tenements by fine, by recovery, or by certain other means; and thereby to defeat the interest as well of his own issue, though unborn, as also of the reversioner, except in the case of the crown: secondly, he is now liable to forfeit them for high treason: and, lastly, he may charge them with reasonable leases, and also with such of his debts as are due to the crown on specialties, or have been contracted with his fellow-subjects in a course of extensive commerce.

TAILZIE, in *Scots Law*, the same with Tail. See Law, N° clxxx. 9.

TALAPOINS or Talopins, priests of Siam.—They enjoy great privileges, but are enjoined celibacy and austerity of life. They live in monasteries contiguous to the temples: and what is singular, any one may enter into the priesthood, and after a certain age may quit it to marry, and return to society. There are talapoinesses too, or nuns, who live in the same convents, but are not admitted till they have passed their fortieth year. The talapoins educate children; and at every new and full moon explain the precepts of their religion in their temples; and during the rainy season they preach from six in the morning till noon, and from one in the afternoon till five in the evening. They dress in a very mean garb, go bareheaded and barefooted; and no person is admitted among them who is not well skilled in the Baly language.

They believe that the universe is eternal; but admit that certain parts of it, as this world, may be destroyed and again regenerated. They believe in a universal pervading spirit, and in the immortality and transmigration of the soul; but they extend this last doctrine, not only to all animals, but to vegetables and rocks. They have their good and evil genii, and particular deities, who preside over forests and rivers, and interfere in all sublunary affairs.

For the honour of human nature, we are happy to find so pure a system of morality prevail among these people: It not only forbids its followers to do ill, but enjoins the necessity of doing good, and of stifling every improper thought or criminal desire.

Those who wish to peruse a more particular account of the Talapoins, may consult *Voyage de M. de la Loubere;* and Sketches relating to the History, &c. of the Hindoos.

TALC, a species of mineral arranged under the magnesian earths. See Mineralogy *Index*.

TALENT, signifies both a weight and a coin very common among the ancients, but very different among different nations.

The common Attic talent of weight contains 60 Attic minæ, or 6000 Attic drachmæ; and weighed, according to Dr Arbuthnot, 59 lbs. 11 oz. $17\frac{1}{7}$ gr. English Troy weight. There was another Attic talent, by some said to consist of 80, by others of 100 minæ. The Egyptian talent was 80 minæ; the Antiochian also 80; the Ptolemaic of Cleopatra $86\frac{2}{3}$; that of Alexandria 96; and the Insular talent 120. In the valuation of money, the Grecian talent, according to Dr Arbuthnot, was equal to 60 minæ, or, reckoning the mina at 3l. 4s. 7d. equal to 193l. 15s. The Syrian talent, in this valuation, consisted of 15 Attic minæ; the Ptolemaic of 20; the Antiochian of 60; the Euboic of 60; the Babylonic of 70; the Greater Attic of 80; the Tyrian of 80; the Eginean of 100; the Rhodian of 100; and the Egyptian of 80 minæ.

There is another talent much more ancient, which Dr Arbuthnot calls the *Homeric talent* of gold, which seems to have weighed six Attic drachms or three darics, a daric weighing very little more than a guinea. According to this talent, some reckon the treasure of King David, particularly that mentioned 1 Chron. xxii. 14. which, according to the common reckoning, would amount in gold talents to the value of 547,500,000l. and the silver to above 342,000,000l.; or, reckoning according to the decuple proportion of gold to silver, the two sums would be equal. As David reigned in Judæa after the siege of Troy, it is not improbable but Homer and he might use the same numeral talent of gold.

Among the Romans there were two kinds of talents, the *little* and the *great* talent: the little was the common talent; and whenever they say simply *talentum*, they are to be understood of this. The little talent was 60 minæ or Roman pounds; the mina or pound estimated at 100 drachmæ or denarii: it was also estimated at 24 great sesterces, which amounted to 60 pounds.

The great talent exceeded the less by one-third part.

Budæus

Budæus computes, that the little talent of silver was worth 75l. sterling, and the greater 99l. 6s. 8d. sterling. The greater of gold was worth 1125l. sterling.

TALENT, as a species or money, among the Hebrews, was sometimes used for a gold coin, the same with the shekel of gold, called also *stater*, and weighing only four drachms. The Hebrews reckoned by these talents as we do by pounds, &c. Thus a million of gold, or million of talents of gold, among them, was a million of shekels or nummi; the nummus of gold being the same weight with the shekel, viz. four drachms.

But the Hebrew talent weight of silver, which they called *cicar*, was equivalent to that of 3000 shekels, or 113 lb. 10 oz. 1 dwt. $10\frac{2}{7}$ gr. English Troy weight, according to Arbuthnot's computation.

TALIACOTIUS, GASPAR, chief surgeon to the great duke of Tuscany, was born at Bononia in Italy in 1553. He wrote a Latin treatise entitled *Chirurgia Nota de Curtis Membris*, in which he teaches the art of engrafting noses, ears, lips, &c. giving representations of the instruments and proper bandages; many, however, are of opinion that he never put his art in practice. But his doctrine is not singular; for Alexander Benedictus, a famous chirurgical writer, has described a similar operation.

TALIO, (*lex talionis*), a species of punishment in the Mosaic law, whereby an evil is returned similar to that committed against us by another; hence that expression, "Eye for eye, tooth for tooth." This law was at first inserted in the 12 tables amongst the Romans; but afterwards set aside, and a power given to the prætor to fix upon a sum of money for the damage done.

TALISMANS, magical figures cut or engraved with superstitious observations on the characterisms and configurations of the heavens, to which some astrologers have attributed wonderful virtues, particularly that of calling down celestial influences. The talismans of Samothrace, so famous of old, were pieces of iron formed into certain images, and set in rings; these were esteemed preservatives against all kinds of evils. There were likewise talismans taken from vegetables, and others from minerals.

TALLAGE, (*tallagium*), from the French *taillé*, is metaphorically used for a part or share of a man's substance carved out of the whole, paid by way of tribute, toll, or tax.

TALLOW, in *Commerce*, the fat of certain animals melted and clarified. It is procured from most animals, but chiefly from bullocks, sheep, hogs, and bears. Some kinds of tallow are used as unguents in medicine, some for making soap and dressing leather, and some for making candles. See FAT, CHEMISTRY *Index*.

TALLOW-Tree. See CROTON, BOTANY *Index*.

TALLY, is a stick cut in two parts, on each whereof is marked, with notches or otherwise, what is due between debtor and creditor, as now used by brewers, &c. And this was the ancient way of keeping all accounts, one part being kept by the creditor, the other by the debtor, &c. Hence the tallier of the exchequer, whom we now call the *teller*. But there are two kinds of tallies mentioned in our statutes to have been long used in the exchequer. The one is termed *tallies of debt*, which are in the nature of an acquittance for debts paid to the king, on the payment whereof these tallies are delivered to the debtors, who carrying them to the clerk of the pipe-office, have there an acquittance in parchment for their full discharge. The other are *tallies of reward* or allowance, being made to sheriffs of counties as a recompense for such matters as they have performed to their charge, or such money as is cast upon them in their accounts of course, but not leviable, &c. In the exchequer there is a tally-court, where attend the two deputy-chamberlains of the exchequer and the tally-cutter: and a tally is generally the king's acquittance for money paid or lent, and has written on it words proper to express on what occasion the money is received.

TALLY-Man, a person that sells or lets goods, clothes, &c. to be paid by so much a-week.

TALMUD, a collection of Jewish traditions. There are two works which bear this name, the Talmud of Jerusalem, and the Talmud of Babylon. Each of these is composed of two parts; the Mishna, which is the text, and is common to both, and the Gemara or commentary. See MISHNA and GEMARA.

The Mishna, which comprehends all the laws, institutions, and rules of life which, beside the ancient Hebrew scripture, the Jews thought themselves bound to observe, was composed, according to the unanimous testimony of the Jews, about the close of the second century. It was the work of Rabbi Jehuda (or Juda) Hakkadosh, who was the ornament of the school at Tiberias, and is said to have occupied him forty years. The commentaries and additions which succeeding Rabbis made were collected by Rabbi Jochanan Ben Eliezer, some say in the 5th, others say in the 6th, and others in the 7th century, under the name of *Gemara*, that is, *completion*; because it completed the Talmud. A similar addition was made to the Mishna by the Babylonish doctors in the beginning of the 6th century according to Enfield, and in the 7th according to others.

The Mishna is divided into six parts, of which every one which is entitled *order* is formed of treatises, every treatise is divided into chapters, and every chapter into mishnas or aphorisms. In the *first* part is discussed whatever relates to seeds, fruits, and trees: in the *second* feasts: in the *third* women, their duties, their disorders, marriages, divorces, contracts, and nuptials: in the *fourth* are treated the damages or losses sustained by beasts or men, of things found, deposits, usuries, rents, farms, partnerships in commerce, inheritance, sales and purchases, oaths, witnesses, arrests, idolatry; and here are named those by whom the oral law was received and preserved: in the *fifth* part are noticed what regards sacrifices and holy things: and the *sixth* treats on purifications, vessels, furniture, clothes, houses, leprosy, baths, and numerous other articles. All this forms the Mishna.

As the learned reader may wish to obtain some notion of rabbinical composition and judgment, we shall gratify his curiosity sufficiently by the following specimen: "Adam's *body* was made of the earth of Babylon, his *head* of the land of Israel, his other *members* of other parts of the world. R. Meir thought he was compact of the earth gathered out of the whole earth; as it is written, *thine eyes did see my substance*. Now it is elsewhere written, *the eyes of the Lord are over all the earth*. R. Aha expressly marks the twelve hours in which his various parts were formed. His stature was from one end of the world to the other; and it was for his transgression that the Creator, laying his hand in anger on him, lessened

sened him; for before (says R. Eleazar), 'with his hands he reached the firmament.' R. Jehuda thinks his sin was heresy; but R. Isaac thinks that 'it was nourishing his foreskin.'

The Talmud of Babylon is most valued by the Jews; and this is the book which they mean to express when they talk of the Talmud in general. An abridgement of it was made by Maimonides in the 12th century, in which he rejected some of its greatest absurdities. The Gemara is stuffed with dreams and chimeras, with many ignorant and impertinent questions, and the style very coarse. The Mishna is written in a style comparatively pure, and may be very useful in explaining passages of the New Testament where the phraseology is similar. This is indeed the only use to which Christians can apply it; but this renders it valuable. Lightfoot had judiciously availed himself of such information as he could derive from it. Some of the popes, with a barbarous zeal, and a timidity of spirit for the success of the Christian religion, which the belief of its divinity can never excuse, ordered great numbers of the Talmud to be burned. Gregory IX. burned about 20 cart-loads, and Paul IV. ordered 12,000 copies of the Talmud to be destroyed.

The last edition of the Talmud of Babylon, printed at Amsterdam, is in 12 vols folio. The Talmud of Jerusalem is in one large folio.

TALPA, the MOLE; a genus of quadrupeds belonging to the order of *feræ*. See MAMMALIA *Index*.

TAMANDAU. See MYRMECOPHAGA, MAMMALIA *Index*.

TAMARUNDIS, the TAMARIND-TREE; a genus of plants; according to Linnæus belonging to the class of triandria; but Woodville, Schreber, and other botanists, have arranged it under the class of monadelphia. See BOTANY *Index*.

TAMARIX, the TAMARISC, a genus of plants belonging to the class pentandria; and in the natural system ranging under the 13th order, *Succulentæ*. See BOTANY *Index*.

TAMBOUR, in *Architecture*, a term applied to the Corinthian and Composite capitals, as bearing some resemblance to a drum, which the French call *tambour*. Some choose to call it the *vase*, and others *campana* or the bell.

TAMBOUR is also used for a little box of timber work, covered with a ceiling, withinside the porch of certain churches; both to prevent the view of persons passing by, and to keep off the wind, &c. by means of folding-doors, &c.

TAMBOUR, also denotes a round course of stone, several whereof form the shaft of a column, not so high as a diameter.

TAMBOUR, in the arts is a species of embroidery. The tambour is an instrument of a spherical form, upon which is stretched, by means of a string and buckle, or other suitable appendage, a piece of linen or thin silken stuff; which is wrought with a needle of a particular form, and by means of silken or gold and silver threads, into leaves, flowers, or other figures.

TAMBOURIN, is the name of a dance performed on the French stage. The air is lively, and the movements are quick.

The same name is applied to a musical instrument, formed of a hoop, over which is stretched a piece of parchment or vellum, while bells and hollow hemispheres of brass are loosely hung in holes cut in the hoop. The tambourin is used only as an accompaniment to other instruments.

TAMERLANE, or TIMUR BEK, a celebrated prince and conqueror. At the age of 25 he attained the highest dignities, with surprising courage, and an ambition astonishing to all the world. Endeavouring to perfect the great talents which he had received from nature, he spent nine years in different countries; where his great sense and elevated genius appeared in councils and assemblies, while his intrepidity and valour, whether in personal combats or pitched battles, drew upon him the admiration of all mankind. He made himself master of the three empires of Jagatay Khân, Tushi Khân, and Hûlâkû Khân; so that his power, riches, and magnificence, were immense. There remain vast monuments of his grandeur in the cities, towns, castles, and walls, which he built; in the rivers and canals which he dug, as well as the bridges, gardens, palaces, hospitals, mosques, and monasteries, which he erected in divers parts of Asia in so great a number, that a king might be accounted very powerful and magnificent, who should have employed 36 years only in building the great edifices which Timûr caused to be founded.

Timûr, according to the historian Arabshâh, was in his person very corpulent and tall. He had a large forehead and big head. His countenance was agreeable, and his complexion fair. He wore a large beard, was very strong and well limbed; had broad shoulders, thick fingers, and long legs. His constitution was amazingly vigorous; but he was maimed in one hand and lame of the right side. His eyes appeared full of fire; his voice was loud and piercing; he feared nothing; and when far advanced in years, his understanding was sound and perfect, his body vigorous and robust, his mind constant and unshaken like a rock.

He did not like raillery, and could not bear a lie. There was no joking or fooling before him; for he loved the naked truth, even although it was to his own disadvantage. He neither grieved if he miscarried in any attempt, nor appeared overjoyed on any great success. The device of his seal was, "I am sincere and plain." He had a clear and solid understanding, was surprisingly happy in his conjectures; vigilant, active, and unshaken in his resolutions. He took great delight in reading history, and was well versed in the state of countries, provinces, and cities. He was penetrating, subtle, close, and dissembling; just by inclination, liberal from disposition; but ambition had in a great measure extinguished his humanity: war had familiarized him to blood; and his religious zeal had inspired him with the most cruel, implacable, and pernicious fanaticism.

He died on the 1st of April 1405, in the 71st year of his age and 36th of his reign. When he found death approaching, he sent for his principal officers, declared his grandson his heir, and made them swear to execute his will. Having recommended brotherly love and concord to the princes his children, he ordered one of the doctors to read the Koran at his bed's head, and often repeat the unity of God. At night he several times made profession of his belief, "That there is no other God than God," and then expired. See MOGULS, N° 15, &c.

TAMTAM, a flat drum used by the Hindoos, resembling a tabor, but it is larger, and sounds louder.

TAMUS, BLACK BRIONY, a genus of plants belonging

ing to the class diœcia; and in the natural system ranking under the 11th order, *Sarmentaceæ*. See BOTANY *Index*.

TAN, the bark of the oak after it has been ground and used by the tanner. The smallest sort is generally made up in little square cakes called *turf*, and sold for firing. The coarser sort is sometimes dried in the sun, and used by bakers for heating their ovens, &c. but its chief use is for making hot-beds to raise pine-apples and other plants.—William III. introduced the use of it from Holland, for the purpose of raising orange trees; after which it was discontinued for many years: but about 1719, when *ananas* were first brought into England, it came into general use, and has ever since been in great estimation with gardeners for all the purposes of forcing, &c. on account of its strong and lasting fermentation. The smaller the tan the quicker it heats; but the larger sort acquires heat more gradually and retains it longer: the skilful gardener therefore uses the one or the other, or a mixture of both, according to the time and purpose for which it is wanted. It is some time after the tan comes out of the tanner's pit before it begins to heat, and therefore it is not fit for immediate use; but having lain a week or two, it enters into a state of fermentation, and if put into hot-beds properly prepared, will retain a moderate heat for three or four months. When it becomes useless for the hot-house, it is said by Miller and others to be an excellent manure for some kinds of land.

The word *tan* is sometimes, though improperly, used for the *bark* itself, which is the chief ingredient in the tanning of leather. Oak bark, on account of its great astringency and gummy-resinous properties, is preferred to all other substances for the purpose of tanning, as it not only preserves the leather from rotting, but also, by condensing the pores, renders it impervious to water. See TANNING.

For an account of tan or *tannin*, considered as a chemical principle, see CHEMISTRY, N° 2504.

TANACETUM, TANSY, a genus of plants belonging to the class syngenesia; and in the natural system ranging under the 49th order, *Compositæ*. See BOTANY *Index*.

TANÆCIUM, a genus of plants belonging to the didynamia class; and in the natural method ranking under the 25th order, *Putamineæ*. See BOTANY *Index*.

TANAGRA, TANAGER, a genus of birds belonging to the order of *passeres*. See ORNITHOLOGY *Index*.

TANAIS, or DON. See DON.

TANGENT *of an* ARCH, is a right line drawn perpendicularly from the end of a diameter, passing to one extremity of the arch, and terminated by a right line drawn from the centre through the other end of that arch, and called the *secant*. See GEOMETRY.

TANGIER, a port-town of Africa, in the empire of Morocco and kingdom of Fez, situated at the entrance of the straits of Gibraltar, in W. Long. 5. 50. N. Lat. 38. 49. In 1662, this place belonged to the Portuguese, and was given to King Charles II. upon his marriage with the Infanta of Portugal; but, he growing weary of the charge of keeping it, caused it to be blown up and destroyed in 1684; ever since which time it has been only a poor fishing town. Anciently it was called *Tingis*, and gave name to the province of Mauritania Tingitana.

TANK, in the language of Indostan, a place inclosed for receiving and retaining rain water. During the periodical rains the tanks are filled, and thus in the dry season furnish water for the rice fields and cattle. Some of them are of great extent, measuring 300 or 400 feet on the side; they are of a quadrangular form, and lined with granite, descending in regular steps from the margin to the bottom.

TANNER, one who dresses hides by tanning them. See TANNING.

TANNER, *Dr Thomas*, an English prelate and celebrated antiquarian, born in 1674. He was admitted of Queen's college Oxford, where a similarity of taste for antiquities produced a close friendship between him and Edmund Gibson afterwards bishop of London. In 1697, he was chosen fellow of his college; and having already published some specimens of his antiquarian researches; soon after became known to Dr Moore bishop of Norwich, who made him chancellor of his diocese. In 1722, he was made archdeacon of Norwich, and in 1731, bishop of St Asaph. He died at Oxford in 1735; and after his death was published an elaborate work, in which he is said to have been employed for 40 years, under this title, *Bibliotheca Britannica Hibernica, sive de Scriptoribus qui in Anglia, Scotia, et Hibernia, ad sæculi* XVII. *initium floruerunt*, &c.

TANNING, the art of converting hides and skins into leather. This art has been practised for many centuries in Britain; but some improvements have been made on it, especially in France, suggested by the discoveries of modern chemistry. These improvements we shall briefly notice after having described the method lately practised in the neighbourhood of London, where the best British leather is manufactured. The general principles on which the improvements are founded, will naturally come to be considered, after describing the processes themselves.

1 Different kinds of leather.

The leather tanned in England is generally divided by the manufacturers into three kinds, *butts* or *backs*, *hides*, and *skins*. *Butts* are made from the stoutest and heaviest ox hides, and are used chiefly for the soles of stout shoes and boots. *Hides*, or *crop-hides*, are made from cow hides, or the lighter ox hides, and are employed for ordinary soles. The term *skins* is applied to all the other kinds of leather, comprehending that made from the skins of calves, seals, dogs, kids, &c.

2 Method of tanning butts.

Butts are tanned as follows. After the horns are taken off, the hides are laid smooth in heaps for two days in summer, and five or six in winter; they are then hung on poles in a close room, called a smoke-house, in which is kept a smouldering fire of wet tan; this occasions a small degree of putrefaction, by which means the hair more easily comes off, by spreading the hide on a sort of wooden horse or beam, and scraping it with a crooked knife. The hair being taken off, the hide is thrown into a pool of water, to cleanse it from the dirt, &c. which being done, it is again spread on the wooden beam, and the grease, loose flesh, extraneous filth, &c. carefully taken off: the hides are then put into a pit of strong liquor, called *ooze*, prepared in pits kept for the purpose, by infusing ground oak bark in water, which is termed *colouring*. The hides are then removed into another pit, called a *scouring*, which consists of water strongly impregnated with vitriolic or sulphuric acid, or a vegetable acid prepared from rye or barley. This operation

Tanning. operation is called *raising*. The hides are then taken out of the scouring, and spread smooth in a pit usually filled with water, called a *binder*, with a quantity of ground bark strewed between each. After lying a month or six weeks, they are taken up, and the decayed bark and liquor being drawn out of the pit, it is again filled with strong ooze, when they are put in as before, with bark between each hide. They now lie two or three months, at the expiration of which the same operation is repeated; they then remain four or five months, when they again undergo the same process, and after being three months in the last pit, are completely tanned, unless the hides are so remarkably stout as to require an additional pit or layer. The whole process requires from 11 to 18 months, and sometimes two years, according to the substance of the hide, and discretion of the tanner. When taken out of the pit to be dried, they are hung on poles; and after being compressed by a steel pin, and beaten out smooth by wooden beetles, the operation is completed.

3 Of tanning hides.

Hides are thus managed. After the horns are taken off, and the hide is washed, they are put into a pit of water, saturated with lime, and having mixed with it a quantity of the same substance, where they remain a few days, when they are taken out, and the hair scraped off on a wooden beam, as before described; they are then washed in a pit or pool of water, and the loose flesh, &c. being taken off, they are removed into a pit of weak ooze, where they are taken up and put down two or three times a day, for the first week; every second or third day they are shifted into a pit of fresh ooze, somewhat stronger than the former, till at the end of a month or six weeks they are put into a strong ooze, in which they are handled once or twice a week with fresh bark for two or three months. They are then removed into another pit, called a *layer*, in which they are laid smooth, with bark ground very fine, strewed above each hide. After remaining here two or three months, they are generally taken up, when the ooze is withdrawn, and the hides put in again with fresh ooze and fresh bark, where, after lying two or three months more, they are completely tanned; except a very few stout hides which may require an extra layer. They are then taken out and hung on poles, and being smoothed by a steel pin, are, when dry, ready for sale.

4 Of tanning skins.

Skins are to be washed in water, &c. and put into lime pits as before mentioned, where they are taken up and put down every third or fourth day for two or three weeks, in order to destroy the scarf-skin. The hair is then scraped off, and the excrescences being removed, they are put into a pit of water impregnated with pigeons dung, called a *grainer*, which in a week or 10 days soaking out the lime, grease, and saponaceous matter, softens the skins, and prepares them for the reception of the ooze. They are then put into a pit of weak ooze, in the same manner as the hides, and being frequently handled, are by degrees removed into a stronger, and still stronger liquor, for a month or six weeks, when they are put into a very strong ooze, with fresh bark ground very fine, and at the end of two or three months, according to their substances, are sufficiently tanned; when they are taken out, hung on poles, and dried.

The lighter sorts of hides, called *dressing hides*, as well as horse hides, are managed nearly in the same manner as skins, and are used for coach work, harness work, &c.

4 Objections to the old methods.

The principal objections to this old method of tanning are, that it is extremely tedious, and very expensive. Various means have been suggested for introducing a cheaper and more expeditious method of tanning. Among the earliest of these we may notice that of Dr Macbride.

5 Dr Macbride's improvement.

This method consists chiefly in the use of sulphuric instead of acetous acid, for raising or distending the pores of the leather, and in substituting lime water, or a solution of lime, for what has been called the *milk* of lime, or a considerable quantity of lime diffused in water. According to a report made to the committee of commerce of the Dublin society, it appeared that Dr Macbride's method produced a saving of more than 20 per cent. to the manufacturer, while the hides were completely tanned in a much shorter time. It does not appear, however, that this method ever came into general use.

The experiments of M. Seguin, made in the end of the 18th century, on the nature of the tanning principle led him to suggest a method of tanning which is certainly much more expeditious than the old method. It has been adopted in England by Mr William Desmond, and by his directions has been practised with considerable success, by some of the principal tanners in Warwickshire, Staffordshire, and some of the neighbouring counties. The following directions, communicated by Mr Desmond to the editor of the Philosophical Magazine, will sufficiently explain this new process.

6 Mr Desmond's method.

Provide five vessels, called *digesters*, of any convenient materials and dimensions, with an aperture at the bottom of each. Let them be placed near each other, and elevated on stillages or otherwise; so that a small vessel may be placed under them. Fill the digesters with tan, viz. the bark of certain trees, such as of oak, cut small, or ground to a coarse powder. Pour water on the tan in the first digester, where it may stand some time, or be immediately drawn off. This liquor is to be poured on the tan in the second digester; from that to the third, and so on, until it comes through the tan in the last digester. The liquor is then highly coloured, and marks from 6° to 8° on the hydrometer for salts. This liquor is to be used for tanning the thickest hides, and may be called the *tanning lixivium*. If you take a small quantity of it in a glass, and pour on it a few drops of a solution of animal glue, the clear liquor becomes turbid, and a whitish substance falls to the bottom. The precipitate thus obtained, is a sure indication that the liquor contains the tanning principle; for this reason, that glue being of the same nature with the skins or hides of which it is made, whatever substance unites itself indissolubly with the former, will do so likewise with the latter.

This solution is made by dissolving a little common glue in water over a moderate fire; by means of it, not only oak bark, but also the bark of several other trees, as well as different shrubs and plants, all which may be called *tan*, are found to contain the tanning principle; and by employing the solution as before, it will be always easy to ascertain whether any given substance contains this principle.

In the course of these lixiviations it may be observed, 1. That the liquor running from the first digester, at length

Tanning.

length loses its colour. If in this state a little of it be put into a glass, and the former experiment be repeated, the liquor no longer becomes turbid, but remains clear, which shews that it contains no more of the tanning principle; but if a few drops of a solution of sulphate of iron be poured into the same glass, the liquor becomes thick and black, which is not to be poured on the tan in the second digester, but afterwards used for taking off the hair or wool. It is known by the name of *gallic lixivium*, as it appears to contain the same principles with galls.

The liquid sulphate of iron is obtained by dissolving a small quantity of iron in diluted sulphuric acid, or by dissolving green copperas in water. This solution serves to ascertain such substances as contain the gallic principle. Lime water will also produce this effect.

When the liquor ceases to grow black by the mixture of the sulphate of iron, it will be in vain to pour any more water on the tan in the first digester. This tan being thus exhausted, must be removed, and new tan put in its place.

The liquor, after running through all the digesters, at last grows weak. All the liquor that marks from 6° to 8° on the hydrometer, must be added to the stock of tanning lixivium. What proceeds afterwards from the last digester is to be poured on the new tan in the first. Then the fresh water is to be conveyed on the tan in the second digester, and the liquor of the first set aside, while it marks 6° or 8° on the hydrometer, and added to the tanning lixivium, which must always be carefully separated from the gallic. In this manner, the tan in all the digesters may be renewed, and the lixiviations continued.

The number of these lixiviations, as well as the mode of making them, may be varied at pleasure; the essential point is to repeat them so as to give the liquor a sufficient degree of concentration, which may be determined by the hydrometer, and proportioned to the quickness required in the operation, and the thickness of the hides and skins to be tanned; all which experience will soon teach. As all kinds of tan are not equally good, it will sometimes happen that six or more filtrations will be necessary to obtain a lixivium of 6° or 8°, in which case the number of digesters must be increased, and the same method pursued as above; and when a weaker lixivium is wanted, three or four filtrations will be sufficient.

The person directing these lixiviations should be provided with the solution of glue and sulphate of iron, already described, in order to ascertain the qualities of the different lixivia, as well as with a hydrometer properly graduated, to determine their degree of concentration or specific gravity.

In tanning cow and ox hides with this lixivium, they should first be washed in running water, well cleaned, and fleshed in the usual way. For removing the hair, the hides are to be steeped for two or three days in a vat filled with the gallic lixivium, and a mixture of sulphuric acid, marking 66° on the hydrometer for acids, and in the proportion of one to a thousand, or one pint to 125 gallons. During this steeping, the hair is separated from the hides in such a manner, that it may be easily known when they are to be taken out of the vat, that is, when the hair is quite loose. It is to be scraped off with a round knife on the horse or beam.

When raising is necessary, the hides are immersed for 10 or 12 hours in a vat filled with water, and $\frac{1}{100}$ of its volume of mineral acid, of the same quality with the former, and the operation of raising is finished. The hides are repeatedly washed, and the round knife is used, after which they are prepared for tanning.

The rest of the process consists in tanning, properly so called; for which purpose, the hides are to be steeped some hours in a weak lixivium of only 1° or 2°; to obtain which, that is to be taken which runs from the second digester, or some already used for tanning. They are next put into a stronger lixivium, where in a few days they will be brought to the same degree of saturation with the liquor in which they are immersed. The strength of the liquor being then much diminished, it must be renewed; and when the hides are completely saturated, or fully tanned, which is known by cutting off a bit of the edge, remove the leather, and let it dry slowly in a shady place.

For calf skins, goat skins, &c. these are first fleshed with the knife, and worked in running water like the others. They are then steeped in lime water, in which there should be more lime than the water can dissolve at once. What is not dissolved will subside, but must be mixed with the water, by stirring it several times a-day. In two or three days the skins are to be removed; when the hair is found quite loose, it is scraped off on the horse. They are then washed and pressed well, till the water running from them is perfectly clear, and the lime totally extracted. They are first steeped in a weak lixivium, then tanned as above; but the tanning lixivium must not be nearly so strong as that for hides.

Lime is used for these soft skins instead of a mixture of gallic lixivium and sulphuric acid, because the acid always swells the leather more or less, and because the lime may be more easily extracted from them, by washing and compressing them, than from the thick hides, which, when limed, are harsh and apt to crack, if the lime be not wholly extracted before they are tanned.

Among the different methods of immersion which may be practised in the course of these operations, the best way seems to be that of suspending the hides and skins vertically in the lixivia, by means of transverse rods or bars, and at such a distance asunder as not to touch each other in any one point. If they are laid out the one over the other, they will require frequent *handling*, in order that all the parts may be equally saturated, and to prevent the folds or plaits that would otherwise be formed in them. In some cases it will be found expedient to mix fresh tan from time to time with the lixivium, which will depend on the state and quality of the hides and skins to be tanned, as well as on the purposes for which they are intended. All these considerations must be left to the judgment of the manufacturer; but they do not change the principle on which this mode of tanning is founded.

Mr Desmond asserts, that besides the very great savings in point of time and labour, the leather tanned according to the above method being more completely saturated, will be found to weigh heavier, to wear better, and to be less susceptible of moisture, than the leather tanned in the usual way*.

* Philos. Mag. xi. 20.

7 Principles of tanning.

In explaining the principles on which the several parts of the tanning process depend, we must first remark, that the principal object of tanning is, to combine

Tanning. bine the gelatinous part of the hides with the tanning principle of astringent vegetables as intimately as possible, and thus produce that compound which we call leather, and which is insoluble in water. The chief part of the process therefore consists in steeping the hides in a solution of tannin till they are sufficiently impregnated with the tanning principle; and to this operation the others are subservient, only as they prepare the hides to be more easily acted on by the tanning principle.

The infusions of oak bark, when chemically examined, are found to contain two principal substances, one precipitable by solution of gelatine made from glue or isinglass, and this gives a dense black, with solution of common sulphate of iron; the other not precipitable by solution of gelatine, but precipitating the salts of iron of a brownish black, and the salts of tin of a fawn colour.

The former of these is the tanning principle, or the tannin of Seguin; it is essential to the conversion of skin into leather. The latter is the colouring or extractive matter; it is capable of entering into union with skin, and it gives to it a brown colour; but it does not render it insoluble in boiling water.

It has been generally supposed that the infusion of oak bark contains a peculiar acid, called gallic acid; but some late experiments render this opinion doubtful; and this principle, if it exists in oak bark, is in intimate combination with the extractive or colouring matter.

In the common process of tanning, the skin, which is chiefly composed of gelatine, slowly combines in its organized form with the tannin and extractive matter of the infusions of bark; the greater proportion of its increase of weight, however, is owing to tannin, and from this substance the leather derives its characteristic properties; but its colour, and the degree of its flexibility, appear to be influenced by the quantity of colouring matter that it contains. When skin, in large quantity, is suffered to exert its full action on a small portion of infusion of bark, containing tannin and extractive matter, the fluid is found colourless. It gives no precipitate to solution of gelatine, and produces very little effect on the salts of iron or of tin. The tanning principle of oak bark is more soluble in water than the extractive matter; and the relative proportion of tannin to extractive matter is much greater in strong infusions of oak bark than in weak ones; and when strong infusions are used for tanning, a larger proportion of tannin is combined with the matter of skin.

The state of the skin with regard to its impregnation with tannin may be easily ascertained by cutting it transversely with a sharp knife, as the tanned part will appear of a nutmeg colour, while the unimpregnated part retains its whiteness. Though the impregnation of the skins with tannin be an essential part of the process, something more is required to give the leather its proper degree of strength and pliability. The infusions of oak bark, especially the weaker infusions, contain, besides tannin, more or less of extractive matter, which is absorbed by the skins during the tanning process. Hence it appears, that a solution of tannin alone would not convert the skins into leather; and that as concentrated infusions of oak bark contain a less proportional quantity of extractive matter, they are not so well calculated for the purposes of tanning as the weaker infusions. This is an important conclusion, as it shews that the vulgar opinion of tanners respecting the propriety of the old methods, and what they call *feeding* the leather, is founded on rational principles. In fact it appears, that, though, in the quick method, recommended by Seguin and Desmond, the leather may be more expeditiously, and perhaps more completely impregnated with tannin, it is deficient in strength and pliability, from the want of its due proportion of extractive matter.

Having thus explained the principles on which the material part of the tanning process depends, we must briefly notice the *rationale* of the preliminary operations.

Chaptal has shewn, that when skin is immersed in a tanning liquor, without having been previously freed from its cuticle or scarf-skin, the impregnation of tannin takes place only on the flesh side. This shews the necessity, especially in the thicker hides or butts, of removing the cuticle, before steeping the hides in the tanning liquor. The small degree of putrefaction to which the butts are subjected, has this effect, and the steeping of the hides and skins in lime water contributes to the same end; for though lime does not seem to be capable of dissolving the cuticle, it renders it friable, so that it is easily removed by the instruments employed for scraping off the hair. Not only the cuticle, but likewise the soft matter of the extremity of the hair is acted on by lime; and this effect must considerably tend to facilitate the process of depilation. The same substance mixing with the fat on the fleshy side of the skins, forms a soapy compound, which, with other extraneous matter, is removed by the subsequent washings.

It has been supposed that the acids in which the skins are steeped, previous to their immersion in tanning liquors, have the effect of opening their pores, and thus rendering them more easily penetrable by the tanning principle and extractive matter. We believe that this opinion is erroneous, as we cannot see how acids, the obvious effect of which seems to be that of contracting animal matter, can enlarge the pores of the skins. It is probable that they produce some other advantageous effect not yet sufficiently understood, in preparing the skins for being more perfectly acted on by the tanning liquors.

The principal effect of the grainer, or the pigeons dung employed in the thinner skins, seems to be that of promoting putrefaction, and rendering the skins less elastic, though the alkali evolved during the fermentation of the dung, may assist in removing the fat on the flesh side of the skins.

Substitutes for oak bark. As from the present great demand, and consequent scarcity of oak timber, oak bark has become a very expensive article, it may be proper to enumerate a few of the principal vegetable substances, especially those indigenous to Great Britain, that may be substituted for it. Of these the bark of the Scotch fir appears to be most deserving of attention, and was some years ago employed by a gentleman in Ireland with great success. Several species of willow afford a good substitute for oak bark, particularly the Leicester willow, of which the entire bark produces a greater quantity of solid extract than the entire bark of oak. Next to these may be mentioned the bark of the common elm, the root of tormentil (*tormentilla vulgaris*, Lin.) which has been long employed in the north of Scotland as an article of domestic

mestic tanning. To these may be added the herb avens (*geum urbanum*, Lin.), several species of cinquefoil, and of bistort, common ladies mantle (*alchemilla vulgaris*), and the root of the common water-flag (*iris pseudacorus*, Lin.). Of plants not indigenous to Britain, but generally cultivated here, we may particularly notice the *horse-chesnut*, the bark of which is a strong astringent, and might be employed, we think, with great advantage in tanning. The most powerful tanning substance, however, with which we are acquainted, is the juice or extract of the *mimosa catechu*, commonly called *Japan earth*, one pound of which will tan as much leather as seven or eight pounds of oak bark.

Our limits will not permit us to extend this article, by describing the processes for tanning employed in other countries. On the method pursued in Russia, our readers may consult Tooke's *View of the Russian Empire;* and of the French method of tanning, an ample account has been given in a publication by De Lalande. Another on the same subject may soon be expected from Chaptal. The most complete work on British tanning, and on other processes to which leather is subjected, with which we are acquainted, is a small volume entitled *The Art of Tanning and Currying Leather*, published by the Dublin Society in 1780. Several useful papers on this subject may also be found in Nicholson's *Philosophical Journal*, and Tilloch's *Philosophical Magazine.*

For an account of other processes connected with the leather manufacture, see LEATHER and CURRYING.

TANTALIUM, a new metal which has been detected in two minerals. See MINERALOGY, p. 250.

TANTALUS, in fabulous history, king of Phrygia and Paphlagonia, was the son of Jupiter and the nymph Plota. He one day entertained the gods at his table; when, to prove their divinity, he served up his son Pelops cut in pieces. All the deities, except Ceres, perceived his cruelty and impiety, and would not touch his provisions. That goddess, whose thoughts were solely employed about her daughter Proserpine, inadvertently ate a part of his left shoulder. Pelops, however, was restored to life; and an ivory shoulder given him in the room of that which had been eaten; while Tantalus was thrown into Tartarus, where he was punished with perpetual hunger and thirst. He was chained in a lake; the water of which reached up to his chin, but retired when he attempted to drink. The branch of a tree loaded with fruit hung down even to his lips, but on his attempting to pluck the fruit the branch sprung upwards.

TANTALUS, a genus of birds belonging to the order of grallæ. See ORNITHOLOGY *Index*.

TANTALUS's Cup. See *SCIENCE, Amusements of*, N° 33.

TANZY, or TANSY. See TANACETUM, BOTANY *Index*.

TAORMINA, a town in Sicily, which is situated on a high rock, and is 88 miles south of Messina. Of its origin little is known. A colony from the isle of Naxos settled at the foot of Etna, at no great distance from the shore, and at about a league or a league and a half from the present situation of Taormina. Dionysius the Tyrant attacked this colony, and either took or set fire to their city. The inhabitants retired to the rocks of Mount Taurus; among which they found a tract of

ground sufficiently level and secure, and of sufficient extent. Here therefore they built a city; which, after the mountain, they named *Tauromenium*. It was at length raised to a very flourishing state by trade, and became celebrated as a seat of the arts, the remains of which show that the fine arts must have been once successfully cultivated at Tauromenium.

Among other remains are still to be seen a spacious theatre, a tomb, and a long natural grotto, which appears to have been anciently adorned within with artificial ornaments. After the inhabitants of Taormina embraced Christianity, they still continued to visit this grotto with devout veneration. Instead of the Pagan divinities to whom it had before been sacred, they substituted a saint, the venerable St Leonard. But St Leonard did not long draw crowds to this grotto; and the Christians have either defaced its Pagan decorations, or suffered them to fall into decay by the injuries of time. It is now black and smoky; and it is with difficulty that any remains of the Greek paintings with which it was once ornamented can be distinguished.

TAPE-WORM. See TÆNIA, HELMINTHOLOGY *Index*.

TAPER, TAPERING, is understood of a piece of timber, or the like, when thick at one end, and gradually diminishing to the other; as is the case in pyramids, cones, &c.

To measure TAPER-Timber, &c. See *SLIDING Rule.*

TAPER-Bored, is applied to a piece of ordnance when it is wider at the mouth than towards the breech.

TAPER, also denotes a kind of tall wax candle, placed in a candlestick, and burnt at funeral processions, and in other church solemnities.

Tapers are made of different sizes; in some places, as Italy, &c. they are cylindrical; but in most other countries, as England, France, &c. they are conical or taper; whence possibly the name; unless we rather choose to derive taper, in the adjective sense from the substantive taper, in the Saxon *tapen* or *tapon*, *cereus*, "wax-candle." Both kinds are pierced at bottom for a pin in the candlestick to enter.—There are two ways of making tapers, the first with the ladle, the second by hand; for which see CANDLE.

Paschal TAPER, among the Romanists, is a large taper, whereon the deacon applies five bits of frankincense, in holes made for the purpose in form of a cross; and which he lights with new fire in the ceremony of Easter Saturday.

The Pontifical makes Pope Zosimus the author of this usage; but Baronius will have it more ancient, and quotes a hymn of Prudentius to prove it. That pope he supposes to have only established the use thereof in parish-churches, which, till then, had been restrained to greater churches.

F. Papebroch explains the original of the paschal taper more distinctly, in his *Conatus Chronico-Historicus*, &c. It seems, though the council of Nice regulated the day whereon Easter was to be celebrated, it laid it on the patriarch of Alexandria to make a yearly canon thereof, and to send it to the pope. As all the other moveable feasts were to be regulated by that of Easter, a catalogue of them was made every year; and this was written on a taper, *cereus*, which was blessed in the church with much solemnity.

Taper, Tapestry.

This taper, according to the abbot Chastelain, was not a wax-candle made to be burnt; it had no wick, nor was it any thing more than a kind of column of wax, made on purpose to write the list of moveable feasts on; and which would suffice to hold that list for the space of a year.

For among the ancients, when any thing was to be written to last for ever, they engraved it on marble or steel; when it was to last a long while, they wrote it on Egyptian paper; and when it was only to last a short time, they contented themselves to write it on wax. In process of time they came to write the moveable feasts on paper, but they still fastened it to the paschal taper. Such is the original of the benediction of the paschal taper.

TAPESTRY, a kind of cloth made of wool and silk, adorned with figures of different animals, &c. and formerly used for lining the walls of rooms, churches, &c.

The art of weaving tapestry is supposed to have been borrowed from the Saracens; accordingly the workmen employed in this manufacture in France were formerly called *Sarazins* or *Sarazinois*. Guicciardini ascribes the invention of tapestry hangings to the inhabitants of the Netherlands; but he has not mentioned at what time the discovery was made. This art was brought into England by William Sheldon, near the end of Henry VIII.'s reign. In 1619 a manufacture was established at Mortlake in Surry by Sir Francis Crane, who received 2000l. from King James to encourage the design. The first manufacture of tapestry at Paris was set up under Henry IV. in 1606 or 1607, by several artists whom that monarch invited from Flanders. Under Louis XIV. the manufacture of the Gobelins was instituted, which has introduced very beautiful cloths, remarkable for strength, for elegance of design, and a happy choice of colours. The finest paintings are copied, and eminent painters have been employed in making designs for the work.

Tapestry-work is distinguished by the workmen into two kinds, viz. that of high and that of low warp; though the difference is rather in the manner of working than in the work itself; which is in effect the same in both: only the looms, and consequently the warps, are differently situated; those of the low warp being placed flat and parallel to the horizon, and those of the high warp erected perpendicularly. The English anciently excelled all the world in the tapestry of the high warp; and they still retain their former reputation, though with some little change: their low warps are still admired; but as for the high ones, they are quite laid aside by the French. The French, before the revolution, had three considerable tapestry manufactures besides that of the Gobelins; the first at Aubusson in Auvergne, the second at Felletin in the Upper Marche, and the third at Beauvais. They were all equally established for the high and the low warp; but they had all laid aside the high warp excepting the Gobelins. There were admirable low warps likewise in Flanders, generally exceeding those of France; the chief and almost only Flemish manufactures were at Brussels, Antwerp, Oudenard, Lisle, Tournay, Bruges, and Valenciennes; but of the state of these manufactures now we are ignorant.

The usual widths of tapestry are from two ells to three ells Paris measure.

The Manufacture of Tapestry of the High Warp.—The loom on which it is wrought is placed perpendicularly: it consists of four principal pieces; two long planks or cheeks of wood, and two thick rollers or beams. The planks are set upright, and the beams across them, one at the top and the other at the bottom, or about a foot distance from the ground. They have each their trunnions, by which they are suspended on the planks, and are turned with bars. In each roller is a groove, from one end to the other, capable of containing a long round piece of wood, fastened therein with hooks. The use of it is to tie the ends of the warp to. The warp, which is a kind of worsted, or twisted woollen thread, is wound on the upper roller; and the work, as fast as wove, is wound on the lower. Withinside the planks, which are seven or eight feet high, fourteen or fifteen inches broad, and three or four thick, are holes pierced from top to bottom, in which are put thick pieces of iron, with hooks at one end serving to sustain the coat-stave: these pieces of iron have also holes pierced, by putting a pin in which the stave is drawn nearer or set farther off; and thus the coats or threads are stretched or loosened at pleasure. The coat-stave is about three inches diameter, and runs all the length of the loom; on this are fixed the coats or threads, which make the threads of the warp cross each other. It has much the same effect here as the spring stave and treddles have in the common looms. The coats are little threads fastened to each thread of the warp with a kind of sliding knot, which forms a sort of mesh or ring. They serve to keep the warp open for the passage of broaches wound with silks, woollens, or other matters used in the piece of tapestry. In the last place, there are a number of little sticks of different lengths, but all about an inch in diameter, which the workman keeps by him in baskets, to serve to make the threads of the warp cross each other, by passing them across; and, that the threads thus crossed may retain their proper situation, a packthread is run among the threads above the stick.

The loom being thus formed, and mounted with its warp, the first thing the workman does is to draw on the threads of this warp the principal lines and strokes of the design to be represented on the piece of tapestry; which is done by applying cartoons made from the painting he intends to copy to the side that is to be the wrong side of the piece, and then, with a black lead pencil, following and tracing out the contours thereof on the thread of the right side; so that the strokes appear equally both before and behind.

As for the original design the work is to be finished by, it is hung up behind the workmen, and wound on a long staff, from which a piece is unrolled from time to time as the work proceeds.

Besides the loom, &c. here described, there are three other principal instruments required for working the silk or the wool of the woof within the threads of the warp; these are a broach, a reed, and an iron needle. The broach is made of a hard wood, seven or eight inches long, and two-thirds of an inch thick, ending in a point with a little handle. This serves as a shuttle; the silks, woollens, gold, or silver, to be used in the work

work being wound on it. The reed or comb is also of wood, eight or nine inches long, and an inch thick on the back, whence it grows less and less to the extremity of the teeth, which are more or less apart, according to the greater or less degree of fineness of the intended work. Lastly, the needle is made in form of the common needle, only bigger and longer. Its use is to press close the wool and silks when there is any line or colour that does not fit well.

All things being prepared for the work, and the workman ready to begin, he places himself on the wrong side of the piece, with his back towards the design: so that he works as it were blindfold, seeing nothing of what he does, and being obliged to quit his post, and go to the other side of the loom whenever he would view and examine the piece, to correct it with his pressing-needle. To put silk, &c. in the warp, he first turns and looks at the design; then, taking a broach full of the proper colour, he places it among the threads of the warp, which he brings cross each other with his fingers, by means of the coats or threads fastened to the staff; this he repeats every time he is to change his colour. Having placed the silk or wool, he beats it with his reed or comb; and when he has thus wrought in several rows over each other, he goes to see the effects they have, in order to reform the contours with his needle, if there be occasion. As the work advances, it is rolled upon the lower beam, and they unroll as much warp from the upper beam as suffices them to continue the piece: the like they do of the design behind them. When the pieces are wide, several workmen may be employed at once.

We have but two things to add: the first is, that the high warp tapestry goes on much more slowly than the low warp, and takes up almost twice the time and trouble. The second is, that all the difference that the eye can perceive between the two kinds, consists in this, that in the low warp there is a red fillet, about one-twelfth of an inch broad, running on each side from top to bottom, which is wanting in the high warp.

Manufacture of Tapestry of the Low Warp.—The loom or frame, whereon the low warp is wrought, is much like that of the weavers; the principal parts thereof are two strong pieces of wood forming the sides of the loom, and bearing a beam or roller at each end: they are sustained at bottom with other strong pieces of wood in manner of trestles; and, to keep them the firmer, they are likewise fastened to the floor with a kind of buttresses, which prevent any shaking, though there are sometimes four or five workmen leaning on the fore-beam at once.

The rollers have each their trunnions, by which they are sustained: they are turned by large iron pins three feet long. Along each beam runs a groove, wherein is placed the wich, a piece of wood of about two inches diameter, and almost of the length of the roller: this piece fills the groove entirely, and is fastened therein, from space to space, by wooden pins. To the two wiches are fastened the two extremities of the warp, which is wound on the farther roller, and the work, as it advances, on the nearer.

Across the two sides, almost in the middle of the loom, passes a wooden bar, which sustains little pieces of wood, not unlike the beam of a balance: to these pieces are fastened strings, which bear certain spring staves, wherewith the workman, by means of two treddles under the loom whereon he sets his feet, gives a motion to the coats, and makes the threads of the warp rise and fall alternately. Each loom has more or fewer of these spring-staves, and each staff more or fewer coats, as the tapestry consists of more or fewer threads.

The design or painting the tapestry-man is to follow is placed underneath the warp; where it is sustained from space to space with strings, by means of which the design is brought nearer the warp.

The loom being mounted, there are two instruments used in working it, viz. the reed and the flute. The flute does the office of the weaver's shuttle; it is made of an hard polished wood, three or four lines thick at the ends, and somewhat more in the middle, and three or four inches long. On it are wound the silks or other matters to be used as the woof of the tapestry. The comb or reed is of wood or ivory; it has usually teeth on both sides; it is about an inch thick in the middle, but diminishes each way to the extremity of the teeth: it serves to beat the threads of the woof close to each other, as fast as the workman has passed and placed them with his flute amongst the threads of the warp.

The workman is seated on a bench before the loom, with his breast against the beam, only a cushion or pillow between them; and, in this posture, separating, with his fingers, the threads of the warp, that he may see the design underneath, and taking a flute, mounted with a proper colour, he passes it among the threads, after having raised or lowered them, by means of the treddles moving the spring-staves and coats.

Lastly, to press and close the threads of the silk or yarn, &c. thus placed, he strikes each course (i. e. what the flute leaves in its passing and coming back again) with the reed.

TAPIOCA, a species of starch, which the Brazileans make from the roots of the cassada plant. See JATROPHA, BOTANY *Index*.

TAPIR, a quadruped of the order of belluæ, resembling the hippopotamus. See MAMMALIA *Index*.

TAPPING, in general, the act of piercing a hole in a vessel, and applying a tube or canula in the aperture, for the commodious drawing off the liquor contained therein.

TAPPING, in *Surgery*. See PARACENTESIS, SURGERY *Index*.

TAPROBANA, the ancient name of the island of Ceylon. See CEYLON, and GEOGRAPHY, N° 28.

TAR, a thick, black, unctuous substance, obtained chiefly from old pines and fir-trees by burning them with a close smothering heat. It is prepared in great quantities in Norway, Sweden, Germany, Russia, and North America, and in other countries where the pine and fir abound.

Becher the celebrated chemist, first proposed to make tar from pit-coal. Manufactures for this purpose have been established many years ago in the bishopric of Liege, and in several parts of England. In the year 1781, the earl of Dundonald obtained a patent for extracting tar from pit-coal by a new process of distillation. Great hopes were entertained of the value of this discovery, but we have not heard that it has answered expectation.

Tar, which is well known for its economical uses, is properly an empyreumatic oil of turpentine, and has been much used as a medicine both internally and externally. Tar-water, or water impregnated with the more soluble parts of tar, was formerly a very popular remedy.

TARANTO, the ancient TARENTUM, a sea-port town of Italy, in the kingdom of Naples, and in the Terra de Otranto. It is a strong and populous place, with an archbishop's see, and the title of a principality. It is seated on a peninsula, and is defended by a strong castle; but the harbour is choked up. E. Long. 17. 29. N. Lat. 40. 35.

TARANTULA, a species of aranea, so called from Taranto, the place where it is said to abound. See ARANEA, ENTOMOLOGY *Index*.

TARASCON, an ancient and populous town of France, in the department of the Mouths of the Rhone, and late province of Provence, with a well-built castle, seated on the river Rhone, opposite Beaucaire, with which it communicates by a bridge of boats. Its commerce consists in oil, brandy, starch, and stuffs that are much worn, one sort being of coarse silk, and the other of the same material and wool. It is 10 miles north of Arles, and 375 south by east of Paris. E. Long. 4. 45. N. Lat. 43. 46.

TARAZONA, a strong town of Spain, in the kingdom of Arragon, and on the frontiers of Old Castile, with a bishop's see. It is seated partly on a rock, and partly in a fertile plain, on the river Chiles. It was taken from the Moors in 1110. W. Long. 1. 26. N. Lat. 42. 10.

TARCHONANTHUS, FLEA-BANE, a genus of plants belonging to the class syngenesia; and in the natural system ranging under the 49th order, *Compositæ*. See BOTANY *Index*.

TARE, is an allowance for the outside package that contains such goods as cannot be unpacked without detriment; or for the papers, threads, bands, &c. that inclose or bind any goods imported loose; or though imported in casks; chests, &c. yet cannot be unpacked and weighed neat.

TARE, or VETCH. See VICIA, BOTANY *Index*.

TARGET, a kind of shield or weapon of defence made use of by the ancients.

TARGIONIA, a genus of plants belonging to the class of cryptogamia, and natural order of *Algæ*. See BOTANY *Index*.

TARGUM, a name given to the Chaldee paraphrases of the books of the Old Testament. They are called *paraphrases* or *expositions*, because they are rather comments and explications than literal translations of the text. They are written in the Chaldee tongue, which became familiar to the Jews after the time of their captivity in Babylon, and was more known to them than the Hebrew itself. So that when the Hebrew text was read in the synagogue, or in the temple, they generally added to it an explication in the Chaldee tongue for the service of the people, who had but a very imperfect knowledge of the Hebrew tongue. It is probable, that even from the time of Ezra this custom began, since this learned scribe, reading the law to the people in the temple, explained it with the other priests that were with him, to make it understood by the people (Nehem. viii. 7—9.).

But though the custom of making these sorts of expositions in the Chaldee language be very ancient among the Hebrews, yet have they no written paraphrases or targums before the era of Onkelos and Jonathan, who lived about the time of our Saviour. Jonathan is placed about 30 years before Christ, under the reign of Herod the Great. Onkelos is something more modern. The Targum of Onkelos is the most of all esteemed, and copies are to be found in which it is inserted verse for verse with the Hebrew. It is so short and so simple, that it cannot be suspected of being corrupted. This paraphrast wrote only upon the books of Moses; and his style approaches nearly to the purity of the Chaldee, as it is found in Daniel and Ezra. This targum is quoted in the Misna, but was not known either to Eusebius, St Jerome, or Origen.

The Targum of Jonathan son of Uziel is upon the greater and lesser prophets. He is much more diffuse than Onkelos, and especially upon the lesser prophets, where he takes great liberties, and runs on in allegories. His style is pure enough, and approaches pretty near to the Chaldee of Onkelos. It is thought that the Jewish doctors who lived above 700 years after him made some additions to him.

The Targum of Joseph the Blind is upon the Hagiographa. This author is much more modern, and less esteemed than those we have now mentioned. He has written upon the Psalms, Job, the Proverbs, the Canticles, Ecclesiastes, Ruth, and Esther. His style is a very corrupt Chaldee, with a great mixture of words from foreign languages.

The Targum of Jerusalem is only upon the Pentateuch; nor is that entire or perfect. There are whole verses wanting, others transposed, others mutilated; which has made many of opinion that this only is a fragment of some ancient paraphrase than is now lost. There is no targum upon Daniel, or upon the books of Ezra and Nehemiah.

These targums are of great use for the better understanding not only of the Old Testament, on which they are written, but also of the New. As to the Old Testament, they serve to vindicate the genuineness of the present Hebrew text, by proving it to be the same that was in use when these targums were made, contrary to the opinion of those who think the Jews corrupted it after our Saviour's time. They help to explain many words and phrases in the Hebrew original, and they hand down to us many of the ancient customs of the Jews. And some of them, with the phraseologies, idioms, and peculiar forms of speech, which we find in them, do in many instances help as much for the better illustration and better understanding of the New Testament as of the Old; the Jerusalem Chaldee dialect, in which they are written, being the vulgar language of the Jews in our Saviour's time. They also very much serve the Christian cause against the Jews, by interpreting many of the prophecies of the Messiah in the Old Testament in the same manner as the Christians do. Many instances are produced to this purpose by Dr Prideaux in his *Connect. of the Hist.* of the Old and New Testament, vol. iv. p. 777, &c.

These targums are published in the second edition of the great Hebrew Bible set forth at Basil by Buxtorf the father, anno 1610; for he has rectified the Chaldee text, and reformed the vowel pointings in it; the targums having at first been written without vowel points, which were afterwards added very erroneously by some Jews.

Tarif || Tartary.

TARIF, a table containing the names of different sorts of merchandise, with the duties to be paid as settled among trading nations.

TARPA, Spurius Mecius, a Latin critic in the time of Julius Cæsar and Augustus. He had his tribunal in the temple of Apollo, where, with four assistants, he passed sentence on the works of the poets. Cicero and Horace make honourable mention of this critic.

TARPAULIN, a piece of canvas, well tarred over, to keep off the rain from any place. The term is also often applied in a burlesque sense to a person that has been all his life bred to the sea.

TARPEIAN, in Roman antiquity, an appellation given to a steep rock in Rome; whence, by the law of the twelve tables, those guilty of certain crimes were precipitated. It took its name from Tarpeia, a vestal virgin, who was killed by the Sabines, as related under the article Rome, N° 24.

TARQUIN the Elder, king of Rome, succeeded Ancus Martius 615 B. C. See Rome, N° 35—40.

Tarquin the *Proud*, a tyrant and usurper. See Rome, N° 49—51, &c.

TARRAGON, or Dragon-wort. See Botany *Index*.

TARROCK, a species of lorus. See Ornithology *Index*.

TARSHISH, a town frequently mentioned by ancient authors, the situation of which it is difficult to ascertain. See Ophir.

TARTAN, in sea language, a small coasting vessel navigated in the Mediterranean, with only one mast and a bowsprit, the principal sail, which is very large, being extended by a lateen-yard. When tartans put up a square sail, it is called a *sail of fortune*.

TARTAR, a hard solid substance which separates from wine after complete fermentation, and adheres to the top and sides of the casks. It is an impure tartrate of potash with the acid in excess. See Chemistry, N° 999.

TARTARIC acid. See Chemistry, p. 529.

1 Divisions.

TARTARY, a name given by geographers and historians to a considerable extent of territory in Asia, lying between Russia and China, and including a great variety of nations, now chiefly dependent on these two empires. The whole country is usually divided into *Western Tartary*, and *Eastern* or *Chinese Tartary*, of which the former includes Western Turkistan, Kharism, and Great Bucharia; while the latter comprehends the country of the *Monguls* and the *Mandshurs*, now both subject to Russia, and Little Bucharia. The geography of several parts of this extensive tract has already been considered under the articles Bucharia, China, and Russia, and we shall here confine ourselves to that which is now commonly known by the name of *Independent Tartary*, by which we understand that extent of country now possessed by the *Kirghises*, and the Usbeck Tartars, including the Kharism, and Great and Little Bucharia.

2 Extent, &c. of Independent Tartary.

Independent Tartary thus defined, extends from the Caspian sea on the west to the mountains of Belur on the east, a space of about 870 British miles, and from the mountains of Gaur in the south, to the southern boundaries of the Russian empire on the north, including nearly 1500 British miles. About half of this extent is occupied by the Kirghises to the north, and the Usbecks to the south.

Tartary.

3 Kirghises.

The country of the Kirghises is separated from Siberia by the great steppe or desert of Issim, an extensive plain intersected by a river of the same name, and abounding with lakes of salt and bitter waters. Even the soil of this steppe is in many places impregnated with salt and nitre, though in several spots the soil is by no means unfruitful. There are no towns, as the inhabitants dwell wholly in tents.

The Kirghises have been long divided into three principal hordes, called the *great*, *middle*, and *lesser*. Of these, the two latter are now regarded as subjects of the Russian empire, though they seem by no means to be dependent on that power. The great horde, defended by mountains on the south and east, are properly independent. This last horde is supposed to contain about 60,000 families, while the lesser and middle hordes are said to comprehend each about half that number. The whole population is computed at about 500,000.

The Kirghises have gradually moved from the east towards the west. Their manners are described at considerable length by Pallas. Their tents are of a sort of felt; their drink kumiss, made of acidulated mares milk. The great horde is considered as the source of the other two. Being settled near the mountains of Alak, or *Ala Tau*, this horde has been called the Alatanian Kirghises. They lead a wandering life, from the borders of the Upper Sirr, near Tashkund, to the steppe of Issim. Each horde has its particular khan; but the middle horde, when Pallas visited this country, was contented with a prince, who seemed to acknowledge the khan of the lesser horde; and in 1777, this khan was called Nur Hali, an equitable prince. Their features are Tartaric, with flat nose and small eyes, but not oblique like those of the Monguls and Chinese. They have horses, camels, cattle, sheep, and goats. Some individuals of the middle horde, it is said, had 10,000 horses, 300 camels, 4000 cattle, 20,000 sheep, and upwards of 2000 goats; while in the lesser horde were proprietors of 5000 horses, and a proportional number of the other animals. Their dromedaries furnish a considerable quantity of woolly hair, sold to the Russians and Bucharians, being annually clipped like that of sheep. Their chief food is mutton; and the lamb is so exquisite, that it is sent from Orenburg to St Petersburg for the tables of the palace. The lamb skins are the most celebrated next to those of Bucharia; but the wool of the sheep is coarse, and used only for domestic purposes, for felts and thick cloths. The steppes supply them with objects of the chase, wolves, foxes, marmots, antelopes, &c. In the southern and eastern mountains are found wild sheep, the ox of Tibet, which seems to delight in snowy alps; with chacals, tigers, and wild asses.

As the Kirghisians regard each other as brethren, they are obliged to employ slaves who are captives taken in their incursions. Their dress consists of close vests, large trowsers, and pointed boots. The ladies adorn their heads with the necks of herons, disposed like horns. They appear to be Mahometans, but have a more relaxed creed.

The Kirghisians carry on some trade with Russia. The chief traffic is at Orenburg, and wholly by exchange; but the middle horde proceed to Omsk. About 150,000 sheep are annually brought to Orenburg, with horses, cattle, lamb skins, camels wool, and sometimes slaves.

Tartary. slaves. In return they take manufactured articles, chiefly clothes and furniture. From Bucharia, Khiva, and Tashkund, they receive arms and coats-of-mail, which Russia refuses, in return for camels and cattle. They are extremely fond of the Kalmuk women, who long retain their charms; and often marry them if they will adopt the Mahometan religion. They have an annual festival in honour of the dead. About the beginning of the 17th century this people, who were formerly Shamanians, became children of circumcision, by the exertions of the priests of Turkistan.

4 Usbeks. The country of the Usbek Tartars includes Kharism and part of Great Bucharia. The former of these extends from the river Gihon to the Caspian sea, and is bounded on the north and east by vast deserts. Its length is about 400 British miles, and its breadth rather less than 350. The chief town is Khiva, besides which there are five walled cities or towns, within half a day's journey of each other. The khan is absolute, and independent of any but the high priest, or lama, by whom he is controlled. The Kievinski Tartars differ little from the Kirghises, but surpass even them in treachery. Their manners are nearly the same, except that the Kirghises live in tents, while the others inhabit cities and villages. Their only trade is with Bokhara and Persia; whither they carry cattle, furs, and hides, which they procure from the Kirghises and Turkoman Tartars. The place itself produces little more than cotton, lamb furs, of a bad quality, and some raw silk; part of

5 Town of Khiva. which they manufacture. The town of Khiva stands on a rising ground, with three gates, and a strong thick wall of earth much higher than the houses, with turrets at small distances, and a broad deep ditch full of water. It occupies a large space, and commands a pleasant prospect; but the houses are built with mud, having flat roofs covered with earth. It is 17 days journey from the Caspian sea, and 33 from Orenburg, allowing 40 versts to the day's journey.

The people of Khiva bring to Orenburg large quantities of raw cotton; but the coasts of the Caspian are held by some remains of Turkomans in the north, and by Usbeks in the south. A considerable trade is carried on with Mangushlak. As the merchants of Khiva brought gold and gems to Astrakan, probably from the two Bucharias, it was suggested to Peter the Great that these products were found in Kharism, in consequence of which he attempted a settlement. But the Russians, to the number of 3000, were cut off by the Usbeks.

6 Great Bucharia. Great Bucharia, by far the most important part of Independent Tartary, extends for about 700 British miles in length from north to south, by a medial breadth of about 350, being bounded on the north by the mountains of Argun, and divided from Kharism and Corazan by the river Amu, and extensive deserts, while on the south and east it has for its boundaries the mountains of Gaur and of Beber.

The chief city of Great Bucharia is SAMARCAND, on the southern bank of the river Sogd. The other places of note are BOKHARA on the same river, Balk on the river Dehash, Zouf, and Kotlan.

The face of the country presents a great variety, abounding with rivers, hills, and mountains, but being in general deficient in wood. Near the rivers the soil is very productive, the grass sometimes exceeding the height of a man; and in some parts much industry is shown in the cultivation of rice and other grain.

The rivers are, the Amu and Sirr. Besides the sea of Aral, already described under that head, there are several considerable lakes, particularly that of Palkati, Tengis, or Balcash, being about 140 miles long by 70 broad.

"In all the regions of the earth (says Sir William Ouseley), there is not a more flourishing or a more delightful country than this, especially the district of Bokhara. If a person stand on the Kohendis (or ancient castle) of Bokhara, and cast his eyes around, he shall not see any thing but beautiful and luxuriant verdure on every side of the country; so that he would imagine the green of the earth and the azure of the heavens were united; and as there are green fields in every quarter, so there are villas interspersed among the green fields. The Sogd, for eight days journey, is all delightful country, affording fine prospects, and full of gardens and orchards, and villages, corn fields, and villas, running streams, reservoirs, and fountains, both on the right hand and on the left. You pass from corn fields into rich meadows and pasture lands; and the straits of Sogd are the finest in the world." 7 Religion of the Tartars.

The religion of the Usbeks and Bucharians is the Mahometan of the Sunni sect, and the government of the khans is despotic. There are no accounts to be met with of the state of the population, but it is believed that on any emergency they could muster an army of 100,000. The revenue of these fertile provinces is not certainly known, though that of Corasan is said to amount to half a million sterling annually, and it is probable that the revenue of Great Bucharia is at least equal to that of Corasan. 8 Trade.

Besides the caravans to Persia, Hindostan, and China, some trade is carried on with the Russians; the Bucharian merchants not only furnishing their own products, but others from the eastern countries to which they trade. 9 Manners.

The manners and customs of the Usbeks are similar to those of the other Tartars; but they are supposed to be the most spirited and industrious of these barbarians. Though many reside in tents in the summer, yet in winter they inhabit the towns and villages. They are accustomed to make sudden inroads into the Persian provinces. The native Bucharians are comparatively fair, and correspond in form and features with those of Little Bucharia. The Bucharians never bear arms. The Usbeks, on the contrary, are no strangers to the use of the musket, and it is said that even their women are not averse to warfare. The language is Turkish, but that of the Bucharians has never been investigated, though it be probably a dialect of the Persian. Their literature would furnish an ample theme, Samarcand having been a celebrated school of oriental science, cultivated even by monarchs, as Ulug Beg and others.

"Such are the generosity and liberality of the inhabitants, that no one (says Sir William Ouseley), turns aside from the rites of hospitality; so that a person contemplating them in this light, would imagine *that all the families of the land were but one house*. When a traveller arrives there, every person endeavours to attract him to himself, that he may have opportunities of performing kind offices for the stranger; and the best proof of their hospitable and generous disposition is that every

every peasant, though possessing but a bare sufficiency, allots a portion of his cottage for the reception of a guest. On the arrival of a stranger they contend one with another for the pleasure of taking him to their home, and entertaining him. Thus, in acts of hospitality, they exceed their incomes. I happened once to be in Sogd, and there I saw a certain palace, or great building, the doors of which were fastened back with nails against the walls. I asked the reason of this, and they informed me that it was a hundred years and more since those doors had been shut, all that time they had continued open day and night; strangers might arrive there at the most unseasonable hours, or in any numbers, for the master of the house had provided every thing necessary both for the men and for their beasts; and he appeared with a delighted and joyful countenance when the guests tarried a while."

For a more particular account of the manners and customs of the Tartars, see the articles BUKHARIA and KALMUKS; Pallas's *Travels in the Southern Provinces of the Russian Empire*, and Tooke's *View of the Russian Empire*. An account of the Baschkirs, also a tribe of wandering Tartars, and of the Tartars of the Krimea, has been given under RUSSIA.

We cannot here enter on the history of Tartary. The most interesting parts of it will be found under the articles CHINA and MOGUL, and we may refer those who wish for a more detailed account to the 4th volume of the *Modern Universal History*, and to the *Asiatic Researches*.

Krim TARTARY. See CRIMEA.

TARTRATES, in *Chemistry*, are saline bodies, composed of an alkaline, earthy, or metallic base, and tartaric acid.

TASSEL, a pendant ornament at the corners of a cushion, &c. In building, tassels denote those pieces of board that lie under the ends of the mantlet trees.

TASSO, TORQUATO, celebrated Italian poet, was born at Sorrento in the kingdom of Naples, in 1544. He was the son of Bernardo Tasso, and of Portia de Rossi, a lady of an illustrious family of Naples.

At three years of age Tasso was committed by his father to the care of Angeluzza, a man of great learning, who at this tender age, it is said, began to teach him grammar; at four he was sent to the Jesuits college, and at seven he was well acquainted with Latin and Greek. At the age of 12 he went from Rome to Mantua, where his father had entered into the service of the duke Guglielmo Gonzaga; he had then completed his knowledge of the Latin and Greek languages; he was well acquainted with rhetoric and poetry, and master of Aristotle's Ethics. He was soon after sent to the university of Padua; and at 18, published his Rinaldo, a poem on the plan of Homer's Odyssey. This extended his fame through all Italy; but his father went to Padua, to remonstrate against his apparent purpose of giving himself up to philosophy and poetry, and made use of many harsh expressions, which Tasso heard with great patience. "Of what use is that philosophy on which you value yourself so much?" "It has enabled me (replied Tasso) to endure the harshness of your reproofs."

He soon after went to Bologna, by the invitation of the city and college; but in a short time he returned to Padua at the urgent desire of Scipio Gonzaga, who had been elected prince of the academy established in that city under the name of the *Ætherei*. In this retreat he formed the design of his *Jerusalem Delivered*, invented the fable, disposed the parts, and determined to dedicate it to the house of Este; and being pressed to reside at Ferrara, he gave his consent. The duke of Ferrara gave him an apartment in his palace, where he lived in peace and affluence, and prosecuted his work, which he determined to dedicate to the duke, and which was published book by book, as he finished them.

At the age of 30 he finished his *Jerusalem*, and the whole was reprinted and published together, the success of which was astonishing. It was translated into Latin, French, Spanish, and even the oriental languages, almost as soon as it appeared. Soon after the publication of his *Jerusalem* he lost his father, who had been appointed governor of Ostia on the Po by the duke of Mantua; and a pretended friend to Tasso, belonging to Ferrara, to whom he had incautiously committed some transactions of a very delicate nature concerning his patron the duke, had the perfidy to betray him. This coming to the ears of the duke, he shut up Tasso in prison, from which, however, he found means to escape, after a year's confinement, and retired to Turin, being then about 34 years of age, and was recommended to the duke of Savoy, who shewed him many marks of esteem and regard. Fearing, however, that he might be delivered up to the duke of Mantua, he secretly retired to Rome, and went directly to his friend Mauritio Cataneo, by whom he was received with great kindness, and his presence made the whole city rejoice. Here he endeavoured to make his peace with the duke, and was fortunate enough to succeed.

After this he lived at Mantua about a year, in great favour with the prince; but growing weary of a state of dependence, he resolved to go to Naples, and endeavour to recover his mother's jointure, which had been seized by her relations; but as this law suit had no appearance of being soon determined, he went from Naples to Rome, where he continued about a year, in high favour with Pope Sextus Quintus, and then went to Florence, at the earnest desire of Ferdinando, grand duke of Tuscany, who had been cardinal at Rome when Tasso first resided there.

Having spent another year at Florence, he returned to Naples, where he corrected his Jerusalem Delivered.

Cardinal Cynthio, who was a great patron of learning and genius, and knew Tasso when he first resided at Rome, prevailed with him once more to leave his retreat at Naples and live with him in that city, where he continued till he was 50, and then returned to Naples to prosecute his law suit, from which place, however, he was soon recalled; and being introduced to the pope, his holiness said, "that his merit would confer as much honour on the laurel he was about to receive, as the laurel had formerly conferred on others."

It happened that while they waited for fair weather, for the purpose of celebrating the solemnity of Tasso's coronation with laurel, that great poet took his last illness, and died on the 15th day of his sickness, aged 51. His poems have acquired him an immortal reputation, the chief of which are, 1. Jerusalem Delivered. 2. Jerusalem Conquered. 3. Rinaldo. 4. The Seven Days of the Creation. 5. The Tragedy of Torimond.

6.

Tasso, Taste.

6. Aminta, &c. All his works were printed together at Florence in 1724, in 6 vols. folio, with the pieces for and against his Jerusalem Delivered.

TASTE, a certain sensation excited in the mind by certain bodies, which are called *sapid*, applied to the tongue and palate, and moistened with saliva. This is the original and proper meaning of the word *taste* (see METAPHYSICS, N° 46.); but as the qualities of bodies which produce these sensations are unknown, they have got the names of the sensations themselves, by substituting the cause for the effect. Tastes have been divided into simple and compound, and philosophers have endeavoured to ascertain the number of each species. Attempts have likewise been made to determine from their tastes the effects of different substances on the human body, taken into the stomach as food or physic; but by stating the results of such inquiries, we should be more likely to mislead than to communicate useful information.

TASTE is likewise used in a figurative sense, to denote that faculty by which we perceive whatever is beautiful or sublime in the works of nature or of art. This faculty relishes some things, is disgusted with others, and to many is indifferent. It has also been called an internal *sense*, and by one philosopher, a *reflex sense*, while others have considered it as the joint exertion of perception and judgment in some cases, and as a play of the imagination in others.

To decide among these different opinions, it will be necessary to ascertain, if we can, what are the objects of this faculty. *Scarlet*, *blue*, *green*, and *yellow*, are all beautiful colours, and a *cube* and a *sphere* are beautiful figures; but it does not appear to us, that a man could be said to have either a good or a bad taste for relishing the perception of a *scarlet* more than that of a *yellow* colour, or a *spherical* more than a *cubical* figure.

With respect to the objects of the external sense, we are so constituted by nature as to relish those kinds of food which are most wholesome, and such a taste is justly said to be sound and uncorrupted. It is in the highest perfection too at first, for it depends not on culture of any kind, and is incapable of improvement. The reverse is the case with respect to internal taste. Every voice, it is true, unites in applauding elegance, simplicity, spirit in writing, and in blaming affectation, or a false brilliancy; but when critics come to particulars, this seeming unanimity vanishes. Perhaps no man ever beheld the rising or setting sun without feeling emotions of pleasure; yet it is certain that the emotions of the clown are not the same, at least in degree, with those of the philosopher. Any beautiful object presented to the eye, gives a pleasing sensation to the mind; and it appears to us that the clown feels nothing more than a mere sensation from the view of the rising sun, similar to what he would feel from a blazing heath. In poetry and painting the vulgar are always delighted with the melody of the verse, and the brilliancy of the colours, and think of nothing else as beauties.

If this be so, the pleasures which the vulgar derive from what are called objects of taste, are mere gratifications of the senses; but very different is the pleasure which the man of cultivated taste derives from the beauties of nature or of art. The mere sensation of the clown is followed by a train of ideas which hurries him beyond the object before him to its beneficent effects and its Almighty Creator.

Taste.

The nature of any person's taste, therefore, is generally determined from the character of his imagination and the soundness of his judgment. The simple perception of the object we find is insufficient to excite these emotions, unless it is accompanied with this operation of mind. Thus, when we feel the beauty or sublimity of natural scenery, we are conscious of a variety of images in our minds very different from those which the objects themselves can present to the eye.

If the mind is in such a state as to prevent this freedom of imagination, the emotion is not perceived. In so far as the beauties of nature or art affect the external senses, their effect is the same on every man who is in possession of these senses. But to a man in pain or in grief, the same scene will not produce any feeling of admiration, which at other times would have produced it in perfection.

There are many objects of taste which produce not their full effect on the imagination, but through the medium of the judgment. The beauty of the Farnese Hercules is one kind of beauty; that of the gladiators in the palace of Chighi, another; and that of the Apollo Belvidere a third. Each of these figures is acknowledged to be perfect in its kind; but according to Sir Joshua Reynolds, the highest perfection of the human figure is not to be found but in that form which might be taken from them all, and which would partake of the activity of the gladiator, of the delicacy of the Apollo, and of the muscular strength of the Hercules. In this view the perfection of these statues consists in something which being perceived by the eye, is referred by the understanding to what we know of the characters of Hercules, Apollo, and the gladiator, and which we suppose it was the intention of the statuaries to express. There are besides, objects of which taste is sometimes said to judge, though they have little or no effect whatever on the imagination. A book of abstract science, written in a prolix and intricate style, may be said to be in a bad taste; and had Swift, in his clear and simple style, written an *Essay on the Human Understanding*, his work, supposing him master of the subject, would undoubtedly have displayed more taste than Locke's in which the terms are sometimes vague, and the period often encumbered. This is the case of Berkeley, who is admitted by all to have been a writer of good taste, though neither the Principles of Human Knowledge, the Dialogues on Matter, nor the Minute Philosopher, is capable of affording pleasure, either to the senses or the imagination. His beauty consists merely in the perspicuity of his style, of which the understanding alone is the judge. The metaphysical writings of Dr Reid possess in an eminent degree the same beauty; and no man of true taste can read them without admiring the elegant simplicity of the composition as much as the strength of the reasoning, and feeling from the whole a pleasure which the poetical style of Shaftesbury cannot communicate.

If this be a just account of the pleasures of taste, that faculty cannot be properly considered as a mere internal sense, since to its enjoyments a well-stored fancy is necessary in some cases, and the reasoning power in all; and the poet and the painter who wished to excel in their

Taste.

their respective professions, must not content themselves, the one with filling the ear of the reader with mellifluous sounds, and the other with dazzling or deceiving the eye of the spectator by the brilliancy of his colours, but both must strive for fame by captivating the imagination; whilst the architect, who aspires to a similar celebrity, must make the purpose of his ornaments obvious to every person capable of judging. The landscapes of Claude Lorrain, the music of Handel, and poetry of Milton, excite feeble emotions in our minds, when our attention is confined to the qualities they present to our senses, or when it is to such qualities of their composition that we turn our regard. It is then only we feel the sublimity or beauty of their productions, when our imaginations are kindled by their power, when we lose ourselves amid the number of images that pass before our minds, and when we waken at last from this play of fancy as from the charm of a romantic dream.

It is well observed by Sir Joshua Reynolds *, that taste is sometimes praised in such terms by orators and poets, who call it *inspiration*, and *a gift from heaven*, that though a student by such praise may have his attention roused, and a desire excited of obtaining this gift, he is more likely to be deterred than encouraged in the pursuit of his object. "He examines his own mind, and perceives *there* nothing of that divine inspiration with which he is told so many others have been favoured. He never travelled to heaven to gather new ideas; and he finds himself possessed of no other qualifications than what mere common observation and a plain understanding are able to confer. Thus he becomes gloomy amidst the splendour of figurative declamation, and thinks it hopeless to pursue an object which he supposes out of the reach of human industry. But on this, as on many other occasions, we ought to distinguish how much is to be given to enthusiasm, and how much to common sense; taking care not to lose in terms of vague admiration that solidity and truth of principle upon which alone we can reason." Whoever possesses the ordinary powers of perception, sensibility of heart, good sense, and an imagination capable of being roused by the striking objects of nature and of art, may, without inspiration, become, by mere experience, a man of fine taste in the objects of which he aspires to be a critical judge.

* *Discourse delivered at the Royal Academy*, Dec. 14. 1770.

This being the case, we may easily account for the variety of tastes which prevail among man, not only as individuals but as nations. We have already mentioned the difference in one instance between the European taste and the African respecting female beauty; and we may now affirm, as we hope to prove our affirmation, that the one taste is equally correct with the other. The charms of female beauty exist not in the mere external form and colour considered by themselves (for then the inanimate statue of the Venus de Medicis would give more delight to the European beholder than the finest woman that ever lived); but we associate external beauty with sweetness of disposition, and with all the train of endearments which take place in the union of the sexes; and it is this association which delights the man of taste, as giving refinement to an appetite which itself is gross and sensual. A similar association must be formed in the breast of the African who has any taste; and as he never knew feminine softness, or any of the endearing qualities of the sex, but as united with thick lips, a flat nose, a black skin, and woolly hair—a sable beauty of that description must excite in his breast the same emotions that are excited in the breast of an European by the fair woman with Grecian features.

But is there not an ideal or perfect beauty of the human form? There certainly is, as of every other natural object; but it cannot be the same in Europe as in Africa, unless to a Being who is acquainted with all the peculiarities of form, national and individual, that are to be found among the inhabitants of the whole earth. It has been supposed, and we think completely proved, by one of the best writers that we have on the philosophy of taste *, that the sublimity or beauty of forms arises altogether from the associations we connect with them, or the qualities of which they are expressive to us. The qualities expressed by the male and female forms are very different; and we would by no means think the woman beautiful who should have the form of the Farnese Hercules, or admire the shapes of the hero who should be formed like the Venus de Medicis; because the proportions of such a woman would indicate strength and intrepidity, where we wish to find only gentleness and delicacy; and the delicate form of the hero would indicate softness and effeminacy, where the opposite qualities only can be esteemed. As we associate with the female form many desirable qualities, every woman is esteemed more or less beautiful as her figure and features indicate a greater or smaller number of these qualities; and the same is the case with respect to the qualities which adorn the male character, and the form and features by which they are expressed. Upon comparing a number of human beings with one another, we find, that with respect to every feature and limb, there is one central form to which nature always tends, though she be continually deviating from it on the right hand and on the left: (See NOSE). This form therefore is considered as the most perfect form of the species, and most expressive of the qualities for which that species is valued; but in Africa, the central form, with respect to the proportions of the human body and the features of the human face, is very different from what it is in Europe; and therefore the ideal or perfect beauty of the human form and features cannot be the same in both countries. No doubt, if a man could examine the limbs and features of every individual of the human race, he would discover one central form belonging to the whole, and be led to esteem it the standard of beauty; but as this is obviously impossible, the common idea or central form belonging to each great class of mankind must be esteemed the standard of beauty in that class, as indicating most completely the qualities for which individuals are esteemed. Thus there is a common form in childhood and a common form in age; each of which is the more perfect as it is the more remote from peculiarities: but though age and childhood have something in common, we should not deem the child beautiful who was formed exactly like the most handsome man, nor the man handsome who was formed exactly like the most beautiful child. This doctrine is well illustrated by Sir Joshua Reynolds, who has applied it to every object esteemed beautiful in nature; and proved, that the superiority of Claude Lorrain over the landscape-painters of the Dutch and Flemish

* *Mr Alison.*

Taste.

Flemish schools, arise chiefly from his having generalized his conceptions, and formed his pictures by compounding together the various draughts which he had previously made from various beautiful scenes and prospects. "On the whole (says he), it seems to me that there is but one presiding principle which regulates and gives stability to every art. The works, whether of poets, painters, moralists, or historians, which are built upon general nature, live for ever; while those which depend for their existence on particular customs and habits, a particular view of nature, or the fluctuation of fashion, can only be coeval with that which first raised them from obscurity. All the individual objects which are exhibited to our view by nature, upon close examination, will be found to have their blemishes and defects. The most beautiful forms have something about them like weakness, minuteness, or imperfection. But it is not every eye that perceives these blemishes: It must be an eye long used to the contemplation and comparison of these forms; which alone can discern what any set of objects of the same kind has in common, and what each wants in particular."

From these reasonings the same great artist concludes, that the man who is ambitious of the character of possessing a correct taste, ought to acquire a "habit of comparing and digesting his notions. He ought not to be wholly unacquainted with that part of philosophy which gives him an insight into human nature, and relates to the manners, characters, passions, and affections. He ought to know *something* concerning *mind*, as well as a great deal concerning the *body*, and the various external works of nature and of art; for it is only the power of distinguishing right from wrong that is properly denominated *taste*.

"Genius and taste, in the common acceptation, appear to be very nearly related; the difference lies only in this, that genius has superadded to it a habit or power of execution. Or we may say, that taste, when this power is added, changes its name, and is called *genius*. They both, in the popular opinion, pretend to an entire exemption from the restraint of rules. It is supposed that their powers are intuitive; that under the name of *genius* great works are produced, and under the name of *taste* an exact judgment is given, without our knowing why, and without being under the least obligation to reason, precept, or experience.

"One can scarce state these opinions without exposing their absurdity; yet they are constantly in the mouths of men, and particularly of illiterate and affected connoisseurs. The natural appetite, or taste of the human mind, is for *truth;* whether that truth results from the real agreement or equality of original ideas among themselves, from the agreement of the representation of any object with the thing represented, or from the correspondence of the several parts of any arrangement with each other It is the very same taste which relishes a demonstration in geometry, that is pleased with the resemblance of a picture to an original, and touched with the harmony of music.

"But besides *real*, there is also *apparent* truth, or opinion, or prejudice. With regard to real truth, when it is known, the taste which conforms to it is and must be uniform. With regard to the second sort of truth, which may be called *truth upon sufferance*, or *truth by courtesy*, it is not fixed but variable. However, whilst these opinions and prejudices on which it is founded continue, they operate as truth; and the art, whose office it is to please the mind as well as instruct it, must direct itself according to *opinion*, or it will not attain its end. In proportion as these prejudices are known to be generally diffused or long received, the taste which conforms to them approaches nearer to certainty, and to a sort of resemblance to real science, even where opinions are found to be no better than prejudices. And since they deserve, on account of their duration and extent, to be considered as really true, they become capable of no small degree of stability and determination by their permanent and uniform nature.

"Of the judgment which we make on the works of art, and the preference that we give to one class of art over another, if a reason be demanded, the question is perhaps evaded by answering, I judge from my taste; but it does not follow that a better answer cannot be given, though for common gazers this may be sufficient. Every man is not obliged to investigate the causes of his approbation or dislike. The arts would lie open for ever to caprice and casualty, if those who are to judge of their excellencies had no settled principles by which they are to regulate their decisions, and the merit or defect of performances were to be determined by unguided fancy. And indeed we may venture to assert, that whatever speculative knowledge is necessary to the artist, is equally and indispensably necessary to the critic and the connoisseur.

"The first idea that occurs in the consideration of what is fixed in art or in taste, is that presiding principle which we have already mentioned, the general idea of nature. The beginning, the middle, and the end of every thing that is valuable in taste, is comprised in the knowledge of what is truly nature; for whatever ideas are not conformable to those of nature or universal opinion, must be considered as more or less capricious; the idea of nature comprehending not only the forms which nature produces, but also the nature and internal fabric and organization, as I may call it, of the human mind and imagination. General ideas, beauty, or nature, are but different ways of expressing the same thing, whether we apply these terms to statues, poetry, or picture. Deformity is not nature, but an accidental deviation from her accustomed practice. This general idea therefore ought to be called *nature:* and nothing else, correctly speaking, has a right to that name. Hence it plainly appears, that as a work is conducted under the influence of general ideas, or partial, it is principally to be considered as the effect of a good or a bad taste."

Upon the whole, we may conclude that the real substance, as it may be called, of what goes under the name of *taste*, is fixed and established in the nature of things; that there are certain and regular causes by which the imagination and passions of men are affected; and that the knowledge of these causes is acquired by a laborious and diligent investigation of nature, and by the same slow progress as wisdom or knowledge of every kind, however instantaneous its operations may appear when thus acquired. A man of real taste is always a man of judgment in other respects; and those inventions which either disdain or shrink from reason, are generally more like the dreams of a distempered brain than the exalted enthusiasm of a sound and true genius. In the midst of the highest flights of fancy or imagination, reason ought to to preside from first to last; and he who shall decide on the beauties of any one of the fine arts by an imaginary innate sense or feeling, will make as ridiculous an appearance as the connoisseur mentioned by Dr Moore, who praised as a work of the divine Raphael the wretched daubing by a Swiss copyist. The reader who wishes for further instruction in the philosophy of taste, may consult Gerard's Essay on Taste, with the dissertations of Voltaire, D'Alembert, and Montesquieu; Alison's Essays on the Nature and Principles of Taste; and Sir Joshua Reynold's Discourses delivered in the Royal Academy. See also the article BEAUTY, SUPPLEMENT.

TATE, NAHUM, an English poet, born in Ireland about the middle of the reign of Charles II. where he received his education. He was made poet-laureat to King William upon the death of Shadwell, and held that place until the reign of George I. whose first birth-day ode he lived to write, and executed it with unusual spirit. He died in the Mint in 1716. He was the author of nine dramatic performances, a great number of poems, and a version of the Psalms in conjunction with Dr Brady.

TATIAN, a writer of the primitive church in the second century. He was born in Assyria, and trained up in the heathen religion and learning. Coming over to Christianity, he became the disciple of Justin Martyr, whom he attended to Rome. While Justin lived, he continued steadily orthodox: but after Justin's death he made a schism, and became the author of a new sect, condemning marriage, enjoining abstinence from wine and animal food, and suffering only water to be used in the holy mysteries; whence his followers were called *Encratitæ* and *Hydroparastatæ*. None of his works are now extant, but his piece against the Gentiles; or, as it is usually entitled, his *Oration to the Greeks*.

TATIUS, ACHILLES, a native of Alexandria, was the author of a book on the sphere, which Father Petau translated into Latin. There is also attributed to him a Greek romance on the loves of Leucippe and Clitophon, of which Salmasius has given a beautiful edition in Greek and Latin with notes. Suidas says, that this Achilles Tatius was a Pagan, but that he afterwards embraced the Christian religion, and became a bishop. Photius mentions him in his Bibliotheca.

TATONNEUR. See LEMUR, MAMMALIA *Index*.

TATTOOING, or TATTOWING, an operation in use among the islanders in the South sea for marking their bodies with figures of various kinds which they consider as ornamental. It is performed by puncturing the skin, and rubbing a black colour into the wounds. The instrument used somewhat resembles a comb, the teeth of which are repeatedly struck into the skin by means of a small mallet. It is very painful; but the children are forced by their relations to submit to it.

TATTOU, a beat of a drum at night to advertise the soldiers to retreat, or repair to their quarters in the garrison, or to their tents in a camp.

TAVERNIER, JOHN BAPTIST, a French traveller, was born in 1605. In the course of 40 years he travelled six times to Turkey, Persia, and the East Indies, and visited all the countries in Europe, travelling mostly on foot. His travels have been frequently reprinted in six volumes 12mo. He died on his seventh journey to the east, at Moscow, in 1686.

TAVIRA, or TAVILA, a considerable town of Portugal, and capital of the province of Algarve, with a handsome castle, and one of the best harbours in the kingdom, defended by a fort. It is seated in a fertile country, at the mouth of the river Gilaon, between Cape Vincent and the strait of Gibraltar, 100 miles west-by-north of Cadiz. W. Long. 7. 46. N. Lat. 37. 18.

TAVISTOCK, a town of Devonshire in England, situated on the river Tavey or Tave, containing 4723 inhabitants in 1811. W. Long. 4. 12. N. Lat. 50. 37. It sends two members to parliament, and gives the title of *marquis* to the noble family of Russel duke of Bedford.

TAUNTON, a large, elegant, and well built town of Somersetshire, 146 miles from London. It consists principally of four streets paved and lighted; the market-place is spacious, and has a handsome market-house, with a town hall over it, which was finished in 1773. It has an extensive woollen manufactory; and in 1780 a silk manufactory was introduced. Its castle, the ruins of which remain, was in 1645 defended for the parliament by Colonel Blake against an army of 10,000 men under Lord Goring, but was dismantled by Charles II. In 1685 the duke of Monmouth made this place his head-quarters. Its church, which is large and beautiful, is a fine specimen of the florid Gothic style of architecture. The tower, which is lofty, is of excellent workmanship, crowned at the top with four stately pinnacles, 32 feet high. The whole perhaps is not equalled in the kingdom. Taunton is pleasantly seated on the river Tone, which is navigable to Bridgewater; is reckoned the best town in the county; sends two members to parliament; and contained 6997 inhabitants in 1811. W. Long. 3. 17. N. Lat. 50. 59.

TAURIS, or TEBRIS, a town of Persia, and capital of Aderbeitzan. It was formerly the capital of Persia, and is now the most considerable next to Ispahan; for it contains 15,000 houses, besides many separate shops, and about 200,000 inhabitants. It is about five miles in circumference, and carries on a prodigious trade in cotton, cloth, silks, gold and silver brocades, fine turbans, and shagreen leather. There are 300 caravanseras, and 250 mosques. Some travellers suppose it to be the ancient Ecbatana; but of this there is no certainty. It is seated in a delightful plain, surrounded with mountains, from whence a stream issues, which runs through the city. E. Long. 47. 50. N. Lat. 38. 18.

TAURUS, a great chain of mountains in Asia, which begin at the eastern part of Little Carimania, and extend very far into India. In different places they have different names.

TAURUS, in *Astronomy*, one of the 12 signs of the zodiac.

TAUTOLOGY, a needless repeating of the same thing in different words.

TAWING, the art of dressing skins in white, so as to be fit for divers manufactures, particularly gloves, &c.

All skins may be tawed; but those chiefly used for this purpose are lamb, sheep, kid, and goat skins.

The method of tawing is this: Having cleared the skins of wool or hair by means of lime, they are laid in a large vatt of wood or stone, set on the ground, full of water, in which quicklime has been slaked; wherein they are allowed to lie a month or six weeks according as the weather is more or less hot, or as the skins are required to be more or less soft and pliant.

While they are in the vatt, the water and lime are changed twice, and the skins are taken out and put in again every day: and when they are taken out for the last time, they are laid all night to soak in a running water, to get out the greatest part of the lime; and in the morning are laid together by sixes one upon another, upon a wooden leg, and are scraped stoutly one after another, to get the flesh off from the fleshy side, with a cutting two-handled instrument called a *knife*; and then they cut off the legs (if they are not cut off before) and other superfluous parts about the extremes. Then they are laid in a vatt or pit with a little water, where they are fulled with wooden pestles for the space of a quarter of an hour; and then the vatt is filled up with water, and they are rinsed in it.

In the next place, they are thrown on a clean pavement to drain, and afterwards cast into a fresh pit of water, out of which they rinse them well, and are laid again on the wooden leg, six at a time, with the hair side outermost: after which they rub a kind of whetstone very briskly, to soften and fit them to receive four or five more preparations, given them on the leg both on the flesh side and the hair-side, with the knife, after the manner above mentioned.

After this they are put into a pit of water and wheaten bran, and stirred about in it with wooden poles, till the bran is perceived to stick to them, and then they are left: as they rise of themselves to the top of the water by a kind of fermentation, they are plunged down again to the bottom; and at the same time fire is set to the liquor, which burns as easily as if it were brandy, but goes out the moment the skins are all covered.

They repeat this operation as often as the skins rise above the water; and when they have done rising they take them out, lay them on the wooden leg, the fleshy side outwards, and pass the knife over them to scrape off the bran.

Having thus cleared them of the bran, they lay the skins in a large basket, and load them with huge stones to promote the draining: and when they have drained sufficiently, they give them their feeding; which is performed after the manner following:

For 100 of large sheep skins, and for smaller in proportion, they take eight pounds of alum and three of sea-salt, and melt the whole with water in a vessel over the fire, pouring the solution out, while yet lukewarm, into a kind of trough, in which is twenty pounds of the finest wheat-flour, with the yolks of eight dozen of eggs; of all which is formed a kind of paste, a little thicker than children's pap; which, when done, is put into another vessel, to be used in the following manner.

They pour a quantity of hot water into the trough in which the paste was prepared, mixing two spoonfuls of the paste with it; to do which they use a wooden spoon, which contains just as much as is required for a dozen of skins: and when the whole is well diluted, two dozen of the skins are plunged into it; but they take care that the water be not too hot, which would spoil the paste and burn the skins.

After they have lain some time in the trough they take them out, one after another, with the hand, and stretch them out; this they do twice: and after they have given them all their paste, they put them into tubs, and there full them afresh with wooden pestles.

They then put them into a vatt, where they are suffered to lie for five or six days, or more; then they take them out in fair weather, and hang them to dry on cords or racks: and the quicker they are dried the better; for if they be too long a drying, the salt and alum within them are apt to make them rise in a grain, which is an essential fault in this kind of dressing.

When the skins are dry, they are made up into bundles, and just dipt in fair water, and taken out and drained: they are then thrown into an empty tub; and after having lain some time are taken out and trampled under foot.

They then draw them over a flat iron instrument, the top of which is round like a battledore, and the bottom fixed into a wooden block, to stretch and open them; and having been opened, they are hung in the air upon cords to dry; and being dry, they are opened a second time, by passing them again over the same instrument.

In the last place, they are laid on a table, pulled out, and laid smooth, and are then fit for sale.

TAXATION. Besides those expences which are necessary to the existence, or conducive to the comfort and enjoyment of private individuals, there are others of which the benefit is directly applicable to the whole society. These benefits indeed are chiefly of a negative kind, but they are not therefore the less essential. They consist in the preservation of person and property from that violence both internal and external, to which the irregular passions of human nature continually expose them. The regular administration of justice, and defence against foreign enemies, are so essential to the well-being of a people, that they can with no propriety hesitate, when necessary, to part even with a large portion of their income in order to provide for the proper accomplishment of these objects. A certain pomp and magnificence too, in those who are to take the lead in these departments, have been deemed both ornamental to the society, and necessary for securing respect and obedience from the body of the people. If, besides these grand and indispensable advantages of foreign and internal security, public funds can be applied to any other purposes, evidently tending to promote the national well-being, yet beyond the reach of private exertions,—to canals, high roads, or public institutions of any description,—there can be no doubt surely as to the propriety of such an application.

It is evident, therefore, that the money which is necessary for the above purposes, forms a perfectly necessary and proper part of national expenditure. The government of the country, indeed may, as elsewhere observed (POLITICAL ECONOMY), economically speaking, be considered as part of its fixed capital, essential to the advantageous employment of the rest. Without the security which the labourer thence derives, of reaping the fruits of his industry, he would have little motive to action; every thing would be the prey of the strongest, and

and all impulse to activity ceasing, universal poverty would ensue. At the same time we may observe with regard to this as to other fixed capitals, that the expence is expedient only so far as it is necessary, and that if the same functions can be performed at a smaller cost, a decided gain arises to the public. It becomes therefore an important object to inquire in what manner the offices of government may be adequately performed, with the least burden on the people.

We have formerly, under the head of POLITICAL ECONOMY, slightly illustrated some leading principles respecting public revenue. But as the subject is important, we shall consider it here in somewhat greater detail.

Taxes may be arranged in the following manner. 1. *Assessed taxes*, or those which the subject is required to pay directly into the hands of the sovereign or commonwealth. Under this title are comprehended all the taxes which bear the above name; all income or capitation taxes, and every species of land taxes. These taxes are almost always intended to fall upon income. 2. Taxes upon commodities, which are paid, in the first instance, not by the consumer, but by the producer, or importer. These taxes fall upon consumption; the man who does not use the articles, pays no tax. They operate thus partly as sources of revenue, and partly as sumptuary laws. 3. *Stamp duties*, or duties upon those deeds which regulate the transference of property. These duties fall chiefly upon capital.

1. *Assessed Taxes.*—Assessed taxes, according to the above definition, seem to be the most simple and direct mode of raising a revenue. The money comes at once from the pockets of the people into those of the sovereign. No tax is so certain of yielding a revenue. The money is demanded, and must be paid. Where properly arranged also, they may probably be made to fall more equally than any other, upon the different classes, according to their ability. In absolute governments, therefore, and in governments little skilled in the science of finance, these taxes are commonly preferred, as those which can be levied with the least trouble. They have likewise this merit that they cost little in the collection, and consequently nearly their whole amount is brought into the treasury.

Assessed taxes, however, are liable to many objections. None are so heavily felt. In other cases the tax is concealed under the price of the commodity with which it confounds itself; but here the money is paid directly without any thing in return. It must generally too be paid in a considerable sum at once, a circumstance which must often be productive of serious inconvenience, while the same sum, broken down into small portions, might have been paid without difficulty. For these reasons, much greater discontent is excited by these taxes than by taxes upon commodities. A double revenue perhaps, may, in the latter way, be raised with less murmuring. In popular governments, therefore, and in those where finance has been reduced to a system, the object has generally been to avoid direct assessment as much as possible. In this country, the greater part, by far, of the revenue had been raised by taxes upon commodities, till, within these last twenty years, the pressure of public wants made it necessary to have recourse to every mode of raising money which promised to be effectual, and thus the assessed taxes have been raised to a very great amount. The most important of these taxes may be included under *land tax*, *capitation taxes*, *house tax*, and *income tax*.

Land Tax.—There is no class of men who may with more propriety be burthened with an extraordinary imposition, than the proprietors of land. They enjoy commonly a liberal income, without care or trouble of their own. Their property, being of permanent value, is much preferable to any source of income which expires with its possessor. From being local and immoveable, it is peculiarly dependent on the protecting influence of government, and may therefore be reasonably called upon to contribute something more than the common share to its support. In almost all countries, therefore, the landholders, besides being liable to the same burdens with the rest of the society, are subject to a peculiar tax, called *land tax*.

In India and other great oriental empires, the principal revenue of the sovereign is derived from land. It arises, however, not properly in the way of tax, but of rent. The sovereign, in those absolute governments, is judged to be the sole proprietor of all the land in his dominions, which are let out by him or his deputy, to the farmers. This is also the principal source of the revenue which we derive from our East Indian possessions. It is otherwise, however, in all the European countries. There, almost all the land is private property, and the contribution which government draws from it is therefore a tax.

The adherents of the economical system have proposed to substitute a land tax in the room of every other. They maintain that all taxes must finally fall upon the produce of land, since it alone affords that surplus revenue, out of which public contributions can be drawn. Were this doctrine true, much trouble and expence would doubtless be saved, exchanging the present complicated and laborious system of taxation, for one so simple and easy. But we have already endeavoured to show, under the head of POLITICAL ECONOMY, that the principles of this sect have no solid foundation; that manufactures and commerce are sources of wealth, as well as agriculture, though in a somewhat inferior degree. It will follow, therefore, that they are equally liable to be affected by taxation. It is in vain to urge that the merchant must have his profit, and the labourer his hire, and that otherwise they will not employ their capital and labour. Were a tax to be imposed upon any one branch of industry, leaving the rest untouched, there is no doubt, that wages and profit in that branch must rise, till the merchant or labourer is placed on a level with the rest of the community, otherwise he will transfer his capital and industry to some other branch. But where the imposition falls indiscriminately upon the different employments of labour and stock, there is no such refuge; the labourer and merchant must suffer a diminution of income; nor is there any process by which he can throw this diminution upon the landlord.

Other persons of a much less informed character, are often heard urging, that we have only to lay the imposition upon the landlords; and that they will not be long of indemnifying themselves by raising the rent of their lands. Such arguments will make little impression upon those who have at all attended to the true principles of political economy. The value of lands, as of every other article, is determined by the demand and the

the supply. A tax upon the rent of land would have no tendency, either to increase the one, or to diminish the other, consequently no tendency to raise the value of land. Indeed, were we to suppose, according to this hypothesis, that proprietors have an unlimited power of raising their lands, whenever they are so inclined, it is quite contrary to common sense to suppose that they should not exert that power, without waiting for the stimulus of a tax.

For these reasons, land cannot, with any propriety, be made the sole subject of taxation; but it is very fair, as above observed, that it should pay somewhat more than other sources of revenue. A difficulty, however, arises from the variations to which its value is subject, sometimes on the decreasing, but more commonly on the increasing side. The rate which, at one time, is equitable, becomes quite otherwise at another. An attempt, on the part of government, to keep up a continual survey of all the lands in the kingdom, would be attended with a very heavy expence, and would, after all, be probably fruitless. Besides, such a measure would operate as a discouragement to the improvement of land, when so large a share would go out of the hands of the improver. These objections have weighed so strongly with the legislature of this country, that they have not raised this tax, since its first imposition in the reign of King William. It was then meant to be at the rate of four shillings in the pound, though in fact, it was by no means so much. It was also very unequally distributed, even at the beginning; a serious evil, which, however, it might have required very great trouble to avoid. Since that time, a great and general rise has taken place in the value of land, which has made this tax much higher still, than when it was originally imposed. It has also rendered it, however, still more unequal. Although almost all the land in Great Britain has improved; yet this improvement has taken place in very different proportions, according as each district differed in natural advantages, and in the industry of the inhabitants. The land tax accordingly is, at the present moment, most exceedingly unequal; but as it fortunately happens, that there is scarcely a district in Great Britain which has not improved more or less, the general moderation of the tax has rendered its inequality less grievous.

A method has been proposed of obviating this disadvantage, by keeping a register, in which the landlord and tenant shall be jointly obliged to enter the rent which the land bears, a new entry being made at every variation. A valuation may be made of the lands which the proprietor keeps in his own possession. Something of this kind, it is said, actually takes place in the Venetian territory. The discouragement to improvement indeed still remains, but even this might be obviated by an equitable, and even liberal allowance being made, for any sums which the landlord may satisfactorily prove to have been expended in this way. The chief objection to the plan seems to be the danger of collusion between the farmer and landlord, who would have a mutual interest in representing the rent as less than it really was. The agreement indeed might, by law, be made obligatory on the farmer only to the extent of the sum registered; but it may be doubtful, whether even this regulation would always be an adequate security against fraud. The valuations would necessarily depend a good deal upon the discretion of the revenue officer; which, in an arbitrary government at least, might become a serious objection. The additional expence of such a plan would be considerable; but, provided it could be made to answer the purpose, this ought not to deter from its adoption.

Frederick of Prussia imposed a higher tax upon lands held by a noble, than upon those held by a base tenure. He conceived that the privileges and flattering advantages of nobility were such as to compensate for this additional charge. We are rather disposed to consider this proceeding as severe. A nobleman, with the same income, is poorer than a commoner, because he has a greater rank to support; and in the present state of Europe, a great proportion of the nobility are extremely poor. This extreme, however, is much better than that of France before the revolution, of the Austrian states, and of most of the old governments of Europe. There the nobility, possessing the chief influence in the administration, had obtained for themselves liberal exemptions, and thrown the principal weight of this, as of other taxes, upon the inferior orders. In Sardinia, and in some provinces of France, lands held by a noble tenure paid nothing whatever.

Some taxes upon land are proportioned, not to its rent, but to its produce. This is the case in the Asiatic countries. In China, a tenth, and in India, a fifth of the whole produce of the land, are claimed by government. In England and Ireland, the church is supported by a tax of this kind, which is called *tithe*.

These taxes are liable to two very great objections. They are, in the first place, unequal. It is rent only that can be the proper subject of taxation; that part of the produce which is necessary to pay the expence of cultivation, ought to remain untouched. But this expence is far greater in poor than in rich lands. In the former, perhaps, the produce may be little more than sufficient to pay the expences incurred; while in rich lands not only the necessity of labour is less, but the produce greater. If, by well employed capital, and costly cultivation, the farmer succeeds in extracting tolerable crops from an ungrateful soil, it is both cruel and unjust that he should be obliged to pay as much as if he had no such obstacle to struggle with.

But if this tax be objectionable on the ground of equity, it is still more so, on that of expediency. The first excitement to labour and improvements of every kind, must undoubtedly be the prospect of enjoying their fruits. Where the rate of taxation is fixed, this prospect remains unimpaired; for whatever addition the proprietor or farmer can, by such means, make to the produce of his land, is all his own. But the case is very different, when it must be so deeply shared in by persons who have done nothing to forward this increase of produce. A sovereign prince indeed may derive, from such an arrangement, some motive to encourage agriculture, and improve the means of communication, so as to raise the value of its produce. But this advantage, which will scarcely ever counterbalance the attendant evils, disappears altogether, when this imposition is to be paid for the support of an ecclesiastical body. These, being only life-renters, and seldom possessed of much capital, cannot be expected to co-operate in in any measure for the improvement of the lands. The jarrings too, which are likely to take place between the pastor and his flock, form a moral argument against this mode of support.

It must not be concealed, however, that a permanent commutation of tithes would be a measure little favourable to the interests of the clergy. It seems both just to themselves, and advantageous to the public, that when the country is in a state of improvement, this body should not be left behind; it should be able to keep pace with the other members of the society. This it can never do, if it has merely a certain fixed sum allotted for its maintenance, without the possibility of augmentation. This evil has, in fact, been seriously felt in the church of Scotland, the income of whose members, notwithstanding all that has been done for their relief, is still very inferior to what it was thirty or forty years ago. A source of income, which rises or falls with the value of land, seems the most effectual mode of maintaining this proportion between the income of the clergy, and of the rest of the society; we need not, therefore, wonder, that the clergy should be so tenacious of it.

To reconcile these contrarieties, would certainly be attended with difficulty; yet it does not seem to be absolutely impossible. The first object would be, to transfer the tax from the produce to the rent. This might be done by forming a correct estimate, on an average of a few years, of the value of the tithe; and then assigning a claim to such a proportion of the rent, as would be equal to that value. This would remove all discouragements to the exertion of the cultivator. Those which press against the exertions of the landlord would indeed remain in full force, though without any increase. In most cases, these exertions would be of very small importance, when compared with those of the former. But, besides, a scheme might probably be contrived similar to that above suggested, by which the landlord might receive an adequate allowance for any improvements he might make.

The ground-rent of houses forms part of the rent of land. In remote country situations, it is often no more than the same land would yield, if employed for the purposes of agriculture. But in the vicinity, and still more in the heart of a great town, competition, and the value attached by convenience or fashion to some particular situations, raise this rent to a very extravagant height.

Ground-rent seems to be a still more proper subject of taxation than that of common land. It arises commonly from circumstances entirely independent of any care or attention on the part of the proprietor. Yet ground rents have never been considered as a separate subject of taxation. This has probably been from the difficulty of distinguishing them from the building rent. In every tax upon houses, however, part must fall upon the ground rent, provided that be able to bear it. By diminishing the demand for houses, it will diminish also the demand for ground to build them on.

Capitation or *Poll Taxes*,—afford one of the easiest and more obvious modes of taxation. To lay an assessment upon every individual without exception, seems the most effectual mode of preventing all trouble, and leaving no room for evasion. In most of the absolute governments, where the sovereign does not claim the sole property of the lands, as in Turkey and Russia, poll taxes are imposed in lieu of land tax.

The rudest form of this imposition is, when it is laid equally upon every individual. An equality of this kind is the most grievous inequality. To make the poorest subject pay as much as the richest, is palpably unjust. The only case, where such a tax can be proper, is where it falls upon slaves. In this case, it is paid, not by the slave, but by the master. The number of slaves forms the most accurate test of the value of his property; and accordingly, in Russia, an estate is described, not by the number of acres, but by the number of slaves which it contains. This tax has also the good property of encouraging manumission. In all other cases, such a tax can only be rendered tolerable by its extreme moderation.

Nations were not long of perceiving the preposterous nature of this arrangement, and of seeking to substitute some more equitable one in its place. Fortune was evidently the most correct standard to proceed upon; but a close inquisition into private concerns was conceived to be burdensome and oppressive, If each individual were to report his own fortune, could the report be trusted to? If, on the other hand, the assessment were to be regulated by the officers of government, according to what they supposed to be his wealth, a door was opened to vexatious and arbitrary proceedings. In order to avoid these opposite dangers, it has been common to regulate the contribution according to the rank of the contributor, which it is supposed will bear at least a certain proportion to his fortune. This was the case with the different poll taxes imposed in this country during the reign of King William. It was the case also in France with regard to that part of the *taille* which fell upon the nobility. It is extremely unequal; for many men of rank have no fortune corresponding; and where it so happens, their rank impoverishes them, by the expence which is requisite for its support. Yet, as rank affords a certain approximation to fortune, it is certainly better to fix it according to that standard, than to leave it to the arbitrary appointment of the officers of government. Inequality is a less evil than uncertainty.

In that part of the *taille* which fell upon the inferior orders, the latter mode was adopted. This tax was the subject perhaps of more grievous discontent, than any other which yielded an equal revenue. It cannot be supposed that the intendant should not be often swayed by motives of favouritism, private interest, or private resentment; and the very uncertainty to which the people were exposed, formed a severe hardship. They were tempted to conceal their wealth, and even to employ inadequate instruments of trade or agriculture, in order to deceive the watchful eye of the intendant.

House Tax.—In order to avoid the defects incident to the above modes of assessment, rent of houses has been fixed upon as affording the best criterion of the amount of a man's income. It certainly affords a tolerable criterion of his expenditure; and though this may often differ considerably from his means, yet as it is rather the object of government to discourage profuse expenditure, there may be no harm in such inequality.

The most equitable mode of taxing houses, would evidently be in the proportion of their rent. In this country, accordingly, part of the land tax is made to fall upon the rent of houses. This branch of the land tax

tax is subject to the same inequalities, both original and acquired, as the other branches. The assessment, not upon each house, but upon each district, continues invariably the same. In general, it is still higher than upon land. The value of houses, however, has not risen so invariably as that of land; hence, in some districts where the population has decreased, the tax falls with considerable weight. Since that time another tax has been imposed upon houses which is in proportion to the rent, and varies with it. The heaviest tax upon houses, however, is now that which is regulated by the number of *windows*.

At the time of the original imposition of the house tax, it seems to have been considered difficult or impossible to ascertain and follow the fluctuations of the rent. Some obvious and undeniable circumstance, connected with the very form and construction of the house, was therefore selected. The most ancient is the number of hearths. Hearth money is a very ancient duty, and seems to have existed even before the Conquest. Under Charles II. a tax of two shillings on all hearths was granted to the crown for ever. This tax was grievous to the people, on account of the domiciliary visits to which it necessarily subjects them. It had besides the worst kind of inequality, pressing harder on the poor than the rich. A man of 20l. a-year may have two hearths; a man of 200l. not above four or five. A man of 1000l. will scarcely have ten. Hearth money, therefore, was abolished at the Revolution. In its stead was afterwards substituted the window tax, which could be ascertained without entering the house of the contributor. It was soon found, however, to be liable to the same inequality as hearth money. In consideration of this, the rate was greatly increased with the increase of the number of windows, and houses having less than six were entirely exempted. If, however, as would rather appear, the rent can be ascertained in a satisfactory manner, it would seem better to lay the whole of the house tax upon it directly, rather than by any circuitous and doubtful mode.

There are two parts of house rent; the ground rent, or that which is given for the use of the ground on which the house stands; and the building rent, which is paid to the builder, as a remuneration for his trouble and expence. The ground rent, as above observed, must pay a share of the tax; but the building rent cannot be affected by it. The builder must have his profit, otherwise he would turn his capital and industry into another direction. This rule, however, is somewhat modified by the very durable nature of the subject. When the tax is first imposed, it is very probable that the supply of houses may continue for some time nearly adequate to the demand; in which case the proprietor must lower his price in order to get his houses let. As the old houses decay, however, new ones are wanted, which will not be built without an adequate remuneration; and thus the general law will again operate.

Income Tax.—The object of all the different assessed taxes is to make the subject contribute an equitable proportion of his income to the expences of the state. But those which we have above enumerated, though they may procure an approximation to this point, can never attain it with perfect precision. If therefore an income tax, established on just principles, could be collected without any farther grievances, than the always unavoidable payment of the contribution, it would certainly be the most equitable assessment of any, and might with propriety supersede all other taxes of this description. Serious, however, are the difficulties which attend it. The correctness of the estimate must always depend, in a great measure, on the honour of the contributors; but all men are not honest; and the cheating of the king, is, according to the popular code, so venial an offence, that accurate returns cannot, in all cases, be expected. If, on the other hand, the collectors, as in the French *taille*, take upon themselves to form this estimate, a door is opened to arbitrary and oppressive exactions. The impossibility also of escaping the tax by any species of privation makes its weight more sensibly felt, than in those which are in any degree voluntary. For all these reasons, an income tax has hitherto been among the last resources to which a nation has had recourse in its extremest necessity.

Most of the capitation taxes, as formerly observed, partook more or less of the nature of the income tax. The subsidies, so frequent in our early finance, were, like the *taille*, composed, partly according to rank, and partly according to fortune. Among the nobility, alienation of estates was yet rare, and the disproportion between rank and wealth much greater than in subsequent times. The estimate of income seems to have been made by the collectors. Such impositions, however, were ill brooked by a free and turbulent people; the subsidies became more and more unproductive; and at last were entirely given up. The first was imposed under Richard II. in 1370; the last under Charles II. in 1673.

In some small republican states, a tax of this kind is levied, the amount of which is entirely regulated by the good faith of the contributor. At Hamburgh every citizen is said to have placed in the public coffers a sum, which is declared upon oath to be one fourth per cent. of his whole property, which, reckoning interest at five per cent. would be one twentieth of his income. It was not supposed that this mode of collection gave occasion to any fraud. The good faith of the people and their confidence in their government, supplied the place of compulsory laws. The secrecy was considered necessary by a mercantile state; but in some of the small Swiss republics, every citizen declared publicly upon oath the amount of his income, and was assessed accordingly. Such unsuspected good faith could only exist in these small states, where patriotism was ardent, and the confidence of the people in their government entire.

Since the discontinuance of subsidies, nothing of this kind had been attempted in Britain, till the year 1798, when the accumulating weight of public debt suggested to Mr Pitt the necessity of raising a large portion of the supplies within the year. For this purpose, there appeared a necessity for having recourse to an income tax; and so strong a sense was entertained by the nation of the pressing nature of the exigency, that it was submitted to with less reluctance than might have been expected.

An attempt was at first made to connect this imposition with the former assessed taxes. These were to be tripled; but if any person was able to prove, that this charge amounted to more than a tenth of his income, he was relieved from all which exceeded that proportion. At the same time, a voluntary subscription was opened;

opened; but the produce, though honourable to national patriotism, afforded but a slender supply to public wants. These irregular and uncertain approximations towards an income tax were soon given up, and their place supplied by the tax itself, in its own shape.

To obviate the inconveniences of disclosure or arbitrary assessment, measures have been adopted, as effectual probably as any that could be devised. The commissioners of income tax are chosen by the freeholders of the county, or by the electors in a borough, in the same manner as a member of parliament, excepting that a smaller qualification is requisite. To the office of these commissioners, public opinion attaches a certain dignity, which makes it be performed gratuitously, and by the most distinguished persons in the district. These are, by oath, bound to secrecy. The statements are given, in the first instance, by the contributor; but if the commissioners are not satisfied with his return, they can require from him satisfactory explanations. According to the sources of income, the person is assessed at the amount of one year, or at an average of three years. The result of these regulations seems to have been such as to obviate, almost entirely, the chief inconveniences attached to this mode of taxation. The simple payment of the income tax indeed, is most grievously complained of: but the accessories of disclosure, or arbitrary assessment, which were considered as presenting unsurmountable obstacles to this measure, scarcely seem to be complained of at all.

The most important consideration in such a tax relates to the proportion in which it should be paid by the different members of the community. That the lowest orders, who subsist by the labour of their hands, ought to be exempted, seems universally agreed. This would produce the same effect as a tax upon the necessaries of life, the effects of which we shall discuss hereafter. But independent of this class, an equal imposition upon the higher and middling classes of the community would be extreme inequality. The larger the income, the less of it must be spent upon necessaries or common conveniences, and the more upon objects of mere show and ostentation. These last can certainly admit more easily of retrenchment; and as the opulent have a greater stake in the country, it seems reasonable that they should contribute somewhat more in a season of public exigency. A gradation continually augmenting, such as takes place in most of the other assessed taxes, seems to be strongly called for in this. The full proportion of ten per cent. was, from the first, imposed upon incomes of 200l. a-year, and though this was infinitely too low, yet at a subsequent period (in 1806) it was brought down to 150l. This sum, according to the present rate of expence is the very lowest at which any family in the middling rank can possibly be supported. The whole of this class, therefore, a class which has so many claims to the favour of the legislature, is assessed to the very same amount as the highest classes. The first conveniences of life are taxed at the same rate as its most superfluous luxuries. Certainly 1000l. a-year ought to be the first income liable to the very heavy charge of 10 per cent.; and the deficiency hence arising might be very fairly supplied by an increase, gradually augmenting, upon incomes above that amount. Fifteen per cent. perhaps, ought to be the utmost that it ever rose to; but this charge might doubtless be more easily supported by an income of 10,000l. a-year, than half of it by one of 200l. or 300l.

Modifications ought also to take place, according to the source from which the income is derived. That which arises from capital is undoubtedly of greater value than mere professional income. It does not expire with its possessor; it relieves him from the care and anxiety of laying up a provision for his family, and allows him to spend his whole income, when, to another person, it would be the most culpable imprudence. Of all species of capital, land seems to be the most valuable and durable. It stands also most in need of the protection of the state. It generally, too, comes to its possessor by inheritance, and is not the fruit of his own industry. With regard to money, although its value is still much superior to salaries or professional profits, yet it seems rather to be the policy of government to favour its accumulation, which a very great addition of charge might discourage. Money besides is a more moveable species of property than land, or even than professional income. If heavily taxed, the proprietor might withdraw into another country, and his capital, with the industry which it supported, be thus lost to the community.

The present tax makes no distinction between income which dies with its possessor, and income arising from land or capital. Yet such a distinction, if it appeared eligible, might easily be made under the present system of collection, which demands a statement, not only of the amount of income, but of the source from which it arises. The propriety, however, of such a charge demands some consideration. Land, it is true, is well able to bear a considerable share of the public burthens. But land, in this country, and in almost every other, is the subject of a peculiar tax, over and above what is paid by income arising from other sources. If therefore it were also to pay a greater proportion of the income tax, the pressure might become unjustly severe. The land tax in this country amounts to about two millions. Were we to suppose the share of the income paid by land to amount to 5,000,000l. (a large allowance), land would then pay fourteen per cent. which seems as much as can reasonably be exacted. No such burden, at least in any sensible degree, falls upon stock; but for the reasons above stated, the propriety of taxing it heavily seems somewhat equivocal.

According to the original bill, as proposed by Mr Pitt, very liberal exemptions were granted on account of children. To encourage marriage and the rearing of families, has been generally considered by legislators as an important object. From some recent speculations, however, it has appeared doubtful whether it be desirable to remove the obstacles to marriage which arise from the difficulty of subsistence. Whether from these views, or for the mere wish of rendering the tax more productive, this exemption has been gradually circumscribed. The last regulation made respecting it seems to be of a very capricious nature. An allowance of four per cent. is given, but only for the number of children exceeding two. This allowance besides is given, not out of the income tax itself, but out of the assessed taxes. As this tax was entirely a war tax, its abolition was strongly called for after the close of the late war, and was carried in 1816, though opposed by the ministry.

Other Assessed Taxes—A considerable revenue is raised in this country by taxes on men servants, pleasure horses, carriages, dogs, &c. These are all luxuries, the use of which is confined to the most opulent classes; they form, therefore, extremely proper subjects of taxation. The income tax indeed, modified as above stated, might perhaps come instead of all such taxes; but while that tax favours the higher above the middling classes, these in question tend to remedy that inequality. One assessment, however, is of a different nature; that upon labouring horses. It is not likely, and certainly could never be intended, that this tax should restrain the use of these indispensable instruments of agriculture. Neither can the duty fall upon the farmer, who, in all cases, must have his profits. To secure this, he must pay the less rent, in proportion as he pays the more tax; and this duty will finally operate as a land tax. It does not seem, however, to have any advantages above a direct assessment of the same nature. It will bear hard upon the farmer who is in the middle of his lease at the time of its being imposed. If at all heavy, it may have some tendency to limit the use of such horses, and to encourage inferior substitutes. The tax was first laid at 2s. and was justified only by its extreme lightness. It was then gradually raised to 14s.; but a proposal to raise it still higher was thrown out by parliament, and has never been again revived.

2. *Taxes upon Commodities*.—The experience of the discontent excited by direct assessments, and of the difficulty of proportioning them equally, led to the imposition of taxes on consumable commodities. These being laid in the first instance on the commodity at the time of its production or importation, are finally paid by the consumer in the increased price of his goods. No taxes are so little felt, or excite so little discontent. The duty, mingling with the price of the goods, is confounded with it; and, unless when the tax is first imposed, and a sudden rise in consequence takes place, the great mass of the people are even ignorant, how much of what they pay goes to government, and how much constitutes the mere price of the goods. The payment is also made in the most convenient manner, and may be divided into the smallest portions. The power of not paying by ceasing to consume the article taxed, goes a great way in supressing murmurs. Thus, indeed, those whose expence does not keep pace with their fortunes, pay an unequal share of the common contribution. But as the law is generally disposed to recommend economy, it will not perhaps consider this as a serious objection.

For these reasons, the modern system of finance, particularly in this country, where it is so much an object to avoid discontent, has shewn a decided favour to this mode of raising a revenue. And perhaps, upon the whole, they are the best of any; yet the evils with which they are attended are by no means inconsiderable.

1. These taxes take more out of the pocket of the people, in proportion to what they put in that of the public, than any other. This arises from the extensive and minute superintendance which is necessary for their proper collection. For this purpose, a number of officers must be kept, whose salaries form a serious deduction from the produce. In Smith's time, this expence amounted to above $5\frac{1}{2}$ per cent. on the duties of excise, and above 10 per cent. on those of customs. The great augmentation of revenue which has taken place since that time, has been produced more by an increase of duty on articles formerly taxed, than by the introduction of new subjects of taxation. The expence of collection, however, bears still a larger proportion to the amount collected, than either in the stamps or assessed taxes.

There is another way, in which the burden of these taxes is rendered heavier on the public. The merchant or producer advances the tax, often a considerable time before he can dispose of the article. He must therefore have not only indemnification to the amount of the duty, but also profit on the advance which he has made. It is universally observed, that when a new tax is imposed, the article rises more than in proportion to it. The public commonly murmur, and complain that the merchant has merely made the tax a pretence for this disproportionate increase in the price of his article. The truth is, however, that the merchant has a reasonable claim to receive the same profit on that part of his capital, which he has employed in advancing the tax, as upon that which he employed in the original purchase of the commodity.

2. Though the collection of these taxes is less grievous to the great mass of the people, yet it falls heavier on certain classes. These are the dealers in exciseable commodities. As evasion is much easier here than in assessed taxes, a more grinding system of superintendance becomes requisite. The tax-gatherer must have continual access to every part, not only of the workshop, but even of the private house, of the dealer in them. No time, no place, can be exempt from his visits. The power with which he is invested may also, if he be so disposed, give occasion to insolence at least, if not to oppression. Now, as the dealers in these commodities form a part, and even a pretty numerous part of the society, any hardship falling upon them must be a considerable evil. It is felt, besides, though not directly, by the rest of the society. It has already been observed, under the head of POLITICAL ECONOMY, that every disagreeable circumstance attendant on any profession, necessarily raises the rate of wages and profit in that profession. It cannot be supposed, that the dealers in these commodities will submit to the hardships we have noticed without claiming some indemnification in the price of their goods. Thus the first inconvenience will be augmented, and still more will be taken from the people, without any addition to the revenue of the public.

3. These taxes give birth to the trade of smuggling, a trade at once injurious to the public, and ruinous to the individual. Unfortunately the lax state of public morals, in regard to this point offers a strong temptation to grasp at the extraordinary profits which smuggling affords; and from the same cause, the produce of such traffic, when successful, is always sure of a ready sale. This trade, however, in the end, generally ruins not only the fortune, but also the morals of him by whom it is pursued. It trains to the practice of falsehood, perjury, and other vices, without which it cannot be carried on with any chance of success.

4. Such taxes always alter more or less, the natural, and consequently the most advantageous direction of national industry. The tax upon wine must diminish the consumption of that article, and consequently the industry

dustry employed in producing it. Wine indeed is not a commodity of British production; but it must be purchased with British commodities, and if the merchant cannot import it, neither can he afford a market for these British articles which were to be given in exchange for it. Dr Smith seems to imagine, that these taxes produce an absolute defalcation in the amount of national produce; a supposition in which we are inclined to differ from him. Although there is a diminution in the demand for this particular article; yet as the sum levied is not withdrawn from the national expenditure, but is merely transferred from one class of persons to another, it must still support a demand, if not for the same, at least for some other species of commodities. Thus the public will suffer chiefly from the inconveniences attendant on the change. Other restraints, however, for which there is no such compensation, are necessarily attendant on the collection of such duties. In order to render this efficacious, regulations must often be made, as to the manner in which the trade is to be carried on; and it is always to be apprehended, that governments will be more attentive to the security of the revenue, than to the ease of the public. In arbitrary and unenlightened governments, this propensity becomes often so powerful, as to throw the most formidable obstacles in the way of that free circulation of commodities on which the prosperity of trade, and of all industry, essentially depends.

The commodities on which these duties are imposed, may be either the necessaries or the luxuries of life. Between these two divisions the line is not easily drawn. Necessaries, strictly speaking, are confined to those things, without which life cannot be supported or health preserved. Yet, though the philosopher may reason thus, the sovereign cannot confine his people within such strict limits. In regard to food indeed, which is entirely a domestic arrangement, this definition may hold; but in clothing and lodging, the arrangements of which are in the eye of the public, long custom may impose obligations of decency and propriety, which fall little short of absolute necessity. Every thing, in this respect, must be considered as necessary, which a common labouring person of the lowest class cannot want, without incurring the reproach, or exciting the commiseration, of others in the same station.

Taxes upon the necessaries of life have the same effect with taxes upon the wages of labour. Dr Smith, and most other writers, seem to conceive that the immediate effect of such taxes is to raise the wages of labour. But we do not see that such can be the case. Nothing can raise the wages of labour, except an augmentation of the funds destined for its support. But these funds, far from being raised by such taxes, are somewhat diminished. The employers of the poor, being themselves affected by them, will be less able to pay wages than before. It is quite a fallacy to urge, that the labourer, if he does not get sufficient wages, will refuse to work. This might be, if the tax affected only a certain class of labourers, and left the rest free. The labourer, if he could not, over and above the tax, obtain the regular standard rate, would withdraw to other employments. The consequence would be, a rise of the wages of the taxed labour, with a slight fall in those of every other, proportioned to the additional number who would thus be thrown upon it. But where the tax falls equally upon labour of every description, as taxes upon the necessaries of life must do, there is no new quarter to which the labourer can turn; there is nothing either to raise or to lower wages; the supply of and demand for labour continue the same. The effect of the tax is merely to diminish the subsistence of the labourer in proportion to its amount.

This, however, is merely the first effect; for the diminished subsistence will soon begin to act upon the population, which furnishes the supply of labour. Were wages at the time so low as to furnish merely the necessaries of life according to the first definition, that is, such necessaries as it could not subsist without, the inevitable consequence seems to be, that part of the labouring poor must perish for want. Such a calamitous effect seems actually to result, in the crowded population of some eastern empires, when a deficient crop produces a scarcity of subsistence. Happily, however, the labouring poor are seldom so wholly without resource. In general the wages are sufficient to allow them a portion of the other description of necessaries, and even of luxuries, by retrenching which, they can, in the event of such a tax, preserve themselves from absolute starvation. In the end, however, the discouragement to marriage, and difficulty of rearing children, will reduce the population. This reduction, diminishing the supply of labour, will increase wages, till they cover the amount of the tax. The same sum, divided among a smaller number, will make more to each.

High wages operate as a complete tax upon every species of manufactured produce. The manufacturer must charge upon the price of his goods the whole sum which he has paid to his workmen with a profit. In the market of the world, therefore, he must, *cæteris paribus*, be undersold by the manufacturer who resides in a country where labour is cheaper. When these high prices, however, are the result of national prosperity, when they improve the subsistence of the labourer, and lay a foundation for increased population, this disadvantage will weigh very light in the balance. But where they are the result of diminished population, and attended with no improvement in the condition of the labouring poor, they form one of the greatest evils with which a nation can be afflicted.

For these reasons, taxes upon the necessaries of life, though certainly productive, have always been found to be oppressive and ruinous to the prosperity of a state. Luxuries, therefore, form the proper objects of taxation. As every one, if unable to purchase his usual quantity, can either diminish it or abstain altogether, the rise of the article has no tendency to induce such a degree of want, as to check population, and thus cause a rise to the wages of labour. This power of abstinence may indeed lead to a certain inequality; but as this inequality is altogether voluntary, it can neither excite murmuring, nor be considered as a serious hardship. The greatest irregularity is in the case of absentees, by whom such taxes are evaded altogether.

It is not, however, we must observe, from the mere luxuries of shew and ostentation that any important or permanent revenue is to be drawn. These are confined chiefly to persons of large fortune, who are few in number, and are always subject to the influence of fashion, so that little dependence can be placed on their regular consumption. The luxuries from which alone a great

 revenue

Taxation. revenue can be drawn are those which, among the higher and middling classes, have come to be considered almost as necessaries, and which are extensively used by such as are in easy circumstances, even among the lower orders. The only drink necessary for supporting the human constitution in perfect health, seems to be pure water. Men, however, have an universal propensity for something more, both to gratify their taste, and to exhilarate their spirits. Fermented and spirituous liquors, tea, coffee, &c. are had recourse to with this view, and are habitually used in various forms and degrees, by almost every inhabitant of this country. Such articles form therefore the grand basis of this system of taxation.

Of all superfluities, tea seems to be one of the greatest. It affords neither nourishment nor strength, and is generally considered by physicians as injurious to the human constitution. Being imported besides from a remote country, the intercourse with which was, by the mercantile system, stigmatized as injurious, it was considered as every way a fair subject of taxation. Very high duties were accordingly accumulated upon it, which, in 1783, amounted to nearly 30 per cent. on the value, besides an excise of 1s. on every pound. It was found that so high a duty opened a wide door to the smuggling of a commodity of so small bulk, and which was then imported in large quantities by all the neighbouring countries. It was calculated, that though duty was paid on five or six millions of pounds, the consumption of Great Britain amounted to more than double that quantity. A plan was therefore brought forward by Mr Pitt to substitute in its room an additional tax on windows. Smuggling was no doubt checked, and the people were, on the whole, gainers; yet the new tax, being assessed, was more heavily felt by the public than its predecessor, which was only a duty on consumption. Since that time, the exigency of the times has made it again necessary to have recourse to this article; and the tax upon tea has been raised even higher than it was previous to the commutation tax. The diminution, however, of the Indian trade carried on by the other powers, joined to the stricter precautions against smuggling, has prevented its renewal to nearly the same extent as formerly. Tobacco is a still more complete superfluity than tea, yet its use is very extensive. It has therefore been justly considered as one of the properest of all subjects of taxation, and duties have been laid upon it, amounting to five or six times the original value of the article.

Wine is the wholesomest of all fermented liquors, and is even pretty extensively used as a medicine. These circumstances might seem to entitle it to some favour, which, however, it has not experienced. Being entirely a foreign commodity, and being particularly cultivated by a nation long the object of our commercial jealousy, it has incurred the decided hostility of the mercantile system. Duties have been imposed, considerably exceeding the original value. A preference has also been shewn to the wines of Portugal and Spain, (though inferior in quality), which has rendered them the common drink of this country.

Spirits are an article extensively consumed in this country, and on which a high duty may, with the greatest propriety, be imposed, for the purposes not only of revenue, but of moral regulation. They afford no nourishment, and are in the highest degree liable to abuse. They are affected by the general tax on malt; but pay, besides, a considerable one when manufactured. In order to obviate the smuggling which was carried to a great extent in the making of spirits, it has been found advisable to lay the duty on the still, in proportion to its contents. It is paid by the month; and the distiller, when he chooses at any time to intermit his operations for that period, may, by giving due notice to the officers of revenue, avoid being charged. When this plan was first adopted, the duty was comparatively very low. But Mr Pitt soon found himself completely deceived as to the productiveness of this rate of duty. It was raised therefore successively to 162l. its present rate. This system lays the distiller under a temptation to work very rapidly, which is supposed to be injurious to the quality of the spirits. It obliges them also to work without intermission, which they did at first without even the exception of Sunday, till that practice was prohibited by the legislature. It may be proper to notice, that this mode of imposition is confined to Scotland, and that in England it is laid upon the wort or wash.

Fermented liquors from malt are much more useful. They are the most nutritive perhaps of any species of drink, and are on that account well suited to those who are engaged in hard labour. Neither do they offer the same temptations to excess; yet their extensive use, and the necessity of raising a revenue, have led the legislature to consider them as a staple subject of taxation, and they are now charged with a duty of nearly 100 per cent. Dr Smith advises the transference of the whole tax on beer to the malt tax. The latter appears to be less liable to smuggling, and it obviates the present exemption enjoyed by private brewers, which is evidently unreasonable and unequal. The only objection seems to be, that, being imposed at an earlier period of the manufacture, it obliges the manufacturer to lie longer out of his advance, and consequently to demand a greater profit; though this might perhaps be obviated by allowing him a longer credit. The additional taxes, however, imposed upon this article, have been all laid upon beer or porter. In general, it would appear that considerable unnecessary trouble is occasioned by taxing successively different stages of a manufacture. By laying the whole either upon malt, or upon beer, a considerable expence of collection might be saved, without any diminution of the produce.

There are many species of food which cannot, strictly speaking, be considered as necessaries of life, since their place can be supplied by some less expensive substitute. Butcher meat can be supplied by eggs, butter, and other products of milk; wheaten bread by other bread of inferior grains. It may be observed, however, that the imposition of a tax on the superior article would produce an increased demand for the inferior; and consequently raise its price. Accordingly, both butcher meat and wheaten bread are universally numbered among the necessaries of life; nor do we recollect, in the British system of taxation, an instance of solid food liable to duty. This is not the case in other countries, particularly in Holland. Heavy taxes are there imposed upon both articles. All butcher meat pays a duty of more than 7 per cent. of its value. All cattle, besides, pay about 5s. per annum. The tax upon ground corn is also very heavy and undistinguishing. Wheat pays.

pays 104 florins (nearly 9l.) per last. Nor are the inferior grains entirely exempted. Rye pays 42 florins (about 3l. 10s.); barley, beans, and oats, about 2l. Smith is not disposed to censure these heavy impositions, as they may have been rendered necessary by the long wars in which this people were engaged for the support of their independence; and when proper subjects of taxation are exhausted, recourse must be had to improper ones. Upon examining the list, however, of Dutch taxes, we do not find that the taxes upon articles of luxury are so very high, as to have reduced the legislators of that country to such an extremity. The excise upon the *aam* of wine, equal to 40 English gallons, is only 14 florins, or about 1l. 5s. Tobacco, so fair an article of taxation, and so much used in Holland, is taxed only by a slight license, estimated at little more than a halfpenny a pound. Beer and spirits are taxed still more moderately than wine. Besides, even supposing all the articles of luxury to be exhausted, we should conceive it more advisable to have recourse to assessments upon income to the necessary extent, than to duties upon articles of necessity. Accordingly, in this country, a larger revenue in proportion to the population, is now raised than ever was raised in Holland, without having recourse to these ruinous resources.

Clothes and furniture are, to a certain extent, as much necessaries of life as food. The quantity of them, however, which comes under this description, is much less; by far the greater part of the expence which is laid out in this way being for the purpose of convenience at most, if not of mere shew and ostentation. There seems therefore no reason for sparing any, beyond those plainest articles which decency demands from the lowest of the people. This class of commodities, however, has met with peculiar indulgence, in consequence of the favour entertained by the mercantile system for manufactures of every kind. Woollens and hardwares, the two staples of England, have been completely exempted. The same favour has been shown to linen, the staple of the sister kingdoms. Yet, provided a corresponding drawback were allowed on exportation, there does not appear any good reason why the finer sorts of all these fabrics should not be made a subject of revenue. Printed linens and cottons, which have recently been so abundantly produced both in England and Scotland, have been made to pay a considerable tax.

But though the legislature of this country has been thus laudably attentive to avoid touching on the first necessaries of life, there are still several particulars in which it has failed. One of the most important of these is coal, an article of the first utility, the universal fuel of this country, and the material of many of its most important manufactures. It is the less able to bear any duty, because from its local and bulky nature, the expence of transport is often very heavy. London is supplied with coal from Newcastle, which is 300 miles distant. If a bounty could in any case be advisable, it would be in such a case. The legislature, however, has judged otherwise, and has imposed upon every ton of sea-borne coal, a duty of 3s. 6d. Coals carried by land or inland navigation are duty free. Through the exertion of Lord Melville, Scotland, to the north of St Abb's Head, has been freed from this duty; a circumstance which has materially contributed to her rapid prosperity.

Salt, though it may not be requisite for the support of life, has yet, by immemorial usage among civilized nations, been constituted a necessary of life. Notwithstanding this, the small quantity used by each individual, and the minute portions in which it is purchased, make a tax upon it be levied with less murmuring than most other taxes. Governments, taking advantage of this circumstance, have almost universally made it a source of revenue.

In this country the tax on this article presses with the greater severity, as salt is essential to the fishery, one of the most important sources of national wealth. It is true, the duty is drawn back, when salt is so employed: but the facility of smuggling by means of this drawback, produces the necessity of strict regulations, which cramp extremely this branch of industry, especially when carried on in that small scale which is peculiarly suited to it.

Leather, soap, and candles, are also necessaries of life taxed in this country. But though these articles are to a certain extent necessary, by far the greatest consumption of them is for purposes of luxury. Although therefore these taxes do press upon the poor, their weight is not very severe. It might seem easy enough, at least in the first and last of them, to exempt those coarser forms of the commodity, which are used by the lower classes, and thus the deficiency of revenue might be compensated by an increase on the more expensive forms.

Taxes may be imposed either upon exportation or importation. The duties of customs were at first levied on both indiscriminately; but as the mercantile system gained ground, and an anxious desire prevailed to encourage exportation and check importation, in the hope of increasing the specie in the country, all the new duties were laid upon the latter, while the former was more and more exempted. Although this system may not have taken its rise from the most enlightened views, yet no reasonable exception can be taken to it. The taxes imposed by any government ought to fall upon the consumption of its own people, not upon that of others; and as this is a maxim of justice, so it is equally recommended by policy. Were a government to tax its own exported commodities, these commodities would also have to pay the taxes of the country into which they were imported. Loaded with this double burden, they could not advantageously come into competition with similar articles, either the produce of that country, or imported from another which followed a more liberal policy. It is only therefore upon goods imported or produced for home consumption, that these taxes can with propriety fall. From similar views, the materials of manufacture have been generally exempted from duty. We have already observed, that, provided these manufactures be objects of luxury, there is no good reason why they should not pay a tax. But there is an evident advantage in levying the duty *after*, rather than *before*, the manufacturing process. In the latter case, the merchant being obliged to advance it so early, must have a profit on his advance, proportioned to the length of time which elapses till the commodity is fit for sale; and this profit must be paid by the consumer in the price of the goods.

Should we suppose indeed a nation to possess a monopoly of any particular commodity, such a nation might impose

impose a tax on its export, without danger of its merchants being supplanted in the foreign market. Still this could not but be considered as a somewhat illiberal system; and it would also bear hard upon the producer, who would still probably have a double system of duties to pay, since it cannot be supposed that the foreign country should regard these monopolized commodities with peculiar favour.

With the view of following up the principles of the mercantile system, importation duties have often been laid upon goods, so heavy as to amount to a prohibition. Such duties are not intended to produce any revenue, but to favour some home manufacture, or to injure that of some foreign nation, which is an object of commercial jealousy. In the same manner, bounties are given to forward the growth of some branch of industry, which is the object of peculiar favour. In both cases, the revenue is sacrificed, without any real advantage accruing to the public. The industry and capital of the nation are thus turned from their natural direction into one which is less advantageous, and the public is injured instead of being benefited.

It is an undoubted principle, that whether the tax be paid at the time of importation, or at manufacture, it ought to be paid only once. Some governments, profoundly ignorant of the true principles of political economy, have repeated the imposition at every successive sale of the property. This is obviously unequal. The value of property, and the frequency of its transference, are two things altogether distinct. One species of goods may thus come to pay ten or twelve times as much as another of the same value. But great as is its inequality, its impolicy is still more glaring. It forms the most powerful check to that free interchange of commodities which is the very soul of all industry. It tends to confine the consumption of every article to the place of its production, and thus to exclude all those benefits which arise from the extension of the market. Of this ruinous nature is the Spanish *alcavala*, which consists in an imposition, originally of 10, but now only of 6 per cent. on every sale without exception, whatever be the nature of the property, or however frequently repeated. The mere undistinguishing nature of such a tax must be a great evil; but it is rendered far more pernicious by the obstruction which it thus throws in the way of every species of commercial intercourse.

It may be established as a principle in regard to these taxes, that they ought to be as uniform as possible, and not to vary in different parts of the country. Such variations necessarily lead to restraints on the free circulation of commodities. Each province becomes as an independent kingdom, the frontier of which is guarded by customhouses and by chains of officers, through which whoever passes must submit not only to the payment of duties, but to the inconvenience and delay of having his goods searched. Such was the case both in France and in Spain, where each province having formerly been separate and independent, retained still its distinct system of taxation. The transporting of goods from one province to another was like exporting them to a foreign country; the same barriers of customhouses, duties, and revenue officers, obstructed their passage. One of the circumstances which has most contributed to the prosperity of Great Britain is the uniformity of taxation throughout, and consequently the entire freedom of commerce from one part of the island to the other. This was the principal advantage which Scotland derived from the union; and it has been such as fully to compensate for the increased burdens to which that measure subjected her.

Duties upon consumption, instead of being levied upon the trader, may be levied upon the person consuming, who may be made to pay a certain sum as a *license* to use the commodity. Such a mode of levy has some of the advantages of assessed taxes, in regard to the facility and cheapness of collection. It is still also in some degree spontaneous; but it must obviously be, in most cases, very unequal. Of two persons, who should pay the same sum for a license to use wine, one might consume twenty times the quantity of the other. A license has besides the disadvantage of being paid all at once, and of being more sensibly felt than taxes which confound themselves with the price of the commodity. In general, therefore, it is a much less eligible form. There are a few instances, however, of very costly and durable goods, such as coaches, plate, &c. where it is found to be the most convenient. Wine and other liquors, when consumed in taverns, may, it is supposed, be fairly required to pay more than when consumed in private houses. An attempt, however, to proportion this addition to the quantity consumed, would be attended with unsurmountable difficulties. A license is therefore required to be taken out by innkeepers who deal in these articles. This tax falls with equal weight upon the great and small dealers; but it may be rather considered as desirable to check the multiplication of the last.

3. *Stamp Duties.*—Under the title of stamp duties, we would include all those which fall upon the deeds which regulate the transference of property.

The first of these duties, of which we find any mention, are those upon testamentary donations. A law of Augustus imposed the *vicesima hereditatum*, or twentieth penny, upon all inheritances. It was in Holland, however, which was pressed by the severest necessity of raising a revenue, and not very discriminating in the mode of doing it, that the system of *stamp* duties first originated, and was carried to a formidable extent. Such were the difficulties of that state, that they are said to have publicly proposed a reward to any one who should suggest a new source of revenue. This plan was proposed and approved. From Holland it was, in 1671, imported into this country, and has since become one of the great sources of public income. In other countries, deeds regarding the transference of property are required to be entered in a public register, and the tax laid on the registration. A considerable revenue was thus raised in France. Auction duties upon the sale of property, both moveable and immoveable, though somewhat different in point of form, coincide exactly with these taxes in their essence and tendency.

Taxes of this nature are attended with considerable conveniences to the contributors. From the nature of the transaction, there must always be money in hand with which the tax can be paid; and the time of payment is thus the most convenient of any. In many cases, the sum to be paid at a time is small. It is only part of the society which is liable to them to any great extent, and these only occasionally; they are not felt as intrenching on daily and habitual comforts; nor do they

they excite that general murmur, which is alone formidable to government. It is not to be wondered at, therefore, if the latter should avail themselves of this passive disposition in the people for the extension of this source of supply. The truth is, however, that in all essential respects, these taxes are among the most improper of any.

1. They are unequal, inasmuch as the value of any property is altogether unconnected with the frequency of its transference. This inequality would subsist, even though the stamp duty were always in exact proportion to the value of the property. But this is, in general, far from being strictly the case. It may be noticed, however, that in the recent additions made to the stamp duties in this country, the principle of equality has been more attended to.

2. The greater part of such taxes fall not upon the income, but upon the capital of the country; not upon that fund which may be properly and safely expended, but upon that, the expenditure of which must be ultimately ruinous. This circumstance is peculiar to these duties; for though others, when very severe, may oblige the contributor to encroach on his capital, they alone fall directly and immediately upon that fund. An objection of this nature would alone be sufficient to dissuade their adoption.

3. Such taxes, when they fall upon moveable goods, have a direct tendency to check commerce, and through it every kind of industry. They are then a complete *alcavala*, differing from that ruinous impost only by being more moderate.

Thus we find, that the facility of collection, and the avoiding of discontent, which have tempted modern governments to extend so much this source of revenue, are altogether fallacious advantages, and bear no proportion to the ill consequences with which such taxes are necessarily attended. It would therefore be much better that the duties upon the transference of moveable goods should be laid upon their original production. They would thus pay only once, and no impediment would be thrown in the way of their free circulation. Duties upon the sale of land and other immoveable goods ought to be converted into assessed taxes, payable on their yearly use. In the present circumstances of this country indeed, it is perhaps too much to expect that taxes, which are paid without much murmuring, should be taken off; but the considerations now stated ought certainly to deter from any farther addition to them.

Legacies from any distant relation are a sort of accidental and unexpected advantage, and it is therefore to be supposed, that the person receiving will have secured a regular source of subsistence independent of them. He will not therefore, it is likely, be disposed to complain very grievously, if this extrinsic source of wealth be somewhat diminished by a duty to government. In this country, accordingly, such legacies are chargeable with a duty of 10 per cent. This tax seems one of the most unexceptionable of the kind, and only liable to the objection of falling upon capital. It is otherwise with money left by a father or other very near relation. The death of such persons commonly diminishes, instead of increasing, the wealth of the family; and the sum left forms often the sole dependence of a great part of it. Accordingly, in Great Britain, the duty on legacies to the nearest relations is very slight, and gradually increases as the consanguinity becomes more remote.

Receipt stamps, though they are formally paid by the seller, fall really upon the purchaser. The merchant, who must have his profit, will calculate the expence which he is likely to be at in stamps, and will lay a corresponding augmentation on the price of his goods. Such taxes, unless very heavy, will fall upon income only, not upon capital.

Bills of exchange, and policies of insurance, being necessary instruments of trade, seem as improper subjects of taxation as can well be. The only thing tolerable in these taxes, as imposed in this country, is their moderation.

Auction duties seem liable to every objection which can be stated against taxes of this description. They are the more severe, as they must fall often upon unfortunate persons who are reduced to the necessity of disposing, in this manner, of their property.

Stamps upon law proceedings tend to increase the expence of obtaining justice, which is already complained of in general as too heavy. They may indeed be supposed to be of some use in checking a litigious spirit; but this seems already to be done pretty effectually by the other expences attendant on judicial proceedings.

Taxes upon indentures, or upon the entrance to any profession, produce a monopoly to the persons exercising that profession. They thus tend at once to raise the price of their labour and of its fruits, and to diminish the necessity of qualifying themselves for its performance. The chief weight of these taxes falls upon the persons exercising the profession of the law. The public are apt to regard such persons with a degree of hostility, which has probably induced government to believe it might tax them without danger of exciting any general murmur. The truth is, however, that these taxes fall not on the practitioners themselves, but on those who complain of them, on the persons engaged in litigation; so that their effect is precisely the same with that of taxes on law proceedings. It differs from them only as a license differs from a duty upon commodities, and is less eligible, as falling more unequally. The persons who pay the same sum at entrance, carry on their profession with very different degrees of success.

Some impositions, which assume the form of stamp duties, are in reality taxes upon commodities. Such are the game duty, the duty on cards, hats, plate, &c. But most of these seem to be unexceptionable subjects.

TAXUS, the YEW-TREE, a genus of plants belonging to the class diœcia, and in the natural system ranging under the 51st order, *Coniferæ*. See BOTANY *Index*.

TAY, in Latin *Tavus*, or *Taus*, the largest river in Scotland, rises in Braidalbane, on the frontiers of Lorn; and having in the passage of a few miles augmented its stream by the accession of several small rills, spreads itself into the lake called *Loch Dochart;* out of which having run but a little space, it expands itself again. Leaving this second lake, it rolls some miles with a considerable body of water, and then diffuses itself in the spacious Loch Tay; which, reckoning from the sources of the river, is 24 miles in length, though, strictly speaking,

speaking, the lake is but 13: almost as soon as it issues from hence, it receives the river Lyon, coming out of Loch Lyon, and running through Glen Lyon; which, having travelled in a manner parallel to it, from its source, for a space of 25 miles, at length joins the Tay as it enters Athol, which it next traverses, and, directing its course in a manner due east, receives almost all the waters of that country. Bending then to the south, at the distance of six miles, it reaches Dunkeld; which, in the language of our ancestors, signifies "the hill of hazels," was the very centre of the old Caledonia, and is at present esteemed the heart of the Highlands. The river is very broad here, insomuch that there is a ferry-boat over it at each end of the town. Declining still to the south-east, with a winding course, for above 12 miles, the Tay receives a large supply of waters from the county of Angus; and then running south west for eight miles more, is joined in that space by several rivers, the most considerable of which is the Almond. Turning then to the south-east, at the distance of about three miles, this copious river comes with a swelling stream to Perth.

The Tay, continuing still a south-east course, receives, a few miles below Perth, the river Erne; which, issuing from a loch of the same name, traverses the county of Strathern, and passes by Abernethy, once the capital of the Pictish kingdom. Swelled by the waters of this last river, the Tay, running next directly east, enlarges itself till it becomes about three miles broad; but contracts again before the town of Dundee; soon after which it opens into the German ocean. At the entrance of the frith, there are sands both on the north and on the south side; the former styled *Goa*, the latter *Aberlay* and *Drumlan*; and before these, in the very mouth of the frith, those which are called the *Cross Sands*. At Buttonness, which is the northern promontory, there are two light-houses. The space between the north and the south sands may be near a mile, with about three fathoms water; but being within the frith, it grows deeper, and in the road of Dundee is full six fathoms. The frith of Tay is not indeed so large or so commodious as that of Forth, but from Buttonness to Perth it is not less than 40 miles; and the whole may be, without any great impropriety, styled a harbour, which has Fife on one side, and the shires of Perth and Angus on the other, both very fertile and pleasant countries.

TAYLOR, Dr Jeremy, bishop of Down and Connor in Ireland, was the son of a barber at Cambridge, where he was educated. Upon entering into orders, he became divinity lecturer of St Paul's in London; and was, by the interest of Archbishop Laud, elected fellow of All-Souls college, Cambridge, in 1636. Two years after he became one of the chaplains of the archbishop, who bestowed on him the rectory of Uppingham in Rutlandshire. In 1642, he was chaplain to the king; and a frequent preacher before him and the court at Oxford. He afterwards attended in the king's army in the condition of a chaplain. Upon the declining of his majesty's cause, he retired into Wales, where he was permitted to officiate as minister, and to keep a school, in order to maintain himself and his children. In this retirement he wrote several of his works. Having spent several years there, his family was visited with sickness; and he lost three sons of great hopes within the space of two or three months. This affliction touched him so sensibly, that it made him desirous to leave the country; and, going to London, he for a time officiated in a private congregation of loyalists to his great hazard. At length meeting with Edward lord Conway, that nobleman carried him over with him into Ireland, and settled him at Portmore, where he wrote his *Ductor Dubitantium*. Upon the Restoration he returned to England. Soon after, he was advanced to the bishopric of Down and Connor in Ireland; and had the administration of the see of Dromore granted to him. He was likewise made privy-counsellor and vice-chancellor of the university of Dublin; which place he held till his death. He died of a fever at Lisnegarvy in 1667, and was interred in a chapel which he himself had built on the ruins of the old cathedral of Dromore.

Taylor, *Dr Brook*, was born at Edmonton, August 18th 1685. He was the son of John Taylor, Esq. of Bifrons house in Kent, by Olivia, daughter of Sir Nicholas Tempest, of Durham, Baronet. His grandfather, Nathaniel Taylor, was one of those puritans whom "Cromwell thought fit to elect by a letter, dated June 14th 1653, to represent the county of Bedford in parliament." The character of his father partook in no small degree of the austerity that had been transmitted to him in the line of his ancestors, and by the spirit of the times in which they lived; and to this cause may be ascribed the disaffection which sometimes subsisted between the father and even such a son as is the subject of this article. The old gentleman's morose temper, however, yielded to the powers of music; and the most eminent professors of the art in that period were hospitably welcomed in his house. His son Brook was induced, by his natural genius, and by the disposition of his father, which he wished by all the means in his power to conciliate, to direct his particular attention to music; and he became in very early life a distinguished proficient in it.—"In a large family piece, he is represented at the age of 13 sitting in the centre of his brothers and sisters; the two elder of whom, Olivia and Mary, crown him with laurel, bearing the insignia of harmony."

To music he added another accomplishment, in which he equally excelled. "His drawings and paintings, of which some are still preserved, require not those allowances for error or imperfection with which we scan the performances of even the superior *dilettanti*;—they will bear the test of scrutiny and criticism from artists themselves, and those of the first genius and professional abilities." Though he was eminent in the culture and practice both of music and drawing in his early youth, his whole attention was not occupied by these fascinating arts. His classical education was conducted at home under a private tutor; and his proficiency in the ordinary branches of the languages and the mathematics was so great, that he was deemed qualified for the university at the early age of 15.

In 1701 he was entered a fellow commoner of St John's College, Cambridge. At that period mathematics engaged more particularly the attention of the university; and the examples of eminence in the learned world, derived from that branch of science, attracted the notice and roused the emulation of every youth possessed of talents and of application. We may presume, that Brook Taylor, from the very hour of his admission at

Taylor.

at college, adopted the course of study which a Machin, a Keil, and, above all, a Newton, had opened to the mind of man, as leading to discoveries of the celestial system.—That he applied early to these studies, and without remission, is to be inferred from the early notice and kind attention with which he was honoured by those eminent persons, and from the extraordinary progress which he made in their favourite science."

In 1708 he wrote his treatise On the Centre of Oscillation, which was not published in the Philosophical Transactions till some years afterwards. In 1709, he took his degree of Bachelor of Laws. In 1712, he was chosen a Fellow of the Royal Society. During the interval between these two periods, he corresponded with Professor Keil on several of the most abstruse subjects of mathematical disquisition. Sir William Young informs us, that he has in his possession a letter, dated in 1712, addressed to Mr Machin, which contains at length a solution of Kepler's problem, and marking the use to be derived from that solution. In this year he presented to the Royal Society three different papers: one On the Ascent of Water between two Glass Planes; a second, On the Centre of Oscillation; and a third, on the Motion of a stretched String. It appears from his correspondence with Keil, that in 1713 he presented a paper on his favourite subject of Music; but this is not preserved in the Transactions.

His distinguished proficiency in those branches of science, which engaged the particular attention of the Royal Society at this period, and which embroiled them in contests with foreign academies, recommended him to the notice of its most illustrious members; and in 1714 he was elected to the office of secretary. In this year he took at Cambridge his degree of Doctor of Laws: and at this time he transmitted, in a letter to Sir Hans Sloane, An Account of some curious Experiments relative to Magnetism; which, however, was not delivered to the Society till many years afterward, when it was printed in the Transactions. His application to those studies to which his genius inclined was indefatigable; for we find that in 1715 he published in Latin his *Methodus Incrementorum;* also a curious essay preserved in the Philosophical Transactions, entitled An Account of an Experiment for the Discovery of the Laws of Magnetic Attraction; likewise a treatise well known to mathematicians, and highly valued by the best judges, on the Principles of Linear Perspective. In the same year (such were his admirable talents, and so capable were they of being directed to various subjects), he conducted a controversial correspondence with the Count Raymond de Montmort, on the Tenets of Malebranche; which occasioned his being particularly noticed in the eulogium pronounced by the French academy on the decease of that eminent metaphysician.

The new philosophy of Newton (as it was then called) engaged the attention of mathematicians and philosophers both at home and abroad. At Paris it was in high estimation; and the men of science in that city were desirous of obtaining a personal acquaintance with the learned secretary of the Royal Society, whose reputation was so generally acknowledged, and who had particularly distinguished himself in the Leibnitzian or German controversy, as we may denominate it, of that period. In consequence of many urgent invitations, he determined to visit his friends at Paris in the year 1716. He was received with every possible token of affection and respect; and had an opportunity of displaying many traits of character, which mark the general scholar and accomplished gentleman, as well as the profound mathematician. His company was courted by all "who had temper to enjoy, or talents to improve, the charms of social intercourse." Besides the mathematicians, to whom he had always free access, he was here introduced to Lord Bolingbroke, the Count de Caylus, and Bishop Bossuet.

Early in 1717 he returned to London, and composed three treatises, which were presented to the Royal Society, and published in the 30th volume of the Transactions. About this time his intense application had impaired his health to a considerable degree; and he was under the necessity of repairing, for relaxation and relief, to Aix-la-Chapelle. Having likewise a desire of directing his attention to subjects of moral and religious speculation, he resigned his office of secretary to the Royal Society in 1718.

After his return to England in 1719, he applied to subjects of a very different kind from those that had employed the thoughts and labours of his more early life. Among his papers of this date, Sir William Young has found detached parts of A Treatise on the Jewish Sacrifices, and a dissertation of considerable length On the Lawfulness of eating Blood. He did not, however, wholly neglect his former subjects of study, but employed his leisure hours in combining science and art; with this view he revised and improved his treatise on Linear Perspective. Drawing continued to be his favourite amusement to his latest hour; and it is not improbable, that his valuable life was shortened by the sedentary habits which this amusement, succeeding his severer studies, occasioned. "He drew figures with extraordinary precision and beauty of pencil. Landscape was yet his favourite branch of design. His original landscapes are mostly painted in water colours, but with all the richness and strength of oils. They have a force of colour, a freedom of touch, a varied disposition of planes of distance, and a learned use of aerial as well as linear perspective, which all professional men who have seen these paintings have admired."

The work of Dr Brook Taylor in linear perspective was censured by Bernoulli, in a treatise published in the Acts of Leipsic, as "abstruse to all, and as unintelligible to artists for whom it was more especially written." It must be acknowledged that this excellent work, for so it deserves to be called, was not level to the apprehensions of practitioners in the art of drawing and design; but it was much esteemed by mathematicians. Three editions of it have been published: and as it is now scarce, a republication of it in its most improved and perfect state would be very acceptable. Mr Kirby, however, has made it more plain and popular, in his treatise entitled "Brook Taylor's Perspective made easy;" and this book, detailing and illustrating the principles of the original work, has been the *vade mecum* of artists. Dr Brook Taylor was incensed by the invidious attacks of Bernoulli; and he published An Apology against J. Bernoulli's Objections, which may be seen in the 30th volume of the Philosophical Transactions. Bernoulli, with his usual envy of British mathematicians, had disputed our author's right to his own work.

work. We have no reason to doubt Dr Taylor's claims to the undecided discovery of the method which he describes, though he is not an original inventor. This method was long before published by Guido Ubaldi, in his Perspective, printed at Pesaro in 1600; where it is delivered very clearly, and confirmed by most elegant demonstrations; and where it is actually applied to the art of delineating the scenes of a theatre.

Toward the end of the year 1720, Dr Brook Taylor accepted the invitation of Lord Bolingbroke to spend some time at La Source, a country-seat near Orleans, which he held in right of his wife, the widow of the Marquis de Villette, nephew of Madame de Maintenon. In the next year he returned to England, and published the last paper which appears with his name in the Philosophical Transactions, entitled, An Experiment made to ascertain the Proportion of Expansion of Liquor in the Thermometer, with regard to the degree of Heat.

In 1721, Dr Brook Taylor married Miss Bridges of Wallington in the county of Surry, a young lady of good family, but of small fortune; and this marriage occasioned a rupture with his father, whose consent he had never obtained. The death of this lady in 1725, and that of an infant son, whom the parents regarded as the presage and pledge of reconciliation with the father, and who actually proved such, deeply affected the sensibility of Dr Taylor. However, during the two succeeding years he resided with his father at Bifrons, where "the musical parties, so agreeable to his taste and early proficiency, and the affectionate attentions of a numerous family welcoming an amiable brother, so long estranged by paternal resentment, not only soothed his sorrows, but ultimately engaged him to a scene of country retirement, and domesticated and fixed his habits of life. He could no more recur to the desultory resources, and cold solace of society, which casual visits, slight acquaintance, and distant friendships, afford the man—who hath *none to make and cheer a constant home*."

In 1725 he formed a new connection; and with the full approbation of his father and family, married Sabetta, daughter of John Sawbridge, Esq. of Olantigh, in Kent. In 1729, on the death of his father, he succeeded to the family estate of Bifrons. In the following year he lost his wife in childbed. The daughter whose birth occasioned this melancholy event survived, and became the mother of Sir William Young, to whom we owe these memoirs of his grandfather.

In the interval that elapsed between the years 1721 and 1730, no production by Brook Taylor appears in the Philosophical Transactions; nor did he publish in the course of that time any work. His biographer has found no traces of his learned labour, excepting a Treatise of Logarithms, which was committed to his friend Lord Paisley (afterward Abercorn), in order to be prepared for the press; but which probably never was printed. His health was now much impaired; relaxation became necessary, and he was diverted by new connections from the habit of severe study, which had distinguished the early period of his life, and which had contributed to contract the duration of it. Happy in the social circle of domestic enjoyment, and devoting his attention to business or amusement as they occurred, his application and his literary emulation seem to have declined. He did not long survive the loss of his second wife; and his remaining days were days of increasing imbecility and sorrow.

"The essay entitled *Contemplatio Philosophica*, published by Sir William Young, 1793, appears to have been written about this time, and probably with a view to abstract his mind from painful recollections and regret. It was the effort of a strong mind, and is a most remarkable example of the close logic of the mathematician applied to metaphysics. But the blow was too deep at heart for study to afford more than temporary relief. The very resource was hurtful, and intense study but accelerated the decline of his health. His friends offered every comfort; in particular Lord Bolingbroke pressed his consolation, and sought to call his mind from regret of domestic endearments to social friendship at Dawley.

The attention and kindness of his friends, however, could not ward off the approaches of dissolution. "Having survived his second wife little more than a year, Dr Brook Taylor died of a decline in the 46th year of his age, December the 29th 1731, and was buried in the church-yard of St Ann's Soho. I am spared (says his descendant) the necessity of closing this biographical sketch with a prolix detail of his character: in the best acceptation of duties relative to each situation of life in which he was engaged, his own writings, and the writings of those who best knew him, prove him to have been the finished Christian, gentleman, and scholar."

Taylor-Bird. See Motacilla, Ornithology *Index*.

TEA, the dried leaves of the tea plant.—A commodity with which we are so well acquainted, which affords a beverage so generally used and so generally agreeable, and which forms so considerable an article of commerce, must excite curiosity to know something of its history, and of the nature of the plant from which it is obtained.

The tea plant is a native of Japan, China, and Tonquin, and has not, as far as we can learn, been found growing spontaneously in any other parts of the world. Linnæus arranged it under the class of *polyandria*, and order of *monogynia*, and Thunberg, one of the most distinguished pupils of that illustrious botanist, who resided 16 months in Batavia and Japan, has classed it in the same manner as his master. Several of the British botanists, on the other hand, refer it to the order of *trigynia;* deriving their authority from a plant in the duke of Northumberland's garden at Sion-house, which had three styles.

Linnæus says that there are two species of the tea plant; the *bohea*, the corolla of which has six petals; and the *viridis* or green tea, which has nine petals. Thunberg makes only one species, the bohea, consisting of two varieties; the one with broad and the other with narrow leaves.

The tea plant, which is an evergreen, grows to the height of five or six feet; Le Compte says ten or twelve. The leaves, which are the only valuable part of it, are about an inch and a half long, narrow, indented, and tapering to a point, like those of the sweet briar, and of a dark green colour. The root is like that of the peach tree, and its flowers resemble those of the white wild rose. The stem spreads into many irregular branches.

branches. The wood is hard, of a whitish green colour, and the bark is of a greenish colour, with a bitter, nauseous, and astringent taste. The fruit is small, and contains several round blackish seeds, about the bigness of a bean or large pea.

This plant delights in valleys, is frequent on the sloping sides of mountains and the banks of rivers, where it enjoys a southern exposure. It flourishes in the northern latitudes of Pekin as well as round Canton, but attains the greatest perfection in the mild temperate regions of Nankin. It is said only to be found between the 30th and 45th degree of north latitude. In Japan it is planted round the borders of fields, without regard to the soil; but as it is an important article of commerce with the Chinese, whose fields are covered with it, it is by them cultivated with care. The Abbé Rochen says, it grows equally well in a poor as in a rich soil; but that there are certain places where it is of a better quality. The tea which grows in rocky ground is superior to that which grows in a light soil; and the worst kind is that which is produced in a clay soil. It is propagated by seeds; from six to twelve are put into a hole about five inches deep, at certain distances from each other. The reason why so many seeds are sown in the same hole is said to be, that only a fifth part vegetate. Being thus sown, they grow without any other care. Some, however, manure the land, and remove the weeds; for the Chinese are as fond of good tea, and take as much pains to procure it of an excellent quality, as the Europeans do to procure excellent wine.

The leaves are not fit for being plucked till the shrub be of three years growth. In seven years it rises to a man's height; but as it then bears but few leaves, it is cut down to the stem, and this produces a new crop of fresh shoots the following summer. We are informed by Kœmpfer, that there are three seasons in which the leaves are collected in the isles of Japan, from which the tea derives different degrees of perfection.

The first gathering commences at the end of February or beginning of March. The leaves are then small, tender, and unfolded, and not above three or four days old: these are called *ficki-tsiaa*, or "tea in powder," because it is pulverised; it is also called *imperial tea*, being generally reserved for the court and people of rank; and sometimes also it is named *bloom tea*. It is sold in China for 20d. or 2s. per pound. The labourers employed in collecting it do not pull the leaves by handfuls, but pick them one by one, and take every precaution that they may not break them. However long and tedious this labour may appear, they gather from 4 to 10 or 15 pounds a-day.

The second crop is gathered about the end of March or beginning of April. At this season part of their leaves have attained their full growth, and the rest are not above half their size. This difference does not, however, prevent them from being all gathered indiscriminately. They are afterwards picked and assorted into different parcels, according to their age and size. The youngest, which are carefully separated from the rest, are often sold for leaves of the first crop, or for imperial tea. Tea gathered at this season is called *too-tsiaa*, or "Chinese tea," because the people of Japan infuse it, and drink it after the Chinese manner.

The third crop is gathered in the end of May or in the month of June. The leaves are then very numerous and thick, and have acquired their full growth. This kind of tea, which is called *ben-tsiaa*, is the coarsest of all, and is reserved for the common people. Some of the Japanese collect their tea only at two seasons of the year, which correspond to the second and third already mentioned; others confine themselves to one general gathering of their crop, towards the month of June: however, they always form afterwards different assortments of their leaves.

The finest and most celebrated tea of Japan is that which grows near Ud-si, a small village situated close to the sea, and not far distant from Meaco. In the district of this village is a delightful mountain, having the same name, the climate of which is said to be extremely favourable to the culture of tea; it is therefore inclosed by a hedge, and surrounded with wide ditches, which prevent all access to it. The tea shrubs that grow on this mountain are planted in regular order, and are divided by different avenues and alleys.

The care of this place is entrusted to people who are ordered to guard the leaves from dust, and to defend them from the inclemency of the weather. The labourers who are appointed to collect the tea abstain from every kind of gross food for some weeks before they begin, that their breath and perspiration may not in the least injure the leaves. They gather them with the most scrupulous nicety, and never touch them but with very fine gloves. When this choice tea has undergone the process necessary for its preparation, it is escorted by the superintendant of the mountain and a strong guard to the emperor's court, and reserved for the use of the imperial family.

As the tea shrub grows often on the rugged banks of steep mountains, access to which is dangerous, and sometimes impracticable, the Chinese, in order to come at the leaves, are said to use a singular stratagem: These steep places are generally frequented by great numbers of monkeys, which being irritated and provoked, to revenge themselves tear off the branches, and shower them down upon those who have insulted them. The Chinese immediately collect these branches, and strip them of their leaves.

When the tea leaves have been collected, they are exposed to the steam of boiling water; after which they are put upon plates of copper, and held over the fire until they become dry and shrivelled, and appear such as we have them in Europe. According to the testimony of Kœmpfer, tea is prepared in the same manner in the isles of Japan. "There are to be seen there (says this traveller) public buildings erected for the purpose of preparing the fresh gathered tea. Every private person who has not suitable conveniences, or who is unacquainted with the operation, may carry his leaves thither as they dry. These buildings contain a great number of small stoves raised about three feet high, each of which has a broad plate of iron fixed over its mouth. The workmen are seated round a large table covered with mats, and are employed in rolling the tea leaves which are spread out upon them. When the iron plates are heated to a certain degree by the fire, they cover them with a few pounds of fresh gathered leaves, which being green and full of sap, crackle as soon as they touch the plate. It is then the business of the workman to stir them with his naked hands as quickly as possible, until they become so warm that he cannot

 easily

Tea.

easily endure the heat. He then takes off the leaves with a kind of shovel, and lays them upon mats. The people who are employed in mixing them, take a small quantity at a time, roll them in their hands always in the same direction; while others keep continually stirring them, in order that they may cool sooner, and preserve their shrivelled figure the longer. This process is repeated two or three times, and even oftener, before the tea is deposited in the warehouses. These precautions are necessary to extract all the moisture from the leaves."

The people of Japan and China generally keep their tea a year before using it, because, when quite fresh and newly gathered, it possesses a narcotic quality which hurts the brain. Imperial tea is generally preserved in porcelain vases, or in leaden or tin canisters covered with fine mats made of bamboo. Common tea is kept in narrow-mouthed earthen pots; and coarse tea, the flavour of which is not so easily injured, is packed up in baskets of straw.

An infusion of tea is the common drink of the Chinese; and indeed when we consider one circumstance in their situation, we must acknowledge that Providence has displayed much goodness in scattering this plant with so much profusion in the empire of China. The water is said to be unwholesome and nauseous, and would therefore perhaps, without some corrective, be unfit for the purposes of life. The Chinese pour boiling water over their tea, and leave it to infuse, as we do in Europe; but they drink it without any mixture, and even without sugar. The people of Japan reduce theirs to a fine powder, which they dilute with warm water until it has acquired the consistence of thin soup. Their manner of serving tea is as follows: They place before the company the tea equipage, and the box in which this powder is contained: they fill the cups with warm water, and taking from the box as much powder as the point of a knife can contain, throw it into each of the cups, and stir it with a tooth-pick until the liquor begins to foam; it is then presented to the company, who sip it while it is warm. According to F. du Halde, this method is not peculiar to the Japanese; it is also used in some of the provinces of China.

The first European writer who mentions tea is Giovanni Botero, an eminent Italian author, who published a treatise about the year 1590, Of the Causes of the Magnificence and Greatness of Cities. He does not indeed mention its name, but describes it in such a manner that it is impossible to mistake it. "The Chinese (says he) have an herb out of which they press a delicate juice, which serves them for drink instead of wine: it also preserves their health, and frees them from all those evils which the immoderate use of wine produces among us *."

* *Anderson's Commerce*, vol. i. p. 138.

Tea was introduced into Europe in the year 1610 by the Dutch East India Company. It is generally said, that it was first imported from Holland into England, in 1666, by the lords Arlington and Ossory, who brought it into fashion among people of quality. But it was used in coffee-houses before this period, as appears from an act of parliament made in 1660, in which a duty of 8d. was laid on every gallon of the infusion sold in these places. In 1666 it was sold in London for 60s. per pound, though it did not cost more than 2s. 6d. or 3s. 6d. at Batavia. It continued at this price till 1707. In 1715 green tea began to be used; and as great quantities were then imported, the price was lessened, and the practice of drinking tea descended to the lower ranks †. In 1720 the French began to send it to us by a clandestine commerce. Since then the demand has been increasing yearly, and it has become almost a necessary of life in several parts of Europe, and among the lowest as well as the highest ranks.

† *Hanway's Journal.*

The following table shews the quantity of tea imported annually into Great Britain and Ireland since 1717:

From 1717 to 1726	-	700,000 lbs.
1732 to 1742	-	1,200,000
1755 near	-	4,000,000
1766 -	-	6,000,000
1785 about	-	12,000,000
1794 from		16 to 20,000,000

Since 1794 the increase has still been very great. The whole revenue derived from tea in Great Britain in the year ending 5th January 1819, was 3,309,845l.

Besides the quantities imported into Britain and Ireland, much has been brought to Europe by other nations. In 1766 the whole tea imported into Europe from China amounted to 17 millions of pounds; in 1785 it was computed to be about 19 millions of pounds ‡.

‡ *Raynal*, vol. i. and *Robertson's India.*

Several researches have been made in Europe to determine whether the tea plant grows spontaneously, but these researches have been hitherto in vain. When Captain Cook visited Teneriffe in his last voyage, Mr Anderson his surgeon was informed by a gentleman of acknowledged veracity, that a shrub is common near Santa Cruz which agrees exactly with the description given of the tea-plant by Linnæus. It is considered as a weed, and large quantities are rooted out of the vineyards every year: But the Spaniards who inhabit the island sometimes make use of it, and ascribe to it all the qualities of the tea imported from China.

Many attempts have been made to introduce this valuable plant into Europe; but from want of proper precautions most of these attempts have miscarried. The seeds, being of an oily nature, are apt to grow rancid during a long voyage, unless proper care is taken to preserve them. There are two methods of preserving these seeds: The first is, to inclose them in wax after they have been dried in the sun; the second is, to leave them in their husks, and shut them up closely in a box made of tin: but neither of these methods has been attended with general success, whatever care has been taken to obtain fresh seeds, or to preserve them. The best method would be, to sow fresh seeds in fine light earth immediately on leaving Canton, and to cover them with wire to secure them from rats and other animals that might attack them. The boxes ought not to be too much exposed to the air, nor to that kind of dew which rises from the sea. The earth in the boxes must neither be hard nor dry, and should from time to time be gently watered with fresh or rain water; and when the shoots begin to appear, they ought to be kept in a slight moisture, and sheltered from the sun. The tea-plants to be found in England have been procured by these means only; and though several of the young rising shoots perished, the last method proposed is probably that which may be followed with greatest success.

The finest tea-plant known in England was raised in Kew

Kew gardens; it was carried thither by Sir J. Ellis, who brought it from seed: but the first that ever flourished in Europe was one belonging to the duke of Northumberland at Sion, from a drawing of which our engraving is taken. The plants which are cultivated in the gardens near London thrive well in the green-house during winter, and some stand that season in the open air. Linnæus, who obtained this shrub in its growing state, contrived to preserve it in the open air in the northern latitude of Sweden. France has also procured some plants. There can be no doubt but they would succeed in many countries of Europe, if proper care were paid to their cultivation till they became inured to the climate. It will be a great advantage if we can rear that plant, which can never suffer so much from change of soil as from growing musty during the long voyage from China. Besides, the demand for tea is now become so great, that the Chinese find it necessary, or at least profitable, to adulterate it. Bad tea is now become an universal complaint. The abbé Grosier tells us, that there is a kind of moss which grows in the neighbourhood of the little city of Mang-ing-hien, which is sold as a delicate species of tea. If this delicious commodity is adulterated in China, can we flatter ourselves that none comes to us but what is pure and unmixed? How would our fine ladies like to be told, that instead of tea they drink nothing but the infusion of moss from the rocks of Mang-ing-hien (F)?

Of the chemical qualities and effects of tea on the constitution, many various and opposite opinions have been formed. About a century ago, Bontikoe, a Dutch physician, bestowed extravagant encomiums on the benefits of tea. With him it was good for every thing; and any quantity might be drunk, even to the amount of 200 dishes in a day. Whether Bontikoe in this case acted as a physician, or, being a Dutchman, was eager to encourage the sale of an important article of his country's commerce, is not easy to say. On the other hand, the pernicious effects of tea upon the nervous system have been often repeated, and very opposite effects have been ascribed to it. Some affirm that green tea is mildly astringent; others say it is relaxing: Some say it is narcotic, and procures sleep; while others contend, that taken before bed-time it assuredly prevents it.

Dr Lettsom, who has written the Natural History of the Tea Tree, made several experiments to determine its chemical qualities. He found an infusion of it preserved beef fresh; it is therefore antiseptic; and from its striking a purple colour with the salt (sulphate) of iron, he justly concludes that it is astringent; and he thinks also, that the essential qualities of tea reside in its fragrant and volatile parts.

We have heard much of the bad effects of tea, but we have neither felt nor observed them. If it were so pernicious as it has been represented by some, its effects must certainly be evident in China, where it is drunk by all ranks; yet so far from being thought hurtful in that country, it is in high estimation. The present emperor has composed a kind of eloge on the virtues of tea. We are told by those who have written the history of China, that inflammatory diseases are less frequent there than in many other countries, which is ascribed solely to the liberal use of tea. It must be observed by all, that tea is an antidote against intemperance, and that he who relishes the one seldom runs into the other. Raynal says, that tea has contributed more to the sobriety of this nation than the severest laws, the most eloquent harangues of Christian orators, or the best treatises of morality. We have no doubt but it may be hurtful to some constitutions in particular circumstances; but we suspect that the nervous disorders so often attributed to tea, are rather owing to hereditary diseases, to want of exercise, and to irregularity in food or sleep, than to tea.

"Weak tea drunk too hot (says Dr Leake) will enervate, and if very strong, may prove equally pernicious by affecting the head or stomach. But when it is drunk in moderation, and not too warm, with a large addition of milk, I believe it will seldom prove hurtful, but, on the contrary, salutary. After study or fatigue it is a most refreshing and grateful repast; it quenches thirst, and cheers the spirits, without heating the blood; and the pleasing society, in which we so often partake of it is no inconsiderable addition to its value; for whatever affords rational pleasure to the mind, will always contribute to bodily health.

In this country teas are generally divided into three kinds of green, and five of bohea: The former are, 1. Imperial or bloom tea, with a large loose leaf, light green

(F) The numerous instances in 1817 and 1818, of dealers being convicted of selling spurious tea, show that the process of adulteration is carried on to a great extent in this country. Mr Twining, a considerable tea dealer in London, published a pamphlet some years ago, in which he has exposed this infamous traffic. The information (he says) was obtained from a gentleman who had made very accurate inquiries into this subject.

The smouch for mixing with black teas is made of the leaves of the ash. When gathered, they are first dried in the sun, then baked: they are next put upon a floor, and trod upon until the leaves are small, then sifted and steeped in copperas with sheep's dung; after which, being dried on a floor, they are fit for use. There is also another mode: When the leaves are gathered, they are boiled in a copper with copperas and sheep's dung; when the liquor is strained off, they are baked and trod upon, until the leaves are small, after which they are fit for use. The quantity manufactured at a small village, and within eight or ten miles thereof, cannot be ascertained, but is supposed to be about 20 tons in a year. One man acknowledges to have made 600 weight in every week for six months together. The fine is sold at 4l. 4s. per cwt. equal to 9d per lb. The coarse is sold at 2l. 2s. per cwt. equal to $4\frac{1}{2}$ per lb. Elder buds are manufactured in some places to represent fine teas.

For the honour of human nature, we hope such a traffic as this is not very common: but if it be, those concerned in it deserve exemplary punishment. The only way (Mr Twining says) to escape this adulterated tea, is never to purchase from those who offer their teas to sale at lower prices than genuine teas can be afforded; but to purchase them only from persons of character.

green colour, and a faint delicate smell. 2. Hyson, so called from the name of the merchant who first imported it; the leaves of which are closely curled and small, of a green colour, verging to a blue: And, 3. Singlo tea, from the name of the place where it is cultivated. The boheas are, 1. Souchong, which imparts a yellow green colour by infusion. 2. Cambo, so called from the place where it is made; a fragrant tea, with a violet smell; its infusion pale. 3. Congo, which has a larger leaf than the following, and its infusion somewhat deeper, resembling common bohea in the colour of the leaf. 4. Pekoe tea; this is known by the appearance of small white flowers mixed with it. 5. Common bohea, whose leaves are of one colour. There are other varieties, particularly a kind of green tea, done up in roundish balls, called *gunpowder-tea.*

Tea-Tree of New Zealand, is a species of myrtle, of which an infusion was drunk by Captain Cook's people in their voyages round the world. Its leaves were finely aromatic, astringent, and had a particular pleasant flavour at the first infusion; but this went off at the next filling up of the tea-pot, and a great degree of bitterness was then extracted; for which reason it was never suffered to be twice infused. In a fine soil in thick forests this tree grows to a considerable size; sometimes 30 or 40 feet in height, and one foot in diameter. On a hilly and dry exposure it degenerates into a shrub of five or six inches; but its usual size is about eight or ten feet high, and three inches in diameter. In that case its stem is irregular and unequal, dividing very soon into branches, which arise at acute angles, and only bear leaves and flowers at top. The flowers are white, and very ornamental to the whole plant.

Mr White, in his Journal of a Voyage to New South Wales, mentions a shrub which he calls a *tea-tree* merely from its being used by the convicts as a succedaneum for tea; for he had not seen the flower, nor did he know to what genus it belonged. It is a creeping kind of a vine, running to a great extent along the ground; the stalk slender; the leaf not so large as the common bay leaf; the taste sweet, exactly like the liquorice root of the shops.

TEACHERS, persons employed in conducting the education of the young.

We will venture to say, that there is no class of men to whom a nation is so much indebted as to those employed in instructing the young: For if it be education that forms the only distinction between the civilized and the savage, much certainly is due to those who devote themselves to the office of instruction. It must be the duty therefore of every state to take care that proper encouragement be given to those who undertake this office. There ought to be such a salary as would render it an object of ambition to men of abilities and learning, or at least as would keep the teacher respectable. In Scotland, the office of a schoolmaster was formerly much more lucrative than at present, and most of that class had received liberal education; and this is the reason why the common people in Scotland have been famous even to a proverb, for their learning. But at present the salary of a country schoolmaster, independent of fees for scholars, is not greater than a ploughman can earn, being seldom more than 8l. 6s. 8d. the consequence of which is that this, which is in fact an honourable, because an useful profession, is now sinking into contempt. It is no longer an object to a man of learning; and we must soon be satisfied with schoolmasters that can read, write, and cast accounts, a little better than the lowest of the people, or who from some natural deformity are unable to exercise a trade. And what in this case must become of the minds of the common people! They must be totally uncultivated.

We have observed a great difference between the cultivation of the common people in one part of Scotland compared with another; and we have found, that wherever a schoolmaster is looked upon as a mean profession there is scarcely a duly qualified person to be found to undertake the office; and in those places the common people are lamentably ignorant. In other places again, where the schoolmaster is considered as one of the principal persons in the parish, there men of a liberal education, young divines, and preachers, do not think themselves disgraced by exercising this profession; and there the common people show a degree of acuteness, knowledge, and observation, and possess such polished manners, as raise them very high above those of their own rank in other parts of the country.

Many and keen have been the debates about a reform of government of late years; but little attention has been paid to the formation of the minds of the common people, who constitute the greater part of the nation; of course they are ready to join the standard of every seditious demagogue who sounds the alarm of oppression; and should they at length be roused, their cruelty and barbarity, like the common people of France, would be exactly in proportion to their ignorance and want of principle.

We are willing to hope, then, that the government and the moneyed men of the nation, who alone have property to lose and money to bestow, will at length find it to be their interest to patronize schoolmasters.

TEAL. See ANAS, ORNITHOLOGY *Index.*

TEARS, a lymph or aqueous humour, which is limpid, and a little saltish: it is separated from the arterial blood by the lachrymal glands and small glandulous grains on the inside of the eyelids.

TEASELS, a plant cultivated in the west of England for the use of clothiers. See DIPSACUS, BOTANY *Index.*

TEBETH, the tenth month of the Jewish ecclesiastical year, and fourth of the civil. It answers to our month of December.

TECLENBURG, a town of Germany, in the circle of Westphalia, capital of a county of the same name, with a castle built on a hill. It was bought by the king of Prussia in 1707. E. Long. 8. 2. N. Lat. 52. 20.

TECHNICAL, expresses somewhat relating to arts or sciences: in this sense we say technical terms. It is also particularly applied to a kind of verses wherein are contained the rules or precepts of any art, thus digested to help the memory to retain them; an example whereof may be seen in the article MEMORY.

TECTONA, TEAK-WOOD, a genus of plants belonging to the class pentandria. See BOTANY, p. 139.

TE DEUM, the name of a celebrated hymn, used in the Christian church, and so called because it begins with these words, *Te Deum laudamus*, We praise thee, O God. It is sung in the Romish church with great pomp

pomp and solemnity upon the gaining of a victory, or other happy event; and is believed to be the composition of St AMBROSE bishop of *Milan*.

TEES, a river which rises on the confines of Cumberland, and running eastward, divides the county of Durham from Yorkshire, and falls into the German sea below Stockton.

TEETH, the bones placed in the jaws for chewing food, that it may be the more easily digested in the stomach. The anatomical structure of the teeth has already been described under ANATOMY. The diseases to which they are liable, as well as the most successful remedies for removing them, are fully detailed under MEDICINE and SURGERY.

Much attention has been paid to the beauty and preservation of the teeth among most nations. The Romans rubbed and washed them with great care; and when they lost them, supplied their place with artificial teeth made of ivory; and sometimes, when loose, bound them with gold. Ligatures of wire have been found to hurt the natural teeth with which the artificial are connected: whereas silken twist cannot affect them to any considerable degree for several years.

Guilleman gives us the composition of a paste for making artificial teeth, which shall never grow yellow: the composition is white wax granulated, and melted with a little gum elemi, adding powder of white mastich, coral, and pearl.

When several teeth are out in the same place, it is best to make a set, or the number wanted, out of one piece, all adhering together, which may be fastened to the two next of the sound or natural teeth. And even a whole set of artificial teeth may be made for one or both jaws, so well fitted to admit of the necessary motions, and so conveniently retained in the proper situation by means of springs, that they will answer every purpose of natural teeth, and may be taken out, cleaned, and replaced, by the patient himself with great ease.

The common trick of mountebanks and other such practitioners, is to use various washes for teeth, the sudden effects of which, in cleaning and whitening the teeth, surprise and please people; but the effects are very pernicious. All the strong acid spirits will do this. As good a mixture as any thing can be, on this occasion, is the following: take plantane-water an ounce, honey of roses two drams, muriatic acid ten drops; mix the whole together, and rub the teeth with a piece of linen rag dipped in this every day till they are whitened. The mouth ought to be well washed with cold water after the use of this or any other acid liquor; and indeed the best of all teeth washes is cold water, with or without a little salt; the constant use of this will keep them clean and white, and prevent them from aching.

After all the numerous cures which have been proposed for preventing the toothach, we will venture to recommend the keeping the teeth clean as the most efficacious, and avoiding every kind of hot food, especially hot liquids, as tea, &c. They who are constantly using powders generally destroy their teeth altogether, as the valetudinarian does his health.

TEETHING in children. See MEDICINE.

TEFF, a kind of grain, sown all over Abyssinia, from which is made the bread commonly used throughout the country. We have no description of this plant but from Mr Bruce, who says that it is herbaceous; and that from a number of weak leaves surrounding the root proceeds a stalk of about 28 inches in length, not perfectly straight, smooth, but jointed or knotted at particular distances. This stalk is not much thicker than that of a carnation or julyflower. About eight inches from the top, a head is formed of a number of small branches, upon which it carries the fruit and flowers; the latter of which is small, of a crimson colour, and scarcely perceptible by the naked eye but from the opposition of that colour. The pistil is divided into two, seemingly attached to the germ of the fruit, and has at each end small capillaments forming a brush. The stamina are three in number; two on the lower side of the pistil, and one on the upper. These are each of them crowned with two oval stigmata, at first green, but after crimson. The fruit is formed in a capsula, consisting of two conical hollow leaves, which, when closed, seems to compose a small conical pod, pointed at the top. The fruit or seed is oblong, and is not so large as the head of the smallest pin; yet it is very prolific, and produces these seeds in such quantity as to yield a very abundant crop in the quantity of meal.

Our author, from the similarity of the names, conjectures it to be the *tipha* mentioned, but not described, by Pliny; but this conjecture, which he acknowledges to be unsupported, is of very little importance.

There are three kinds of meal made from teff, of which the best (he says) is as white as flour, exceedingly light, and easily digested; the second is of a browner colour; and the last, which is the food of soldiers and servants, is nearly black. This variety he imagines to arise entirely from the difference of soils in which the seeds are sown, and the different degrees of moisture to which the plant is exposed when growing. The manner of making the meal or flour into bread is by taking a broad earthen jar, and having made a lump of it with water, they put it into an earthen jar at some distance from the fire, where it remains till it begins to ferment or turn sour; they then bake it into cakes of a circular form, and about two feet in diameter: it is of a spungy soft quality, and not a disagreeable sourish taste. Two of these cakes a-day, and a coarse cotton cloth once a year, are the wages of a common servant.

At their banquets of raw meat, the flesh being cut in small bits, is wrapt up in pieces of this bread, with a proportion of fossil salt and Cayenne pepper. Before the company sits down to eat, a number of these cakes of different qualities are placed one upon the other, in the same manner as our plates, and the principal people sitting first down, eat the white teff; the second or coarser sort serves the second-rate people that succeed them, and the third is for the servants. Every man, when he is done, dries or wipes his fingers upon the bread which he is to leave for his successor, for they have no towels; and this is one of the most beastly customs among them.

Of this teff bread the natives makes a liquor, by a process which our author describes in the following words. The bread, when well toasted, is broken into small pieces, which are put into a large jar, and have warm water poured upon them. It is then set by the fire, and frequently stirred for several days, the mouth of the jar being close covered. After being allowed to settle three or four days, it acquires a sourish taste, and is what they call *bouza*, or the common beer of the country. The bouza in Atbara is made in the same manner, only instead

stead of teff, cakes of barley meal are employed. Both are very bad liquors, but the worst is that made of barley.

TEFFLIS, or TIFFLIS, a town of Asia, in Georgia, one of the seven nations between the Black sea and the Caspian. It is the capital of that country, the place of residence of its sovereign, and is called by the inhabitants *Thilis-Cabar*, "warm town," from the warm baths in its neighbourhood. Though its circumference does not exceed two English miles, it contains 20,000 inhabitants, of which more than half are Armenians; the remainder are principally Georgians, with some Tartars. According to Major Rennel, it has 20 Armenian and 15 Greek churches, and three metsheds. But Mr Coxe, on the authority of Professor Guldenstaedt, states the places of worship to be one Roman Catholic, 13 Greek, and seven Armenian churches. There are some magnificent caravanseras, bazars, and palaces in the city, but no mosques; for the Georgians, though living under a Mohammedan government, have always risen up in arms as often as any attempts have been made to erect such places of Mohammedan worship. Many of the Romish missionaries live here in disguise under the denomination of physicians, surgeons, and chemists; and the great cures which they perform procure them much esteem, though they are sometimes exposed to the insults of the people when they attempt to make any proselytes to their church. All the houses are of stone, with flat roofs, which serve, according to the customs of the East, as walks for the women. They are neatly built; the rooms are wainscotted, and the floors spread with carpets. The streets seldom exceed seven feet in breadth; and some are so narrow as scarcely to allow room for a man on horseback: they are consequently very filthy.

Tefflis is a place of considerable trade, especially in furs, which are conveyed hence to Constantinople by the way of Erzerum. As for the silks of this country, they are bought up on the spot by the Armenians, and conveyed to Smyrna and other ports of the Mediterranean; but the greatest part is first sent to Erzerum to be manufactured, the Georgians being very ignorant and unskilful in that respect. From hence, likewise, great quantities of a root called *boya* is sent to Erzerum and Indostan for the use of the linen dyers. Here is likewise a foundery, at which are cast a few cannon, mortars, and balls, all of which are very inferior to those of the Turks. The gunpowder made here is very good. The Armenians have likewise established in this town all the manufactures carried on by their countrymen in Persia: the most flourishing is that of printed linens. Tefflis is seated on the river Kur, at the foot of a mountain; and on the south side of it stands a large castle or fortress, built by the Turks in 1576, when they made themselves masters of the city and country, under the command of the famous Mustapha Pacha. It is 125 miles west of Terki. E. Long. 63. 3. N. Lat. 41. 59.

TEGERHY, a principal town in Fezzan, in Africa, about 80 miles south-west of the capital. It collects from its lands little other produce than dates and Indian corn. In this, as in every town in Fezzan, a market for butcher-meat, corn, fruit, and vegetables, is regularly held. Mutton and goats flesh are sold by the quarter without weighing; the usual price is from 32 to 40 grains of gold-dust, or four or five shillings English money. The flesh of the camel, which is much more highly valued, is commonly sold at a dearer rate, and is divided into smaller lots. Agriculture and pasturage seem to be the principal occupations.

TEGUMENT, any thing that surrounds or covers another.

TEIND, in *Scots Law*. See LAW, N° clxx.

Commission of TEINDS. See COMMISSION.

TEINTS and SEMITEINTS, in *Painting*, denote the several colours used in a picture, considered as more or less high, bright, deep, thin, or weakened and diminished, &c. to give the proper relievo, softness, or distance &c. of the several objects.

TELEGRAPH (derived from τηλε and γραφω), is the name very properly given to an instrument, by means of which information may be almost instantaneously conveyed to a considerable distance.

The telegraph, though it has been generally known and used by the moderns only for a few years, is by no means a modern invention. There is reason to believe that amongst the Greeks there was some sort of telegraph in use. The burning of Troy was certainly known in Greece very soon after it happened, and before any person had returned from thence. Now that was altogether so tedious a piece of business, that conjecture never could have supplied the place of information. A Greek play begins with a scene, in which a watchman descends from the top of a tower in Greece, and gives the information that Troy was taken. "I have been looking out these ten years (says he) to see when that would happen, and this night it is done." Of the antiquity of a mode of conveying intelligence quickly to a great distance, this is certainly a proof.

The Chinese, when they send couriers on the great canal, or when any great man travels there, make signals by fire from one day's journey to another, to have every thing prepared; and most of the barbarous nations used formerly to give the alarm of war by fires lighted on the hills or rising grounds.

Polybius calls the different instruments used by the ancients for communicating information πυρσιαι, *pyrsiæ*, because the signals were always made by means of fire. At first they communicated information of events merely by torches; but this method was of little use, because it was necessary before-hand to fix the meaning of every particular signal. Now as events are exceedingly various, it was impossible to express the greater number of them by any premeditated contrivance. It was easy, for instance, to express by signals that a fleet had arrived at such a place, because this had been foreseen, and signals accordingly had been agreed upon to denote it; but an unexpected revolt, a murder, and such accidents, as happen but too often, and require an immediate remedy, could not be communicated by such signals; because to foresee them was impossible.

Æneas, a contemporary of Aristotle, who wrote a treatise on the duties of a general, endeavoured to correct those imperfections, but by no means succeeded. "Those (says he) who would give signals to one another upon affairs of importance, must first prepare two vessels of earth, exactly equal in breadth and depth; and they need be but four feet and a half deep, and a foot and a half wide. They then must take pieces of cork, proportioned to the mouth of these vessels, but not quite so wide, that they may be let down with ease to the bottom of these vessels. They next fix in the middle of this

this cork a stick, which must be of equal size in both these vessels. This stick must be divided exactly and distinctly, by spaces of three inches each, in order that such events as generally happen in war may be written on them. For example, on one of these spaces the following words may be written: 'A BODY OF HORSE ARE MARCHED INTO THE COUNTRY.' On another, 'A BODY OF INFANTRY, heavily armed, are arrived hither.' On a third, 'INFANTRY LIGHTLY ARMED.' On a fourth, 'HORSE AND FOOT.' On another, 'SHIPS;' then 'PROVISIONS;' and so on till all the events which may probably happen in the war that is carrying on are marked in these intervals.

This being done, each of the two vessels must have a little tube or cock of equal bigness, to let out the water in equal proportion. Then the two vessels must be filled with water; the pieces of cork, with their sticks thrust through them, must be laid upon them, and the cocks must be opened. Now, it is plain, that as these vessels are equal, the corks will sink, and the sticks descend lower in the vessels, in proportion as they empty themselves. But to be more certain of this exactness, it will be proper to make the experiment first, and to examine whether all things correspond and agree together, by an uniform execution on both sides. When they are well assured of this, the two vessels must be carried to the two places where the signals are to be made and observed: water is poured in, and the corks and sticks are put in the vessels. When any of the events which are written on the sticks shall happen, a torch or other light is raised, which must be held aloft till such time as another is raised by the party to whom it is directed. (This first signal is only to give notice that both parties are ready and attentive). Then the torch or other light must be taken away, and the cocks set open. When the interval, that is that part of the stick where the event of which notice is to be given or written, shall be fallen to a level with the vessels, then the man who gives the signal lifts up his torch; and on the other side, the correspondent signal-maker immediately turns the cock of his vessel, and looks at what is writ on that part of the stick which touches the mouth of the vessel: on which occasion, if every thing has been executed exactly and equally on both sides, both will read the same thing."

This method was defective, because it could not convey any other intelligence except what was written on the sticks, and even that not particularly enough. With regard to all unforeseen events, it was quite useless.

Polybius. ibid.

A new method was invented by Cleoxenus (others say by Democlitus), and very much improved by Polybius, as he himself informs us. He describes this method as follows: Take the letters of the (Greek) alphabet, and divide them into five parts, each of which will consist of five letters, except the last division, which will have only four. Let these be fixed on a board in five columns. The man who is to give the signals is then to begin by holding up two torches, which he is to keep aloft till the other party has also shown two. This is only to show that both sides are ready. These first torches are then withdrawn. Both parties are provided with boards, on which the letters are disposed as formerly described. The person who then gives the signal is to hold up torches on the left to point out to the other party from what column he shall take the letters as they are pointed out to him. If it is to be from the first column, he holds up one torch; if from the second, two; and so on for the others. He is then to hold up torches on the right, to denote the particular letter of the column that is to be taken. All this must have been agreed on before-hand. The man who gives the signals must have an instrument (διοπτραν), consisting of two tubes, and so placed as that, by looking through one of them, he can see only the right side, and through the other only the left, of him who is to answer. The board must be set up near this instrument; and the station on the right and left must be surrounded with a wall (παραπεφραχθαι) ten feet broad, and about the height of a man, that the torches raised above it may give a clear and strong light, and that when taken down they may be completely concealed. Let us now suppose that this information is to be communicated,—*A number of the auxiliaries, about a hundred, have gone over to the enemy.* In the first place, words must be chosen that will convey the information in the fewest letters possible: as, *A hundred Cretans have deserted,* Κρητες εκατον αφ' ημων ηυτομολησαν. Having written down this sentence, it is conveyed in this manner. The first letter is a κ, which is in the second column; two torches are therefore to be raised on the left hand to inform the person who receives the signals to look into that particular column. Then five torches are to be held up on the right, to mark the letter *k*, which is the last in the column. Then four torches are to be held up on the left to point out the ρ (*r*), which is in the fourth column, and two on the right to show that it is the second letter of that column. The other letters are pointed out in the same manner. —Such was the *pyrsia* or telegraph recommended by Polybius.

But neither this nor any other method mentioned by the ancients seems ever to have been brought into general use; nor does it appear that the moderns had thought of such a machine as a *telegraph* till the year 1663, when the Marquis of Worcester, in his CENTURY OF INVENTIONS, affirmed that he had discovered "a method by which, at a window, as far as eye can discover black from white, a man may hold discourse with his correspondent, without noise made or notice taken; being according to occasion given, or means afforded, *ex re nata*, and no need of provision before hand; though much better if foreseen, and course taken by mutual consent of parties." This could be done only by means of a telegraph, which in the next sentence is declared to have been rendered so perfect, that by means of it the correspondence could be carried on "by night as well as by day, though as dark as pitch is black."

About 40 years afterwards M. Amontons proposed a new telegraph. His method was this: Let there be people placed in several stations, at such a distance from one another, that by the help of a telescope a man in one station may see a signal made in the next before him; he must immediately make the same signal, that it may be seen by persons in the station next after him, who are to communicate it to those in the following station, and so on. These signals may be as letters of the alphabet, or as a cipher, understood only by the two persons who are in the distant places, and not by those who make the signals. The person in the second station making the signal to the person in the third the very moment he sees it in the first, the news may be carried to the greatest

Telegraph.

distance in as little time as is necessary to make the signals in the first station. The distance of the several stations, which must be as few as possible, is measured by the reach of a telescope. Amontons tried this method in a small tract of land before several persons of the highest rank at the court of France.

It was not, however, till the French revolution that the telegraph was applied to useful purposes. Whether M. Chappe, who is said to have invented the telegraph first used by the French about the end of 1793, knew any thing of Amontons's invention or not, it is impossible to say; but his telegraph was constructed on principles nearly similar. The manner of using this telegraph was as follows. At the first station, which was on the roof of the palace of the Louvre at Paris, M. Chappe, the inventor, received in writing, from the committee of public welfare, the words to be sent to Lisle, near which the French army at that time was. An upright post was erected on the Louvre, at the top of which were two transverse arms, moveable in all directions by a single piece of mechanism, and with inconceivable rapidity. He invented a number of positions for these arms, which stood as signs for the letters of the alphabet; and these, for the greater celerity and simplicity, he reduced in number as much as possible. The grammarian will easily conceive that sixteen signs may amply supply all the letters of the alphabet, since some letters may be omitted not only without detriment but with advantage. These signs, as they were arbitrary, could be changed every week; so that the sign of B for one day might be the sign of M the next; and it was only necessary that the persons at the extremity should know the key. The intermediate operators were only instructed generally in these sixteen signals; which were so distinct, so marked, so different the one from the other, that they were easily remembered. The construction of the machine was such, that each signal was uniformly given in precisely the same manner at all times: It did not depend on the operator's manual skill; and the position of the arm could never, for any one signal, be a degree higher or a degree lower, its movement being regulated mechanically.

M. Chappe having received at the Louvre the sentence to be conveyed, gave a known signal to the second station, which was Mont Martre, to prepare. At each station there was a watch tower, where telescopes were fixed, and the person on watch gave the signal of preparation which he had received, and this communicated successively through all the line, which brought them all into a state of readiness. The person at Mont Martre then received, letter by letter, the sentence from the Louvre, which he repeated with his own machine; and this was again repeated from the next height, with inconceivable rapidity, to the final station at Lisle.

English Review, June 1796.

The first description of the telegraph was brought from Paris to Frankfort on the Maine by a former member of the parliament of Bourdeaux, who had seen that which was erected on the mountain of Belville. As given by Dr Hutton from some of the English papers, it is as follows. AA is a beam or mast of wood placed upright on a rising ground (fig. 1.), which is about 15 or 16 feet high. BB is a beam or balance moving upon the centre AA. This balance-beam may be placed vertically or horizontally, or any how inclined, by means of strong cords, which are fixed to the wheel D, on the edge of which is a double groove to receive the two cords. This balance is about 11 or 12 feet long, and nine inches broad, having at the ends two pieces of wood CC, which likewise turn upon angles by means of four other cords that pass through the axis of the main balance, otherwise the balance would derange the cords; the pieces C are each about three feet long, and may be placed either to the right or left, straight, or square, with the balance-beam. By means of these three the combination or movement is very extensive, remarkably simple, and easily performed. Below is a small wooden gouge or hut, in which a person is employed to observe the movements of the machine. In the mountain nearest to this another person is to repeat these movements, and a third to write them down. The time taken up for each movement is 20 seconds; of which the motion alone is four seconds, the other 16 the machine is stationary. Two working models of this instrument were executed at Frankfort, and sent by Mr W. Playfair to the duke of York; and hence the plan and alphabet of the machine came to England.

Plate DXXVIII. fig. 1.

Various experiments were in consequence tried upon telegraphs in this country; and one was soon after set up by government in a chain of stations from the admiralty-office to the sea coast. It consists of six octagon boards, each of which is poised upon an axis in a frame, in such a manner that it can be either placed vertically, so as to appear with its full size to the observer at the nearest station, as in fig. 2. or it becomes invisible to him by being placed horizontally, as in fig. 3. so that the narrow edge alone is exposed, which narrow edge is from a distance invisible. Fig. 2. is a representation of this telegraph, with the parts all shut, and the machine ready to work. T, in the officer's cabin, is the telescope pointed to the next station. Fig. 3. is a representation of the machine not at work, and with the ports all open. The opening of the first port (fig. 2.) expresses *a*, the second *b*, the third *c*, the fourth *d*, the fifth *e*, the sixth *f*, &c.

Fig. 2.

Fig. 3.

Six boards make 36 changes, by the most plain and simple mode of working; and they will make many more if more were necessary: but as the real superiority of the telegraph over all other modes of making signals consists in its making letters, we do not think that more changes than the letters of the alphabet, and the ten arithmetical ciphers, are necessary; but, on the contrary, that those who work the telegraphs should avoid communicating by words or signs agreed upon to express sentences; for that is the sure method never to become expert at sending unexpected intelligence accurately.

This telegraph is without doubt made up of the best number of combinations possible; five boards would be insufficient, and seven would be useless. It has been objected to it, however, that its form is too clumsy to admit of its being raised to any considerable height above the building on which it stands; and that it cannot be made to change its direction, and consequently cannot be seen but from one particular point.

Several other telegraphs have been proposed to remedy these defects, and perhaps others to which the instrument is still liable. The dial-plate of a clock would make an excellent telegraph, as it might exhibit 144 signs so as to be visible at a great distance. A telegraph on this principle, with only six divisions instead of twelve, Telegraph.

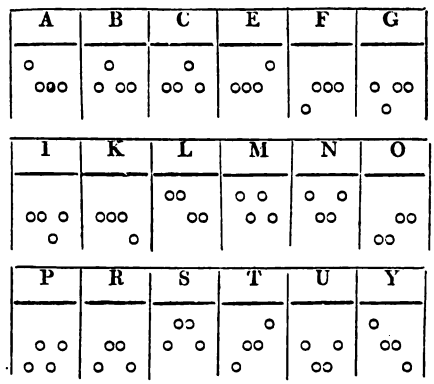
twelve, would be simple and cheap, and might be raised 20 or 30 feet high above the building, without any difficulty: it might be supported on one post, and therefore turn round, and the contrast of colours would always be the same.

Supplement for 1794.

A very ingenious improvement of the telegraph has been proposed in the Gentleman's Magazine. It consists of a semicircle, to be properly elevated, and fixed perpendicularly on a strong stand. The radius 12 feet; the semicircle consequently somewhat more than 36. This to be divided into 24 parts. Each of these will therefore comprise a space of 18 inches, and an arch of $7^{\circ} 30'$ on the circumference. These 24 divisions to be occupied by as many circular apertures of six inches diameter; which will leave a clear space of six inches on each side between the apertures. These apertures, beginning from the left, to denote the letters of the alphabet, omitting K, J consonant, V, X, and Q, as useless for this purpose. There are then 21 letters. The four other spaces are reserved for signals. The instrument to have an index moveable by a windlass on the centre of the semicircle, and having two tops, according as it is to be used in the day or night; one, a circular top of lacquered iron or copper, of equal diameter with the apertures (and which consequently will eclipse any of them against which it rests); the other, a spear or arrow-shaped top, black and highly polished, which, in standing before any of the apertures in the day-time, will be distinctly visible. In the night, the apertures to be reduced by a diaphragm fitting close to each, so as to leave an aperture of not more than two inches diameter. The diaphragm to be of well-polished tin; the inner rim lacquered black half an inch. All the apertures to be illuminated, when the instrument is used in the night-time, by small lamps; to which, if necessary, according to circumstances, convex lenses may be added, fitted into each diaphragm, by which the light may be powerfully concentrated and increased. Over each aperture one of the five prismatic colours least likely to be mistaken (the remaining two being less distinguishable, and not wanted, are best omitted) to be painted; and, in their natural order, on a width of eighteen inches and a depth of four, red, orange, yellow, green, blue; or, still to heighten the contrast, and render immediately successive apertures more distinguishable, red, green, orange, blue, yellow. The whole inner circle beneath and between the apertures to be painted black.

When the instrument is to be used, the index to be set to the signal apertures on the right. All the apertures to be covered or dark when it begins to be used, except that which is to give the signal. A signal gun to be fired to apprise the observer. If the index is set to the first aperture, it will denote that words are to be expressed; if to the second, that figures; if to the third, that the figures cease; and that the intelligence is carried on in words. When figures are to be expressed, the alternate apertures from the left are taken in their order, to denote from 1 to 10 inclusively; the second from the right denotes 100; the fifth 1000. This order, and these intervals, are taken to prevent any confusion in so peculiarly important an article of the intelligence to be conveyed.

Perhaps, however, none of the telegraphs hitherto offered to the public exceeds the following, either in simplicity, cheapness, or facility in working, and it might perhaps, with a few trifling additions, be made exceedingly distinct. It is thus described in the Repertory of Arts and Manufactures: For a nocturnal telegraph, let there be four large patent reflectors, lying on the same plane, parallel to the horizon, placed on the top of an observatory. Let each of these reflectors be capable, by means of two winches, either of elevation or depression to a certain degree. By elevating or depressing one or two of the reflectors, eighteen very distinct arrangements may be produced, as the following scheme will explain (A).



For the sake of example, the above arrangements are made to answer to the most necessary letters of the alphabet; but alterations may be made at will, and a greater number of changes produced, without any addition to the reflectors. In the first observatory there need only be a set of *single* reflectors; but in the others each reflector should be double, so as to face both the preceding and subsequent observatory; and each observatory should be furnished with two telescopes. The proper diameter of the reflectors, and their distance from each other, will be ascertained by experience.

To convert this machine into a diurnal telegraph, nothing more is necessary than to insert, in the place of the reflectors, gilt balls, or any other conspicuous bodies.

Were telegraphs brought to so great a degree of perfection, that they could convey information speedily and distinctly; were they so much simplified, that they could be constructed and maintained at little expence—the advantages which would result from their use are almost inconceivable. Not to speak of the speed with which information could be communicated and orders given in time of war, by means of which misfortunes might be prevented or instantly repaired, difficulties removed, and disputes precluded, and by means of which the whole kingdom could be prepared in an instant to oppose an invading

(A) Each reflector, after every arrangement, must be restored to its place.

invading enemy; it might be used by commercial men to convey a commission cheaper and speedier than an express can travel. The capitals of distant nations might be united by chains of posts, and the settling of those disputes which at present take up months or years might then be accomplished in as many hours. An establishment of telegraphs might then be made like that of the post; and instead of being an expence, it would produce a revenue. Until telegraphs are employed to convey information that occurs very frequently, the persons who are stationed to work them will never become expert, and consequently will neither be expeditious nor accurate, though, with practice, there is no doubt but they will attain both in a degree of perfection of which we can as yet have but little conception.

Various other improvements of the telegraph might have been mentioned, but our limits do not permit us to dwell longer on the subject.

TELEMACHUS, the son of Ulysses and Penelope, was still in the cradle when his father went with the rest of the Greeks to the Trojan war. At the end of this celebrated war, Telemachus, anxious to see his father, went to seek him; and as the place of his residence, and the cause of his long absence, were then unknown, he visited the court of Menelaus and Nestor to obtain information. He afterwards returned to Ithaca, where the suitors of his mother Penelope had conspired to murder him, but he avoided their snares; and by means of Minerva he discovered his father, who had arrived in the island two days before him, and was then in the house of Eumæus. With this faithful servant and Ulysses Telemachus concerted how to deliver his mother from the importunities of her suitors, and it was effected with great success. After the death of his father, Telemachus went to the island of Ææa, where he married Circe, or, according to others, Cassiphone the daughter of Circe, by whom he had a son called *Latinus*. He some time after had the misfortune to kill his mother-in-law Circe, and fled to Italy, where he founded Clusium. Telemachus was accompanied in his visit to Nestor and Menelaus by the goddess of wisdom under the form of Mentor. It is said that, when a child, Telemachus fell into the sea, and that a dolphin brought him safe to shore, after he had remained some time under water. From this circumstance Ulysses had the figure of a dolphin engraved on the seal which he wore on his ring.

From these stories, collected from Homer and the other poets of antiquity, the celebrated Fenelon, archbishop of Cambray, took the idea of his well-known *Adventures of Telemachus*; which, though not composed in verse, is justly intitled to be esteemed a poem. "The plan of the work (says Dr Blair) is in general well contrived; and is deficient neither in epic grandeur nor unity of object. The author has entered with much felicity into the spirit and ideas of the ancient poets, particularly into the ancient mythology, which retains more dignity, and makes a better figure in his hands than in those of any other modern poet. His descriptions are rich and beautiful; especially of the softer and calmer scenes, for which the genius of Fenelon was best suited; such as the incidents of pastoral life, the pleasures of virtue, or a country flourishing in peace. There is an inimitable sweetness and tenderness in several of the pictures of this kind which he has given;" and his measured prose, which is remarkably harmonious, gives the style nearly as much elevation as the French language is capable of supporting even in regular verse.

Lectures on Rhetoric and the Belles Lettres.

According to the same eminent critic, "the best executed part of the work is the first six books, in which Telemachus recounts his adventures to Calypso. The narration throughout them is lively and interesting. Afterwards, especially in the last 12 books, it becomes more tedious and languid; and in the warlike adventures which are attempted, there is a great defect of vigour. The chief objection against this work being classed with epic poems, arises from the minute details of virtuous policy, into which the author in some places enters; and from the discourses and instructions of Mentor, which recur upon us too often, and too much in the strain of common-place morality. Though these were well suited to the main design of the author, which was to form the mind of a young prince, yet they seem not congruous to the nature of epic poetry; the object of which is to improve us by means of actions, characters, and sentiments, rather than by delivering professed and formal instruction."

TELEPHIUM, True Orpine, a genus of plants belonging to the class pentandria; and in the natural system ranging under the 54th order, *Miscellaneæ*. See Botany *Index*.

TELESCOPE, an optical instrument for viewing distant objects; so named by compounding the Greek words τηλε, *far off*, and σκοπεω, *I look at* or *contemplate*. This name is commonly appropriated to the larger sizes of the instrument, while the smaller are called PERSPECTIVE-GLASSES, SPY-GLASSES, OPERA-GLASSES. A particular kind, which is thought to be much brighter than the rest, is called a NIGHT-GLASS.

To what has been said already with respect to the inventor of this most noble and useful instrument in the article Optics, we may add the two following claims.

Mr Leonhard Digges, a gentleman of the 17th century of great and various knowledge, positively asserts in his *Stratioticos*, and in another work, that his father, a military gentleman, had an instrument which he used in the field, by which he could bring distant objects near, and could know a man at the distance of three miles. He says, that when his father was at home he had often looked through it, and could distinguish the waving of the trees on the opposite side of the Severn. Mr Digges resided in the neighbourhood of Bristol.

Francis Fontana, in his *Celestial Observations*, published at Naples in 1646, says, that he was assured by a Mr Hardy, advocate of the parliament of Paris, a person of great learning and undoubted integrity, that on the death of his father, there was found among his things an old tube, by which distant objects were distinctly seen; and that it was of a date long prior to the telescope lately invented, and had been kept by him as a secret.

It is not all improbable, that curious people, handling spectacle glasses, of which there were by this time great varieties, both convex and concave, and amusing themselves with their magnifying power and the singular effects which they produced in the appearances of things, might sometimes chance so to place them as to produce distinct and enlarged vision. We know perfectly, from the table and scheme which Sirturus has given us of the tools or dishes in which the spectacle-makers

Telescope. makers fashioned their glasses, that they had convex lenses formed to spheres of 24 inches diameter, and of 11 inferior sizes. He has given us a scheme of a set which he got leave to measure, belonging to a spectacle-maker of the name of *Rogette* at Corunna in Spain; and he says that this man had tools of the same sizes for concave glasses. It also appears, that it was a general practice (of which we do not know the precise purpose) to use a convex and concave glass together. If any person should chance to put together a 24-inch convex and a 12-inch concave (wrought on both sides) at the distance of six inches, he would have distinct vision, and the object would appear of double size. Concaves of six inches were not uncommon, and one such combined with the convex of 24, at the distance of nine inches, would have distinct vision, and objects would be quadrupled in diameter. When such a thing occurred, it was natural to keep it as a curiosity, although the *rationale* of its operation was not in the least understood. We doubt not but that this happened much oftener than in these two instances. The chief wonder is, that it was not frequent, and taken notice of by some writer. It is pretty plain that Galileo's first telescope was of this kind, made up of such spectacle-glasses as he could procure; for it magnified only three times in diameter; a thing easily procured by such glasses as he could find with every spectacle-maker. And he could not but observe, in his trials of their glasses, that the deeper concaves and flatter convexes he employed, he produced the greater amplification; and then he would find himself obliged to provide a tool not used by the spectacle-makers, viz. either a much flatter tool for a convex surface, or a much smaller sphere for a concave; and, notwithstanding his telling us that it was by reflecting on the nature of refraction, and without any instruction, we are persuaded that he proceeded in this very way. His next telescope magnified but five times. Now the slightest acquaintance with the obvious laws of refraction would have directed him at once to a very small and deep concave, which would have been much easier made, and have magnified more. But he groped his way with such spectacle-glasses as he could get, till he at last made tools for very flat object-glasses and very deep eye-glasses, and produced a telescope which magnified about 25 times. Sirturus saw it, and took the measures of it. He afterwards saw a scheme of it which Galileo had sent to a German prince at Inspruck, who had it drawn (that is, the circles for the tools) on a table in his gallery. The object-glass was a plano-convex, a portion of a sphere of 24 inches diameter; the eye-glass was a double concave of two inches diameter; the focal distances were therefore 24 inches and one inch nearly. This must have been a very lucky operation, for Sirturus says it was the best telescope he had seen: and we know that it requires the very best work to produce this magnifying power with such small spheres. Telescopes continued to be made in this way for many years; and Galileo, though keenly engaged in the observation of Jupiter's satellites, being candidate for the prize held out by the Dutch for the discovery of the longitude, and therefore much interested in the advantage which a convex eye-glass would have given him, never made them of any other form. Kepler published his Dioptrics in 1611; in which he tells us, all that he or others had discovered of the law of refraction, viz. that in very small obliquities of incidence, the angle of refraction was nearly one-third of the angle of incidence. This was indeed enough to have pointed out, with sufficient exactness, the construction of every optical instrument that we are even now possessed of; for this proportionality of the angles of incidence and refraction is assumed in the construction of the optical figure for all of them; and the deviation from it is still considered as the *refinement* of the art, and was not brought to any rule till 50 years after by Huyghens, and called by him ABERRATION. Yet even the sagacious Kepler seems not to have seen the advantage of any other construction of the telescope; he just seems to acknowledge the possibility of it: and we are surprised to see writers giving him as the author of the astronomical telescope, or even as hinting at its construction. It is true, in the last proposition he shows how a telescope may be made *apparently* with a convex eye-glass: but this is only a frivolous fancy; for the eye-glass is directed to be made convex externally, and a very deep concave on the inside; so that it is, in fact, a meniscus with the concavity prevalent. In the 86th proposition, he indeed shows that it is possible so to place a convex glass behind another convex glass, that an eye shall see objects distinct, magnified, and inverted; and he speaks very sagaciously on the subject. After having said that an eye placed behind the point of union of the first glass will see an object inverted, he shows that a small part only will be seen; and then he shows that a convex glass, duly proportioned and properly placed, will show more of it. But in showing this, he speaks in a way which shows evidently that he had formed no distinct notions of the manner in which this effect would be produced, only saying vaguely that the convergency of the second glass would counteract the divergency beyond the focus of the first. Had he conceived the matter with any tolerable distinctness, after seeing the great advantage of taking in a field greater in almost any proportion, he would have eagerly catched at the thought, and enlarged on the immense improvement. Had he but drawn one figure of the progress of the rays through two convex glasses, the whole would have been open to his view.

This step, so easy and so important, was reserved for Father Scheiner, as has been already observed in the article OPTICS; and the construction of this author, together with that of Jansen, are the models on which all refracting telescopes are now constructed; and in all that relates to their magnifying power, brightness, and field of vision, they may be constructed on Kepler's principle, that the angles of refraction are in a certain given proportion to the angles of incidence.

But after Huyghens had applied his elegant geometry to the discovery of Snellius, viz. the proportionality, not of the angles, but of the sines, and had ascertained the aberrations from the foci of infinitely slender pencils, the reasons were clearly pointed out why there were such narrow limits affixed by nature to the performance of optical instruments, in consequence of the indistinctness of vision which resulted from constructions where the magnifying power, the quantity of light, or the field of vision, were extended beyond certain moderate bounds. The theory of aberrations, which that most excellent geometer established, has enabled us to diminish this indistinctness arising from any of these causes; and this diminution

Telescope. diminution is the sole aim of all the different constructions which have been contrived since the days of Galileo and Scheiner.

The description which has been already given of the various constructions of telescopes in the article Optics, is sufficient for instructing the reader in the general principles of their construction, and with moderate attention will show the manner in which the rays of light proceed, in order to ensure the different circumstances of amplification, brightness, and extent of field, and even distinctness of vision, in as far as depends on the proper intervals between the glasses. But it is insufficient for giving us a knowledge of the improvements which are aimed at in the different departures from the original constructions of Galileo and Scheiner, the advantage of the double eye-glass of Huyghens, and the quintuple eye-glass of Dolland: still more is it insufficient for showing us why the highest degrees of amplification and most extensive field cannot be obtained by the mere proportion of the focal distances of the glasses, as Kepler had taught. In short, without the Huyghenian doctrine of aberrations, neither can the curious reader learn the limits of their performance, nor the artist learn why one telescope is better than another, or in what manner to proceed to make a telescope differing in any particular from those which he servilely copies.

Although all the improvements in the construction of telescopes since the publication of Huyghen's Dioptrics have been the productions of this island, and although Dr Smith of Cambridge has given the most elegant and perspicuous account of this science that has yet appeared, we do not recollect a performance in the English language (except the Optics of Emerson) which will carry the reader beyond the mere schoolboy elements of the science, or enable a person of mathematical skill to understand or improve the construction of optical instruments. The last work on this subject of any extent (Dr Priestley's History of Vision) is merely a parlour book for the amusement of half-taught dilettanti, but is totally deficient in the mathematical part, although it is here that the science of optics has her chief claim to pre-eminence, and to the name of a DISCIPLINA ACCURATA. But this would have been *ultra crepidam;* and the author would in all probability have made as poor a figure here as he has done in his attempts to degrade his species in his Commentaries on the *Vibratiunculæ* of Hartley; motions which neither the author nor his amplificator were able to understand or explain. We trust that our readers, jealous as we are of every thing that sinks us in the scale of nature's works, will pardon this transient ejaculation of spleen, when our thoughts are called to a system which, of *absolute and unavoidable necessity*, makes the DIVINE MIND nothing but a quivering of *that matter* of which it is the AUTHOR and unerring DIRECTOR. *Sed missum faciamus.*

We think therefore that we shall do the public some service, by giving such an account of this *higher branch* of optical science as will at least tend to the complete understanding of this noble instrument, by which our conceptions of the extent of almighty power, and wisdom, and beneficence, are so wonderfully enlarged. In the prosecution of this we hope that many general rules will emerge, by which artists who are not mathematicians may be enabled to construct optical instruments with intelligence, and avoid the many blunders and defects which result from mere servile imitation.

The general aim in the construction of a telescope is, to form, by means of mirrors or lenses, an image of the distant object, as large, as bright, and as extensive as is possible, consistently with distinctness; and then to view the image with a magnifying glass in any convenient manner. This gives us an arrangement of our subject. We shall first show the principles of construction of the object-glass or mirror, so as that it shall form an image of the distant object with these qualities; and then show how to construct the magnifying glass or eye-piece, so as to preserve them unimpaired.

This indistinctness which we wish to avoid arises from two causes; the spherical figures of the refracting and reflecting surfaces, and the different refrangibility of the differently coloured rays of light. The first may be called the SPHERICAL and the second the CHROMATIC indistinctness; and the deviations from the foci, determined by an elementary theorem, given under Optics, may be called the SPHERICAL and the CHROMATIC aberrations.

The limits of a work like this will not permit us to give any more of the doctrine of aberrations than is absolutely necessary for the construction of achromatic telescopes; and we must refer the reader for a general view of the whole to Euler's *Dioptrics*, and other works of that kind. Dr Smith has given as much as was necessary for the comparison of the merits of different glasses of similar construction, and this in a very plain and elegant manner.

We shall begin with the aberration of colour, because it is the most simple.

Let white or compounded light fall perpendicularly on the flat side PQ (fig. 1.) of a plano-convex lens PVQ, whose axis is CV and vertex V. The white ray p P falling on the extremity of the lens is dispersed by refraction at the point P of the spherical surface, and the red ray goes to the point r of the axis, and the violet ray to the point v. In like manner the white ray q Q is dispersed by refraction at Q, the red ray going to r, and the violet to v. The red ray P r crosses the violet ray Q v in a point D, and Q r crosses P v in a point E; and the whole light refracted and dispersed by the circumference whose diameter is PQ, passes through the circular area, whose diameter is DE. Supposing that the lens is of such a form that it would collect red rays, refracted by its whole surface in the point r, and violet in the point v; then it is evident that the whole light which occupies the surface of the lens will pass through this little circle, whose diameter is DE. Therefore white light issuing from a point so distant that the rays may be considered as parallel, will not be collected in another point or focus, but will be dispersed over the surface of that little circle: which is therefore called the *circle of chromatic dispersion;* and the radiant point will be represented by this circle. The neighbouring points are in like manner represented by circles; and these circles encroaching on and mixing with each other, must occasion haziness or confusion, and render the picture indistinct. This indistinctness will be greater in the proportion of the number of circles which are in this manner mixed together. This will be in the proportion of the room that is for them; that is, in proportion to the area of the circle, or in the duplicate proportion

Plate DXXVI I. fig. 1.

tion of its diameter. Our first business therefore is, to obtain measures of this diameter, and to mark the connection between it and the aperture and focal distance of the lens.

Let i be to r as the sine of incidence in glass to the sine of refraction of the red rays; and let i be to v as the sine of incidence to the sine of refraction of the violet rays. Then we say, that when the aperture PQ is moderate, $v-r : v+r-2i = \text{DE} : \text{PQ}$, very nearly. For let DE, which is evidently perpendicular to V r, meet the parallel incident rays in K and L and the radii of the spherical surface in G and H. It is plain that GPK is equal to the angle of incidence on the posterior or spherical surface of the lens; and GP r and GP v are the angles of the refraction of the red and the violet rays; and that GK, GD, and GE, are very nearly as the sines of those angles, because the angles are supposed to be small. We may therefore institute this proportion $\text{DE} : \text{KD} = v-r : r-i$; then, by doubling the consequents $\text{DE} : 2\,\text{KD} = v-r : 2r-2i$. Also $\text{DE} : 2\,\text{KD} + \text{DE} = v-r : 2r-2i+v-r, = v-r : r+v-2i$. But $2\,\text{KD} + \text{DE}$ is equal to KL or PQ. Therefore we have $\text{DE} : \text{PQ} = v-r : r+v-2i$. *Q. E. D.*

Cor. 1. Sir Isaac Newton, by most accurate observation, found, that in common glass the sines of refraction of the red and violet rays were 77 and 78 where the sine of incidence was 50. Hence it follows, that $v-r$ is to $v+n-2i$ as 1 to 55; and that the diameter of the smallest circle of dispersion is $\frac{1}{55}$th part of that of the lens.

2. In like manner may be determined the circle of dispersion that will comprehend the rays of any particular colour or set of colours. Thus all the orange and yellow will pass through a circle whose diameter is $\frac{1}{250}$th of that of the lens.

3. In different surfaces, or plano-convex lenses, the angles of aberration r P v are as the breadth PQ directly, and as the focal distance VF inversely; because any angle DPE is as its subtense DE directly and radius DP inversely. N. B. We call VF the focal distance, because at this distance, or at the point F, the light is most of all constipated. If we examine the focal distance by holding the lens to the sun, we judge it to be where the light is drawn into the smallest spot.

When we reflect that a lens of $5\frac{1}{2}$ inches in diameter has a circle of dispersion $\frac{1}{10}$th of an inch in diameter, we are surprised that it produces any picture of an object that can be distinguished. We should not expect greater distinctness from such a lens than would be produced in a camera obscura without a lens, by simply admitting the light through a hole of $\frac{1}{10}$th of an inch in diameter. This, we know, would be very hazy and confused. But when we remark the superior vivacity of the yellow and orange light in comparison with the rest, we may believe that the effect produced by the confusion of the other colours will be much less sensible. But a stronger reason is, that the light is much denser in the middle of the circle of dispersion, and is exceedingly faint towards the margin. This, however, must not be taken for granted; and we must know distinctly the manner in which the light of different colours is distributed over the circle of chromatic dispersion, before we pretend to pronounce on the immense difference between the indistinctness arising from colour and that arising from the spherical figure. We think this the more necessary, because the illustrious discoverer of the chromatic aberration has made a great mistake in the comparison, because he did not consider the distribution of the light in the circle of spherical dispersion. It is therefore proper to investigate the chromatic distribution of the light with the same care that we bestowed on the spherical dispersion in Optics, and we shall then see that the superiority of the reflecting telescope is incomparably less than Newton imagined it to be.

Therefore let EB (fig. 2.) represent a plano-convex lens, of which C is the centre and C r the axis. Let us suppose it to have no spherical aberration, but to collect rays occupying its whole surface to single points in the axis. Let a beam of white or compounded light fall perpendicularly on its plane surface. The rays will be so refracted by its curved surface, that the extreme red rays will be collected at r, the extreme violet rays at w, and those of intermediate refrangibility at intermediate points, o, y, g, b, p, v, of the line rw, which is nearly $\frac{1}{28}$th of rC. The extreme red and violet rays will cross each other at A and D; and AD will be a section or diameter of the circle of chromatic dispersion, and will be about $\frac{1}{55}$th of EB. We may suppose wr to be bisected in b, because wb is to br very nearly in the ratio of equality (for $rb : r\text{C} = b\text{A} : c\text{E}, = b\text{A} : c\text{B}, = wb : w\text{C}$). The line rw will be a kind of prismatic spectrum, red from r to o, orange-coloured from o to y, yellow from y to g, green from g to b, blue from b to p, purple from p to v, and violet from v to w. Fig. 2.

The light in its compound state must be supposed uniformly dense as it falls upon the lens; and the same must be said of the rays of any particular colour. Newton supposes also, that when a white ray, such as c E, is dispersed into its component coloured rays by refraction at E, it is uniformly spread over the angle DEA. This supposition is indeed gratuitous; but we have no argument to the contrary, and may therefore consider it as just. The consequence is, that each point w, v, p, b, &c. of the spectrum is not only equally luminous, but also illuminates uniformly its corresponding portion of AD: that is to say, the coating (so to term it) of any particular colour, such as purple, from the point p, is uniformly dense in every part of AD on which it falls. In like manner, the colouring of yellow, intercepted by a part of AD in its passage to the point y, is uniformly dense in all its parts. But the density of the different colours in AD is extremely different: for since the radiation in w is equally dense with that in p, the density of the violet colouring, which radiates from w, and is spread over the whole of AD, must be much less than the density of the purple colouring, which radiates from p, and occupies only a part of AD round the circle b. These densities must be very nearly in the inverse proportion of $w\,b^2$ to $p\,b^2$.

Hence we see, that the central point b will be very intensely illuminated by the blue radiating from $p\,b$ and the green intercepted from $b\,g$. It will be more faintly illuminated by the purple radiating from $v\,p$, and the yellow intercepted from $g\,y$; and still more faintly by the violet from $w\,v$, and the orange and red intercepted from $y\,r$. The whole colouring will be a white, tending a little to yellowness. The accurate proportion of these

these colourings may be computed from our knowledge of the position of the points $o, y, g,$ &c. But this is of little moment. It is of more consequence to be able to determine the proportion of the total intensity of the light in b to its intensity in any other point I.

For this purpose draw r IR, I w W, meeting the lens in R and W. The point I receives none of the light which passes through the space RW: for it is evident that b I : CR$=b$ A : CE, $=1:55$, and that CR$=$CW; and therefore, since all the light incident on EB passes through AB, all the light incident on RW passes through I i ($b\,i$ being made$=b$ I). Draw o IO, y IY, g IG, I p P, I v V. It is plain that I receives red light from RO, orange from OY, yellow from YG, green from GE, a little blue from BP, purple from PV, and violet from VW. It therefore wants some of the green and of the blue.

That we may judge of the intensity of these colours at I, suppose the lens covered with paper pierced with a small hole at G. The green light only will pass through I; the other colours will pass between I and b, or between I and A, according as they are more or less refrangible than the particular green at I. This particular colour converges to g, and therefore will illuminate a small spot round I, where it will be as much denser than it is at G as this spot is smaller than the hole at G. The natural density at G, therefore, will be to the increased density at I, as $g\,\mathrm{I}^2$ to $g\,\mathrm{G}^2$, or as $g\,b^2$ to $g\,\mathrm{C}^2$, or as $b\,\mathrm{I}^2$ to CG^2. In like manner, the natural density of the purple coming to I through an equal hole at P will be to the increased density at I as $b\,\mathrm{I}^2$ to CP^2. And thus it appears, that the intensity of the differently coloured illuminations of *any* point of the circle of dispersion, is inversely proportional to the square of the distance from the centre of the lens to the point of its surface through which the colouring light comes to this point of the circle of dispersion. This circumstance will give us a very easy, and, we think, an elegant solution of the question.

Bisect CE in F, and draw FL perpendicular to CE, making it equal to CF. Through the point L describe the hyperbola KLN of the second order, that is, having the ordinates EK, FL, RN, &c. inversely proportional to the squares of the abscissæ CE, CF, CR, &c.; so that $\mathrm{FL}:\mathrm{RN}=\frac{1}{\mathrm{CF}^2}:\frac{1}{\mathrm{CR}^2}$, or $=\mathrm{CR}^2:\mathrm{CF}^2$, &c. It is evident that these ordinates are proportional to the densities of the severally coloured lights which go from them to any points whatever of the circle of dispersion.

Now the total density of the light at I depends both on the density of each particular colour and on the number of colours which fall on it. The ordinates of this hyperbola determine the first; and the space ER measures the number of colours which fall on I, because it receives light from the whole of ER, and of its equal BW. Therefore, if ordinates be drawn from any point of ER, their sum will be as the whole light which goes to I; that is, the total density of the light at I will be proportional to the area NREK. Now it is known that CE$\times$EK is equal to the infinitely extended area lying beyond EK; and CR$\times$RN is equal to the infinitely extended area lying beyond RN. Therefore the area NREK is equal to CR$\times$RN$-$CE$\times$EK. But RN and EK are respectively equal to $\frac{\mathrm{CF}^3}{\mathrm{CR}^2}$ and $\frac{\mathrm{CF}^3}{\mathrm{CE}^2}$. Therefore the density at I is proportional to $\mathrm{CF}^3\times\left(\frac{\mathrm{CR}}{\mathrm{CR}^2}-\frac{\mathrm{CE}}{\mathrm{CE}^2}\right), =\mathrm{CF}^3\times\left(\frac{1}{\mathrm{CR}}-\frac{1}{\mathrm{CE}}\right), =\mathrm{CF}^3\times\frac{\mathrm{CE}-\mathrm{CR}}{\mathrm{CE}\times\mathrm{CR}}$ $=\mathrm{CF}^3\times\frac{\mathrm{ER}}{\mathrm{CE}\times\mathrm{CR}}, =\frac{\mathrm{CF}^3}{\mathrm{CE}}\times\frac{\mathrm{ER}}{\mathrm{CR}}.$ But because CF is $\frac{1}{2}$ of CE, $\frac{\mathrm{CF}^3}{\mathrm{CE}}$ is $=\frac{\mathrm{CF}^3}{2\,\mathrm{CF}}, =\frac{\mathrm{CF}^2}{2}$, a constant quantity. Therefore the density of the light at I is proportional to $\frac{\mathrm{ER}}{\mathrm{CR}}$, or to $\frac{\mathrm{AI}}{b\,\mathrm{I}}$, because the points R and I are similarly situated in EC and A b.

Farther, if the semiaperture CE of the lens be called 1, $\frac{\mathrm{CF}^2}{2}$ is $=\frac{1}{8}$, and the density at I is $=\frac{\mathrm{AI}}{8\,b\,\mathrm{I}}$.

Here it is proper to observe, that since the point R has the same situation in the diameter EB that the point I has in the diameter AD of the circle of dispersion, the circle described on EB may be conceived as the magnified representation of the circle of dispersion. The point F, for instance, represents the point f in the circle of dispersion, which bisects the radius b A; and f receives no light from any part of the lens which is nearer the centre than F, being illuminated only by the light which comes through EF and its opposite BF′. The same may be said of every other point.

In like manner, the density of the light in f, the middle between b and A, is measured by $\frac{\mathrm{EF}}{\mathrm{CF}}$, which is $=\frac{\mathrm{EF}}{\mathrm{EF}}$, or 1. This makes the density at this point a proper standard of comparison. The density there is to the density at I as 1 to $\frac{\mathrm{AI}}{b\,\mathrm{I}}$, or as b I to AI; and this is the simplest mode of comparison. The density half way from the centre of the circle of dispersion is to the density at any point I as b I to AI.

Lastly, through L describe the common rectangular hyperbola k L n, meeting the ordinates of the former in k, L, and n: and draw $k\,h$ parallel to EC, cutting the ordinates in $g, f, r,$ &c. Then CR : CE$=$E k : R n, and CR : CE$-$CR$=$E k : R $n-$E k, or CR : RE$=$E k : $r\,n$, and b 1 : IA$=$E k : $r\,n$. And thus we have a very simple expression of the density in any point of the circle of dispersion. Let the point be anywhere, as at I. Divide the lens in R as AD is divided in I, and then $r\,n$ is as the density in I.

These two measures were given by Newton; the first in his *Treatise de Mundi Systemate*, and the last in his *Optics*, but both without demonstration.

If the hyperbola k L n be made to revolve round the axis CQ, it will generate a solid spindle, which will measure the whole quantity of light which passes through different portions of the circle of dispersion. Thus the solid produced by the revolution of L $k\,f$ will measure all the light which occupies the outer part of the circle of dispersion lying without the middle of the radius. This space is $\frac{3}{4}$ths of the whole circle; but the quantity of light is but $\frac{1}{4}$th of the whole.

A

Telescope.

A full more simple expression of the whole quantity of light passing through different portions of the circle of chromatic dispersion may now be obtained as follows:

It has been demonstrated, that the density of the light at I is as $\frac{\text{AI}}{b\,\text{I}}$, or as $\frac{\text{ER}}{\text{CR}}$. Suppose the figure to turn round the axis. I or R describe circumferences of circles; and the whole light passing through this circumference is as the circumference, or as the radius, and as the density jointly. It is therefore as $\frac{\text{ER}}{\text{CR}} \times \text{CR}$, that is, as ER. Draw any straight line E m, cutting RN in s, and any other ordinate FL in x R s. The whole light which illuminates the circumference described by I is to the whole light which illuminates the centre b as ER to EC, or as R s to C m. In like manner, the whole light which illuminates the circumference described by the point f in the circle of dispersion is to the whole light which illuminates the centre b, as F x to C m. The lines C m, RS, F x, are therefore proportional to the whole light which illuminates the corresponding circumferences in the circle of dispersion. Therefore the whole light which falls on the circle whose radius is b I, will be represented by the trapezium in CRS; and the whole light which falls on the ring described by IA, will be represented by the triangle E s R; and so of any other portions.

By considering the figure, we see that the distribution of the light is exceedingly unequal. Round the margin it has no sensible density; while its density in the very centre is incomparably greater than in any other point, being expressed by the asymptote of a hyperbola. Also the circle described with the radius $\frac{\text{A}\,b}{2}$ contains $\frac{1}{4}$ths of the whole light. No wonder then that the confusion caused by the mixture of these circles of dispersion is less than one should expect; besides, it is evident that the most lively or impressive colours occupy the middle of the spectrum, and are there much denser than the rest. The margin is covered with an illumination of deep red and violet, neither of which colours are brilliant. The margin will be of a dark claret colour. The centre revives all the colours, but in a proportion of intensity greatly different from that in the common prismatic spectrum, because the radiant points L, p, b, g, &c. by which it is illuminated, are at such different distances from it. It will be white; but we apprehend not a pure white, being greatly overcharged with the middle colours.

These considerations show that the coloured fringes which are observed to border very luminous objects seen on a dark ground through optical instruments, do not proceed from the object-glass of a telescope or microscope, but from an improper construction of the eye-glasses. The chromatic dispersion would produce fringes of a different colour, when they produce any at all, and the colours would be differently disposed. But this dispersion by the object-glass can hardly produce any fringes: its effect is a general and almost uniform mixture of circles all over the field, which produces an uniform haziness, as if the object were viewed at an improper distance, or out of its focus, as we vulgarly express it.

We may at present form a good guess at the limit which this cause puts to the performance of a telescope. A point of a very distant object is represented, in the picture formed by the object-glass, by a little circle, whose diameter is at least $\frac{1}{100}$th of the aperture of the object-glass, making a very full allowance for the superior brilliancy and density of the central light. We look at this picture with a magnifying eye-glass. This magnifies the picture of the point. If it amplify it to such a degree as to make it an object individually distinguishable, the confusion is then sensible. Now this can be computed. An object subtending one minute of a degree is distinguished by the dullest eye, even although it be a dark object on a bright ground. Let us therefore suppose a telescope, the object glass of which is of six feet focal distance, and one inch aperture. The diameter of the circle of chromatic dispersion will be $\frac{1}{100}$th of an inch, which subtends at the centre of the object-glass an angle of about $9\frac{1}{2}$ seconds. This, when magnified six times by an eye-glass, would become a distinguishable object; and a telescope of this length would be indistinct if it magnified more than six times, if a point were thus spread out into a spot of uniform intensity. But the spot is much less intense about its margin. It is found experimentally that a piece of engraving, having fine cross hatches, is not sensibly indistinct till brought so far from the limits of perfectly distinct vision, that this indistinctness amounts to 6′ or 5′ in breadth.—Therefore such a telescope will be sensibly distinct when it magnifies 36 times; and this is very agreeable to experience.

We come, in the second place, to the more arduous task of ascertaining the error arising from the spherical figure of the surfaces employed in optical instruments.—Suffice it to say, before we begin, that although geometers have exhibited other forms of lenses which are totally exempt from this error, they cannot be executed by the artist; and we are therefore restricted to the employment of spherical surfaces.

Of all the determinations which have been given of spherical aberration, that by Dr Smith, in his Optics, which is an improvement of the fundamental theorem of that most elegant geometer Huyghens, is the most perspicuous and palpable. Some others are more concise, and much better fitted for after use, and will therefore be employed by us in the prosecution of this article. But they do not keep in view the optical facts, giving the mind a picture of the progress of the rays which it can contemplate and discover amidst many modifying circumstances. By ingenious substitutions of analytical symbols, the investigation is rendered expeditious, concise, and certain; but these are not immediate symbols of things, but of operations of the mind; objects sufficiently subtle of themselves, and having no need of substitutions to make us lose sight of the real subject; and thus our occupation degenerates into a process almost without ideas. We shall therefore set out with Dr Smith's fundamental Theorem.

1. *In Reflections.*

Let AVB (fig. 3.) be a concave spherical mirror, of which C is the centre, V the vertex, CV the axis, and F the focus of an infinitely slender pencil of parallel rays passing Fig. 3.

Telescope. passing through the centre. Let the ray a A, parallel to the axis, be reflected in AG, crossing the central ray CV in f. Let AP be the sine of the semi-aperture AV, AD its tangent, and CD its secant.

The aberration Ff from the principal focus of central rays is equal to $\frac{1}{2}$ of the excess VD of the secant above the radius, or very near equal to $\frac{1}{2}$ of VP, the versed sine of the semi-aperture.

For because AD is perpendicular to CA, the points C, A, D, are in a circle, of which CD is the diameter; and because Af is equal to Cf, by reason of the equality of the angles fAC, fCA, and CA a, f is the centre of the circle through C, A, D, and fD is $= \frac{1}{2}$ CD. But FC is $= \frac{1}{2}$ CV. Therefore Ff is $\frac{1}{2}$ of VD.

But because DV : VP = DC : VC, and DC is very little greater than VC when the aperture AB is moderate, DV is very little greater than VP, and Ff is very nearly equal to $\frac{1}{2}$ of VP.

Cor. 1. The longitudinal abberration is $= \frac{AV^2}{4CV}$, for PV is very nearly $= \frac{AV^2}{2CV}$.

Cor. 2. The lateral aberration FG is $= \frac{AV^3}{2CV^2}$. For FG : Ff = AP : Pf, = AV : $\frac{1}{2}$ CV nearly, and therefore FG $= \frac{AV^2}{4CV} \times \frac{2}{CV} = \frac{AV^3}{2CV^2}$.

2. *In Refractions.*

Fig. 4. or 5. Let AVB (fig. 4. or 5.) be a spherical surface separating two refracting substances, C the centre, V the vertex, AV the semi-aperture, AP its sine, PV its versed sine, and F the focus of parallel rays infinitely near to the axis. Let the extreme ray a A, parallel to the axis, be refracted into AG, crossing CF in f, which is therefore the focus of extreme parallel rays.

The rectangle of the sine of incidence, by the difference of the sines of incidence and refraction, is to the square of the sine of refraction, as the versed sine of the semi-aperture is to the longitudinal aberration of the extreme rays.

Call the sine of incidence i, the sine of refraction r, and their difference d.

Join CA, and about the centre f describe the arch AD.

The angle ACV is equal to the angle of incidence, and CAf is the angle of refraction. Then, since the sine of incidence is to the sine of refraction as VF to CF, or as Af to Cf, that is, as Df to Cf, we have

CF : FV = Cf : fD
by conversion CF : CV = Cf : CD
altern. conver. CF—Cf : CV—CD=CF : CV
or Ff : VD=CF : CV, = r : d.

Now PV $= \frac{AP^2}{CP+CV}$, $= \frac{AP^2}{2CV}$ nearly, and PD $= \frac{AP^2}{fP+fV}$ $= \frac{AP^2}{2fV}$ nearly, $= \frac{AP^2}{2FV}$ nearly. Therefore PV : PD = FV : CV, and DV : PV=CF : FV nearly.

We had above Ff : VD=r : d;
and now - VD : PV=CF : FV, = r : i;
therefore - Ff : PV=r^2 : $d\,i$,

and F$f = \frac{r^2}{d\,i} \times$ PV. *Q. E. D.*

The aberration will be different according as the refraction is made towards or from the perpendicular; that is, according as r is less or greater than i. They are in the ratio of $\frac{r^2}{d\,i}$ to $\frac{i^2}{d\,r}$, or of r^3 to i^3. The aberration therefore is always much diminished when the refraction is made from a rare into a dense medium. The proportion of the sines for air and glass is nearly that of 3 to 2. When the light is refracted into the glass, the aberration is nearly $\frac{4}{9}$ of PV; and when the light passes out of glass into air, it is about $\frac{9}{2}$ of PV. Telescope.

Cor. 1. F$f = \frac{r^2}{d\,i} \times \frac{AP^2}{2CV}$ nearly, and it is also $= \frac{r^2}{d^2} \times \frac{AP^2}{2FV}$, because PV $= \frac{AP^2}{2CV}$ nearly, and $i : d =$ FV : CV.

Cor. 2. Because fP : PA=Ff : FG
or FV : AV=Ff : FG nearly,
we have FG, the lateral aberration, $=$ F$f \times \frac{AV}{FV}$, $= \frac{r^2}{d^2} \times \frac{AV^3}{2FV^2}$, $= \frac{r^2}{i^2} \times \frac{AV^3}{2CV^2}$.

Cor. 3. Because the angle FAf is proportional to $\frac{FG}{FV}$, very nearly, we have the angular aberration F A$f = \frac{r^2}{d^2} \times \frac{AV^3}{2FV^3} = \frac{r^2}{i^2} \times \frac{AV^3}{2CV^3}$.

In general, the longitudinal aberrations from the focus of central parallel rays are as the squares of the apertures directly, and as the focal distances inversely; and the lateral aberrations are as the cubes of the apertures directly, and the squares of the focal distances inversely; and the angular aberrations are as the cubes of the aperture directly, and the cubes of the focal distances inversely.

The reader must have observed, that to simplify the investigation, some small errors are admitted. PV and PD are not in the exact proportion that we assumed them, nor is Df equal to FV. But in the small apertures which suffice for optical instruments, these errors may be disregarded.

This spherical aberration produces an indistinctness of vision, in the same manner as the chromatic aberration does, viz. by spreading out every mathematical point of the object into a little spot in its picture; which spots, by mixing with each other, confuse the whole. We must now determine the diameter of the circle of diffusion, as we did in the case of chromatic dispersion.

Let a ray $\beta\,\alpha$ (fig. 6.) be refracted on the other side of the axis, into α H φ, cutting A f G in H, and draw the perpendicular EH. Call AV a, αV α, Vf (or VF, or V φ, which in this comparison may be taken as equal) $=f$, Ff=b, and fE=$\varphi\,x$. Plate DXXIX. fig. 6.

AV^2 : αV^2=Ff : F φ (already demonstrated) and Fφ $= \frac{\alpha^2}{a^2}b$, and Ff—Fφ, (or $f\varphi$) $= b - \frac{\alpha^2}{a^2}b, = \frac{a^2b-\alpha^2b}{a^2}$, $= \frac{b}{a^2} \times \overline{a^2-\alpha^2}, = \frac{b}{a^2} \times \overline{a+\alpha} \times \overline{a-\alpha}$. Also P$f$: PA =fE

$=f\text{E} : \text{EH}$, or $f : a = x : \frac{ax}{f}, = \text{EH}$. And $\text{P}\pi : \text{P}\varphi = \text{EH} : \text{E}\varphi$, or $\alpha : f = \frac{ax}{f} : \frac{ax}{\alpha}, = \text{E}\varphi$. Therefore $f\varphi = \frac{ax}{\alpha} + x, = \frac{\overline{a+\alpha}\,x}{\alpha}, = \frac{x}{\alpha} \times \overline{a+\alpha}$. Therefore $\frac{x}{a} \times \overline{a+\alpha} = \frac{b}{a^2} \times \overline{a+\alpha} \times \overline{a-\alpha}$, and $\frac{x}{a} = \frac{b}{a^2} \times \overline{a-\alpha}$, and $x = \frac{b}{a^2} \times \alpha(a-\alpha)$. Therefore x is greatest when $\alpha \times \overline{a-\alpha}$ is greatest; that is, when $\alpha = \frac{1}{2} a$. Therefore EH is greatest when $\text{P}\pi$ is equal to the half of AP. When this is the case, we have at the same time $\frac{b}{a^2} \times \alpha (a-\alpha) = \frac{b}{a^2} \times \frac{1}{4} a^2$, and $x = \frac{1}{4} b$, or $\text{EH} = \frac{1}{4}\text{FG}$. That is, the diameter of the circle of aberration through which the whole of the refracted light must pass, is $\frac{1}{4}$ of the diameter of the circle of aberration at the focus of parallel central rays. In the chromatic aberration it was $\frac{1}{2}$; so that in this respect the spherical aberration does not create so great confusion as the chromatic.

We are now able to compare them, since we have now the measure of both the circles of aberration.

It has not been found possible to give more than four inches of aperture to an object glass of 100 feet focal distance, so as to preserve sufficient distinctness. If we compute the diameter of the circle EH corresponding to this aperture, we shall find it not much to exceed $\frac{1}{120,000}$ of an inch. If we restrict the circle of chromatic dispersion to $\frac{1}{250}$ of the aperture, which is hardly the fifth part of the whole dispersion in it, it is $\frac{1}{62\frac{1}{2}}$ of an inch, and is about 1900 times greater than the other.

The circle of spherical aberration of a plano-convex lens, with the plane side next the distant object, is equal to the circle of chromatic dispersion when the semi-aperture is about 15°: For we saw formerly that EH is $\frac{1}{4}$ of FG, and that FG is $= \frac{r^2}{i^2}\,\frac{\text{AP}^3}{2\,\text{AC}^2}$, and therefore $\text{EG} = \frac{r^2}{i^2} \times \frac{\text{AP}^3}{8\,\text{AC}^2}$. This being made $= \frac{\text{AP}}{55}$, gives us $\text{AP} = \sqrt{\frac{8\,i^2\text{AC}^2}{53\,r^2}}$ which is nearly $\frac{\text{AC}}{4}$ and corresponds to an aperture of 30° diameter, if r be to i as 3 to 2.

Sir Isaac Newton was therefore well entitled to say, that it was quite needless to attempt figures which should have less aberration than spherical ones, while the confusion produced by the chromatic dispersion remained uncorrected. Since the indistinctness is as the squares of the diameters of the circles of aberration, the disproportion is quite beyond our imagination, even when Newton has made such a liberal allowance to the chromatic dispersion. But it must be acknowledged, that he has not attended to the distribution of the light in the circle of spherical aberration, and has hastily supposed it to be like the distribution of the coloured light, indefinitely rare in the margin, and denser in the centre.

We are indebted to Father Boscovich for the elegant determination of this distribution, which we have given in the article OPTICS. From this it appears, that the light in the margin of the circle of spherical aberration, instead of being incomparably rarer than in the spaces between it and the centre, is incomparably denser. The indistinctness therefore produced by the intersection of these luminous circumferences is vastly great, and increases the whole indistinctness exceedingly. By a gross calculation which we made, it appears to be increased at least 500 times. The proportional indistinctness therefore, instead of being 1900^2 to 1, is only $\frac{1900^2}{500}$, or nearly 7220 to 1; a proportion still sufficiently great to warrant Newton's preference of the reflecting telescope of his invention. And we may now observe, that the reflecting telescope has even a great advantage over a refracting one of the same focal distance, with respect to its spherical aberration: For we have seen (*Cor.* 2.) that the lateral aberration is $\frac{r^2}{i^2}\,\frac{\text{AV}^3}{2\,\text{CV}^2}$. This for a plano-convex glass is nearly $\frac{9}{4}\,\frac{\text{AV}^3}{2\,\text{CV}^2}$. And the diameter of the circle of aberration is one-fourth of this, or $\frac{9}{16} \times \frac{\text{AV}^3}{2\,\text{CV}^2}$. In like manner, the lateral aberration of a concave mirror is $\frac{\text{AV}^3}{2\,\text{CV}^2}$; and the diameter of the circle of dispersion is $\frac{\text{AV}^3}{8\,\text{CV}^2}$; and therefore if the surfaces were portions of the same sphere, the diameter of the circle of aberration of refracted rays would be to that of the circle of aberration of reflected rays as $\frac{9}{16}$ to $\frac{1}{4}$, or as 9 to 4. But when the refracting and reflecting surfaces, in the position here considered, have the same focal distance, the radius of the refracting surface is four times that of the reflecting surface. The proportion of the diameters of the circles of spherical aberration is that of 9×4^2 to 4, or of 144 to 4, or 36 to 1. The distinctness therefore of the reflector is 36×36, or 1296 times greater than that of a plano-convex lens (placed with the plane side next the distant object) of the same breadth and focal distance, and will therefore admit of a much greater magnifying power. This comparison is indeed made in circumstances most favourable to the reflector, because this is the very worst position of a plano-convex lens. But we have not as yet learned the aberration in any other position. In another position the refraction and consequent aberration of both surfaces are complicated.

Before we proceed to the consideration of this very difficult subject, we may deduce from what has been already demonstrated several general rules and maxims in the construction of telescopes, which will explain (to such readers as do not wish to enter more deeply into the subject), and justify the proportion which long practice of the best artists has sanctioned.

Indistinctness proceeds from the commixture of the circles of aberration on the retina of the eye: For any one *sensible* point of the retina, being the centre of a circle of aberration, will at once be affected by the admixture of the rays of as many different pencils of light as there are sensible points in the area of that circle, and will convey to the mind a mixed sensation of as many

 visible

visible points of the object. This number will be as the area of the circle of aberrations, whatever be the size of a sensible point of the retina. Now in vision with telescopes the diameter of the circle of aberration on the retina is as the *apparent* magnitude of the diameter of the corresponding circle in the focus of the eye-glass; that is, as the angle subtended by this diameter at the centre of the eye-glass; that is, as the diameter itself directly, and as the focal distance of the eye-glass inversely. And the area of that circle on the retina is as the area of the circle on the focus of the eye-glass directly, and as the square of the focal distance of the eye-glass inversely. And this is the measure of the apparent indistinctness.

Cor. In all sorts of telescopes, and also in compound microscopes, an object is seen equally distinct when the focal distances of the eye-glasses are proportional to the diameters of the circles of aberration in the focus of the object-glass.

Here we do not consider the trifling alteration which well constructed eye-glasses may add to the indistinctness of the first image.

In refracting telescopes, the apparent indistinctness is as the area of the object-glass directly, and as the square of the focal distance of the eye-glass inversely. For it has been shown, that the area of the circle of dispersion is as the area of the object-glass, and that the spherical aberration is insignificant when compared with this.

Therefore, to make reflecting telescopes equally distinct, the diameter of the object-glass must be proportional to the focal distance of the eye-glass.

But in reflecting telescopes, the indistinctness is as the sixth power of the aperture of the object-glass directly, and as the fourth power of the focal distance of the object-glass and square of the focal distance of the eye-glass inversely. This is evident from the dimensions of the circle of aberration, which was found proportional to $\frac{AV^3}{CV^2}$.

Therefore, to have them equally distinct, the cubes of the apertures must be proportional to the squares of the focal distance multiplied by the focal distance of the eye-glass.

By these rules, and a standard telescope of approved goodness, an artist can always proportion the parts of any instrument he wishes to construct. Mr Huyghens made one, of which the object-glass had 30 feet focal distance and three inches diameter. The eye-glass had 3.3 inches focal distances. And its performance was found superior to any which he had seen; nor did this appear owing to any chance goodness of the object-glass, because he found others equally good which were constructed on similar proportions. This has therefore been adopted as a standard,

It does not at first appear how there can be any difficulty in this matter, because we can always diminish the aperture of the object-glass or speculum till the circle of aberration is as small as we please. But by diminishing this aperture, we diminish the light in the duplicate ratio of the aperture. Whatever be the aperture, the brightness is diminished by the magnifying power, which spreads the light over a greater surface in the bottom of the eye. The apparent brightness must be as the square of the aperture of the telescope directly, and the square of the amplification of the diameter of an object inversely. Objects therefore will be seen equally bright if the apertures of the telescopes be as the focal distances of the object-glasses directly, and the focal distances of the single eyo-glass (or eye-glass equivalent to the eye-piece) inversely. Therefore, to have telescopes equally distinct and equally bright, we must combine these proportions with the former. It is needless to go farther into this subject, because the construction of refracting telescopes has been so materially changed by the correction of the chromatic aberration, that there can hardly be given any proportion between the object-glass and eye-glasses. Every thing now depends on the degree in which we can correct the aberrations of the object-glass. We have been able so far to diminish the chromatic aberration, that we can give very great apertures without its becoming sensible. But this is attended with so great an increase of the aberration of figure, that this last becomes a sensible quality. A lens which has 30° for its semi-aperture, has a circle of aberration equal to its chromatic aberration. Fortunately we can derive from the very method of contrary refractions, which we employ for removing the chromatic aberrations, a correction of the other. We are indebted for this contrivance also to the illustrious Newton.

We call this Newton's contrivance, because he was the first who proposed a construction of an object-glass in which the aberration was corrected by the contrary aberrations of glass and water.

Huyghens had indeed supposed, that our all-wise Creator had employed in the eyes of animals many refractions in place of one, in order to make the vision more distinct; and the invidious detractors from Newton's fame have catched at this vague conjecture as an indication of his knowledge of the possibility of destroying the aberration of figure by contrary refractions. But this is very ill-founded. Huyghens has acquired sufficient reputation by his theory of aberrations. The scope of his writing in the passage alluded to, is to show that, by dividing any intended refraction into parts, and producing a certain convergence to or divergence from the axis of an optical instrument by means of two or three lenses instead of one, we diminish the aberrations four or nine times. This conjecture about the eye was therefore in the natural train of his thoughts. But he did not think of destroying the aberration altogether by opposite refractions. Newton, in 1669, says that opticians need not trouble themselves about giving figures to their glasses other than spherical. If this figure were all the obstacle to the improvement of telescopes, he could show them a construction of an object-glass having spherical surfaces where the aberration is destroyed; and accordingly gives the construction of one composed of glass and water, in which this is done completely by means of contrary refractions.

The general principle is this: When the radiant point R (fig. 7.), or focus of incident rays, and its conjugate focus F of refracted central rays, are on opposite sides of the refracting surface or lens V, the conjugate focus f of marginal rays is nearer to R than F is. But when the focus of incident rays R′ lies on the same side with its conjugate focus F′ for central rays, R′f is greater than R′ F′. Fig. 7.

Now fig. 8. represents the contrivance for destroying the colour produced at F, the principal focus of the Fig. 8.

convex

Telescope. convex lens V, of crown glass, by means of the contrary refraction of the concave lens v of flint glass. The incident parallel rays are made to converge to F by the first lens. This convergence is diminished, but not entirely destroyed, by the concave lens v, and the focus is formed in F. F and F′ therefore are conjugate foci of the concave lens. If F be the focus of V for central rays, the marginal rays will be collected at some point f nearer to the lens. If F be now considered as the focus of light incident on the centre of v, and F′ be the conjugate focus, the marginal ray pF would be refracted to some point f' lying beyond F′. Therefore the marginal ray pf may be refracted to F, if the aberration of the concave be properly adjusted to that of the convex.

This brings us to the most difficult part of our subject, the compounded aberrations of different surfaces. Our limits will not give us room for treating this in the same elementary and perspicuous manner that we employed for a single surface. We must try to do it in a compendious way, which will admit at once the different surfaces and the different refractive powers of different substances. This must naturally render the process more complicated; but we hope to treat the subject in a way easily comprehended by any person moderately acquainted with common algebra; and we trust that our attempt will be favourably received by an indulgent public, as it is (as far as we know) the only dissertation in our language on the construction of achromatic instruments. We cannot but express our surprise at this indifference about an invention which has done so much honour to our country, and which now constitutes a very lucrative branch of its manufacture. Our artists infinitely surpass all the performances of foreigners in this branch, and supply the markets of Europe without any competition; yet it is from the writings on the continent that they derive their scientific instruction, and particularly from the dissertations of Clairaut, who has wonderfully simplified the analysis of optical propositions. We shall freely borrow from him, and from the writings of Abbé Boscovich, who has considerably improved the first views of Clairaut. We recommend the originals to the curious reader. Clairaut's dissertations are to be found in the Memoirs of the Academy of Paris, 1756, &c.; those of Boscovich in the Memoirs of the Academy of Bologna, and in his five volumes of *Opuscula*, published at Bassano in 1785. To these may be added D'Alembert and Euler. The only thing in our language is the translation of a very imperfect work by Schærfer.

Fig. 9. *Lemma* I. In the right-angled triangle MXS (fig. 9.), of which one side MX is very small in comparison of either of the others; the excess of the hypothenuse MS, above the side XS, is very nearly equal to $\frac{MX^2}{2MS}$ or to $\frac{MX^2}{2XS}$. For if about the centre S, with the radius SM, we describe the semicircle AMO, we have $AX \times XO = MX^2$. Now $AX = MS - SX$, and XO, is nearly equal to 2MS or 2XS; on the other hand, MS is nearly equal to $XS + \frac{MX^2}{2XS}$; and in like manner MG is nearly equal to $\frac{MX}{2XG} + XG$, and MH is nearly equal to $\frac{MX^2}{2XH} + XH$.

Prop. I. Let the ray m M, incident on the spherical surface AM, converge to G; that is, let G be the focus of incident rays. It is required to find the focus F of refracted rays?

Let m express the ratio of the sine of incidence and refraction; that is, let m be to 1 as the sine of incidence to the sine of refraction in the substance of the sphere.

Then - MG : GS = sin. MSH : sin. SMG,
and - m : 1 = sin. SMG : sin. SMH;
therefore . $m \times$ MG : GS = sin. MSH : sin. SMH.
Now S, MSH : S, SMH = MH : HS. Therefore, finally,
mMG : GS = MH : HS.

Now let MS, the radius of the refracting surface, be called a. Let AG, the distance of the focus of incident rays from the surface, be called r. And let AH, the focal distance of refracted rays, be called x. Lastly, let the sine MX of the semi-aperture be called e. Observe, too, that a, r, x, are to be considered as positive quantities, when AS, AG, AH, lie from the surface in the direction in which the light is supposed to move. If therefore the refracting surface be concave, that is, having the centre on that side from which the light comes; or if the incident rays are divergent, or the refracted rays are divergent; then a, r, x, are negative quantities.

It is plain that $HS = x - a$; $GS = r - a$; also $AX = \frac{e^2}{2a}$ nearly. $HX = a - \frac{e^2}{2a}$. $GX = r - \frac{e^2}{2a}$. Now add to HX and to GX their differences from MH and MG, which (by the Lemma) are $\frac{e^2}{2x}$ and $\frac{e^2}{2r}$. We get $MH = x - \frac{e^2}{2a} + \frac{e^2}{2x}$, and $MG = r - \frac{e^2}{2a} \times \frac{e^2}{2r}$. In order to shorten our notation, make $k = \frac{1}{a} - \frac{1}{r}$. This will make $MG = r - \frac{ke^2}{2}$.

Now substitute these values in the final analogy at the top of this column, viz. MH : HS = m.MG : GS; it becomes $x - \frac{e^2}{2a} + \frac{e^2}{2x} : x - a = mr - \frac{mke^2}{2} : r - a$ (or ark,) because $k = \frac{r-a}{ar}$, and $ark = r - a$. Now multiply the extreme and mean terms of this analogy. It is evident that it must give us an equation which will give us a value of x or AH, the quantity sought.

But this equation is quadratic. We may avoid the solution by an approximation which is sufficiently accurate, by substituting for x in the fraction $\frac{e^2}{2x}$ (which is very small in all cases of optical instruments), an approximate very easily obtained, and very near the truth. This is the focal distance of an infinitely slender pencil of rays converging to G. This we know by the common optical theorem to be $\frac{amr}{\overline{m-1}\,r \pm a}$. Let this be

called

called φ; if we substitute k in place of $\frac{1}{a}-\frac{1}{r}$, this value of φ becomes $=\frac{am}{m-ak}$.

This gives us, by the by, an easily remembered expression (and beautifully simple) of the refracted focus of an infinitely slender pencil, corresponding to any distance r of the radiant point. For since $\varphi=\frac{am}{m-ak}$, $\frac{1}{\varphi}$ must be $=\frac{m-ak}{am}, =\frac{m}{am}, -\frac{ak}{am}=\frac{1}{a}-\frac{k}{m}$. We may even express it more simply, by expanding k, and it becomes $\frac{1}{\varphi}=\frac{1}{a}-\frac{1}{ma}-\frac{1}{mr}$.

Now put this value of $\frac{1}{\varphi}$ in place of the $\frac{1}{x}$ in the analogy employed above. The first term of the analogy becomes $x-\frac{e^2}{2a}+\frac{e^2}{2a}-\frac{ke^2}{2m}$, or $x-\frac{ke^2}{2m}$. The analogy now becomes $x-\frac{ke^2}{2m}:xa=mr-\frac{mke^2}{2}:ark$. Hence we obtain the linear equation $mrx-\frac{mke^2x}{2}-mra+\frac{mkae^2}{2}=arkx-\frac{arke^2}{2m}$; from which we finally deduce

$$x=\frac{mra-\frac{1}{2}make^2-\frac{ark^2e^2}{2m}}{mr-ark-\frac{1}{2}mke}.$$

We may simplify this greatly by attending to the elementary theorem in fluxions, that the fraction $\frac{x+\dot{x}}{y+\dot{y}}$ differs from the fraction $\frac{x}{y}$ by the quantity $\frac{y\dot{x}-x\dot{y}}{y^2}$; this being the fluxion of $\frac{x}{y}$. Therefore $\frac{x+\dot{x}}{y+\dot{y}}=\frac{x}{y}+\frac{y\dot{x}-x\dot{y}}{y^2}$. Now the preceding formula is nearly in this situation. It may be written thus;

$$\frac{mra\ \left(-\frac{1}{2}make^2-\frac{ark^2e^2}{2m}\right)}{mr-ark\quad -mke^2},$$ when the last terms of the numerator and denominator are very small in comparison with the first, and may be considered as the $\dot{x}$ and $\dot{y}$ while mra is the x, and $mr-ark$ is the y. Treating it in this way, it may be stated thus:

$$x=\frac{mra}{mr-ark}+\frac{(mra)\,\frac{1}{2}mke^2-(mr-ark)\,\left(\frac{1}{2}mkae^2+\frac{ark^2e^2}{2m}\right)}{r^2(m-ak)^2}$$

$$\text{or } x=\frac{mra}{r(m-ak)}+\frac{(mra)\,mk-(mr-ark)\,\left(mka+\frac{ark^2}{m}\right)}{r^2(m-ak)^2}\times\tfrac{1}{2}e^2$$

The first term $\frac{mra}{r(m-ak)}$, or $\frac{ma}{m-ak}$, is evidently $=\varphi$, the focal distance of an infinitely slender pencil.

Therefore the aberration is expressed by the second term, which we must endeavour to simplify.

If we now perform the multiplication indicated by $-(mr-ark)\times\left(mka-\frac{ark^2}{m}\right)$, it is plain that $-mr\times mka$ destroys the first term $mra\times mk$ of the numerator of our small fraction, and there remains of this numerator $\left(ma^2rk^2-ar^2k^2+\frac{a^2r^2k}{m}\right)\frac{1}{2}e^2$, which is equal to $m^2a^2\left(\frac{rk^2}{m}-\frac{r^2k^2}{m^2a}+\frac{r^3k^3}{m^3}\right)\frac{1}{2}e^2$.

The denominator was $r^2(m-ak)^2$, and the fraction now becomes $\frac{m^2a^2}{(m-ak)^2}\left(\frac{k^2}{mr}-\frac{k^2}{m^2a}+\frac{k^3}{m^3}\right)\frac{1}{2}e^2$, which is evidently $=\varphi^2\left(\frac{k^2}{mr}-\frac{k^2}{m^2a}+\frac{k^3}{m^3}\right)\frac{e^2}{2}$. Now recollect that $k=\frac{1}{a}-\frac{1}{r}$. Therefore $\frac{k^3}{m^2}=\frac{k^2}{m^2}\left(\frac{1}{a}-\frac{1}{r}\right)=\frac{k^2}{m^2a}-\frac{k^2}{m^2r}$. Therefore, instead of $-\frac{k^2}{m^2a}$, write $\frac{-k^3}{m^2}-\frac{k^2}{mr}$, and we get the fraction $\varphi^2\left(\frac{k^3}{m^3}-\frac{k^3}{m^2}-\frac{k^2}{m^2r}+\frac{k^2}{mr}\right)\frac{e^2}{2}=\varphi^2\left(\frac{k^3}{m}-\frac{mk^3}{m^3}-\frac{mk^2}{m^3r}+\frac{m^2k^2}{m^3r}\right)\frac{e^2}{2}$, which is equal to $\varphi^2\frac{1-m}{m^3}\left(k^3-\frac{mk^2}{r}\right)\frac{e^2}{2}$, and finally to $-\varphi^2\frac{m-1}{m^3}\left(k^3-\frac{mk^2}{r}\right)\frac{e^2}{2}$.

Therefore the focal distance of refracted rays is $x=\varphi-\varphi^2\frac{m-1}{m^3}\left(k^3-\frac{mk^2}{r}\right)\frac{e^2}{2}$.

This consists of two parts. The first φ is the focal distance of an infinitely slender pencil of central rays, and the other $-\varphi^2\frac{m-1}{m^3}\left(k^3-\frac{mk^2}{r}\right)\frac{e^2}{2}$ is the aberration arising from the spherical figure of the refracting surface.

Our formula has thus at last put on a very simple form, and is vastly preferable to Dr Smith's for practice.

This aberration is evidently proportional to the square of the semi-aperture, and to the square of the distance φ: but in order to obtain this simplicity, several quantities were neglected. The assumption of the equality of AX to $\frac{e^2}{2a}$ is the first source of error. A much more accurate value of it would have been $\frac{2ae^2}{4a^2+e^2}$, for it is really $=\frac{e^2}{2a-AX}$. If for AX we substitute its approximated value $\frac{e^2}{2a}$, we should have $AX=\frac{e^2}{2a-\frac{e^2}{2a}}=\frac{2ae^2}{4a^2-e^2}$. To have used this value would not have much complicated the calculus; but it did not occur to us till we had finished the investigation, and it would have required the whole to be changed. The operation in page 246. col. 1. par. 3. is another source of error. But these errors are very inconsiderable when the aperture

ture is moderate. They increase for the most part with an increase of aperture, but not in the proportion of any regular function of it; so that we cannot improve the formula by any manageable process, and must be contented with it. The errors are precisely the same with those of Dr Smith's theorem, and indeed with those of any that we have seen, which are not vastly more complicated.

As this is to be frequently combined with subsequent operations, we shorten the expression by putting θ for $\frac{m-1}{m^3}\left(k^3-\frac{m\,k^2}{r}\right)\frac{e^2}{2}$. Then $\varphi^2\theta$ will express the aberration of the first refraction from the focal distance of an infinitely slender pencil; and now the focal distance of refracted rays is $f=\varphi-\varphi^2\theta$.

If the incident rays are parallel, r becomes infinite, and $\theta=\frac{m-1}{m^3}k^3\frac{e^2}{2}$. But in this case k becomes $=\frac{1}{a}$, and $\frac{1}{\varphi}=\frac{m-1}{ma}$, and $\varphi=\frac{ma}{m-1}$, and $\varphi^2\theta$ becomes $\frac{m^2a^2}{(m-1)^2}\times\frac{m-1}{m^3}\times\frac{1}{a^3}\times\frac{e^2}{2},=\frac{e^2}{(2m-1)ma}$. This is the aberration of extreme parallel rays.

We must now add the refraction of another surface.

Lemma 2. If the focal distance AG be changed by a small quantity G'g, the focal distance AH will also be changed by a small quantity Hh, and we shall have

$$m\cdot AG^2 : AH^2 = Gg : Hh.$$

Draw Mg, Mh, and the perpendiculars Gi, Hk. Then, because the sines of the angles of incidence are in a constant ratio to the sines of the angles of refraction, and the increments of these small angles are proportional to the increments of the sines, these increments of the angles are in the same constant ratio. Therefore,

We have the angle CMg to HMh as m to 1.

Now $Gg : Gi = AG : AM$,
and $Gi : hk = m\cdot AG : HA$,
and $hk : Hh = MA : AH$:
therefore $Gg : Hh = m\cdot AG^2 : AH^2$

The easiest and most perspicuous method for obtaining the aberration of rays twice refracted, will be to consider the first refraction as not having any aberration, and determine the aberration of the second refraction. Then conceive the focus of the first refraction as shifted by the aberration. This will produce a change in the focal distance of the second refraction, which may be determined by this Lemma.

Fig. 10. PROP. II. Let AM, BN (fig. 10.) be two spherical surfaces, including a refracting substance, and having their centres C and c in the line AG. Let the ray a A pass through the centres, which it will do without refraction. Let another ray m M, tending to G, be refracted by the first surface into MH, cutting the second surface in N, where it is farther refracted into NI. It is required to determine the focal distance BI?

It is plain that the sine of incidence on the second surface is to the sine of refraction into the surrounding air as 1 to m. Also BI may be determined in relation to BH, by means of BH, Nx, Be, and $\frac{1}{m}$, in the same way that AH was determined in relation to AG, by means of AG, MX, AC, and m.

Let the radius of the second surface be b, and let e still express the semi-aperture, (because it hardly differs from Nx). Also let α be the thickness of the lens. Then observe, that the focal distance of the rays refracted by the first surface, (neglecting the thickness of the lens and the aberration of the first surface), is the distance of the radiant point for the second refraction, or is the focal distance of rays incident on the second surface. In place of r therefore we must take φ; and as we made $k=\frac{1}{a}-\frac{1}{r}$, in order to abbreviate the calculus, let us now make $l=\frac{1}{b}-\frac{1}{\varphi}$; and make $\frac{1}{f}=\frac{1}{b}-m\,l$, as we made $\frac{1}{\varphi}=\frac{1}{a}-\frac{k}{m}$. Lastly, in place of $\theta=\frac{m-1}{m^3}\left(k^3-\frac{m\,k^2}{r}\right)\frac{e^2}{2}$, make $\theta'=\left(\frac{1}{m}-1\right)m^3\left(l^3-\frac{l^2}{m\,\varphi}\right)\frac{e^2}{2},=-\frac{m-1}{m}\left(m^2\,l^3-\frac{m^2\,l^2}{\varphi}\right)\frac{e^2}{2}$.

Thus we have got an expression similar to the other; and the focal distance BI, after two refractions, becomes $BI=f-f^2\theta'$.

But this is on the supposition that BH is equal to φ, whereas it is really $\varphi-\varphi^2\theta-\alpha$. This must occasion a change in the value just now obtained of BI. The source of the change is twofold. 1st, Because in the value $\frac{1}{b}-\frac{1}{\varphi}$, we must put $\frac{1}{b}-\frac{1}{\varphi-\varphi^2\theta-\alpha}$, and because we must do the same in the fraction $\frac{m^2\,l^2}{\varphi}$. In the second place, when the value of BH is diminished by the quantity $\varphi^2\theta+\alpha$, BI will suffer a change in the proportion determined by the 2d Lemma. The first difference may safely be neglected, because the value of θ is very small by reason of the coefficient $\frac{e^2}{2}$ being very small, and also because the variation bears a very small ratio to the quantity itself, when the true value of φ differs but little from that of the quantity for which it is employed. The chief change in BI is that which is determined by the Lemma. Therefore take from BI the variation of BH, multiplied by $\frac{m\,BI^2}{BH^2}$, which is very nearly $=\frac{mf^2}{\varphi^2}$. The product of this multiplication is $mf^2\theta+\frac{mf^2\alpha}{\varphi^2}$. This being taken from f, leaves us for the value of BI $f-\frac{f^2m\alpha}{\varphi^2}-f^2(m\theta+\theta')$.

In this value f is the focal distance of an infinitely slender pencil of rays twice refracted by a lens having no thickness; $\alpha\frac{mf^2}{\varphi}$ is the shortening occasioned by the thickness, and $f^2\,(m\theta+\theta')$ is the effect of the two aberrations arising from the aperture.

It will be convenient, for several collateral purposes, to exterminate from these formulæ the quantities k, l and φ. For this purpose make $\frac{1}{n}=\frac{1}{a}-\frac{1}{b}$. We have already $k=\frac{1}{a}-\frac{1}{r}$; and $\frac{1}{\varphi}=\frac{1}{a}-\frac{1}{ma}+\frac{1}{mr}$; and $l=\frac{1}{b}-\frac{2}{\varphi},=\frac{1}{-}-\frac{1}{a}+\frac{1}{ma}-\frac{1}{mr}$. Now for $\frac{1}{b}-\frac{1}{a}$ write $-\frac{1}{n}$, and

and we get $l=\frac{1}{ma}-\frac{1}{mr}-\frac{1}{n}$. Therefore $\frac{1}{f}=\frac{1}{b}-ml$ (by construction, page 347. Prop. II.) becomes $=\frac{1}{b}-\frac{1}{a}+\frac{1}{r}+\frac{m}{n},=\frac{m}{n}+\frac{1}{r}-\frac{1}{n},-\frac{m-1}{n}+\frac{1}{r}$.

This last value of $\frac{1}{f}$ (the reciprocal of the focus of a slender pencil twice refracted), viz. $\frac{m-1}{n}+\frac{1}{r}$, is the simplest that can be imagined, and makes n as a substitute for $\frac{1}{a}-\frac{1}{b}$; a most useful symbol, as we shall frequently find in the sequel. It also gives a very simple expression of the focal distance of parallel rays, which we may call the principal focal distance of the lens, and distinguish it in future by the symbol p; for the expression $\frac{1}{f}=\frac{m-1}{n}+\frac{1}{r}$ becomes $\frac{1}{p}=\frac{m-1}{n}$ when the incident light is parallel. And this gives us another very simple and useful measure of f; for $\frac{1}{f}$ becomes $=\frac{1}{p}+\frac{1}{r}$. These equations $\frac{1}{f}=\frac{m-1}{n}+\frac{1}{r}$, $\frac{1}{p}=\frac{m-1}{n}$, and $\frac{1}{f}=\frac{1}{p}+\frac{1}{r}$, deserve therefore to be made very familiar to the mind.

We may also take notice of another property of n. It is half the radius of an isosceles lens, which is equivalent to the lens whose radii are a and b: for suppose the lens to be isosceles, that is $a=b$; then $n=\frac{1}{a}-\frac{1}{a}$. Now the second a is negative if the first be positive, or positive if the first be negative. Therefore $\frac{1}{a}-\frac{1}{b}=\frac{1+b}{a^2}=\frac{a+a}{a^2}=\frac{2}{a}$, and $\frac{1}{n}=\frac{2}{a}$, and $n=\frac{a}{2}$. Now the focal distance of this lens is $\frac{m-1}{n}$, and so is that of the other, and they are equivalent.

But, to proceed with our investigation, recollect that we had $\theta=\frac{m-1}{m^3}\left(k^3-\frac{m\,k^2}{r}\right)\frac{e^2}{2}$. Therefore $m\,\theta=\frac{m-1}{m}\left(\frac{k^3}{m}-\frac{k^2}{r}\right)\frac{e^2}{2}$. And θ' was $=\frac{m-1}{m}\left(-m^2\,l^3+\frac{m\,l^2}{\varphi}\right)\frac{e^2}{2}$. Therefore $m\,\theta+\theta$, the aberration (neglecting the thickness of the lens) is $f^2\,\frac{m-1}{m}\left(\frac{k^3}{m}-\frac{k^2}{r}-m^2\,l^3+\frac{m\,l^2}{\varphi}\right)\frac{e^2}{2}$.

If we now write for k, l, and φ, their values as determined above, performing all the necessary multiplications, and arrange the terms in such a manner as to collect in one sum the coefficients of a, n, and r, we shall find 4 terms for the value of $m\,\theta$, and 10 for the value of θ'. The 4 are destroyed by as many with contrary signs in the value of θ', and there remain 6 terms to express the value of $m\theta+\theta'$, which we shall express by one symbol q; and the equation stands thus;

$$q=\frac{m-1}{m}\left(\frac{m^3}{n^3}-\frac{2m^2+m}{a\,n^2}+\frac{m+2}{a^2\,n}+\frac{3\,m^2+m}{r\,n^2}-\frac{4\,m+4}{a\,r\,n}+\frac{3m+2}{r^2\,n}\right)\frac{e^2}{2}.$$

The focal distance therefore of rays twice refracted, reckoned from the last surface, or BI, corrected for aberration, and for the thickness of the lens, is $f-f\,\frac{m\,\alpha}{\varphi^2}-f^2\,q$, consisting of three parts, viz. f, the focal distance of central rays; $f^2\frac{m\,\alpha}{\varphi^2}$, the correction for the thickness of the lens; and $f^2\,q$, the aberration.

The formula at the top of this column appears very complex, but is of very easy management, requiring only the preparation of the simple numbers which form the numerators of the fractions included in the parenthesis. When the incident rays are parallel, the terms vanish which have r in the denominator, so that only the three first terms are used.

We might here point out the cases which reduce the aberration expressed in the formula last referred to, to nothing; but as they can scarcely occur in the object-glass of a telescope, we omit it for the present, and proceed to the combination of two or more lenses.

Lemma 3. If AG be changed by a small quantity Gg, BI suffers a change I i, and Gg : I i=AG^2 : BI^2. For it is well known that the small angles GMg and INi are equal; and therefore their subtenses Gk, In are proportional to MG, NI, or to AG, AI nearly, when the aperture is moderate. Therefore we have (nearly)

Gk : In : AG : BI
In : Ii=AM : BI
Gg : Gk=AG : AM
Therefore Gg : Ii=AG^2 : BI^2

PROP. III. To determine the focal distance of rays refracted by two lenses placed near to each other on a common axis.

Let AM, BN (fig. 11.) be the surfaces of the first lens, and CO, DP be the surfaces of the second, and let β be the thickness of the second lens, and δ the interval between them. Let the radius of the anterior surface of the second lens be a', and the radius of its posterior surface be b'. Let m' be to 1 as the sine of incidence to the sine of refraction in the substance of the second lens. Lastly, let p' be the principal focal distance of the second lens. Let the extreme or marginal ray meet the axis in L after passing through both lenses, so that DL is the ultimate focal distance, reckoned from the last surface. Fig. 11.

It is plain that DL may be determined by means of a', b', m', p', and CI, in the same manner that BI was determined by means of a, b, m, p, and AG.

The value of BI is $f-m\,\alpha\,\frac{f^2}{\varphi^2}-f^2\,q$. Take from this the interval δ, and we have CI$=f-m\,\alpha\,\frac{f^2}{\varphi^2}-\delta-f^2\,q$. Let the small part $-m\,\alpha\,\frac{f^2}{\varphi^2}-\delta-f^2\,q$ be neglected for the present, and let CI be supposed $=f$. As we formed φ, f, and q, by means of a, b, m, n, and r,

r, let us now form φ', f', and q', for the second lens, by means of a', b', m', n', $\left(=\frac{1}{a'}-\frac{1}{b'}\right)$, and r'. φ' will be the focal distance of a slender pencil refracted by the first surface, f will be the focal distance of this pencil after two refractions, and q' will be the coefficient of the aberration, neglecting the thickness and interval of the lenses.

Proceeding in this way, DL will be $=f'-m\beta\frac{f^2}{\varphi}-f'^2 q$. But because CI is really less than f, by the quantity $m\alpha\frac{f^2}{\varphi'^2}+\partial+f^2 q'$, we must (by Lemma 3.) subtract the product of this quantity, multiplied by $\frac{\mathrm{DL}}{\mathrm{BI}^2}$, (which is nearly $\frac{f'^2}{f^2}$), from $f'-m\beta\frac{f'^2}{\varphi'^2}f'^2 q'$.

By this process we shall have

$$\mathrm{DL}=f'-f'^2\left(\frac{m\alpha}{\varphi^2}+\frac{\partial}{f^2}+\frac{m'\beta}{\varphi'^2}\right)-f'^2(q+q').$$

The first term f' of this value of DI is the focal distance of a slender pencil of central rays refracted by both lenses, neglecting their thickness and distance; the second term, $-f'^2\left(\frac{m\alpha}{\varphi^2}+\frac{\partial}{f^2}+\frac{m'\beta}{\varphi'^2}\right)$ is the correction necessary for these circumstances; and the third term, $-f'^2(q+q')$, is the correction for the aperture $2e$. And it is evident that q' is a formula precisely similar to q, containing the same number of terms, and differing only by the m', a', n', and r', employed in place of m, a, n, and r.

It is also evident, that if there be a third lens, we shall obtain its focal distance by a process precisely similar to that by which we obtained DL; and so on for any number of lenses.

Thus have we obtained formulæ by which the foci of rays are determined in the most general terms, and in such a manner as shall point out the connection of the curvatures, thicknesses, and distances of the lenses, with their spherical aberrations, and with the final aberration of the compound lens, and give the aberrations in separate symbols, so that we can treat them by themselves, and subject them to any conditions which may enable us to correct one of them by another.

We also see in general, that the corrections for the thickness and distance of the lenses are exhibited in terms which involve only the focal distances of central rays, and have very little influence on the aberrations, and still less on the ratio of the aberrations of the different lenses. This is a most convenient circumstance; for we may neglect them while we are determining q and q', and in determining the ratio of the focal distances of the several lenses, on which the correction of the chromatic abberration chiefly depends. Therefore, in the construction of a compound lens for uniting the different colours, we may neglect this correction for the thickness and distance till the end of the process. When we apply it, we shall find that it chiefly affects the final focal distance, making it somewhat longer, but has hardly any influence either on the chromatic or spherical aberration. We do not hesitate to say, that the final formulæ here given are abundantly accurate, while they are vastly more manageable than those employed by Euler or D'Alembert. We have calculated trigonometrically the progress of the rays through one of the glasses, which will be given as an example, giving it a very extravagant aperture, that the errors of the formulæ might be very remarkable. We found the real aberration exceed the aberration assigned by the formula by no more than $\frac{1}{35}$th part, a difference which is quite insignificant. The process here given derives its simplicity from the frequent occurrence of harmonic proportions in all optical theorems. This enabled Mr Clairaut to employ the reciprocals of the radii and distances with so much simplicity and generality.

We consider it as another advantage of Mr Clairaut's method, that it gives, by the way, formulæ for the more ordinary questions in optics, which are of wonderful simplicity, and most easily remembered. The chief problems in the elementary construction of optical instruments relate to the focal distances of central rays. This determines the focal distances and arrangement of the glasses. All the rest may be called the refinement of optics; teaching us how to avoid or correct the indistinctness, the colours and the distortions, which are produced in the images formed by these simple constructions. We shall mention a few of these formulæ which occur in our process, and tend greatly to abbreviate it when managed by an experienced analyst.

Let m be to 1 as the sine of incidence to the sine of refraction; let a and b be the radii of the anterior and posterior surfaces of a lens; let r be the distance of the radiant point, or the focus of incident central rays, and f the distance of the conjugate focus; and let p be the principal focal distance of the lens, or the focal distance of parallel rays. Make $\frac{1}{n}$ equal to all $\frac{1}{a}-\frac{1}{b}$; let the same letters a', b', r', &c. express the same things for a second lens; and a'', b'', r'', &c. express them for a third; and so on. Then we have $\frac{1}{f}=\frac{m-1}{n}+\frac{1}{r}$; $\frac{1}{f'}=\frac{m'-1}{n'}+\frac{1}{r'}$; $\frac{1}{f''}=\frac{m''-1}{n''}+\frac{1}{r''}$, &c.

Therefore when the incident light is parallel, and r infinite, we have $\frac{1}{p}=\frac{m-1}{n}$; $\frac{1}{p'}=\frac{m'-1}{n'}$; $\frac{1}{p''}=\frac{m''-1}{n''}$, &c.

And when several lenses are contiguous, so that their intervals may be neglected, and therefore $\frac{1}{f}$, belonging to the first lens, becomes $\frac{1}{r}$, belonging to the second, we have

$$1.\ \frac{1}{r'}=\frac{1}{f}=\frac{m-1}{n}+\frac{1}{r},=\frac{1}{p}+\frac{1}{r}.$$

$$2.\ \frac{1}{r''}=\frac{1}{f'},=\frac{m'-1}{n'}+\frac{m-1}{n}+\frac{1}{r},=\frac{1}{p'}+\frac{1}{p}+\frac{1}{r}.$$

$$3.\ \frac{1}{f''}=\frac{m''-1}{n''}+\frac{m'-1}{n}+\frac{m-1}{n}+\frac{1}{r},=\frac{1}{p''}+\frac{1}{p'}+\frac{1}{p}+\frac{1}{r}.$$

Nothing can be more easily remembered than these formulæ, how numerous so ever the glasses may be.

Having thus obtained the necessary analysis and formula,

mula, it now remains to apply them to the construction of achromatic lenses; in which it fortunately happens, that the employment of several surfaces, in order to produce the union of the differently refrangible rays, enables us at the same time to employ them for correcting each other's spherical aberration.

In the article OPTICS we gave a general notion of the principle on which we may proceed in our endeavours to unite the differently refrangible rays. A white or compounded ray is separated by refraction into its component coloured rays, and they are diffused over a small angular space. Thus it appears, that the glass used by Sir Isaac Newton in his experiments diffused a white ray, which was incident on its posterior surface in an angle of 30°, in such a manner that the extreme red ray emerged into air, making an angle of 50° $21\frac{1}{3}'$ with the perpendicular; the extreme violet ray emerged in an angle of 51° $15\frac{1}{3}'$; and the ray which was in the confines of green and blue, emerged in an angle of 50° $48\frac{1}{7}'$. If the sine of the angle 30° of incidence be called 0.5, which it really is, the sine of the emergence of the red ray will be 0.77; that of the violet ray will be 0.78; and that of the intermediate ray will be $0.77\frac{1}{2}$, an exact mean between the two extremes. This ray may therefore be called the mean refrangible ray, and the ratio of $77\frac{1}{2}$ to 50, or of 1.55 to 1, will very properly express the mean refraction of this glass; and we have for this glass $m=1.55$. The sine of refraction, being measured on a scale, of which the sine of incidence occupies 100 parts, will be 154 for the red ray, 155 for the mean ray, and 156 for the violet ray. This number, or its ratio to unity, is commonly taken to represent the refractive power of the glass. There is some impropriety in this, unless we consider ratios as measured by their logarithms: for if m be 1, the substance does not refract at all. The refractive power can be properly measured only by the refraction which it produces; that is, by the change which it makes in the direction of the light, or the angle contained between the incident and refracted rays. If two substances produce such deviations always in one proportion, we should then say that their refractive powers are in that proportion. This is not true in any substances; but the sines of the angles, contained between the refracted ray and the perpendicular, are always in one proportion when the angle of incidence in both substances is the same. This being a cognisable function of the real refraction, has therefore been assumed as the only convenient measure of the refractive powers. Although it is not strictly just, it answers extremely well in the most usual cases in optical instruments: the refractions are moderate; and the sines are very nearly as the angles contained between the rays and the perpendicular; and the real angles of refraction, or deflections of the rays, are almost exactly proportional to $m-1$. The most natural and obvious measure of the refractive powers would therefore be $m-1$. But this would embarrass some very frequent calculations; and we therefore find it best, on the whole, to take m itself for the measure of the refractive power.

The separation of the red, violet, and intervening rays, has been called *dispersion;* and although this arises merely from a difference of the refractive power in respect of the different rays, it is convenient to distinguish this particular modification of the refractive power by a name, and we call it the DISPERSIVE POWER of the refracting substance.

It is susceptible of degrees; for a piece of flint-glass will refract the light, so that when the sine of refraction of the red ray is 77, the sine of the refraction of the violet ray is nearly $78\frac{1}{2}$; or if the sine of refraction of the red ray, measured on a particular scale, is 1.54, the sine of refraction of the violet ray is 1.57. The dispersion of this substance, being measured by the difference of the extreme sines of refraction, is greater than the dispersion of the other glass, in the proportion of 3 to 2.

But this alone is not a sufficient measure of the absolute dispersive power of a substance. Although the ratio of 1.54 to 1.56 remains constant, whatever the real magnitude of the refractions of common glass may be, and though we therefore say that its dispersive power is constant, we know, that by increasing the incidence and the refraction, the absolute dispersion is also increased. Another substance shows the same properties, and in a particular case may produce the same dispersion; yet it has not for this sole reason the same dispersive power. If indeed the incidence and the refraction of the mean ray be also the same, the dispersive power cannot be said to differ; but if the incidence and the refraction of the mean ray be less, the dispersive power must be considered as greater, though the actual dispersion be the same; because if we increase the incidence till it becomes equal to that in the common glass, the dispersion will now be increased. The proper way of conceiving the dispersion therefore is, to consider it as a portion of the whole refraction; and if we find a substance making the same dispersion with half the general refraction, we must say that the dispersive quality is double; because by making the refraction equal, the dispersion will really be double.

If therefore we take $\dot{m}$ as a symbol of the separation of the extreme rays from the middle ray, $\frac{\dot{m}}{m-1}$ is the natural measure of the dispersive power. We shall express this in the Leibnitzian notation, thus $\frac{dm}{m-1}$, that we may avoid the indistinctness which the Newtonian notation would occasion when m is changed for m' or m''.

It is not unusual for optical writers to take the whole separation of the red and violet rays for the measure of the dispersive power, and to compare this with the refracting power with respect to one of the extreme rays. But it is surely better to consider the mean refraction as the measure of the refracting power: and the deviation of either of the extremes from this mean is a proper enough measure of the dispersion, being always half of it. It is attended with this convenience, that being introduced into our computations as a quantity infinitely small, and treated as such for the ease of computation; while it is really a quantity of sensible magnitude; the errors arising from this supposition are diminished greatly, by taking one half of the deviation, and comparing it with the mean refraction. This method has, however, this inconvenience, that it does not exhibit at once the refractive power in all substances respecting any particular colour of light; for it is not the ray of any particular colour that suffers the mean refraction. In common glass it is the ray which is in the confines of the yellow and blue; in flint-glass it is nearly the middle

Telescope.

dle blue ray; and in other substances it is a different ray. These circumstances appear plainly in the different proportions of the colours of the prismatic spectrum exhibited by different substances. This will be considered afterwards, being a great bar to the perfection of achromatic instruments.

The way in which an achromatic lens is constructed is, to make use of a contrary refraction of a second lens to destroy the dispersion or spherical aberration of the first.

The first purpose will be answered if $\frac{dm}{n}$ be equal to $-\frac{dm'}{n'}$. For, in order that the different coloured rays may be collected into one point by two lenses, it is only necessary that $\frac{1}{f'}$, the reciprocal of the focal distance of rays refracted by both, may be the same for the extreme and mean rays, that is, that $\frac{m+dm-1}{n}+\frac{m'+dm'-1}{n'}+\frac{1}{r}$ be of the same value with $\frac{m-1}{n}+\frac{m'-1}{n'}+\frac{1}{r}$, which must happen if $\frac{dm}{n}+\frac{dm'}{n'}$ be $=0$, or $\frac{dm}{n}=-\frac{dm'}{n}$. This may be seen in another way, more comprehensible by such as are not versant in these discussions. In order that the extreme colours which are separated by the first lens may be rendered parallel by the second; we have shown already that n and n' are proportional to the radii of the equivalent isosceles lenses, being the halves of these radii. They are therefore (in these small refractions) inversely proportional to the angles formed by the surfaces at the edges of the lenses. n' may therefore be taken for the angle of the first lens, and n for that of the second. Now the small refraction by a prism, whose angle (also small) is n', is $\overline{m-1}\times n$. The dispersive power being now substituted for the refractive power, we have for this refraction of the prism $dm\times n'$. This must be destroyed by the opposite refraction of the other prism $dm'\times n$. Therefore $dm\times n'=dm'\times n$, or $\frac{dm}{n}=-\frac{dm'}{n'}$. In like manner, this effect will be produced by three lenses if $\frac{dm}{n}+\frac{dm'}{n'}+\frac{dm''}{n''}$ be $=0$, &c.

Lastly, the errors arising from the spherical figure, which we expressed by $-R^2\ (q+q')$ will be corrected if $q+q'$ be $=0$. We are therefore to discover the adjustments of the quantities employed in the preceding formulæ, which will insure these conditions. It will render the process more perspicuous if we collect into one view the significations of our various symbols, and the principal equations which we are to employ.

1. The ratios to unity of the sines of mean incidence in the different media are - m, m' m''.
2. The ratio of the differences of the sines of the extremes - - - - $\frac{dm}{dm'}$, $=u$.
3. The ratio $\frac{m-1}{m'-1}$ - - - - - $=c$.
4. The radii of the surfaces $a, b;\ a', b';\ a'', b''$.
5. The principal focal distances, or the focal distances of parallel central rays, - p, p', p''.
6. The focal distance of the compound lens P.
7. The distance of the radiant point, or of the focus of incident rays on each lens r, r', r''.
8. The focal distance of the rays refracted by each lens - - - - f, f', f''.
9. The focal distance of rays refracted by the compound lens - - - - F.
10. The half breadth of the lens - - - e.

Also the following subsidiary values:

1. $\frac{1}{n}=\frac{1}{a}-\frac{1}{b};\ \frac{1}{n'}=\frac{1}{a'}-\frac{1}{b'};\ \frac{1}{n''}=\frac{1}{a''}-\frac{1}{b''}.$

2. $q=\frac{m-1}{m}\left(\frac{m'^3}{n^3}-\frac{2m^2+m}{an^2}+\frac{m+2}{a^2n}+\frac{3m^2+m}{rn^2}-\frac{4(m+1)}{arn}+\frac{3m+2}{r^2n}\right)\frac{e^2}{2}$. And q' and q'' must be formed in the same manner from m', a', n', r'; and from m'', a'', n'', r'', as q is formed from m, a, n, r.

3. Also because in the case of an object-glass, r is infinitely great, the last term $\frac{1}{r}$ in all the values of $\frac{1}{f}$, $\frac{1}{f'}$, $\frac{1}{f''}$, $\frac{1}{r'}$, $\frac{1}{r''}$, will vanish, and we shall also have F=P.

Therefore in a double object-glass $\frac{1}{P}=\frac{m'-1}{n'}+\frac{m-1}{n}=\frac{1}{p}+\frac{1}{p'}$.

And in a triple object-glass $\frac{1}{P}=\frac{m''-1}{n''}+\frac{m'-1}{n'}+\frac{m-1}{n},=\frac{1}{p''}+\frac{1}{p'}+\frac{1}{p}$.

Also, in a double object-glass, the correction of spherical aberration requires $q+q'=v$.

And a triple object-glass requires $q+q'+q''=v$. For the whole error is multiplied by F^2, and by $\frac{1}{2}e^2$; and therefore the equation which corrects this error may be divided by $F^2\ \frac{1}{2}\ e^2$.

This equation in the fourteenth line from the top of the column, giving the value of q, q', q'', may be much simplified as follows: In the first place, they may be divided by m, m', or m'', by applying them properly to the terms within the parenthesis, and expunging them from the denominator of the general factors $\frac{m-1}{m}$, $\frac{m'-1}{m'}$, $\frac{m''-1}{m''}$. This does not alter the values of q, q', and q''. In the second place the whole equations may be afterwards divided by $m'-1$. This will give the values of $\frac{q}{m'-1}$, $\frac{q'}{m'-1}$, and $\frac{q''}{m'-1}$, which will still be equal to nothing if $q+q'+q''$ be equal to nothing.

This division reduces the general factor $\frac{m'-1}{m'}$ of q' to $\frac{1}{m'}$. And in the equation for q we obtain, in place of the general factor $\frac{m-1}{m}$, the factor $\frac{m-1}{m'-1}$, or c. This will also be the factor of the value of q'' when the third lens is of the same substance with the first, as is general-

 ly

Telescope.

ly the case. And, in the third place, since the rays incident on the first lens are parallel, all the terms vanish from the value of q in which $\frac{1}{r}$ is found, and there remain only the three first, viz. $\frac{m^3}{n^3}-\frac{2m^2+m}{an^2}+\frac{m+2}{a^2n}$.

Performing these operations, we have

$$\frac{q}{m'-1}=c\left(\frac{m^2}{n^3}-\frac{2m+1}{an^2}+\frac{m+2}{ma^2n}\right)\frac{e^2}{2}$$

$$\frac{q'}{m'-1}=\left(\frac{m'^2}{n'^3}-\frac{2'm+1}{a'n'2}+\frac{m'+2}{m'a'^2n'}+\frac{3m'+1}{r'n'^2}-\frac{(4m'+1)}{m'a'r'n'}+\frac{3'm+2}{m'r'^2n'}\right)\frac{e^2}{2}$$

$$\frac{q''}{m'-1}=c\left(\frac{m^2}{n''^3}-\frac{2m+1}{a''n''^2}+\frac{m+2}{m''a''^2n''}+\frac{3m+1}{r''n''^2}+\frac{(4m+1)}{m''a''r''n''}+\frac{3m+2}{m''r''^2n''}\right)\frac{e^2}{2}.$$

Let us now apply this investigation to the construction of an object-glass; and we shall begin with a double lens.

Construction of a Double Achromatic Object-glass.

Here we have to determine four radii a, b, a', and b'. Make $n=1$. This greatly simplifies the calculus, by exterminating it from all the denominators. This gives for the equation $\frac{dm}{n}+\frac{dm'}{n'}=0$, the equation $dm+\frac{dm'}{n'}=0$, or $dm=-\frac{dm'}{n'}$, and $\frac{1}{n'}=-\frac{dm}{dm'}, =-u$. Also we have r', the focal distance of the light incident on the second lens, the same with the principal focal distance p of the first lens, (neglecting the interval, if any). Now $\frac{1}{p}=\frac{m-1}{n}$, which in the present case is $=m-1$. Also $\frac{1}{p}$ is $=-u(m'-1)$, and $\frac{1}{P}=m-1-u(m'-1)=u'$.

Make these substitutions in the values of $\frac{q}{m-1}$ and $\frac{q'}{m'-1}$, and we obtain the following equation:

$$cm^2-\frac{c(2m+1)}{a}+\frac{c(m+2)}{ma^2}-u^3m'^2-\frac{u^2(2m'+1)}{a'}-\frac{u(m'+2)}{m'a'^2}+u^2(3m'+1)(m-1)+\frac{4u(m'+1)(m-1)}{m'a'}-\frac{u(3m'+2)(m-1)^2}{m'}=0.$$

Arrange these terms in order, according as they are factors of $\frac{1}{a^2}$, $\frac{1}{a}$, $\frac{1}{a'^2}$, $\frac{1}{a'}$, or independent quantities. It puts on this form:

$$\frac{c(m+2)}{m}\times\frac{1}{a^2}-c'(2m+1)\times\frac{1}{a}-\frac{u(m'+2)}{m'}\times\frac{1}{a'^2}-\left(u^2(2m'+1)-\frac{4u(m'+1)(m-1)}{m'}\right)\times\frac{1}{a'}+cm^2+u^2(3m'+1)(m-1)-u^3m'^2-\frac{u(3m'+2)(m-1)^2}{m'}=0.$$

Let A be the coefficient of $\frac{1}{a^2}$, B that of $\frac{1}{a}$, C that of $\frac{1}{a'^2}$, D that of $\frac{1}{a'}$, and E the sum of the independent quantity; that is, let A be $=\frac{c(m+2)}{m}$, $B=c(2m+1)$, $C=\frac{u(m'+2)}{m'}$, $D=u^2(2m'+2)-\frac{4u(m'+1)(m-1)}{m'}$ and $E=cm^2+u^2(3m'+1)(m-1)-u^3m^2-\frac{u(3m'+2)(m-1)^2}{m'}$.

Telescope.

Our final equation becomes

$$\frac{A}{a^2}-\frac{B}{a}-\frac{C}{a'^2}-\frac{D}{a'}+E=0.$$

The coefficients of this equation and the independent quantity are all known, from our knowledge of m, m' dm, dm'; and we are to find the value of a and a', and from them and $n=1$ to find the values of b and b'.

But it is evidently an indeterminate equation, because there are two unknown quantities; so that there may be an infinity of solutions. It must be rendered determinate by means of some other conditions to which it may be subjected. These conditions must depend on some other circumstances which may direct our choice.

One circumstance occurs to us which we think of very great consequence. In the passage of light from one substance to another, there is always a considerable portion reflected from the posterior surface of the first and from the anterior surface of the last; and this reflection is more copious in proportion to the refraction. This loss of light will therefore be diminished by making the internal surfaces of the lenses to coincide; that is, by making $b=a'$. This will be attended with another advantage. If we put between the glasses a substance of nearly the same refracting power, we shall not only completely prevent this loss of light, but we shall greatly diminish the errors which arise from an imperfect polish of the surfaces. We have tried this, and find the effect very surprising. The lens being polished immediately after the figure has been given it, and while it was almost impervious to light by reason of its roughness, which was still sensible to the naked eye, performed as well as when finished in the finest manner.

N. B. This condition, by taking away one refraction, obliges us to increase those which remain, and therefore increases the spherical aberrations. And since our formulæ do not fully remove those (by reason of the small quantities neglected in the process), it is uncertain whether this condition be the most eligible. We have, however, no direct argument to the contrary.

Let us see what determination this gives us.

In this case $\frac{1}{a'}=\frac{1}{b}, =\frac{1}{a}-1$. For because $\frac{1}{n}=\frac{1}{a}-\frac{1}{b}$ and $n=1$, we have $1+\frac{1}{b}=\frac{1}{a}$, and $\frac{1}{b}=\frac{1}{a}-1$. Therefore $\frac{1}{a'^2}=\frac{1}{a^2}-\frac{2}{a}+1$. Therefore, in our final equation, put $\frac{1}{a^2}-\frac{2}{a}+1$ in place of $\frac{1}{a'^2}$, and $\frac{1}{a}-1$ in place

place

place of $\frac{1}{a'}$, and it becomes $\frac{A-C}{a^2}-\frac{B+D-2C}{a}+E+D-C=0$.

Thus have we arrived at a common affected quadratic equation, where $\frac{1}{a}$ is the unknown quantity. It has the common form $px^2+qx+r=0$, where p is $=A-C$, q is equal to $2C-B-D$, r is equal to $E+D-C$, and x is equal to $\frac{1}{a}$.

Divide the equation by p, and we have $x^2+\frac{q}{p}x+\frac{r}{p}=0$. Make $s=\frac{q}{p}$ and $t=\frac{r}{p}$, and we have $x^2+sx+t=0$. This gives us finally $\frac{1}{a}$, or $x=-\frac{1}{2}s\pm\sqrt{\frac{1}{4}s^2-t}$.

This value of $\frac{1}{a}$ is taken from a scale of which the unit is half the radius of the isosceles lens which is equivalent to the first lens, or has the same focal distance with it. We must then find (on the same scale) the value of b, viz. $\frac{1}{a}-1$, which is also the value of a', Having obtained a', we must find b' by means of the equation $\frac{1}{n'}=\frac{1}{a'}-\frac{1}{b'}$, and therefore $\frac{1}{b}=\frac{1}{a'}-\frac{1}{n'}$. But $\frac{1}{n'}=u$. Therefore $\frac{1}{b'}=\frac{1}{a'}+u, =\frac{1}{a}+u-1$.

Thus is our object-glass constructed; and we must determine its focal distance, or its reciprocal $\frac{1}{P}$. This is $=m-1-u\,(m'-1)$.

All these radii and distances are measured on a scale of which n is the unit. But it is more convenient to measure every thing by the focal distance of the compound object-glass. This gives us the proportion which all the distances bear to it. Therefore, calling P unity, in order to obtain $\frac{1}{a}$ on this scale, we have only to state the analogy $m-1-u\,(m'-1):1=\frac{1}{a}:\frac{1}{A}$, and A is the radius of our first surface measured on a scale of which P is the unit.

If, in the formula which expresses the final equation for $\frac{1}{a}$, the value of t should be positive, and greater than $\frac{1}{4}s^2$, the equation has imaginary roots; and it is not possible with the glasses employed, and the conditions assumed, to correct both the chromatic and spherical aberrations.

If t is negative and equal to $\frac{1}{4}s^2$, the radical part of the value is $=0$, and $\frac{1}{a}=-\frac{1}{2}s$. But if it be negative or positive, but less than $\frac{1}{4}s^2$, the equation has two real roots, which will give two constructions. That is to be preferred which gives the smallest curvature of the surfaces; because, since in our formulæ which determine the spherical aberration some quantities are neglected, these quantities are always greater when a large arch (that is, an arch of many degrees) is employed. No radius should be admitted which is much less than $\frac{1}{3}$ of the focal distance.

All this process will be made plain and easy by an example.

Very careful experiments have shown, that in common crown-glass the sine of incidence is to the sine of refraction as 1.526 is to 1, and that in the generality of flint-glass it is as 1.604 to 1. Also that $\frac{dm}{dm'}=0.6054=u$. Therefore $m-1=0.526$; $m'-1=0.604$; $c=\frac{m-1}{m'-1}, =0.87086$. By these numbers we can compute the coefficients of our final equation. We shall find them as follows:

$$\begin{aligned} A&=2.012\\ B&=3.529\\ C&=1.360\\ D&=-0.526\\ E&=1.8659\end{aligned}$$

The general equation (p. 252. col. 2. lin. 8.), when subjected to the assumed coincidence of the internal surfaces, is $\frac{A-C}{a^2}-\frac{B+D-2C}{a}+E+D-C=0$. $A-C$ is $=0.652$; $B+D-2C$ is $=0.283$; and $E+D-C$ is $=-0.020$; and the equation with numerical coefficients is $\frac{0.652}{a^2}-\frac{0.283}{a}-0.020=0$, which corresponds to the equation $px^2+qx+r=0$. We must now make $s=\frac{q}{p}, =\frac{0.283}{0.652}, =0.434$, and $t=\frac{r}{p}, =\frac{0.02}{0.652}, =0{,}0307$.

This gives us the final quadratic equation $\frac{1}{a^2}-\frac{0.434}{a}-0.0307=0$. To solve this, we have $-\frac{1}{2}s=0.217$, and $\frac{1}{4}s^2-0.0471$. From this take t, which is $=-0.0307$ (that is, to 0.0471 add 0.0307), and we obtain 0.0778, the square root of which is $=0.2789$. Therefore, finally, $\frac{1}{a}=0.2170\pm0.2789$, which is either 0.4959 or -0.0619. It is plain that the first must be preferred, because the second gives a negative radius, or makes the first surface of the crown-glass concave. Now as the convergence of the rays is to be produced by the crown-glass, the other surface must become very convex, and occasion great errors in the computed aberration. We therefore retain 0.4959 for the value of $\frac{1}{a}$, and a is $=\frac{1}{0.4959}, =2.0166$.

To obtain b, use the equation $\frac{1}{b}=\frac{1}{a}-1$, which gives $\frac{1}{b}=-0.5041$, and therefore a convex surface. b is therefore $=\frac{1}{0.5041}=1.9837$.

a' is the same with b, and $\frac{1}{a'}=-0.5041$.

To obtain b', use the equation $\frac{1}{b'}=\frac{1}{a'}+u$. Now $u=0.6054$, and $\frac{1}{a'}=-0.5041$. The sum of these is 0.1013;

0.1013; and since it is positive, the surface is concave.

$b' = \frac{1}{.1013} = 9.872.$

Lastly, $\frac{1}{P} = m - 1 - u\ (m' - 1) = 0.1603$, and $P = \frac{1}{0.1603}, = 0.2383.$

Now to obtain all the measures in terms of the focal distance P, we have only to divide the measures already found by 6.2383, and the quotients are the measures wanted.

$$\begin{aligned} \text{Therefore } a &= \frac{2.0166}{6.2383} = 0.32325 \\ b &= \frac{1.9837}{6.2383} = -0.31798 \\ a' &= \quad - \ - \quad = -0.31798 \\ b' &= \frac{9.872}{6.2383} = \ \ 1.5825 \\ P &= \quad - \quad \ \ 1. \end{aligned}$$

If it be intended that the focal distance of the object-glass shall be any number n of inches or feet, we have only to multiply each of the above radii by n, and we have their lengths in inches or feet.

Thus we have completed the investigation of the construction of a double object-glass. Although this was intricate, the final result is abundantly simple for practice, especially with the assistance of logarithms. The only troublesome thing is the preparation of the numerical coefficients A, B, C, D, E of the final equation. Strict attention must also be paid to the positive and negative signs of the quantities employed.

We might propose other conditions. Thus it is natural to prefer for the first or crown-glass lens such a form as shall give it the smallest possible aberration. This will require a small aberration of the flint-glass to correct it. But a little reflection will convince us that this form will not be good. The focal distance of the crown-glass must not exceed one-third of that of the compound glass; these two being nearly in the proportion of $dm' - dm$ to dm'. Therefore if this form be adopted, and a be made about $\frac{1}{6}$th of b, it will not exceed $\frac{1}{7}$th of P. Therefore, although we may produce a most accurate union of the central and marginal rays by opposite aberrations, there will be a considerable aberration of some rays which are between the centre and the margin.

It is absolutely impossible to collect into one point the whole rays (though the very remotest rays are united with the central rays), except in a very particular case, which cannot obtain in an object-glass; and the small quantities which are neglected in the formula which we have given for the spherical aberration, produce errors which do not follow any proportion of the aperture which can be expressed by an equation of a manageable form. When the aperture is very large, it is better not to correct the aberration for the whole aperture, but for about $\frac{5}{6}$ths of it. When the rays corresponding to this distance are made to coincide with the central rays by means of opposite aberrations, the rays which are beyond this distance will be united with some of those which are nearer to the centre, and the whole diffusion will be considerably diminished. Dr Smith has illustrated this in a very perspicuous manner in his theory of his Catoptric Microscope.

But although we cannot adopt this form of an object-glass, there may be other considerations which may lead us to prefer some particular form of the crown-glass, or of the flint-glass. We shall therefore adapt our general equation $\frac{A}{a^2} - \frac{B}{a} - \frac{C}{a'^2} - \frac{D}{a'} + E = 0$ to this condition.

Therefore let h express this selected ratio of the two radii of the crown-glass, making $\frac{a}{b} = h$ (remembering always that a is positive and b negative in the case of a double convex, and h is a negative number).

With this condition we have $\frac{1}{b} = \frac{h}{a}$. But when we make n the unit of our formula of aberration, $\frac{1}{b} = \frac{1}{a} - 1$. Therefore $1 = \frac{1}{a} - \frac{h}{a}$, and $\frac{1}{a} = \frac{1}{1-h}$. Now substitute this for $\frac{1}{a}$ in the general equation, and change all the signs (which still preserves it $=0$), and we obtain

$$\frac{C}{a'^2} + \frac{D}{a'} - E - \frac{A}{(1-h)^2} + \frac{B}{1-h} = 0.$$

By this equation we are to find $\frac{1}{a'}$, or the radius of the anterior surface of the flint-glass. The equation is of this form $px^2 + qx + r = 0$, and we must again make $s = \frac{q}{p}$ and $t = \frac{r}{p}$. Therefore $s = \frac{D}{C}$, and $t = \frac{1}{C} \times \left(\frac{B}{1-h} - \frac{A}{(1-h)^2} - E\right)$. Then, finally,

$$\frac{1}{a'} = -\tfrac{1}{2}s \pm \sqrt{\tfrac{1}{4}s^2 - t}.$$

It may be worth while to take a particular case of this condition. Suppose the crown-glass to be of equal convexities on both sides. This has some advantages: We can tell with precision whether the curvatures are precisely equal, by measuring the focal distance of rays reflected back from its posterior surface. These distances will be precisely equal. Now it is of the utmost importance in the construction of an object-glass which is to correct the spherical aberration, that the forms be precisely such as are required by our formulæ.

In this case of a lens equally convex on both sides $\frac{1}{a}$ is $= -\frac{1}{b}, = \frac{1}{2}$. Substitute this value for $\frac{1}{a}$ in the general equation $\frac{A}{a^2} - \frac{B}{a} - \frac{C}{a'^2} - \frac{D}{a'} + E = 0$, and then $\frac{A}{a^2} = \frac{A}{4}$; $\frac{B}{a}$ becomes $\frac{B}{2}$. Now change all the signs, and we have $\frac{C}{a'^2} + \frac{D}{a'} - E - \frac{A}{4} + \frac{B}{2} = 0$, by which we are to find a'. This in numbers is $\frac{1.360}{a'^2} - \frac{0.526}{a'}$

$\frac{0.526}{a'} - 0.6044 = 0$. Then $s = \frac{-0.526}{1.360}, = 0.3867$, and $t = \frac{-0.6044}{1.360}, = -0.4444$. Then $-\frac{1}{2}s = 0.1933$; $\frac{1}{4}s^2 = 0.0374$; and $\sqrt{\frac{1}{4}S^2 - t} = \pm 0.6941$; so that $\frac{1}{a'} = 0.1933 \pm 0.6941$. This gives two real roots, viz. 0.8874, and −0.5008. If we take the first, we shall have a convex anterior surface for the flint-glass, and consequently a very deep concave for the posterior surface. We therefore take the second or negative root −0.5008.

We find $\frac{1}{b'}$, as before, by the equation $\frac{1}{b'} = \frac{1}{a'} + u, = 0.1046$, which will give a large value of b'.

We had $\frac{1}{a} = \frac{1}{2}$

and $\frac{1}{b} = -\frac{1}{2}$

and $\frac{1}{P}$ is the same as in the former case, viz. 0.1603.

Having all these reciprocals, we may find a, b, a', b', and P; and then dividing them by P, we obtain finally

$$\begin{aligned} a &= 0.3206 \\ b &= -0.3206 \\ a' &= -0.3201 \\ b' &= 1.533 \\ P &= 1. \end{aligned}$$

By comparing this object-glass with the former, we may remark, that diminishing a a little increases b, and in this respect improves the lens. It indeed has diminished b', but this being already considerable, no inconvenience attends this diminution. But we learn, at the same time, that the advantage *must* be very small; for we cannot diminish a much more, without making it as small as the smallest radius of the object-glass. This proportion is therefore very near the maximum, or best possible; and we know that in such cases, even considerable changes in the radii will make but small changes in the result: for these reasons we are disposed to give a strong preference to the first construction, on account of the other advantages which we showed to attend it.

As another example, we may take a case which is very nearly the general practice of the London artists. The radius of curvature for the anterior surface of the convex crown-glass is $\frac{5}{6}$ths of the radius of the posterior surface, so that $h = \frac{5}{6}$. This being introduced into the determinate equation, gives

$$\begin{aligned} a &= 0.2938 \qquad & a' &= -0.3443 \\ b &= -0.3526 \qquad & b &= 1.1474 \end{aligned}$$

As another condition, we may suppose that the second or flint-glass is of a determined form.

This case is solved much in the same manner as the former. Taking h to represent the ratio of a' and b', we have $\frac{1}{a'} = \frac{1}{1-h}$. This value being substituted in the general equation $\frac{A}{a^2} - \frac{B}{a} - \frac{C}{a'2} - \frac{D}{a} + E = 0$, gives us $\frac{A}{a^2} - \frac{B}{a} + E - \frac{C}{(1-h)^2} - \frac{D}{1-h} = 0$. This gives for the final equation $x^2 + sx + t = 0$, $s = \frac{B}{A}$, and $t = \frac{1}{A} \times \left(E - \frac{C}{(1-h)^2} - \frac{D}{1-h}\right)$ and $\frac{1}{a} = -\frac{1}{2}\,\frac{1}{2}\,s \pm \sqrt{\frac{1}{4}s^2 - t}$.

We might here take the particular case of the flint-glass being equally concave on both sides. Then because $\frac{1}{n'}, = -u$, and in the case of equal concavities $\frac{2}{a'} = \frac{1}{n'}, = -u$, it is sufficient to put $-\frac{1}{2}u$ for $\frac{1}{a'}$. This being done, the equation becomes $\frac{A}{a} - \frac{B}{a}\,\frac{Cu^2}{4} + \frac{Du}{2} + E = 0$. This gives $s = \frac{B}{A}$, and $t = \frac{1}{A} \times \left(\frac{4Dn - 2Cu^2}{8} + E\right)$.

We imagine that these cases are sufficient for showing the management of the general equation; and the example of the numerical solution of the first case affords instances of the only niceties which occur in the process, viz. the proper employment of the positive and negative quantities.

We have oftener than once observed, that the formula is not perfectly accurate, and that in very large apertures errors will remain. It is proper therefore, when we have obtained the form of a compound object-glass, to calculate trigonometrically the progress of the light through it; and if we find a considerable aberration, either chromatic or spherical, remaining, we must make such changes in the curvatures as will correct them. We have done this for the first example; and we find, that if the focal distance of the compound object-glass be 100 inches, there remains of the spherical aberration nearly $\frac{1}{60}$th of an inch, and the aberration of colour is over corrected above $\frac{1}{9}$th of an inch. The first aberration has been diminished about 6 times, and the other about 30 times. Both of the remaining errors will be diminished by increasing the radius of the inner surfaces. This will diminish the aberration of the crown-glass, and will diminish the dispersion of the flint more than that of the crown. But indeed the remaining error is hardly worth our notice.

It is evident to any person conversant with optical discussions, that we shall improve the correction of the spherical aberration by diminishing the refractions. If we employ two lenses for producing the convergency of the rays to a real focus, we shall reduce the aberration to $\frac{1}{4}$th. Therefore a better achromatic glass will be formed of three lenses, two of which are convex and of crown-glass. The refraction being thus divided between them, the aberrations are lessened. There is no occasion to employ two concave lenses of flint-glass; there is even an advantage in using one. The aberration being considerable, less of it will serve for correcting the aberration of the crown glass, and therefore such a form may be selected as has little aberration. Some light is indeed lost by these two additional surfaces; but this is much more than compensated by the greater apertures which we can venture to give when the curvature of the surface is so much diminished. We proceed therefore to

The Construction of a Triple Achromatic Object-glass.

It is plain that there are more conditions to be assumed

sumed before we can render this a determinate problem, and that the investigation must be more intricate. At the same time, it must give us a much greater variety of constructions, in consequence of our having more conditions necessary for giving the equation this determinate form. Our limits will not allow us to give a full account of all that may be done in this method. We shall therefore content ourselves with giving one case, which will sufficiently point out the method of proceeding. We shall then give the results in some other eligible cases, as rules to artists by which they may construct such glasses.

Let the first and second glasses be of equal curvatures on both sides; the first being a double convex of crown-glass, and the second a double concave of flint-glass.

Still making n the unit of our calculus, we have in the first place $a = -b, = -a', = b'$. Therefore $\frac{1}{a'} - \frac{1}{b'} = -\left(\frac{1}{a} - \frac{1}{b}\right)$, or $\frac{1}{n'} = -\frac{1}{n} = -1$. Therefore the equation $\frac{m}{n} + \frac{dm'}{n'} + \frac{dm''}{n''} = 0$ becomes $u - 1 + \frac{u}{u''} = 0$, or $\frac{1}{n} = \frac{1}{u} - 1$. Let us call this value u'.

We have $\frac{1}{p} = m - 1$; $\frac{1}{p'} = -(m' - 1)$; $\frac{1}{p''} = u'(m-1)$; $\frac{1}{P} = \frac{1}{p} + \frac{1}{p'} + \frac{1}{p''}, = m - m' + u'(m-1)$. And if we make $m' - m = C$, we shall have $\frac{1}{P} = -C, + u'(m=1)$. Also $\frac{1}{r'} = m - 1$; $\frac{1}{r''} = m - 1 - (m' - 1), = m - m', = -C'$.

The equality of the two curvatures of each lens gives $\frac{1}{a} = \frac{1}{2n}$. Therefore $\frac{1}{a} = -\frac{1}{b'}, = -\frac{1}{a'}, = \frac{1}{b'} = \frac{1}{2}$; and $\frac{1}{b''} = \frac{1}{a''} - \frac{1}{n''}, = \frac{1}{a''} - u$.

Substituting these values in the equation (p. 252. col. 2. par. 1.), we obtain the three formulæ.

$$1. \quad cm^2 - \tfrac{1}{2}c(2m+1) + \frac{c(m+2)}{4m}$$

$$2. -m'2 + \tfrac{1}{2}(2m'+1) - \frac{m'+2}{4m'} + (3m'+1)(m-1) - \frac{2(m'+1)(m-1)}{m'} - \frac{(3m'+2)(m-1)^2}{m'}$$

$$3. cu'\,3m^2 - \frac{cu'^2(2m+1)}{a''} + \frac{cu'(m+2)}{ma''^2} - cc'u'^2(3m+1) + \frac{4cc'u'(m+1)}{ma''} + \frac{cc'^2u'(3m+2)}{m} = 0.$$

Now arrange these quantities according as they are coefficients of $\frac{1}{a''^2}$ and of $\frac{1}{a''}$, or independent quantities.

Let the coefficient of $\frac{1}{a''^2}$ be A, that of $\frac{1}{a''}$ be B, and the independent quantity be C, we have $A = \frac{cu'(m+2)}{m}$; $B = cu'^2(2m+1) - \frac{4cc'u'(m+1)}{m}$, and $C = cm^2 + \frac{c(m+2)}{4m} + \frac{1}{2}(2m'+1) + (3m'+1)(m-1) + cu'^3m^2 + \frac{cc'^2u'(3m+2)}{m} - \frac{1}{2}c(2m+1) - m'^2 - \frac{m'+2}{4m} - \frac{2(m'+1)(m-1)}{m'} - \frac{(3m'+2)(m-1)^2}{m'} - cc'u'^2(3m+1)$.

Our equation now becomes $\frac{A}{a''^2} - \frac{B}{a''} + C = 0$.

This reduced to numbers, by computing the values of the coefficients, is $\frac{1.312}{a''^2} - \frac{1.207}{a''} - 0.3257 = 0$.

This, divided by 1.312, gives $s = -0.92$; and $t = -0{,}2482$; $-\frac{1}{2}s = 0.46$; $\frac{1}{4}s^2 = 0.2116$; and $\sqrt{\frac{1}{4}s^2 - t} = \pm 0.6781$.

And, finally, $\frac{1}{a''} = 0.46 \pm 0.6781$.

This has two roots, viz. 0.2181 and $-$ 1.1381. The last would give a small radius, and is therefore rejected.

Now, proceeding with this value of $\frac{1}{a''}$ and the $\frac{1}{n''}$, we get the other radius b'', and then, by means of u', we get the other radius which is common to the four surfaces. Then, by $\frac{1}{P} = \frac{1}{p''} - c'$, we get the value of P.

The radii being all on the scale of which u is the unit, they must be divided by P to obtain their value on the scale which has P for its unit. This will give us

$a = -b, = -a', = b',$	$=0.530$
$a'' =$	1.215
$b'' =$	-0.3046
P=	1.

This is not a very good form, because the last surface has too great curvature.

We thought it worth while to compute the curvatures for a case where the internal surfaces of the lenses coincide, in order to obtain the advantages mentioned on a former occasion. The form is as follows:

The middle lens is a double concave of flint-glass; the last lens is of crown-glass, and has equal curvatures on both sides. The following table contains the dimensions of the glasses for a variety of focal distances. The first column contains the focal distances in inches; the second contains the radii of the first surface in inches; the third contains the radii of the posterior surface of the first lens and anterior surface of the second; and the fourth column has the radii of the three remaining surfaces.

P	a	b, a'	b', a'', b''
12	9.25	6.17	12.75
24	18.33	12.25	25.5
36	27.33	18.25	38.17
48	36.42	24.33	50.92
60	45.42	30.33	63.58
72	54.5	36.42	76.33
84	63.5	42.5	89.
96	72.6	48.5	101.75
108	81.7	54.58	114.42
120	90.7	60.58	127.17

We have had an opportunity of trying glasses of this construction, and found them equal to any of the same length, although executed by an artist by no means excellent in his profession as a glass-grinder. This very circumstance

Telescope. circumstance gave us the opportunity of seeing the good effects of interposing a transparent substance between the glasses. We put some clear turpentine varnish between them, which completely prevented all reflection from the internal surfaces. Accordingly these telescopes were surprisingly bright; and although the roughness left by the first grinding was very perceptible by the naked eye before the glasses were put together, yet when joined in this manner it entirely disappeared, even when the glasses were viewed with a deep magnifier.

The aperture of an object-glass of this construction of 30 inches focal distance was $3\frac{1}{5}$th inches, which is considerably more than any of Mr Dollond's that we have seen.

If we should think it of advantage to make all the three lenses isosceles, that is, equally curved on both surfaces, the general equation will give the following radii:

$$a = +0.639 \quad a' = -0.5285 \quad a'' = +0.6413$$
$$b = -0.639 \quad b' = +0.5285 \quad b'' = -0.6413$$

This seems a good form, having large radii.

Should we choose to have the two crown-glass lenses isosceles and equal, we must make

$$a = +0.6412 \quad a' = -0.5227 \quad a'' = +0.6412$$
$$b = -0.6412 \quad b' = +0.5367 \quad b'' = -0.6412$$

This form hardly differs from the last.

Our readers will recollect that all these forms proceed on certain measures of the refractive and dispersive powers of the substances employed, which are expressed by m, m', $d\,m$, and $d\,m'$: and we may be assured that the formulæ are sufficiently exact, by the comparison (which we have made in one of the cases) of the result of the formula and the trigonometrical calculation of the progress of the rays. The error was but $\frac{1}{60}$th of the whole, ten times less than another error, which unavoidably remains, and will be considered presently. These measures of refraction and dispersion were carefully taken; but there is great diversity, particularly in the flint-glass. We are well informed that the manufacture of this article has considerably changed of late years, and that it is in general less refractive and less dispersive than formerly. This must evidently make a change in the forms of achromatic glasses. The proportion of the focal distance of the crown-glasses to that of the flint must be increased, and this will occasion a change in the curvatures, which shall correct the spherical aberration. We examined with great care a parcel of flint-glass which an artist of this city got lately for the purpose of making achromatic object-glasses, and also some very white crown glass made in Leith; and we obtained the following measures:

$$m = 1.529 \qquad \frac{d\,m}{d\,m'} = \frac{142}{219} = 0.64841.$$
$$m' = 1.578$$

We computed some forms for triple object-glasses made of these glasses, which we shall subjoin as a specimen of the variations which this change of data will occasion.

If all the three lenses are made isosceles, we have

$$a = +0.796 \quad a' = -0.474 \quad a'' = +0.502$$
$$b = -0.796 \quad b' = +0.474 \quad b'' = -0.502$$

Or

$$a = 0.504 \quad a' = -0.475 \quad a'' = +0.793$$
$$b = -0.504 \quad b' = 0.475 \quad b'' = -0.793$$

If the middle lens be isosceles, the two crown-glass lenses may be made of the same form and focal distance, and placed the same way. This will give us

$$a = +0.705 \quad a' = -0.475 \quad a'' = +0.705$$
$$b = -0.547 \quad b' = +0.475 \quad b'' = -0.547$$

N. B. This construction allows a much better form, if the measures of refraction and dispersion are the same that we used formerly. For we shall have

$$a = +0.628 \quad a' = -0.579 \quad a'' = +0.628$$
$$b = -0.749 \quad b' = +0.579 \quad b'' = -0.749$$

And this is pretty near the practice of the London opticians.

We may here observe, upon the whole, that an amateur has little chance of succeeding in these attempts. The diversity of glasses, and the uncertainty of the workman's producing the very curvatures which he intends, is so great, that the object-glass turns out different from our expectation. The artist who makes great numbers acquires a pretty certain guess at the remaining error; and having many lenses, intended to be of one form, but unavoidably differing a little from it, he tries several of them with the other two, and finding one better than the rest, he makes use of it to complete the set.

The great difficulty in the construction is to find the exact proportion of the dispersive powers of the crown and flint-glass. The crown is pretty constant; but there are hardly two pots of flint-glass which have the same dispersive power. Even if constant, it is difficult to measure it accurately; and an error in this greatly affects the instrument, because the focal distances of the lenses must be nearly as their dispersive powers. The method of examining this circumstance, which we found most accurate, was as follows:

The sun's light, or that of a brilliant lamp, passed through a small hole in a board, and fell on another board pierced also with a small hole. Behind this was placed a fine prism A (fig. 14.), which formed a spectrum ROV on a screen pierced with a small hole. Behind this was placed a prism B of the substance under examination. The ray which was refracted by it fell on the wall at D, and the distance of its illumination from that point to C, on which an unrefracted ray would have fallen, was carefully measured. This showed the refraction of that colour. Then, in order that we might be certain that we always compared the refraction of the same precise colour by the different prisms placed at B, we marked the precise position of the prism A when the ray of a particular colour fell on the prism B. This was done by an index AG attached to A, and turning with it, when we caused the different colours of the spectrum formed by A to fall on B. Having examined one prism B with respect to all the colours in the spectrum formed by A, we put another B in its place. Then bringing A to all its former positions successively, by means of a graduated arch HGK, we were certain that when the index was at the same division of the arch it was the very ray which had been made to pass through the first prism B in a former experiment. We did not solicitously endeavour to find the very extreme red and violet rays; because, although we did not learn the whole dispersions of the two prisms, we learned their proportions, which is the circumstance wanted in the construction of achroma- Fig. 14.

Telescope. tic glasses. It is in vain to attempt this by measuring the spectrums themselves; for we cannot be certain of selecting the very same colours for the comparison, because they succeed in an insensible gradation.

The intelligent reader will readily observe, that we have hitherto proceeded on the supposition, that when, by means of contrary refractions, we have united the extreme red and violet rays, we have also united all the others. But this is quite gratuitous. Sir Isaac Newton would, however, have made the same supposition; for he imagined that the different colours divided the spectrum formed by all substances in the proportions of a musical canon. This is a mistake. When a spectrum is formed by a prism of crown glass, and another of precisely the same length is formed by the side of it by a prism of flint glass, the confine between the green and blue will be found precisely in the middle of the first spectrum, but in the second it will be considerably nearer to the red extremity. In short, different substances do not disperse the colours in the same proportion.

The effect of this irrationality (so to call it) of dispersion, will appear plainly, we hope, in the following manner: Let A (fig. 12.) represent a spot of white solar light falling perpendicularly on a wall. Suppose a prism of common glass placed behind the hole through which the light is admitted, with its refracting angle facing the left hand. It will refract the beam of light to the right, and will at the same time disperse this heterogeneous light into its component rays, carrying the extreme red ray from A to R, the extreme orange from A to O, the extreme yellow from A to Y, &c. and will form the usual prismatic spectrum ROYGBPVC. If the whole length RC be divided into 1000 parts, we shall have (when the whole refraction AR is small) RO very nearly 125, RY=200, RG=333, RB=500 RP=667, RV=778, and RC=1000; this being the proportion observed in the differences of the sines of refraction by Sir Isaac Newton.

Fig. 12.

Perhaps a refracting medium may be found such, that a prism made of it would refract the white light from A′, in the upper line of this figure, in such a manner that a spectrum R′O′Y′G′B′P′V′C′ shall be formed at the same distance from A′, and of the same length, but divided in a different proportion. We do not know that such a medium has been found; but we know that a prism of flint-glass has its refractive and dispersive powers so constituted, that if A′H be taken about one-third of AR, a spot of white light, formed by rays falling perpendicularly at H′, will be so refracted and dispersed that the extreme red ray will be carried from H′ to R′, and the extreme violet from H′ to C′, and the intermediate colours to intermediate points, forming a spectrum resembling the other, but having the colours more constipated towards R′, and more dilated towards C; so that the ray which the common glass carried to the middle point B of the spectrum RC is now in a point B′ of the spectrum R′C′, considerably nearer to R′.

Dr Blair has found, on the other hand, that certain fluids, particularly such as contain the muriatic acid, when formed into a prism, will refract the light from H″ (in the lower line) so as to form a spectrum R″C″ equal to RC, and as far removed from A″ as RC is from A, but having the colours more dilated toward R″, and more constipated toward C, than is observed in RC; so that the ray which was carried by the prism of common glass to the middle point B, is carried to a point B″ considerably nearer to C″.

Telescope.

Let us now suppose that, instead of a white spot at A, we have a prismatic spectrum AB (fig. 13.), and that the prism of common glass is applied as before, immediately behind the prism which forms the spectrum AB. We know that this will be refracted sidewise, and will make a spectrum ROYGBPC, inclined to the plane of refraction in an angle of 45°; so that drawing the perpendicular RC′, we have RC′=C′C.

Fig. 13.

We also know that the prism of flint-glass would refract the spectrum formed by the first prism on EHF, in such a manner that the red ray will go to R, the violet to C, and the intermediate rays to points *o*, *y*, *g*, *b*, *p*, *v*, so situated that O′*o* is = R′O′ of the other figure; Y*y* is = R′Y′ of that figure, G*g* = R′G′, &c. These points must therefore lie in a curve R *o y g b p v* C, which is convex towards the axis R′C′.

In like manner we may be assured that Dr Blair's fluid will form a spectrum R *o′ y′ g′ b′ p′ v′* C, concave toward R′C.

Let it be observed by the way, that this is a very good method for discovering whether a medium disperses the light in the same proportion with the prism which is employed for forming the first spectrum AB or EF. It disperses in the same or in a different proportion, according as the oblique spectrum is straight or crooked; and the exact proportion corresponding to each colour is had by measuring the ordinates of the curves R *b* C or R *b′* C.

Having formed the oblique spectrum RBC by a prism of common glass, we know that an equal prism of the same glass, placed in a contrary position, will bring back all the rays from the spectrum RBC to the spectrum AB, laying each colour on its former place.

In like manner, having formed the oblique spectrum R *b* C by a prism of flint-glass, we know that another prism of flint-glass, placed in the opposite direction, will bring all the rays back to the spectrum EHF.

But having formed the oblique spectrum RBC by a prism of common glass, if we place the flint-glass prism in the contrary position, it will bring the colour R back to E, and the colour C to F; but it will not bring the colour B to H, but to a point *h*, such that B *h* is equal to *b* H, and *b* B to *h* H. In like manner, the other colours will not be brought back to the straight line EHF, but to a curve E *h* F, forming a crooked spectrum.

In like manner, the fluids discovered by Dr Blair, when employed to bring back the oblique spectrum RBC formed by common glass will bring its extremities back to E and F, and form the crooked spectrum E *h′* F lying beyond EHF.

This experiment evidently gives us another method for examining the proportionality of the dispersion of different substances.

Having, by common glass, brought back the oblique spectrum formed by common glass to its natural place AB, suppose the original spectrum at AB to contract gradually (as Newton has made it to do by means of a lens), it is plain that the oblique spectrum will also contract, and so will the second spectrum at AB; and it will at last coalesce into a white spot. The effect will be equivalent to a gradual compression of the whole figure, Telescope. figure, by which the parallel lines AR and BC gradually approach, and at last unite.

In like manner, when the oblique spectrum formed by flint-glass is brought back to EHF by a flint-glass prism, and the figure compressed in the same gradual manner, all the colours will coalesce into a white spot.

But when flint-glass is employed to bring back the oblique spectrum formed by common glass, it forms the crooked spectrum E *h* F. Now let the figure be compressed. The curve E *h* F will be doubled down on the line H *h*, and there will be formed a compound spectrum H *h*, quite unlike the common spectrum, being purple or claret-coloured at H by the mixture of the extreme red and violet, and green edged with blue at *h* by the mixture of the green and blue. The fluid prisms would in like manner form a spectrum of the same kind on the other side of H.

This is precisely what is observed in achromatic object-glasses made of crown-glass and flint: for the refraction from A to R corresponds to the refraction of the convex crown-glass; and the contrary refraction from R to E corresponds to the contrary refraction of the concave flint-glass, which still leaves a part of the first refraction, producing a convergence to the axis of the telescope. It is found to give a purple or wine-coloured focus, and within this a green one, and between these an imperfect white. Dr Blair found, that when the eye-glass was drawn out beyond its proper distance, a star was surrounded by a green fringe, by the green end of the spectrum, which crossed each other within the focus; and when the eye-glass was too near the object-glass, the star had a wine-coloured fringe. The green rays were ultimately most refracted. *N. B.* We should expect the fringe to be of a blue colour rather than a green. But this is easily explained: The extreme violet rays are very faint, so as hardly to be sensible; therefore when a compound glass is made as achromatic as possible to our senses, in all probability (nay certainly) these almost insensible violet rays are left out, and perhaps the extreme colours which are united are the red and the middle violet rays. This makes the green to be the mean ray, and therefore the most outstanding when the dispersions are not proportional.

Dr Blair very properly calls these spectrums, H *h* and H *h'*, *secondary spectrums*, and seems to think that he is the first who has taken notice of them. But Mr Clairault was too accurate a mathematician, and too careful an observer, not to be aware of a circumstance which was of primary consequence to the whole inquiry. He could not but observe that the success rested on this very particular, and that the proportionality of dispersion was indispensably necessary.

This subject was therefore touched on by Clairault; and *fully* discussed by Boscovich, first in his Dissertations published at Vienna in 1759; then in the *Comment. Bononiensis;* and, lastly, in his *Opuscula*, published in 1785. Dr Blair, in his ingenious Dissertation on Achromatic Glasses, read to the Royal Society of Edinburgh in 1793, seems not to have known of the labours of these writers; speaks of it as a new discovery; and exhibits some of the consequences of this principle in a singular point of view, as something very paradoxical and inconsistent with the usually received notions on these subjects. But they are by no means so. We are, however, much indebted to his ingenious researches, and his successful endeavours to find some remedy for this imperfection of achromatic glasses. Some of his contrivances are exceedingly ingenious; but had the Doctor consulted these writers, he would have saved himself a good deal of trouble.

Boscovich shows how to unite the two extremes with the most outstanding colour of the secondary spectrum, by means of a third substance. When we have done this, the aberration occasioned by the secondary spectrums must be prodigiously diminished; for it is evidently equivalent to the union of the points H and *h* of our figure. Whatever cause produces this must diminish the curvature of the arches E *h* and *h* F: but even if these curvatures were not diminished, their greatest ordinates cannot exceed one-fourth of H *h*; and we may say, without hesitation, that by uniting the mean or most outstanding ray with the two extremes, the remaining dispersion will be as much less than the uncorrected colour of Dollond's achromatic glass, as this is less than four times the dispersion of a common object-glass. It must therefore be altogether insensible.

Boscovich asserts, that it is not possible to unite more than two colours by the opposite refraction of two substances, which do not disperse the light in the same proportions. Dr Blair makes light of this assertion, as he finds it made in general terms in the vague and paltry extract made by Priestley from Boscovich in his Essay on the History of Optics; but had he read this author in his own dissertations, he would have seen that he was perfectly right. Dr Blair, however, has hit on a very ingenious and effectual method of producing this union of three colours. In the same way as we correct the dispersion of a concave lens of crown-glass by the opposite dispersion of a concave lens of flint-glass, we may correct the secondary dispersion of an achromatic convex lens by the opposite secondary dispersion of an achromatic concave lens. But the intelligent reader will observe, that this union does not contradict the assertion of Boscovich, because it is *necessarily* produced by means of three refracting substances.

The most essential service which the public has received at the hands of Dr Blair is the discovery of fluid mediums of a proper dispersive power. By composing the lenses of such substances, we are at once freed from the irregularities in the refraction and dispersion of flint-glass, which the chemists have not been able to free it from. In whatever way this glass is made, it consists of parts which differ both in refractive and dispersive power; and when taken up from the pot, these parts mix in threads, which may be disseminated through the mass in any degree of fineness. But they still retain their properties; and when a piece of flint-glass has been formed into a lens, the eye, placed in its focus, sees the whole surface occupied by glistening threads or broader veins running across it. Great rewards have been offered for removing this defect, but hitherto to no purpose. We beg leave to propose the following method: Let the glass be reduced to powder, and then melted with a great proportion of alkaline salt, so as to make a liquor silicum. When precipitated from this by an acid, it must be in a state of very uniform composition. If again melted into glass we should hope that it would be free from this defect; if not, the case seems to be desperate.

But by using a fluid medium, Dr Blair was freed from all this embarrassment; and he acquired another

Telescope. immense advantage, that of adjusting at pleasure both the refractive and dispersive powers of his lenses. In solid lenses, we do not know whether we have taken the curvatures suited to the refractions till our glass is finished; and if we have mistaken the proportions, all our labour is lost. But when fluids are used, it is enough that we know nearly the refractions. We suit our focal distances to these, and then select our curvature, so as to remove the aberration of figure, preserving the focal distances. Thus, by properly tempering the fluid mediums, we bring the lens to agree precisely with the theory, perfectly achromatic, and the aberration of figure as much corrected as is possible.

Dr Blair examined the refractive and dispersive powers of a great variety of substances, and found great varieties in their actions on the different colours. This is indeed what every well informed naturalist would expect. There is no doubt now among naturalists about the mechanical connection of the phenomena of nature; and all are agreed that the chemical actions of the particles of matter are perfectly like in kind to the action of gravitating bodies; that all these phenomena are the effects of forces like those which we call attractions and repulsions, and which we observe in magnets and electrified bodies; that light is refracted by forces of the same kind, but differing chiefly in the small extent of their sphere of activity. One who views things in this way will expect, that as the actions of the same acid for the different alkalies are different in degree, and as the different acids have also different actions on the same alkali, in like manner different substances differ in their general refractive powers, and also in the proportion of their action on the different colours. Nothing is more unlikely therefore than the proportional dispersion of the different colours by different substances; and it is surprising that this inquiry has been so long delayed. It is hoped that Dr Blair will oblige the public with an account of the experiments which he has made. This will enable others to co-operate in the improvement of achromatic glasses. We cannot derive much knowledge from what he has already published, because it was chiefly with the intention of giving a popular, though not an accurate, view of the subject. The constructions which are there mentioned are not those which he found most effectual, but those which would be most easily understood, or demonstrated by the slight theory which is contained in the dissertation; besides, the manner of expressing the difference of refrangibility, perhaps chosen for its paradoxical appearance, does not give us a clear notion of the characteristic differences of the substances examined. Those rays which are ultimately most deflected from their direction, are said to have become the most refrangible by the combination of different substances, although, in all the particular refractions by which this effect is produced, they are less refracted than the violent light. We can just gather this much, that common glass disperses the rays in such a manner, that the ray which is in the confine of the green and blue occupies the middle of the prismatic spectrum; but in glasses, and many other substances, which are more dispersive, this ray is nearer to the ruddy extremity of the spectrum. While therefore the straight line RC′ (fig. 13.) terminates the ordinates O*o*′, YY′, G*g*′, &c. which represent the dispersion of common glass, the ordinates which express the dispersions of these substances

Fig. 13.

are terminated by a curve passing through R and C′, but lying below the line RC′. When therefore parallel heterogeneous light is made to converge to the axis of a convex lens of common glass, as happens at F in fig. 6. C, the light is dispersed, and the violet rays have a shorter focal distance. If we now apply a concave lens of greater dispersive power, the red and violet rays are brought to one focus F; but the green rays, not being so much refracted away from F, are left behind at φ, and have now a shorter focal distance. But Dr Blair afterwards found that this was not the case with the muriatic acid, and some solutions in it. He found that the ray which common glass caused to occupy the middle of the spectrum was much nearer to the blue extremity when refracted by these fluids. Therefore a concave lens formed of such fluids which united the red and violet rays in F′, refracted the green rays to *f*′.

Fig. 6.

Having observed this, it was an obvious conjecture, that a mixture of some of these fluids might produce a medium, whose action on the intermediate rays should have the same proportion that is observed on common glass; or that two of them might be found which formed spectra similarly divided, and yet differing sufficiently in dispersive power to enable us to destroy the dispersion by contrary refractions, without destroying the whole refraction. Dr Blair accordingly found a mixture of solutions of ammoniacal and mercurial salts, and also some other substances, which produced dispersions proportional to that of glass, with respect to the different colours.

And thus has the result of this intricate and laborious investigation corresponded to his utmost wishes. He has produced achromatic telescopes which seem as perfect as the thing will admit of; for he has been able to give them such apertures, that the *incorrigible* aberration arising from the spherical surfaces becomes a sensible quantity, and precludes farther amplification by the eye-glasses. We have examined one of his telescopes: The focal distance of the object-glass did not exceed 17 inches, and the aperture was fully 3½ inches. We viewed some single and double stars and some common objects with this telescope; and found, that in magnifying power, brightness, and distinctness, it was manifestly superior to one of Mr Dollond's of 42 inches focal length. It also gave us an opportunity of admiring the dexterity of the London artists, who could work the glasses with such accuracy. We had most distinct vision of a star when using an erecting eye-piece, which made this telescope magnify more than a hundred times; and we found the field of vision as uniformly distinct as with Dollond's 42 inch telescope magnifying 46 times. The intelligent reader must admire the nice figuring and centering of the very deep eye-glasses which are necessary for this amplification.

It is to be hoped that Dr Blair will extend his views to *glasses* of different compositions, and thus give us object-glasses which are solid; for those composed of fluids have inconveniences which will hinder them from coming into general use, and will confine them to the museums of philosophers. We imagine that antimonial glasses bid fair to answer this purpose, if they could be made free of colour, so as to transmit enough of light. We recommend this dissertation to the careful perusal of our readers. Those who have not made themselves much acquainted with the delicate and abstruse theory of aberrations, will find it exhibited in such a popular form

Telescope.

form as will enable them to understand its general aim; and the well-informed reader will find many curious indications of inquiries and discoveries yet to be made.

We now proceed to consider the eye-glasses or glasses of telescopes. The proper construction of an eye-piece is not less essential than that of the object-glass. But our limits will not allow us to treat this subject in the same detail. We have already extended this article to a great length, because we do not know of any performance in the English language which will enable our readers to understand the construction of achromatic telescopes; an invention which reflects honour on our country, and has completed the discoveries of our illustrious Newton. Our readers will find abundant information in Dr Smith's Optics concerning the eye-glasses, chiefly deduced from Huyghen's fine theory of aberration (A). At the same time, we must again pay Mr Dollond the merited compliment of saying, that he was the first who made any scientific application of this theory to the compound eye-piece for erecting the object. His eye-pieces of five and six glasses are very ingenious reduplications of Huyghen's eye-pieces of two glasses, and would probably have superseded all others, had not his discovery of achromatic object-glasses caused opticians to consider the chromatic dispersion with more attention, and pointed out methods of correcting it in the eye-piece without any compound eye-glasses. They have found that this may be more conveniently done with four eye-glasses, without sensibly diminishing the advantages which Huyghens showed to result from employing many small refractions instead of a lesser number of great ones. As this is a very curious subject, we shall give enough for making our readers fully acquainted with it, and content ourselves with merely mentioning the principles of the other rules for constructing an eye-piece.

Such readers as are less familiarly acquainted with optical discussions will do well to keep in mind the following consequences of the general focal theorem.

Fig. 15. If AB (fig. 15.) be a lens, R a radiant point or focus of incident rays, and a the focus of parallel rays coming from the opposite side; then,

1. Draw the perpendicular $a\,a'$ to the axis, meeting the incident ray in a', and a' A to the centre of the lens. The refracted ray BF is parallel to a' A; for R a' : a' A (= R a : a A) = RB : BF (=RA : AF), which is the focal theorem.

2. An oblique pencil BP b proceeding from any point P which is not in the axis, is collected to the point f, where the refracted ray BF cuts the line PA f drawn from P through the centre of the lens: for P a': a' A = PB : B f, which is also the focal theorem.

The Galilean telescope is susceptible of so little improvement that we need not employ any time in illustrating its performance.

Telescope.

The simple astronomical telescope is represented in fig. 16. The beam of parallel rays, inclined to the axis, is made to converge to a point G where it forms an image of the lowest point of a very distant object. These rays decussating from G fall on the eye-glass; the ray from the lowest point B of the object-glass falls on the eye-glass at b; and the ray from A falls on a; and the ray from the centre O falls on o. These rays are rendered parallel, or nearly so, by refraction through the eye-glass, and take the direction $b\,i'$, o I, $a\,i$. If the eye be placed so that this pencil of parallel rays may enter it, they converge to a point of the retina, and give distinct vision to the lowest point of the object. It appears inverted, because the rays by which we see its lowest point come in the direction which in simple vision is connected with the upper point of an object. They come from above, and therefore are thought to proceed from above. We see the point as if situated in the direction I o. In like manner the eye placed at I, sees the upper point of the object in the direction IP, and its middle in the direction IE. The proper place for the eye is I; if brought much nearer the glass, or removed much farther from it, some, or the whole, of this extreme pencil of rays will not enter the pupil. It is is therefore of importance to determine this point. Because the eye requires parallel rays for distinct vision, it is plain that F must be the principal focus of the eye-glass. Therefore, by the common focal theorem, OF : OE = OE : OI, or OF : FE = OE : EI. Fig. 16.

The magnifying power being measured by the magnitude of the visual angle, compared with the magnitude of the visual angle with the naked eye, we have $\frac{o\,I\,p}{o\,O\,p}$, or $\frac{o\,IF}{o\,OF}$ for the measure of the magnifying power. This is very nearly $= \frac{OE}{EI}$ or, $\frac{OF}{FI}$.

As the line OE, joining the centres of the lenses, and perpendicular to their surfaces, is called the axis of the telescope, so the ray OG is called the axis of the oblique pencil, being really the axis of the cone of light which has the object-glass for its base. This ray is through its whole course the axis of the oblique pencil; and when its course is determined, the amplification, the field of vision, the apertures of the glasses, are all determined. For this purpose we have only to consider the centre of the object-glass as a radical point, and trace the process of a ray from this point through the other glasses: this will be the axis of some oblique pencil.

It is evident, therefore, that the field of vision depends on the breadth of the eye-glass. Should we increase this, the extreme pencil will pass through I, because O and I are still the conjugate foci of the eye-glass.

(A) While we thus repeatedly speak of the theory of spherical aberration as coming from Mr Huyghens, we we must not omit giving a due share of the honour of it to Dr Barrow and Mr James Gregory. The first of these authors, in his Optical Lectures delivered at Cambridge, has given every proposition which is employed by Huyghens, and has even prosecuted the matter much further. In particular, his theory of oblique slender pencils is of immense consequence to the perfection of telescopes, by showing the methods for making the image of an extended surface as flat as possible. Gregory, too, has given all the fundamental propositions in his *Optica Promota*. But Huyghens, by taking the subject together, and treating it in a system, has greatly simplified it: and his manner of viewing the principal parts of it is incomparably more perspicuous than the performances of Barrow and Gregory.

Telescope.

glass. On the other hand, the angle resolved on for the extent or field of vision gives the breadth of the eye-glass.

We may here observe, by the way, that for all optical instruments there must be two optical figures considered. The first shows the progress of a pencil of rays coming from one point of the object. The various focuses of this pencil show the places of the different images, real or virtual. Such a figure is formed by the three rays AG *a i*, OG *o* I, BG *b i*.

The second shows the progress of the axes of the different pencils proceeding through the centre of the object-glass. The focuses of this pencil of axes show the places where an image of the object glass is formed; and this pencil determines the field of vision, the apertures of the lenses, and the amplification or magnifying power. The three rays OG *o* I, OFEI, OHPI, form this figure.

See also fig. 24. where the progress of both sets of pencils is more diversified.

The perfection of a telescope is to represent an object in its proper shape, distinctly magnified, with a great field of vision, and sufficiently bright. But there are limits to all these qualities; and an increase of one of them, for the most part, diminishes the rest. The brightness depends on the aperture of the object-glass, and will increase in the same proportion (because *i i'* will always be to AB in the proportion of EF to FO), till the diameter of the emergent pencil is equal to that of the pupil of the eye. Increasing the object-glass any more, can send no more light into the eye. But we cannot make the emergent pencil nearly so large as this when the telescope magnifies much; for the great aperture of the object-glass produces an indistinct image at GF, and its indistinctness is magnified by the eye-glass.

A great field of vision is incompatible with the true shape of the object; for it is not strictly true that all rays flowing from O are refracted to I. Those rays which go to the margin of the eye glass cross the axis between E and I; and therefore they cross it at a greater angle than if they passed through I. Now had they really passed through I, the object would have been represented in its due proportions. Therefore since the angles of the marginal parts are enlarged by the aberration of the eye-glass, the marginal parts themselves will appear enlarged, or the object appear distorted. Thus a chess-board viewed through a reading glass appears drawn out at the corners, and the straight lines are all changed into curves, as is represented in fig. 18. Fig. 18.

The circumstance which most peremptorily limits the extent of field is the necessary distinctness. If the vision be indistinct, it is useless, and no other quality can compensate this defect. The distortion is very inconsiderable in much larger angles of vision than we can admit, and is unworthy of the attention paid to it by optical writers. They have been induced to take notice of it, because the means of correcting it in a considerable degree are attainable, and afford an opportunity of exhibiting their knowledge; whereas the indistinctness which accompanies a large field is a subject of most difficult discussion, and has hitherto baffled all their efforts to express by any intelligible or manageable formulæ.

Quæque tractata nitescere posse
Desperat relinquit.

This subject must, however be considered. The image at GF of a very remote object is not a plain surface perpendicular to the axis of the telescope, but is nearly spherical, having O for its centre. If a number of pencils of parallel rays crossing each other in I fall on the eye-glass, they will form a picture on the opposite side, in the focus F. But this picture will by no means be flat, nor nearly so, but very concave towards E. Its exact form is of most difficult investigation. The elements of it are given by Dr Barrow; and we have given the chief of them in the article OPTICS, when considering the foci of infinitely slender pencils of oblique rays. Therefore it is impossible that the picture formed by the object-glass can be seen distinctly in all its parts by the eye-glass. Even if it were flat, the points G and H (fig. 16.) are too far from the eye-glass when the middle F is at the proper distance for distinct vision. When, therefore, the telescope is so adjusted that we have distinct vision of the middle of the field, in order to see the margin distinctly we must push in the eye-glass: and having so done, the middle of the field becomes indistinct. When the field of vision exceeds 12 or 15 degrees, it is not possible by any contrivance to make it tolerably distinct all over; and we must turn the telescope successively to the different parts of the field that we may see them agreeably. Fig. 16.

The cause of this indistinctness is, as we have already said, the shortness of the lateral foci of lateral and oblique pencils refracted by the eye-glass. The oblique pencil *b* G *a*, by which an eye placed at I sees the point G of the image, is a cone of light, having a circular base on the eye-glass; of which circle *a b* is one of the diameters. There is a diameter perpendicular to this, which, in this figure, is represented by the point *o*. Fig. 17. represents the base of the cone as seen by an eye placed in the axis of the telescope, with the object-glass as appearing behind it. The point *b* is formed by a ray which comes from the lowest point B of the object-glass, and the point *a* is illuminated by a ray from A. The point *c* at the right hand of the circular base of this cone of light came from the point C on the left side of the object-glass; and the light comes to *d* from D. Now the laws of optics demonstrate, that the rays which come through the points *c* and *d* are more convergent after refraction than the rays which come through *a* and *b*. The analogies, therefore, which ascertain the foci of rays lying in planes passing through the axis do not determine the foci of the others. Of this we may be sensible by looking through a lens to a figure on which are drawn concentric circles crossed by radii. When the telescope is so adjusted that we see distinctly the extremity of one of the radii, we shall not see distinctly the circumference which crosses the extremity with equal distinctness, and *vice versa*. This difference, however, between the foci of the rays which come through *a* and *b*, and those which come through *c* and *d*, is not considerable in the fields of vision, which are otherwise admissible. But the same difference of foci obtains also with respect to the dispersion of light, and is more remarkable. Both d'Alembert and Euler have attempted to introduce it into their formulæ; Fig. 17.

Telescope. mulæ; but they have made them useless for any practical purpose by their inextricable complication.

This must serve as a general indication of the difficulties which occur in the construction of telescopes, even although the object-glass were perfect, forming an image without the smallest confusion or distortion.

There is yet another difficulty or imperfection. The rays of the pencil a G b, when refracted through the eye-glass, are also separated into their component colours. The edge of the lens must evidently perform the office of a prism, and the white ray G b will be so dispersed that if $b\,i$ be the path of its red ray, the violet ray, which makes another part of it, will take such a course $b\,n$ that the angle $i'\,b\,n$ will be nearly $\frac{1}{27}$th of G$'$ b i'. The ray G a passing through a part of the lens whose surfaces are less inclined to each other, will be less refracted, and will be less dispersed in the same proportion very nearly. Therefore the two violet rays will be very nearly parallel when the two red rays are rendered parallel.

Hence it must happen, that the object will appear bordered with coloured fringes. A black line seen near the margin on a white ground, will have a ruddy and orange border on the outside and a blue border within: and this confusion is altogether independent on the object-glass, and is so much the greater as the visual angle b IE is greater.

Such are the difficulties: They would be unsurmountable were it not that some of them are so connected that, to a certain extent, the diminution of one is accompanied by a diminution of the other. What are called the *caustic curves* are the geometrical loci of the foci of infinitely slender pencils. Consequently the point G is very nearly in the caustic formed by a beam of light consisting of rays parallel to I o, and occupying the whole surface of the eye-glass, because the pencil of rays which are collected at G is very small. Any thing therefore that diminishes the mutual inclination of the adjoining rays, puts their concourse farther off. Now this is precisely what we want: for the point G of the image formed by the object-glass is already beyond the focus of the oblique slender pencil of parallel rays $i\,a$ and $i'\,b$; and therefore, if we could make this focus go a little farther from a and b, we shall bring it nearer to G, and obtain more distinct vision of this point of the object. Now let it be recollected, that in moderate refractions through prisms, two rays which are inclined to each other in a small angle are, after refraction, inclined to each other in the same angle. Therefore, if we can diminish the aberration of the ray $a\,i$, or o I, or $b\,i'$, we diminish their mutual inclination; and consequently the mutual inclination of the rays G a, G o, Gb', and therefore lengthen the focus, and get more distinct vision of the point G. Therefore we at once correct the distortion and the indistinctness: and this is the aim of Mr Huyghen's great principle of dividing the refractions.

Fig. 19. The general method is as follows: Let o be the object-glass (fig 19.) and E the eye-glass of a telescope, and F their common focus, and FG the image formed by the object-glass. The proportion of their focal distances is supposed to be such as gives as great a magnifying power as the perfection of the object-glass will admit. Let BI be the axis of the emergent pencil. It is known by the focal theorem that GE is parallel to BI: therefore BGE is the whole refraction or deflection of the ray OHB from its former direction. Let it be proposed to diminish the aberrations by dividing this into two parts by means of two glasses D and e, so as to make the ultimate angle of vision $b\,i\,c$ equal to BIE, and thus retain the same magnifying power and visible field. Let it be proposed to divide it into the parts BGC and CGE.

From G draw any line GD to the axis towards O; and draw the perpendicular DH, cutting OG in H; draw H c parallel to GC, cutting GD in g; draw $g\,f$ perpendicular to the axis, and $g\,e$ parallel to GE; draw $e\,b$ perpendicular to the axis; draw D δ parallel to GC, and $d\,\delta$ perpendicular to the axis.

Then if there be placed at D a lens whose focal distance is D d, and another at e whose focal distance is $e\,f$, the thing is done. The ray OH will be refracted into H b, and this into $b\,i$, parallel to BI.

The demonstration of this construction is so evident by means of the common focal theorem, that we need not repeat it, nor the reasons for its advantages. We have the same magnifying power, and the same field of vision; we have less aberration, and therefore less distortion and indistinctness; and this is brought about by a lens HD of a smaller aperture and a greater focal distance than BE. Consequently, if we are contented with the distinctness of the margin of the field with a single eye-glass, we may greatly increase the field of vision; for if we increase DH to the size of EB we shall have a greater field, and much greater distinctness in the margin; because HD is of a longer focal distance, and will bear a greater aperture, preserving the same distinctness at the edge. On this account the glass HD is commonly called the *Field-glass*.

It must be observed here, however, that although the distortion of the object is lessened, there is a real distortion produced in the image $f\,g$. But this, when magnified by the glass e, is smaller than the distortion produced by the glass E, of greater aperture and shorter focus, on the undistorted image GF. But because there is a distortion in the second image $f\,g$, this construction cannot be used for the telescopes of astronomical quadrants, and other graduated instruments; because then equal divisions of the micrometer would not correspond to equal angles.

But the same construction will answer in this case by taking the point D on that side of F which is remote from O (fig. 20.). This is the form now employed in the telescopes of all graduated instruments.

The exact proportion in which the distortion and the indistinctness at the edges of the field are diminished by this construction, depends on the proportion in which the angle BGE is divided by GC; and is of pretty difficult investigation. But it never deviates far (never $\frac{1}{7}$th in optical instruments) from the proportion of the squares of the angles. We may, without any sensible error, suppose it in this proportion. This gives us a practical rule of easy recollection, and of most extensive use. When we would diminish an aberration by dividing the whole refraction into two parts, we shall do it most effectually by making them equal. In like manner, if we divide it into three parts by means of two additional

ditional glasses, we must make each $= \frac{1}{3}$ of the whole; and so on for a greater number.

This useful problem, even when limited, as we have done, to equal refractions, is as yet indeterminate; that is, susceptible of an infinity of solutions: for the point D, where the field-glass is placed, was taken at pleasure; yet there must be situations more proper than others. The aberrations which produce distortion, and those which produce indistinctness, do not follow the same proportions. To correct the indistinctness, we should not select such positions of the lens HD as will give a small focal distance to $b\,c$; that is, we should not remove it very far from F. Huyghens recommends the proportion of 3 to 1 for that of the focal distances of the lens HD and $e\,b$, and says that the distance D e should be $= 2$ F e. This will make $e\,i = \frac{1}{2}\,e$ F, and will divide the whole refraction into two equal parts, as any one will readily see by constructing the common optical figure. Mr Short, the celebrated improver of reflecting telescopes, generally employed this proportion; and we shall presently see that it is a very good one.

It has been already observed that the great refractions which take place on the eye-glasses occasion very considerable dispersions, and disturb the vision by fringing every thing with colours. To remedy this, achromatic eye-glasses may be employed, constructed by the rules already delivered. This construction, however, is incomparably more intricate than that of object-glasses: for the equations must involve the distance of the radiant point, and be more complicated: and this complication is immensely increased on account of the great obliquity of the pencils.

Most fortunately the Huyghenian construction of an eye-piece enables us to correct this dispersion to a great degree of exactness. A heterogeneous ray is dispersed at H, and the red ray belonging to it falls on the lens $b\,e$ at a greater distance from the centre than the violet ray coming from H. It will therefore be less refracted (*cæteris paribus*) by the lens $b\,e$; and it is possible that the difference may be such that the red and violet rays dispersed at H may be rendered parallel at b, or even a little divergent, so as to unite accurately with the red ray at the bottom of the eye. How this may be effected, by a proper selection of the places and figures of the lenses, will appear by the following proposition, which we imagine is new, and not inelegant.

Fig. 21. Let the compound ray OP (fig. 21.) be dispersed by the lens PC; and let PV, PR be its violet and red rays, cutting the axis in G and g. It is required to place another lens RD in their way, so that the emergent rays R r, V v, shall be parallel.

Produce the incident ray OP to Z. The angles ZPR, ZPV, are given, $\left(\text{and RPV is nearly} = \frac{\text{ZPR}}{27}\right)$ and the intersections G and g with the axis. Let F be the focus of parallel red light coming through the lens RD in the opposite direction. Then (by the common optical theorem), the perpendicular F ϱ will cut PR in such a point ϱ, that ϱ F will be parallel to the emergent ray R r, and to V v. Therefore if ϱ D cut PV in u, and $u\,f$ be drawn perpendicular to the axis, we shall have (also by the common theorem) the point f for the focus of violet rays, and DF : D f = D ϱ : D u = 28 : 27 nearly, or in a given ratio.

The problem is therefore reduced to this, "To draw from a point D in the line CG a line D ϱ, which shall be cut by the lines PR and PV in the given ratio."

The following construction naturally offers itself: Make GM : g M in the given ratio, and draw MK parallel to P g. Through *any* point D of CG draw the straight line PDK, cutting MK in K. Join GK, and draw D ϱ parallel to KG. This will solve the problem; and, drawing ϱ F perpendicular to the axis, we shall have F for the focus of the lens RD for parallel red rays.

The demonstration is evident: for MK being parallel to P g, we have GM : gM = GK : HK, = ϱ D : u D = FD f D, in the ratio required.

This problem admits of an infinity of solutions; because the point D may be taken anywhere in the line CG. It may therefore be subjected to such conditions as may produce other advantages.

1. It may be restricted by the magnifying power, or by the division which we choose to make of the whole refraction which produces this magnifying power. Thus, if we have resolved to diminish the aberrations by making the two refractions equal, we have determined the angle R r D. Therefore draw GK, making the angle MGK equal to that which the emergent pencil must make with the axis, in order to produce this magnifying power. Then draw MK parallel to P g, meeting GK in K. Then draw PK, cutting the axis in D, and D ϱ parallel to GK, and ϱ F perpendicular to the axis. D is the place, and DF the focal distance of the eye-glass.

2. Particular circumstances may cause us to fix on a particular place D, and we only want the focal distance. In this case the first construction suffices.

3. We may have determined on a certain focal distance DF, and the place must be determined. In this case let

$$\text{GF} : \text{F}\varrho = 1 : \tan. \text{G}$$
$$\text{F}\varrho : f u = 1 : m,\ m \text{ being} = \tfrac{27}{28}$$
$$f u : f g = \tan. g : 1$$
$$\text{then}\quad \text{GF} : f g = \tan. g : m \tan. \text{G}$$
$$\text{then}\quad \text{GF} - f g : \text{GF} = \tan. g - m \tan. \text{G} : \tan. g$$
$$\text{or}\quad \text{G}g + \text{F}f : \text{GF} = \tan. g - m \tan. \text{G} : \tan. g;$$
$$\text{and}\quad \text{GF} = \text{G}g + \text{F}f \frac{\tan. g}{\tan. g - m \tan. \text{G}},$$

and is therefore given, and the place of F is determined; and since FD is given by supposition, D is determined.

The application of this problem to our purpose is difficult, if we take it in the most general terms; but the nature of the thing makes such limitations that it becomes very easy. In the case of the dispersion of light, the angle GPg is so small that MK may be drawn parallel to PG without any sensible error. If the ray OP were parallel to CG, then G would be the focus of the lens PC, and the point M would fall on C; because the focal distance of red rays is to that of violet rays in the same proportion for every lens, and therefore CG : Cg = DF : Df. Now, in a telescope which magnifies considerably, the angle at the object-glass is very small, and CG hardly exceeds the focal distance; and CG is to C g very nearly in the same proportion of 28 to 27. We may therefore draw through C (fig. 22.) a line CK Fig. 22. parallel

parallel to PG; then draw GK′ perpendicular to the axis of the lenses, and join PK′; draw K′BE parallel to CG, cutting PK in B; draw BHI parallel to GK, cutting GK′ in H: Join HD and PK. It is evident that CG is bisected in F′, and that K′B=2 F′D: also K′H : HG=K′B : BE, =CD : DG. Therefore DH is parallel to CK′, or to PG. But because PF′=F′K′, PD is = DB, and IH=HB. Therefore ϱ D=HB, and FD=K′B, = 2 F′D; and FD is bisected in F′. Therefore $CD=\frac{CG+FD}{2}$.

That is, in order that the eye-glass RD may correct the dispersion of the field-glass PC, *the distance between them must be equal to the half sum of their focal distances* very nearly. More exactly, *the distance between them must be equal to the half sum of the focal distance of the eye-glass, and the distance at which the field-glass would form an image of the object-glass.* For the point G is the focus to which a ray coming from the centre of the object-glass is refracted by the field-glass.

This is a very simple solution of this important problem. Huyghens's eye-piece corresponds with it exactly. If indeed the dispersion at P is not entirely produced by the refraction, but perhaps combined with some previous dispersion, the point M (fig. 21.) will not coincide with C (fig. 22.), and we shall have GC to GM, as the natural dispersion at P to the dispersion which really obtains there. This may destroy the equation $CD=\frac{CG+FD}{2}$.

Fig. 21. Fig. 22.

Thus, in a manner rather unexpected, have we freed the eye-glasses from the greatest part of the effect of dispersion. We may do it entirely by pushing the eye-glass a little nearer to the field-glass. This will render the violet rays a little divergent from the red, so as to produce a perfect picture at the bottom of the eye. But by doing so we have hurt the distinctness of the whole picture, because F is not in the focus of RD. We remedy this by drawing both glasses out a little, and the telescope is made perfect.

Fig. 20. This improvement cannot be applied to the construction of quadrant telescopes, such as fig. 20. Mr Ramsden has attempted it, however, in a very ingenious way, which merits a place here, and is also instructive in another way. The field-glass HD is a plano-convex, with its plane side next the image GF. It is placed very near this image. The consequence of this disposition is, that the image GF produces a vertical image *g f*, which is much less convex towards the glass. He then places a lens on the point C, where the red ray would cross the axis. The violet ray will pass on the other side of it. If the focal distance of this glass be *f c*, the vision will be distinct and free from colour. It has, however, the inconveniency of obliging the eye to be close to the glass, which is very troublesome.

This would be a good construction for a magic-lanthorn, or for the object-glass of a solar microscope, or indeed of any compound microscope.

We may presume that the reader is now pretty familiar with the different circumstances which must be considered in the construction of an eye-piece, and proceed to consider those which must be employed to erect the object.

This may be done by placing the lens which receives the light from the object-glass in such a manner, that a second image (inverted with respect to the first) may be formed beyond it, and this may be viewed by an eye-glass. Such a construction is represented in fig. 23. But, besides many other defects, it tinges the object prodigiously with colour. The ray *o d* is dispersed at *d* into the red ray *d r*, and the violet *d v*, *v* being farther from the centre than *r*, the refracted ray *v v′* crosses *r r′* both by reason of spherical aberration and its greater refrangibility.

Plate DXXX. fig. 23.

But the common day telescope, invented by F. Rheita, has, in this respect, greatly the advantage of the one now described. The rays of compound light are dispersed at two points. The violet ray in its course falls without the red ray, but is accurately collected with it at a common focus, as we shall demonstrate by and by. Since they cross each other in the focus, the violet ray must fall within the red ray, and be less refracted than if it had fallen on the same point with the red ray. Had it fallen there it would have separated from it; but by a proper diminution of its refraction, it is kept parallel to it, or nearly so. And this is one excellence of this telescope: when constructed with three eye-glasses perfectly equal, the colour is sensibly diminished, and by using an eye-glass somewhat smaller, it may be removed entirely.—We say no more of it at present, because we shall find its construction included in another, which is still more perfect.

It is evident at first sight that this telescope may be improved, by substituting for the eye-glass the Huyghenian double eye-glass, or field-glass and eye-glass represented in fig. 19. and 20.; and that the first of these may be improved and rendered achromatic. This will require the two glasses *e f* and *g h* to be increased from their present dimensions to the size of a field-glass, suited to the magnifying power of the telescope, supposing it an astronomical telescope. Thus we shall have a telescope of four eye-glasses. The three first will be of a considerable focal distance, and two of them will have a common focus at *b*. But this is considerably different from the eye-piece of four glasses which are now used, and are far better. We are indebted for them to Mr Dollond, who was a mathematician as well as an artist, and in the course of his research discovered resources which had not been thought of. He had not then discovered the achromatic object-glass, and was busy in improving the eye-glasses by diminishing their spherical aberration. His first thought was to make the Huyghenian addition at both the images of the day telescope. This suggested to him the following eye-piece of five glasses.

Fig. 24. represents this eye-piece, but there is not room for the object glass at its proper distance. A pencil of rays coming from the upper point of the object is made to converge (by the object-glass) to G, where it would form a picture of that part of the object. But it is intercepted by the lens A *a*, and its axis is bent towards the axis of the telescope in the direction *a b*. At the same time, the rays which converged to G converge to *g*, and there is formed an inverted picture of the object at *g f*. The axis of the pencil is again refracted at *b*, Fig. 24.

 b, crosses the axis of the telescope in H, is refracted again at c, at d, and at e, and at last crosses the axis in I. The rays of this pencil, diverging from g, are made less diverging, and proceed as if they came from g', in the line B $g\,g'$. The lens c C causes them to converge to g', in the line G$''$ C g'. The lens d D makes them converge still more to G$''$, and there they form an erect picture G$''$ F$''$; diverging from G$''$, they are rendered parallel by the refraction at e.

At H the rays are nearly parallel. Had the glass B b been a little farther from A, they would have been accurately so, and the object-glass, with the glasses A and B, would have formed an astronomical telescope with the Huyghenian eye-piece. The glasses C, D, and E, are intended merely for bending the rays back again till they again cross the axis in I. The glass C tends chiefly to diminish the great angle BH b; and then the two glasses D and E are another Huyghenian eye-piece.

The art in this construction lies in the proper adjustment of the glasses, so as to divide the whole bending of the pencil pretty equally among them, and to form the last image in the focus of the eye-glass, and at a proper distance from the other glass. Bringing B nearer to A would bend the pencil more to the axis. Placing C farther from B would do the same thing; but this would be accompanied with more aberration, because the rays would fall at a greater distance from the centres of the lenses. The greatest bending is made at the field-glass D; and we imagine that the telescope would be improved, and made more distinct at the edges of the field, by employing another glass of great focal distance between C and D.

There is an image formed at H of the object-glasses, and the whole light passes through a small circle in this place. It is usual to put a plate here pierced with a hole which has the diameter of this image. A second image of the object-glass is formed at I, and indeed wherever the pencils cross the axis. A lens placed at H makes no change in any of the angles, nor in the magnifying power, and affects only the place where the images are formed. And, on the other hand, a lens placed at f, or F$''$, where a real image is formed, makes no change in the places of the images, but affects the mutual inclination of the pencils. This affords a resource to the artist, by which he may combine properties which seem incompatible.

The aperture of A determines the visible field and all the other apertures.

We must avoid forming a real image, such as $f\,g$, or F$''$ G$''$, on or very near any glass. For we cannot see this image without seeing along with it every particle of dust and every scratch on the glass. We see them as making part of the object when the image is exactly on the glass, and we see them confusedly, and so as to confuse the object, when the image is near it. For when the image is on or very near any glass, the pencil of light occupies a very small part of its surface, and a particle of dust intercepts a great proportion of it.

It is plain that this construction will not do for the telescope of graduated instruments, because the micrometer cannot be applied to the second image $f\,g$, on account of its being a little distorted, as has been observed of the Huyghenian eye-piece.

Also the interposition of the glass C makes it difficult to correct the dispersion.

By proper reasoning from the correction in the Huyghenian eye-piece, we are led to the best construction of one with three glasses; which we shall now consider, taking it in a particular form, which shall make the discussion easy, and make us fully masters of the principles which lead to a better form. Therefore let PA (fig. 25.) be the glass which first receives the light proceeding from the image formed by the object-glass, and let OP be the axis of the extreme pencil. This is refracted into PR, which is again refracted into R r by the next lens B r. Let b be the focus of parallel rays of the second lens. Draw P B r. We know that A b : b B=PB : B r, and that rays of one kind diverging from P will be collected at r. But if PR, PV be a red and a violet ray, the violet ray will be more refracted at V, and will cross the red ray in some intermediate point g of the line R r. If therefore the first image had been formed precisely on the lens PA, we should have a second image at $f\,g$ free from all coloured fringes. Fig. 25.

If the refractions at P and R are equal (as in the common day telescope), the dispersion at V must be equal to that at P, or the angle v V r=VPR. But we have ultimately RPV : R r V=BC : AB, (=B b : A b by the focal theorem). Therefore g V r : $g\,r$ V, (or $g\,r$: g V, or C f : f B)=B b : A b, and AB : A b= R r : R g.

This shows by the way the advantage of the common day telescope. In this AB=2 A b, and therefore f is the place of the last image which is free from coloured fringes. But this image will not be seen free from coloured fringes through the eye-glass C r, if f be its focus: For had $g\,r$, $g\,v$ been both red rays, they would have been parallel after refraction; but $g\,v$ being a violet ray, will be more refracted. It will not indeed be so much deflected from parallelism as the violet ray, which naturally accompanies the red ray to r, because it falls nearer the centre. By computation its dispersion is diminished about $\frac{1}{7}$th.

In order that $g\,v$ may be made parallel to $g\,r$ after refraction, the refraction at r must be such that the dispersion corresponding to it may be of a proper magnitude. How to determine this is the question. Let the dispersion at g be to the dispersion produced by the refraction at r (which is required for producing the intended magnifying power) as 1 to 9. Make 9 : 1= $f\,f'$: f' C, = f C : CD, and draw the perpendicular D r' meeting the refracted ray $r\,r'$ in r'. Then we know by the common focal theorem, that if f' be the focus of the lens C r, red rays diverging from g will be united in r'. But the violet ray $g\,v$ will be refracted into $v\,v'$ parallel to $r\,r'$. For the angle $v\,r'\,r$: $v\,g\,r$= (ultimately) f C : CD, =9 : 1. Therefore the angle $v\,r'\,r$ is equal to the dispersion produced at r, and therefore equal to $r'\,v\,v'$, and $v\,v'$ is parallel to $r\,r'$.

But by this we have destroyed the distinct vision of the image formed at $f\,g$, because it is no longer at the focus of the eye-glass. But distinct vision will be restored by pushing the glasses nearer to the object-glass. This makes the rays of each particular pencil more divergent after refraction through A, but scarcely makes any change in the directions of the pencils themselves. Thus the image comes to the focus f', and makes no sensible change in the dispersions.

In

Telescope.

In the common day telescope, the first image is formed in the anterior focus of the first eye-glass, and the second image is at the anterior focus of the last eye-glass. If we change this last for one of half the focal distance, and push in the eye-piece till the image formed by the object-glass is half way between the first eye-glass and its focus, the last image will be formed at the focus of the new eye-glass, and the eye-piece will be achromatic. This is easily seen by making the usual computations by the focal theorem. But the visible field is diminished, because we cannot give the same aperture as before to the new eye-glass; but we can substitute for it two eye-glasses like the former, placed close together. This will have the same focal distance with the new one, and will allow the same aperture that we had before.

On these principles may be demonstrated the correction of colour in eye-pieces with three glasses of the following construction.

Let the glasses A and B be placed so that the posterior focus of the first nearly coincides with the anterior focus of the second, or rather so that the anterior focus of B may be at the place where the image of the object-glass is formed, by which situation the aperture necessary for transmitting the whole light will be the smallest possible. Place the third C at a distance from the second, which exceeds the sum of their focal distances by a space which is a third proportional to the distance of the first and second, and the focal distance of the second. The distance of the first eye-glass from the object-glass must be equal to the product of the focal distance of the first and second divided by their sum.

Let O o, A a, B b, C c, the focal distances of the glasses, be O, a, b, c. Then make $AB = a+b$ nearly; $BC = b + c + \frac{b^2}{b+c}$; $OA = \frac{bc}{b+c}$. The amplification or magnifying power will be $= \frac{ob}{ac}$; the equivalent eye-glass $= \frac{ac}{b}$; and the field of vision $= 3438' \times \frac{\text{Aperture of A}}{\text{foc. dist. ob. gl.}}$.

These eye-pieces will admit the use of a micrometer at the place of the first image, because it has no distortion.

Mr Dollond was anxious to combine this achromatism of the eye-pieces with the advantages which he had found in the eye-pieces with five glasses. This eye-piece of three glasses necessarily has a very great refraction at the glass B, where the pencil which has come from the other side of the axis must be rendered again convergent, or at least parallel to it. This occasions considerable aberrations. This may be avoided by giving part of this refraction to a glass put between the first and second, in the same way as he has done by the glass B put between A and C in his five glass eye-piece. But this deranges the whole process. His ingenuity, however, surmounted this difficulty, and he made eye-pieces of four glasses, which seem as perfect as can be desired. He has not published his ingenious investigation; and we observe the London artists work very much at random, probably copying the proportions of some of his best glasses, without understanding the principle, and therefore frequently mistaking. We see many eye-pieces which are far from being achromatic. We imagine therefore that it will be an acceptable thing to the artists to have precise instructions how to proceed, nothing of this kind having appeared in our language, and the investigations of Euler, d'Alembert, and even Boscovich, being so abstruse as to be inaccessible to all but experienced analysts. We hope to render it extremely simple.

It is evident, that if we make the rays of different colours unite on the surface of the last eye-glass but one, commonly called the *field-glass*, the thing will be done, because the dispersion from this point of union will then unite with the dispersion produced by this glass alone; and this increased dispersion may be corrected by the last eye-glass in the way already shown.

Therefore let A, B (fig. 26.) be the stations which we have fixed on for the first and second eye-glasses, in order to give a proper portion of the whole refraction to the second glass. Let b be the anterior focus of B. Draw PB r through the centre of B. Make A b : b B $=$ AB : BK. Draw the perpendicular K r, meeting the refracted ray in r. We know by the focal theorem, that red rays diverging from P will converge to r; but the violet ray PV, being more refracted, will cross Rr in some point g. Drawing the perpendicular fg, we get f for the proper place of the field-glass. Let the refracted ray Rr, produced backward, meet the ray OP coming from the centre of the object-glass in O. Let the angle of dispersion RPV be called p, and the angle of dispersion at V, that is, r V v, be v, and the angle V r R be r. Fig. 26.

It is evident that $OR : OP = p : v$, because the dispersions are proportional to the sines of the refractions, which, in this case, are very nearly as the refractions themselves.

Let $\frac{OP}{OR}\left(\text{or } \frac{op}{pB} \text{ or } \frac{pB}{bB}\right)$ be made $= m$. Then $v = mp$; also $p : r = BK : AB, = bB : Ab$, and $r = p.\frac{Ab}{bB}$, or making $\frac{Ab}{Bb} = n$, $r = np$; therefore $v : r = m : n, = \frac{pB}{bB} : \frac{Ab}{bB}, = pB : Ab$.

The angle $RgV = gVr + grV = p.\overline{m+n}$; and $RgV : Rrv = Rr : Rg$, or $m+n : n = Rr : Rg$, and $Rg = Rr\frac{n}{m+n}$. But Rr is ultimately $= BK = AB\frac{bB}{Ab} = \frac{AB}{n}$. Therefore $Rg = \frac{AB}{n} \times \frac{n}{m+n} = \frac{n}{m+n}$, and $Bf = \frac{AB}{m+n}$.

This value of Bf is evidently $= bB \times \frac{AB}{pB + Ab}$. Now b B being a constant quantity while the glass B is the same, the place of union varies with $\frac{AB}{pB+Ab}$. If we remove B a little farther from A, we increase AB, and p B, and A b, each by the same quantity. This evidently diminishes Bf. On the other hand, bringing B nearer to A increases Bf. If we keep the distance between the glasses the same, but increase the focal distance b B, we augment Bf, because this change aug-

 ments

Telescope. ments the numerator and diminishes the denominator of the fraction $\frac{b\,B\times AB}{p\,B+A\,b}$.

In this manner we can unite the colours at what distance we please, and consequently can unite them in the place of the intended field-glass, from which they will diverge with an increased dispersion, viz. with the dispersion competent to the refraction produced there, and the dispersion $p\times\overline{m+n}$ conjoined.

It only remains to determine the proper focal distances of the field-glass and eye-glass, and the place of the eye-glass, so that this dispersion may be finally corrected.

This is an indeterminate problem, admitting of an infinity of solutions. We shall limit it by an equal division of the two remaining refractions, which are necessary in order to produce the intended magnifying power. This construction has the advantage of diminishing the aberration. Thus we know the two refractions, and the dispersion competent to each; it being nearly $\frac{1}{27}$th of the refraction. Call this q. The whole dispersion at the field-glass consists of q, and of the angle $\overline{K\,g\,V}$ of fig. 19. which we also know to be $=p\times\overline{m+n}$. Call their sum s.

Fig. 27. Let fig. 27. represent this addition to the eye-piece. $C\,g$ is the field-glass coming in the place of $f\,g$ of fig. 26. and $R\,g\,w$ is the red ray coming from the glass BR. Draw $g\,s$ parallel to the intended emergent pencil from the eye-glass; that is, making the angle $C\,s\,g$ with the axis correspond to the intended magnifying power. Bisect this angle by the line g K. Make $s\,g : g\,q = s : q$, and draw q K, cutting $C\,g$ in t. Draw $t\,\delta$ D, cutting $g\,k$ in δ, and the axis in D. Draw $\delta\,d$ and $D\,r$ perpendicular to the axis. Then a lens placed in D, having the focal distance $D\,d$, will destroy the dispersion at the lens $g\,c$, which refracts the ray $g\,w$ into $g\,r$.

Let $g\,v$ be the violet ray, making the angle $v\,g\,r = s$. It is plain, by the common optical theorem, that $g\,r$ will be refracted into $r\,r'$ parallel to δ D. Draw g D v' meeting $r\,r'$, and join $v\,r'$. By the focal theorem two red rays $g\,r\,g\,v$, will be united in r'. But the violet ray $g\,v$ will be more refracted, and will take the path $v\,v'$, making the angle of dispersion $r'\,v\,v = q$, very nearly, because the dispersion at v does not sensibly differ from that at r. Now, in the small angles of refraction which obtain in optical instruments, the angles $r\,r'\,v$, $r\,g\,v$ are very nearly as $g\,r$ and $r\,r'$, or as g D and D r', or as CD and DT; which, by the focal theorem, are as C d and dD: that is, $D\,d : d\,c = r\,g\,v : r\,r'v$. But $D\,d : d\,C = D\,\delta : \delta\,t, = s\,g : g\,q, = s : q$. But $r\,g\,v = s$; therefore $r\,r'\,v = q, = r'\,v\,v'$, and $v\,v'$ is parallel to $r\,r'$, and the whole dispersion at g is corrected by the lens D r. The focal distance C c of C g is had by drawing C x parallel to K g, meeting R g in x, and drawing $x\,c$ perpendicular to the axis.

It is easy to see that this (not inelegant) construction is not limited to the equality of the refractions $w\,g\,r$, K $r\,r'$. In whatever proportion the whole refraction $w\,g\,s$ is divided, we always can tell the proportion of the dispersions which the two refractions occasion at g and r, and can therefore find the values of s and q. Indeed this solution includes the problem in p. 266. col. 2. par. ult.; but it had not occurred to us till the present occasion. Our readers will not be displeased with this variety of resource. Telescope.

The intelligent reader will see, that in this solution some quantities and ratios are assumed as equal which are not strictly so, in the same manner as in all the elementary optical theorems. The parallelism, however, of $v\,v'$ and $r\,r'$ may be made accurate, by pushing the lens D r nearer to C g, or retiring it from it. We may also, by pushing it still nearer, induce a small divergency of the violet ray, so as to produce accurate vision in the eye, and may thus make the vision through a telescope more perfect than with the naked eye, where dispersion is by no means avoided. It would therefore be an improvement to have the eye-glass in a sliding tube for adjustment. Bring the telescope to distinct vision; and if any colour be visible about the edges of the field, shift the eye-glass till this colour is removed. The vision may now become indistinct: but this is corrected by shifting the place of the whole eye-piece.

We have examined trigonometrically the progress of a red and a violet ray through many eye-pieces of Dollond's and Ramsden's best telescopes; and we have found in all of them that the colours are united on or very near the field-glass; so that we presume that a theory somewhat analogous to ours has directed the ingenious inventors. We meet with many made by other artists, and even some of theirs, where a considerable degree of colour remains, sometimes in the natural order and often in the contrary order. This must happen in the hands of mere imitators, ignorant of principle. We presume that we have now made this principle sufficiently plain.

Fig. 28. represents the eye-piece of a very fine spy-glass by Mr Ramsden; the focal length of its object-glass is $8\frac{1}{2}$ inches, with $1\frac{1}{10}$th of aperture, 2° 05′ of visible field, and 15.4 magnifying power. The distances and focal lengths are of their proper dimensions, but the apertures are $\frac{1}{5}$ larger, that the progress of a lateral pencil might be more distinctly drawn. The dimensions are as follow: Fig. 28.

Foc. lengths $Aa = 0.775$ $Bb = 1.025$ $Cc = 1.01$ $Dd = 0.79$.
Distances $AB = 1.18$ $BC = 1.83$ $CD = 1.105$.

It is perfectly achromatic, and the colours are united, not precisely at the lens C g, but about $\frac{1}{20}$th of an inch nearer the eye-glass.

It is obvious that this combination of glasses may be used as a microscope; for if, instead of the image formed by the object-glass at FG, we substitute a small object, illuminated from behind, as in compound microscopes; and if we draw the eye-piece a very small way from this object, the pencils of parallel rays emergent from the eye-glass D will become convergent to very distant points, and will there form an inverted and enlarged picture of the object, which may be viewed by a Huyghenian eye-piece; and we may thus get high magnifying powers without using very deep glasses. We tried the eye-piece of which we have given the dimensions in this way, and found that it might be made to magnify 180 times with very great distinctness. When used as the magnifier of a solar microscope, it infinitely surpasses every thing we have ever seen. The picture formed by a solar microscope is generally so indistinct, that it is fit only for amusing ladies; but with this magnifier it seemed

Telescope. ed perfectly sharp. We therefore recommend this to the artists as a valuable article of their trade.

The only thing which remains to be considered in the theory of refracting telescopes is the forms of the different lenses. Hitherto we have had no occasion to consider any thing but their focal distances; but their aberrations depend greatly on the adjustment of their forms to their situations. When the conjugate focuses of a lens are determined by the services which it is to perform, there is a certain form or proportion between the curvatures of their anterior and posterior surfaces, which will make their aberrations the smallest possible.

It is evident that this proportion is to be obtained by making the fluxion of the quantity within the parenthesis in the formula at the top of col. 2. p. 248. equal to nothing. When this is done, we obtain this formula for a, the radius of curvature for the anterior surface of a lens. $\frac{1}{a}=\frac{2m^2+m}{2m+4}+\frac{4m+4}{2(m+4)r}$, where m is the ratio of the sine of incidence to the sine of refraction, and r is the distance of the focus of incident rays, positive or negative, according as they converge or diverge, all measured on a scale of which the unit is n, $=$ half of the radius of the equivalent isosceles lens.

It will be sufficiently exact for our purpose to suppose $m=\frac{3}{2}$, though it is more nearly $\frac{31}{20}$. In this case $\frac{1}{a}=\frac{6}{7}+\frac{10}{7r}$, $=\frac{42r+70}{49r}$. Therefore $a=\frac{49r}{42r+70}$. And $\frac{1}{b}=\frac{1}{a}-1$, $=\frac{1-a}{a}$.

As an example, let it be required to give the radii of curvature in inches for the eye-glass be of page 262. col. 1. par. 4. which we shall suppose of $1\frac{1}{2}$ inches focal distance, and that ec $(=r)$ is $3\frac{3}{4}$th inches.

The radius of curvature for the equivalent isosceles lens is 1.5, and its half is 0.75. Therefore $r=\frac{3\frac{3}{4}}{0.75}$, $=5$; and our formula is $a=\frac{49\times 5}{42\times 5+70}$, $=\frac{245}{280}$, $=0.875$; and $\frac{1}{b}=\frac{1-a}{a}$, $=\frac{0.125}{0.875}$, and $b=\frac{0.875}{0.125}$, $=7$.

These values are parts of a scale, of which the unit is 0.75 inches. Therefore

$$a\text{, in inches, }=0.875\times 0.75,=0.65525$$
$$b\text{, in inches, }=7\times 0.75,=5.25.$$

And here we must observe that the posterior surface is concave: for b is a positive quantity, because $1-a$ is a positive quantity as well as a; therefore the centre of sphericity of both surfaces lies beyond the lens.

And this determination is not very different from the usual practice, which commonly makes this lens a plane convex with its flat side next the eye: and there will not be much difference in the performance of these two lenses; for in all cases of maxima and minima, even a pretty considerable change of the best dimensions does not make a sensible change in the result.

The same consideration leads to a rule which is very simple, and sufficiently exact for ordinary situations. Telescope. This is to make the curvatures such, that the incident and emergent pencils may be nearly equally inclined to the surfaces of the lens. Thus in the eye-piece with five glasses, A and B should be most convex on their anterior sides; C should be most convex on the posterior side; D should be nearly isosceles; and E nearly plano-convex.

But this is not so easy a matter as appears at first sight. The lenses of an eye-piece have not only to bend the several pencils of light to and from the axis of the telescope; they have also to form images on the axes of these pencils. These offices frequently require opposite forms, as mentioned in par. 3. col. 2. p. 261. Thus the glass A, fig. 28. should be most convex on the side next the object, that it may produce little distortion Fig. 28. of the pencils. But it should be most convex next the eye, that it may produce distinct vision of the image FG, which is very near it. This image should have its concavity turned towards A, whereas it is towards the object-glass. We must therefore endeavour to make the vertical image fg flatter, or even convex. This requires a glass very flat before and convex behind. For similar reasons the object-glass of a microscope and the simple eye-glass of an astronomical telescope should be formed the same way.

This is a subject of most difficult discussion, and requires a theory which few of our readers would relish; nor does our limits afford room for it. The artists are obliged to grope their way. The proper method of experiment would be, to make eye-pieces of large dimensions, with extravagant apertures to increase the aberrations, and to provide for each station A, B, C, and D, a number of lenses of the same focal distance, but of different forms; and we would advise making the trial in the way of a solar microscope, and to have two eye-pieces on trial at once. Their pictures can be formed on the same screen, and accurately compared; whereas it is difficult to keep in remembrance the performance of one eye-piece, and compare it with another.

We have now treated the theory of refracting telescopes with considerable minuteness, and have perhaps exceeded the limits which some readers may think reasonable. But we have long regretted that there is not any theory on this subject from which a curious person can learn the improvements which have been made since the time of Dr Smith, or an artist learn how to proceed with intelligence in his profession. If we have accomplished either of these ends, we trust that the public will receive our labours with satisfaction.

We cannot add any thing to what Dr Smith has delivered on the theory of reflecting telescopes. There appears to be the same possibility of correcting the aberration of the great speculum by the contrary aberration of a convex small speculum, that we have practised in the compound object-glass of an achromatic refracting telescope. But this cannot be, unless we make the radius of the convex speculum exceedingly large, which destroys the magnifying power and the brightness. This therefore must be given up. Indeed their performance, when well executed, does already surpass all imagination. Dr Herschel has found great advantages in what he calls the *front view*, not using a plane mirror to throw the pencils to one side. But this cannot be-

Telescope. be practised in any but telescopes so large, that the loss of light, occasioned by the interposition of the observer's head, may be disregarded.

Nothing remains but to describe the mechanism of some of the most convenient forms.

To describe all the varieties of shape and accommodation which may be given to a telescope, would be a task as trifling as prolix. The artists of London and of Paris have racked their inventions to please every fancy, and to suit every purpose. We shall content ourselves with a few general maxims, deduced from the scientific consideration of a telescope, as an instrument by which the visual angle subtended by a distant object is greatly magnified.

The chief consideration is to have a steady view of the distant object. This is unattainable, unless the axis of the instrument be kept constantly directed to the same point of it: for when the telescope is gently shifted from its position, the object *seems to move* in the same or in the opposite direction, according as the telescope inverts the object or shows it erect. This is owing to the magnifying power, because the apparent angular motion is greater than what we naturally connect with the motion of the telescope. This does not happen when we look through a tube without glasses.

All shaking of the instrument therefore makes the object dance before the eye; and this is disagreeable, and hinders us from seeing it distinctly. But a tremulous motion, however small, is infinitely more prejudicial to the performance of a telescope, by making the object quiver before us. A person walking in the room prevents us from seeing distinctly; nay, the very pulsation in the body of the observer, agitates the floor enough to produce this effect, when the telescope has a great magnifying power: For the visible motion of the object is then an imperceptible tremor, like that of an harpsichord wire, which produces an effect precisely similar to optical indistinctness; and every point of the object is diffused over the whole space of the angular tremor, and appears coexistent in every part of this space, just as a harpsichord wire does while it is sounding. The more rapid this motion is, the indistinctness is the more complete. Therefore the more firm and elastic and well bound together the frame-work and apertures of our telescope is, the more hurtful will this consequence be. A mounting of lead, were it practicable, would be preferable to wood, iron, or brass. This is one great cause of the indistinctness of the very finest reflecting telescopes of the usual constructions, and can never be totally removed. In the Gregorian form, it is hardly possible to damp the elastic tremor of the small speculum, carried by an arm supported at one end only, even though the tube were motionless. We were witnesses of a great improvement made on a four feet reflecting telescope, by supporting the small speculum by a strong plate of lead placed across the tube, and led by an adjusting screw at each end. But even the great mirror may vibrate enough to produce indistinctness. Refracting telescopes are free from this inconveniency, because a small angular motion of the object-glass round one of its own diameters has no sensible effect on the image in its focus. They are affected only by an angular motion of the axis of the telescope or of the eye-glasses.

This single consideration gives us great help towards judging of the merits of any particular apparatus. We should study it in this particular, and see whether its form makes the tube readily susceptible of such tremulous motions. If it does, the firmer it is and the more elastic it is, the worse. All forms therefore where the tube is supported only near the middle, or where the whole immediately or remotely depend on one narrow joint, are defective.

Reasoning in this way, we say with confidence, that of all the forms of a telescope apparatus, the old fashioned simple stand represented in fig. 29. is by far the best, and that others are superior according as the disposition of the points of support of the tube approaches to this. Let the pivots A, B, be fixed in the lintel and sole of a window. Let the four braces terminate very near to these pivots. Let the telescope lie on the pin F *f*, resting on the shoulder round the eye-piece, while the far end of it rests on one of the pins 1, 2, 3, &c.; and let the distance of these pins from F very little exceed the length of the telescope. The trembling of the axis, even when considerable, cannot affect the position of the tube, because the braces terminate almost at the pivots. The tremor of the brace CD does as little harm, because it is nearly perpendicular to the tube. And if the object-glass were close at the upper supporting pin, and the focus at the lower pin F, even the bending and trembling of the tube will have no effect on its optical axis. The instrument is only subject to horizontal tremors. These may be almost annihilated by having a slender rod coming from a hook's joint in the side of the window, and passing through such another joint close by the pin F. We have seen an instrument of this form, having AB parallel to the earth's axis. The whole apparatus did not cost 50 shillings, and we find it not in the least sensible manner affected by a storm of wind. It was by observations with this instrument that the tables of the motions of the Georgium Sidus, published in the Edinburgh Transactions, were constructed, and they are as accurate as any that have yet appeared. This is an excellent equatorial. Fig. 29.

But this apparatus is not portable, and it is sadly deficient in elegance. The following is the best method we have seen of combining these circumstances with the indispensable requisites of a good telescope.

The pillar VX (fig. 30.) rises from a firm stand, and has a horizontal motion round a cone which completely fills it. This motion is regulated by a rack-work in the box at V. The screw of this rack-work is turned by means of the handle P, of a convenient length, and the screw may be disengaged by the click or detent V, when we would turn the instrument a great way at once. The telescope has a vertical motion round the joint Q placed near the middle of the tube. The lower end of the tube is supported by the stay OT. This consists of a tube RT, fastened to the pillar by a joint T, which allows the stay to move in a vertical plane. Within this tube slides another, with a stiff motion. This tube is connected with the telescope by another joint O, also admitting motion in a vertical plane. The side M of this inner tube is formed into a rack, in which works a pinion fixed to the top of the tube RT, and turned by the flat finger-piece R. The reader will readily see the advantages and the remaining defects of this apparatus. It is very portable, because the telescope is easily disengaged from it, and the legs and stay fold up. If the joint Fig. 30.

joint Q were immediately under A, it would be much freer from all tremor in the vertical plane. But nothing can hinder other tremors arising from the long pillar and the three springy legs. These communicate all external agitations with great vigour. The instrument should be set on a stone pedestal, or, what is better, a cask filled with wet sand. This pedestal, which necessity perhaps suggested to our scientific navigators, is the best that can be imagined.

Fig. 31. Fig. 31. is the stand usually given to reflecting telescopes. The vertical tube FBG is fastened to the tube by finger screws, which pass through the slits at F and G. This arch turns round a joint in the head of the divided pillar, and has its edge cut into an oblique rack, which is acted on by the horizontal screw, furnished with the finger-piece A. This screw turns in a horizontal square frame. This frame turns round a horizontal joint in the off-side, which cannot be seen in this view. In the side of this frame next the eye there is a finger-screw *a*, which passes through the frame, and presses on the round horizontal plate D. By screwing down this finger-screw, the frame is brought up, and presses the horizontal screw to the rack. Thus the elevation of the telescope is fixed, and may be nicely changed by the finger applied to A, and turning this screw. The horizontal round plate D moves stiffly round on another plate of nearly equal diameter. This under plate has a deep conical hollow socket, which is nicely fitted by grinding to a solid cone formed on the top of the great upright pillar, and they may be firmly fixed in any position by the finger-screw E. To the under plate is fastened a box *c*, containing a horizontal screw C, which always works in a rack cut in the edge of the upper plate, and cannot be disengaged from it. When a great vertical or horizontal motion is wanted, the screws *a* and E are slacked, and by tightening them the telescope may be fixed in any position, and then any small movements may be given it by the finger plates A and C.

This stand is very subject to brisk tremor, either from external agitation of the pedestal, or from the immediate action of the wind; and we have seldom seen distinctly through telescopes mounted in this manner, till one end of the tube was pressed against something that was very steady and unelastic. It is quite astonishing what a change this produces. We took a very fine telescope made by James Short, and laid the tube on a great lump of soft clay, pressing it firmly down into it. Several persons, ignorant of our purpose, looked through it, and read a table of logarithms at the distance of 310 yards. We then put the telescope on its stand, and pointed it at the same object; none of the company could read at a greater distance than 235 yards, although they could perceive no tremor. They thought the vision as sharp as before; but the incontrovertible proof of the contrary was, that they could not read at such a distance.

If the round plates were of much greater dimensions; and if the lower one, instead of being fixed to the pillar, were supported on four stout pillars standing on another plate; and if the vertical arch had a horizontal axis turning on two upright frames firmly fixed to the upper plate—the instrument would be much freer from tremor. Such stands were made formerly; but being much more bulky and inconvenient for package, they have gone into disuse.

The high magnifying powers of Dr Herschel's telescopes made all the usual apparatus for their support extremely imperfect. But his judgment, and his ingenuity and fertility in resource, are as eminent as his philosophical ardour. He has contrived for his reflecting telescope stands which have every property that can be desired. The tubes are all supported at the two ends. The motions, both vertical and horizontal, are contrived with the utmost simplicity and firmness. We cannot more properly conclude this article than with a description of his 40 feet telescope, the noblest monument of philosophical and of princely munificence that the world can boast of.

Fig. 32. represents a view of this instrument in a meridional situation, as it appears when seen from a convenient distance by a person placed to the south-west of it. The foundation in the ground consists of two concentric circular brick walls, the outermost of which is 42 feet in diameter, and the inside one 21 feet. They are two feet six inches deep under ground; two feet three inches broad at the bottom, and one foot two inches at the top; and are capped with paving stones about three inches thick, and twelve and three quarters broad. The bottom frame of the whole apparatus rests upon these two walls by twenty concentric rollers III, and is moveable upon a pivot, which gives a horizontal motion to the whole apparatus, as well as to the telescope. Plate DXXXI. fig. 32.

The tube of the telescope, A, though very simple in its form, which is cylindrical, was attended with great difficulties in the construction. This is not to be wondered at; when its size, and the materials of which it is made, are considered. Its length is 39 feet four inches; it measures four feet ten inches in diameter; and every part of it is of iron. Upon a moderate computation, the weight of a wooden tube must have exceeded an iron one at least 3000 pounds; and its durability would have been far inferior to that of iron. It is made of rolled or sheet iron, which has been joined together without rivets, by a kind of seaming well known to those who make iron funnels for stoves.

Very great mechanical skill is used in the contrivance of the apparatus by which the telescope is supported and directed. In order to command every altitude, the point of support is moveable; and its motion is effected by mechanism, so that the telescope may be moved from its most backward point of support to the most forward, and, by means of the pulleys GG suspended from the great beam H, be set to any altitude, up to the very zenith. The tube is also made to rest with the point of support in a pivot, which permits it to be turned sidewise.

The concave face of the great mirror is 48 inches of polished surface in diameter. The thickness, which is equal in every part of it, remains now about three inches and a half; and its weight, when it came from the cast was 2118 pounds, of which it must have lost a small quantity in polishing. To put this speculum into the tube, it is suspended vertically by a crane in the laboratory, and placed on a small narrow carriage, which is drawn out, rolling upon planks, till it comes near the back of the tube; here it is again suspended

suspended and placed in the tube by a peculiar apparatus.

The method of observing by this telescope is by what Dr Herschel calls the *front view*; the observer being placed in a seat C, suspended at the end of it, with his back towards the object he views. There is no small speculum, but the magnifiers are applied immediately to the first focal image.

From the opening of the telescope, near the place of the eye-glass, a speaking pipe runs down to the bottom of the tube, where it goes into a turning point; and after several other inflections, it at length divides into two branches, one going into the observatory D, and the other into the work-room E. By means of the speaking pipe the communications of the observer are conveyed to the assistant in the observatory, and the workman is directed to perform the required motions.

In the observatory is placed a valuable sidereal time-piece, made by Mr Shelton. Close to it, and of the same height, is a polar distance-piece, which has a dial-plate of the same dimensions with the time-piece: this piece may be made to show polar distance, zenith distance, declination, or altitude, by setting it differently. The time and polar distance pieces are placed so that the assistants sit before them at a table, with the speaking pipe rising between them; and in this manner observations may be written down very conveniently.

This noble instrument, with proper eye-glasses, magnifies above 6000 times, and is the largest that has ever been made. Such of our readers as wish for a fuller account of the machinery attached to it, viz. the stairs, ladders, and platform B, may have recourse to the second part of the Transactions of the Royal Society for 1795; in which, by means of 18 plates and 63 pages of letter-press, an ample detail is given of every circumstance relating to joiner's work, carpenter's work, and smith's work, which attended the formation and erection of this telescope. It was completed on August the 28th 1789, and on the same day was the sixth satellite of Saturn discovered.

TELL, WILLIAM, an illustrious Swiss patriot, chief instrument of the revolution which delivered the Swiss cantons from the German yoke in 1307. Grisler, the governor of these provinces for the emperor Albert, having ordered him, under pain of death, to shoot at an apple placed on the head of one of his children; he had the dexterity, though the distance was very considerable, to strike it off without hitting the child. The tyrant, perceiving he had another arrow concealed under his cloak, asked him for what purpose? To which he boldly replied, "To have shot you through the heart, if I had had the misfortune to kill my son." The enraged governor now ordered him to be hanged; but his fellow-citizens, animated by his fortitude and patriotism, flew to arms; attacked and vanquished Grisler, who was shot to death by Tell; and the association for the independency took place that instant.

Tell-Tale, a name sometimes given to the *Perpetual-Log*. See that article.

TELLER, an officer of the exchequer, in ancient records called *tallier*. There are four of these officers, whose duty is to receive all sums due to the king, and to give the clerk of the pells a bill to charge him therewith. They likewise pay all money due from the king, by warrant from the auditor of the receipt; and make weekly and yearly books both of their receipts and payments, which they deliver to the lord treasurer.

TELLINA, a genus of shell-fish. See CONCHOLOGY *Index*.

TEMISSA, a large town in Africa, about 120 miles north-east of Mourzouk, the capital of Fezzan. Here the caravan of pilgrims from Bornou and Nigritia, which takes its departure from Mourzouk, and travels by the way of Cairo to Mecca, usually provides the stores of corn and dates, and dried meat, that are requisite for its dreary passage.

TEMPE, in *Ancient Geography*, a most pleasant place or valley of Thessaly. That it was there, appears from the epithets of *Thessalica* (Livy), *Thessala* (Ovid). The doubts respecting the situation of this celebrated valley have been completely removed by Dr Clarke, who found its name in a Roman inscription on the face of the rock. It is the narrow and steep defile through which the Peneus escapes from the Thessalian plain. This defile is formed by Mount Olympus on the north, and Mount Ossa on the south. It is richly wooded, while lofty precipices present their bare fronts of various colours, amidst the trees. The village of Ampelakia, celebrated for its manufacture of *Turkey red*, lies within this valley on the south side. The Peneus, according to Pliny, running down between Ossa to the south and Olympus to the north for 500 stadia, is for half that space navigable: in the direction of this course lies what is called *Tempe*, extending in length for five miles, in breadth for about an acre and a half, with gentle convexities rising on the right and left hand. Within glides the pure stream of the Peneus, charming in the grass on its banks, and harmoniously vocal with the music of birds. In this description Strabo and Ælian agree; the last adding, that it has an agreeable variety of places of retreat; and that it is not the work of man's hand, but the spontaneous production of nature; and Strabo says, that formerly the Peneus formed a lake in this spot, being checked in its course by the higher grounds about the sea; but that an opening being made by an earthquake, and Mount Ossa torn from Olympus, the Peneus gained a free course between them. But Livy, who calls Tempe a grove, remarks a degree of horror rather than amenity, with which the Roman army was struck on marching over the narrow pass; for, besides the defile, difficult to go over, which runs on for five miles, there are steep rocks on each hand, down which the prospect is apt to cause a dizziness, heightened by the noise and depth of the interfluent Peneus.

TEMPER, in a mechanical sense. See TEMPERING.

TEMPER, in a moral sense, the disposition of mind, whether natural or acquired. The word is seldom used by good writers without an epithet, as a *good* or *bad* temper, though one of the most beautiful poems in the language is entitled *The Triumphs of Temper*.

It is well observed by an elegant Essayist, that more constant uneasiness arises from ill temper than from ill fortune; as a bad temper embitters every sweet, and converts a paradise into a place of torment. For subduing the heart to softness, and preserving a due balance of the passions, a proper culture of the understanding and of the taste is the best method. He who employs his

Temper, Temperament.

his time in the studies of elegant literature, or the fine arts, has almost always a good temper; whilst the man who is absorbed in the pursuits of profound science is apt to acquire a severity of disposition, little less disagreeable, though generally much less pernicious, than the capriciousness of the idler. Music, painting, and poetry, teach the mind to select the agreeable parts of those objects which surround us, and by habituating it to a pure and permanent delight, gradually superinduce an habitual good humour. It is of infinite importance to happiness to accustom the mind, from infancy, to turn from deformed and painful scenes, and to contemplate whatever can be found of moral and natural beauty.

So much of the happiness of private life depends on the government of the temper, that the temper ought to be a principal object of regard in a well-conducted education. The suffering of children to tyrannize without controul over servants and inferiors, is the ruin of many an amiable disposition. The virtues of humanity, benevolence, humility, cannot be too early enforced; at the same time, care should be taken that an infant of two or three years old should never be beaten or spoken to harshly for any offence which it can possibly commit.

TEMPERAMENT, among physicians, the same with constitution, or a certain disposition of the solids and fluids of the human body, by which it may be properly denominated strong, weak, lax, &c.

In every person there are appearances of a temperament peculiar to himself, though the ancients only took notice of four, and some have imagined these were deduced from the theories of the four humours or four cardinal qualities; but it is more probable that they were first founded on observation, and afterwards adapted to those theories, since we find that they have a real existence, and are capable of receiving an explanation. The two that are most distinctly marked are the sanguineous and melancholic, viz. the temperaments of youth and age.

1. *Sanguineous.* Here there is laxity of solids, discoverable by the softness of hair and succulency; large system of arteries, redundancy of fluids, florid complexion; sensibility of the nervous power, especially to pleasing objects; irritability from the plethora; mobility and levity from lax solids. These characters are distinctly marked, and are proved by the diseases incident to this age, as hæmorrhagies, fevers, &c. but these, as they proceed from a lax system, are more easily cured.

2. *Melancholic Habit.* Here greater rigidity of solids occurs, discoverable by the hardness and crispature of the hair; small proportion of the fluids, hence dryness and leanness; small arteries, hence pale colour; venous plethora, hence turgescency of these, and lividity; sensibility, frequently exquisite; moderate irritability, with remarkable tenacity of impressions; steadiness in action and slowness of motion, with great strength; for excess of this constitution in maniacs gives the most extraordinary instance of human strength we know. This temperament is most distinctly marked in old age, and in males. The sanguineous temperament of youth makes us not distinguish the melancholic till the decline of life, when it is very evident, from diseases of the veins, hæmorrhoids, apoplexy, cachexy, obstructions of the viscera, particularly of the liver, dropsies, affections of the alimentary canal, chiefly from weaker influence of the nervous power. So much for the sanguineous and melancholic temperaments; the other two are not so easily explained. The choleric temperament takes place between youth and manhood. In the

3. *Choleric,* the distribution of the fluids is more exactly balanced; there is less sensibility, and less obesity, with more irritability, proceeding from greater tension, less mobility and levity, and more steadiness in the strength of the nervous power. As to the

4. *Phlegmatic.* This temperament cannot be distinguished by any characters of age or sex. It agrees with the sanguineous in laxity and succulency. It differs from that temperament, and the melancholic, by the more exact distribution of the fluids. Again, it differs from the sanguineous, by having less sensibility, irritability, mobility, and perhaps strength, though sometimes indeed this last is found to be great.

These are the ancient temperaments. The temperaments, indeed, are much more various; and very far from being easily marked and reduced to their genera and species, from the great variety which is observable in the constitutions of different men.

Temperament of the Musical Scale, is that modification of the sounds of a musical instrument, by which those sounds may be made to serve for different degrees of different scales. See Music, Chap. VII. 1 Definition.

Temperament, though intimately connected with music, is not, properly speaking, a part of that science. The objects of music, as a science, are, to ascertain the laws of musical sound, as depending on the powers of the human voice. The purpose of temperament is, to regulate, in a way least adverse to these laws, a certain departure from them, rendered necessary by the imperfections of instruments.

Although the temperament of the scale of instruments be practically familiar, the true principles on which it depends have been much disputed. Various opinions have been hazarded, and systems proposed. We offer an abridged view of that which appears to us to merit a preference (A).

Before consideration of the tempered scale, a short review of the nature of the true scale is necessary. 2 Nature of the true scale.

From the conformation of the vocal organs, all nations, in singing, make use of the same inflections of voice. These inflections, called *notes,* are said to be *grave* or *acute,* in proportion to the degree of hoarseness or shrillness with which they are sung. The state of voice with respect to gravity or acuteness with which any one note is sung, is termed its *pitch.* 3 Notes, and their pitch.

Two notes having the same pitch are termed *unisons,* or are said to be *in unison* to one another. The difference of pitch between any note and another is denominated an *interval.* 4 Unisons and intervals.

In

(A) Amongst the very numerous authors on the subject of temperament, we have selected, for our chief guides, the late Dr Robert Smith of Cambridge, and Professor John Robison of Edinburgh.

Temperament.

5 Key note or fundamental.

In all attempts to sing, the ear, either unconsciously, or from the direction of recently hearing it, selects a particular note, from the previous impression of which the voice naturally forms other notes, at certain though unequal intervals. The note, thus selected, is termed the *key note* or *fundamental*. When chosen, it instantly assumes a particular and predominant character. The ear involuntarily refers to it the intonation of all other notes, readily recurs to it during performance, and is dissatisfied unless the voice close upon it.

6 Natural scale and its degrees.

Where the singer has assumed a key note, and, after singing that note, sings the note nearest in acuteness to it without forcing the voice, and so on, the series of notes, thus naturally formed, constitutes what is called the *natural scale*. The notes of it are termed its *degrees*; thus the key note is the first degree of the scale; the natural note next in acuteness to it, is named the second degree, or *second of the scale*, and so on.

7 Difference of pitch of the male and female voice.

Two untaught men, attempting to sing the same scale together, always sing in unison. But a man and a woman, making the same attempt, sing naturally in such a difference of pitch, although they proceed by the same intervals, that the eighth note only of the male voice ascending, is in unison with the key note of the female voice. Were the male voice to ascend to a ninth note, it would be in unison with the second of the female voice; the tenth note of the former would be in unison with the third of the latter, and so on.

We have thus two scales in succession, perfectly similar in the relation of the degrees of each to their respective key notes; but differing in pitch by the interval between these key notes.

8 Octave, what?

This interval, comprehending seven smaller intervals and eight degrees, is, from this last circumstance, called an *octave*: and this term is also applied, somewhat inaccurately, to the series of the eight degrees. Thus we say, that the *octave* formed by the female voice is an *octave* acuter than that which is produced by the male voice; meaning, that the eight degrees sung by the woman are acuter by the interval of an octave, than those sung by the man.

9 All octaves are similar.

Not only are the natural octaves of the male and female voice exactly similar; but the same similarity is found in the extremes of the human voice, and, beyond them, as far as musical sounds can be produced. Many men can sing the second octave below, and most women the second octave above, a given key note common to both voices. Yet the gravest octave of such a male voice, and the acutest octave of such a female voice, are equally similar in their relations (although they differ in pitch by an interval of two octaves), as the two central octaves are.

10 All music contained in one octave of the natural scale.

All the different natural inflections of the human voice are thus contained in one octave, since all other octaves are only repetitions of the same inflections in a graver or acuter pitch.

11 Octave consists of eight degrees and seven intervals.

The octave, then, consists of eight degrees and seven intervals. Two of these intervals, those between the third and fourth, and the seventh and eighth degrees, are sensibly less different in pitch than the others. And although we have no direct measures of the pitch of sounds, we term these smaller intervals *semitonic*, and the others *tonic* intervals, presuming the latter to be equal to each other, and a semitonic interval to be equal to the half of a tonic one.

12 Representation of the scale by letters.

The degrees of the natural scale are, by British musicians, distinguished by the first seven letters of the alphabet. The letter C, for some reason less important than difficult to explain, has been appropriated to the note most easily assumed as a key note by both the male and female voice; the second of the scale is termed D, and the third E, and so on. As the human voice, and consequently most musical compositions, comprehend four octaves, we represent the ordinary octave of the male voice by Roman capitals, and that of the female voice by Roman minuscular letters. The gravest male octave is distinguished by Italic capitals, and the acutest female octave by minuscular Italics. The whole natural scale may therefore be exhibited thus:

Gravest Male Octave.	Ordinary Male Octave.	Ordinary Female Octave.	Acutest Female Octave.
C * *D* * *EF* * *G* * *A* * *B*	C * D * EF * G * A * B	c * d * ef * g * a * b	*c* * *d* * *ef* * *g* * *a* * *bc*.
1. 2. 34. 5. 6. 7	1. 2. 34. 5. 6. 7	1. 2. 34. 5. 6. 7	1. 2. 34. 5. 6. 78.

In this exhibition, the juxtaposition of the thirds and fourths, and of the sevenths and eighths or replicates of the first degree, indicates the semitonic intervals; and the asterisks represent the tonic intervals of the natural scale, or the artificial intercalary sounds, which, as we shall presently see, it becomes necessary to substitute in those intervals.

13 Different voices require different scales.

Were all voices of the same compass, and were musical feelings satisfied with the natural scale, we might rest here. Being furnished with a key note adapted to all voices, and with instruments accurately tuned to that key note, it would be unnecessary to examine whether any other note of the natural scale could be assumed as the key note of a different scale, and if it could, whether any agreeable effect resulted from the discovery.

But the use of different scales, the key notes of which are derived from the different degrees of the natural scales, has been found not only to be one of the chief sources of the pleasure imparted by musical performances, but to be indispensably necessary from the physical inequality of voices.

The central 'c' of the scale, called in music the tenor C, can be produced by every species of voice. The gravest male voices, termed bass, can form this note, but very few notes above it. The treble, or acuter female voice also produces it, but seldom descends farther. The acuter male voices, called tenor, have this 'c' scarcely above the middle of their compass, and it is not much below the middle of that of the counter-tenor or gravest female voices. Now it is obvious that an air in the natural scale, which should rise above 'c', and fall below it in the same proportions, might be sung by the tenor or counter-tenor voice, but would be too acute for the bass voice, and too grave for the treble. Either of these voices, in order to execute the same air, must assume a different key note from 'c'; and as all the

the degrees of the scale are regulated by the key note, the air must of course be executed in a scale different from that of 'c'.

Again, suppose a singer who can sing a given air only in the scale of B, to be accompanied by an instrument tuned in the scale of 'c'. Should the lyrist begin on his own key note, he is a semitone above the key note of the singer; and should he begin on the note which is in unison with the singer's key note, the next degree is wrong, being but a semitonic interval by the instrument, and a tonic interval by the voice. In short, all the degrees but one will be found wrong. This is an evident consequence of the inequality of the semitonic to the tonic intervals; and if the tonic intervals, which we presume to be equal, be not exactly so, the discordance will be still greater.

14 **Intercalary sounds necessary.**

The remedy for this is apparently obvious. If the semitonic intervals are each equal to half of any of the tonic intervals, we need only to interpose other sounds between each two of the degrees which form the tonic intervals; and then, in place of eight degrees and seven unequal intervals, we shall have twelve degrees and twelve equal intervals, each of them equal to a semitone. An instrument thus furnished, appears to be adapted to any voice, and to resemble the modern harpischord or organ, which have twelve seemingly equal intervals in the octave. Such were the practical resources of the Greek musicians, sanctioned by the approbation of Aristoxenus, and of all those who were satisfied with the decision of the ear alone.

15 **Mathematical ratios of musical intervals.**

But philosophers and mathematicians ascertained the existence of a certain connexion between musical intervals and mathematical proportions, and gradually opened the way to the discovery that the relations of the musical scale, as naturally formed by the human voice, depend on principles equally plain and certain with the simplest geometrical propositions.

16 **Ratios of the octave fifth and fourth.**

Pythagoras is said to have discovered, that if two musical chords be in equal tension, and if one of them be half the length of the other, the short one will sound an octave above the long one; if one-third shorter, it will produce the fifth: if one-fourth shorter, it will give the fourth. Thus the relation of the key to its octave was discovered to correspond to the ratio of 2 : 1; that of the key to its fifth to be in the ratio of 3 : 2; and that of the key to its fourth to be in the ratio of 4 : 3. For instance, if a chord of a given size and tension, and 12 inches long, produce 'c', another of the same size and tension, but only six inches long, will give the octave *c*; one eight inches long will sound the fifth 'g'; and one nine inches long will produce the fourth 'f'. Now as the string of eight inches giving the fifth, and that of six inches producing the octave, are in the ratio of 4 : 3, which is that of the fourth; it follows, that the interval between the fifth and octave is a fourth: and as the chord of nine inches producing the fourth, and the octave of six inches, are in the ratio of 3 : 2, the interval between the fourth and octave must be a fifth. Thus the octave 'c' *c*, is divided into a fifth 'c g', and a fourth 'g' *c*, or into a fourth 'c f', and a fifth 'f' *c*, both in succession. The two fourths 'cf', and 'g' *c*, leave an interval 'f g', corresponding, as we have seen, to the ratio of 9 : 8.

17 **Ratio of the major third, minor third, and semitone.**

We have thus the ratios of the octave, of the fifth, and of the fourth; and it does not appear that the ancient theorists proceeded farther. They seem to have preferred the harmony of fourths and fifths to that of thirds and sixths, so essential in modern harmony. By pursuing the system of the mathematical ratios, we find that 5 : 4 gives the major third 'c e'. And the fifth 'g' being already determined by the ratio 3 : 2, we ascertain the ratio of the minor third 'e g' to be 6 : 5, which is the difference between 3 : 2 and 5 : 4. In the same way, the ratio of the third 'e' being 5 : 4, and that of the fourth 'f' being 4 : 3, we ascertain the ratio of the semitone 'e f' to be 16 : 15, or 4 : 3—5 : 4.

18 **Ratio of the major sixth and major seventh.**

A note in the ratio of 5 : 4, or that of a major third to 'f', gives 'a', the major sixth of the neutral scale; and a note in the same ratio of 5 : 4 to 'g' produces 'b', the major seventh of that scale. The ratio of 'g a' will thus be 10 : 9, and that of 'a b' 9 : 8, the same with that of 'fg'; and that of 'b' *c* will thus be 16 : 15 like 'e f'.

19 **Ratio of the major second.**

We have in this way the mathematical ratios of all the degrees of the natural scale except that of the second 'd'. Considering, however, the second to be a perfect fourth graver than the fifth, and having ascertained the fifth 'g' to be a perfect fourth below *c*, as 2 : 1 is to 3 : 2; so 3 : 2 gives 9 : 8, which we take for the ratio of the second.

20 **Aristoxenean and Pythagorean systems.**

Thus have been formed two distinct systems of intonation of the natural scale; that of mean tones and semitones, founded on the rules of Aristoxenus, and the practice of ancient artists, and that of the ratios deduced from the discoveries of Pythagoras, and the calculations of mathematicians.

21 **Circular representation of the scale.**

Plate DXXXII. fig. 1.

The difference between the Aristoxenean system of mean tones and semitones, and the Pythagorean system of mathematical ratios, will best appear from the following construction. Let the circumference of a circle (fig. 1.) be divided by dotted lines (according to the principles of Aristoxenus) into five larger and equal intervals, and two smaller intervals also equal. Let it also be divided by full lines into portions determined by means of the musical ratios. Thus let the arches CD, FG, and AB be proportional to the logarithm of 9 : 8, GA and DE to those of 10 : 9, and EF and BC to those of 16 : 15 (B). Let us divide another circle in the same manner; but instead of having its points of division marked C.D, &c. let them be marked 'key' 2d, 3d, 4th, 5th, 6th, 7th. This circle, which may be described on a piece of card, is to be placed on the other, and is to move round their common centre.

22 **Insufficiency of the natural scale for composition in different scales.**

In whatever point of the outer circle the point 'key' of the inner one be placed, it is obvious that the other points of the outer circle will shew what degrees of it, by corresponding with the other points 2d, 3d, &c. of the inner circle, will serve for degrees of the scale determined by the point 'key'. By this we see clearly the insufficiency of the degrees of the natural scale, for the performance of compositions in different scales, and the

(B) We may make CD=61°, 72; CE=155°, 9; CF=149°, 42; CG=210°, 58; CA=265°, 3; and CB=326° 48.

Temperament.

the inefficacy of the Aristoxenean remedy of mean tones.

23 Galileo's discovery of aerial undulation.

But although the errors of the Aristoxeneans were demonstrated by the certainty of the ratios, and although the dependence of musical intervals on the latter be said to have been known since the days of Pythagoras, the nature of that relation remained unknown for ages. Galileo discovered that the ratios express the frequency of the aërial undulation, by which the several sounds are generated. He demonstrated that the vibrations of two chords, of the same matter and thickness, and of equal tension, will be in the ratio of their lengths, and that the number of oscillations made in a given time will be inversely as their lengths. The frequency of the sonorous undulations of the air is therefore inversely as the length of the string. Thus 2 : 1 being the ratio of the octave, the undulations which produce the acuter sound are twice as frequent as those which generate the graver. The ratio of the fifth, 3 : 2, indicates that in the same time that the ear receives three undulations from the upper sound, it receives only two from the lower. This is not peculiar to sounds produced by the vibration of strings: those produced from the vibration of bells, and from the undulation of the air in pipes, are regulated by the same law.

24 Pitch of sound determined by aerial undulations.

Thus, it is demonstrated that the pitch of musical sound is determined by the undulations of the air; and that a certain frequency of undulations produces a certain and unalterable musical note. It has been found that any noise whatever, if repeated 240 times in a second, at equal intervals, produces the tenor 'c'; if 360 times, the 'g', or fifth above. It had been imagined that musical sound was only to be produced by those regular undulations, which are occasioned by the vibrations of elastic bodies. We are assured that the same effect will be produced by any noise, if repeated not less than 30 or 40 times in a second; and that the experiment has been tried with a quill snapping against the teeth of a wheel.

25 Chords, consonant and dissonant.

By Galileo's discovery, the principles on which the just intonation of the natural scale depends, are shown to be certain and plain. To proceed in our search of an exact measure of temperament of this perfect intonation, we must consider the nature and effects of consonant and dissonant chords.

A chord is a combination of two or more simultaneous musical sounds. If the coalescence be so complete that the compound sounds cannot be distinguished, the chord is said to be consonant; if the separate sounds are distinctly heard, the chord is termed dissonant.

All consonances are pleasing, although some are more so than others. All dissonances are unsatisfactory, and some are very harsh.

26 Beats, what.

In consonances, no inequality of sound is perceptible. In dissonances, the ear is sensible of an alternate increase and diminution of the strength of the sound, without variation of pitch. This is occasioned by the alternate coincidence and bisection of the vibrations of the component sounds. For example, suppose two perfect unisons produced from two pipes each 24 inches long. Each sound has 240 vibrations in a second, either exactly coincident, or exactly alternate. In either case, the vibrations are so frequent and uniform as not to be distinguishable, and the whole appears one sound. But let one of the pipes be only 23 inches and seven-tenths long, it will give 243 vibrations in a second. Therefore the 1st, the 80th, the 160th, and the 240th vibration of the longer pipe, will coincide with the 1st, the 81st, the 162d, and the 243d of the shorter. In the instant of coincidence, the aerial agitation produced by the one vibration is reinforced by that produced by the other. The deviations from coincidence gradually increase till the 40th vibration of the longer pipe, which will commence in the middle of the 41st vibration of the shorter one. The vibrations here bisecting each other, the aerial agitations of both will be weakened. The compounded sound will consequently be stronger at the coincidences and weaker at the bisections of the vibrations. The increase of strength, which is termed the *beat*, will recur thrice in every second. Thus the vibrations are in the ratio of 80 : 81, or of a *comma;* and the compounded sound now supposed is an unison *imperfect by a comma.*

If a third pipe, tuned a perfect fifth to the longer of the two former, be sounded at the same time with the shorter, the dissonance will beat nine times in a second; and is thus shown to be a fifth imperfect by a comma.

The perfection or imperfection of any consonance may thus be ascertained with equal facility and precision: and by this method, any perfect consonance may be altered to any acquired state of temperament.

27 Beats afford an exact measure of temperament.

The theory of beats is therefore valuable, as giving us the management of a phenomenon intimately connected with perfect harmony, as affording us precise and practicable measures of all deviations from it, and as thus forming the basis of the most accurate system of temperament.

For the preparatory process of determining the exact degrees of the scale, let us attend to the following ingenious and amusing experiment.

28 Fundamental experiment.

Let two harpsichord wires be exactly tuned in unison at the pitch of the tenor 'c', to be acted on simultaneously by a wheel rubbed with rosin, like that of a *vielle.* Let a scale of 240 equal parts be described under one of the strings, equal in length to the sounding part of it, and numbered from the end at which the wheel is applied. Let a moveable bridge be placed under this string, but so as not to alter the tension of it in the least.

The two open strings being in perfect unison, without any beating whatever, let the moveable bridge be advanced slowly from the nut, while the wheel is applied to both strings. All kinds of chords, consonant and dissonant, will of course be successively heard. Between the consonances there will be a beating, which will increase as we approach the consonance, cease on our reaching it, appear again as we leave it, diminish as we recede from it, and again increase as we approach to the succeeding consonance.

After this general view, let us more particularly examine the several degrees of the scale.

29 Determination of the octave.

On placing the moveable bridge at 120, we shall hear a perfect octave, without any beating. If the division be not quite exact, there will be a little beating; but by shifting the bridge very gently to either side, the increase or diminution of the beating will guide us to the true place, where it will entirely cease.

30 Determination of the perfect fifth.

On placing the bridge at 160, the perfect concord of the

Temperament.

the key and fifth will be heard. Any alteration of the bridge to either side will produce a disagreeable beating.

31 Determination of the perfect fourth.

A rapid flutter in the vicinity of 180 will cease at that point, and give place to the consonance of the key and fourth.

32 Determination of the major third.

On approaching 192, an angry waspish beating is succeeded at that point by the animating concord of the key and major third.

33 Determination of the minor third.

As we leave 192, the beating assumes a melancholy character, and ceases at 200, the place of the plaintive consonance of the key and minor third.

34 Determination of the second.

Between that point and the nut, we have only a succession of discords. As we were at a loss to ascertain the mathematical ratio of the second of the scale (art. 19), so we have some difficulty in determining its just place by the theory of beats, and the experiment under consideration. We are uncertain whether we shall fix it at a minor tone, or at a major tone above the key. Both form a harsh dissonance with the key. The major tone, however, is thought less disagreeable: it admits of five more concords in the octave than the minor; and the ratio of it 9 : 8, is that suggested by the similarity of its interval with the fifth, to the interval of the fifth and octave (art. 19). On these accounts we prefer it; and its place in the division under our precise consideration is $213\frac{1}{3}$.

35 Determination of the minor sixth.

Let the bridge now be placed near, and slowly moved to 150: the beating subsides into a consonance, slightly pleasing, that of the key and minor sixth.

36 Determination of the major sixth.

At 144, we have the agreeable concord of the key and major sixth. From 144 to 120 we hear nothing but discord.

37 Determination of the seventh.

In this interval, however, we have to find the place of the sensible note or major seventh. The ear informs us, that the interval between the major seventh and the octave, must be similar to that between the major third and the fourth. Applying to the former interval the ratio of the latter, that of 16 : 15, we place the moveable bridge at 128; for as 15 is to 16, so 120 gives 128. We also feel, that the interval between the fifth and major seventh is exactly similar to that between the key and major third, of which the ratio is 5 : 4. Now, applying the same ratio to 160, the place of the fifth, we find 5 : 4 :: 160 : 128. We thus determine 128 to be the place of the major seventh of the scale.

38 Ratios of simple intervals.

The interval or difference between the minor tone 10 : 9, and the major tone 9 : 8, is 81 : 80, termed *comma*. This interval is not employed in practical music, but must be distinctly understood by theorists, and particularly in treating of temperament.

There are therefore four descriptions of simple intervals; that is, intervals which do not include more than a major tone. These are, comma, of which the ratio is 81 : 80; hemitone, or 16 : 15; minor tone or 10 : 9; and major tone, or 9 : 8 (c).

39 Temperament necessary in keyed instruments.

We have now to consider how far the perfect intonation of the natural scale must be departed from in keyed instruments, such as the organ and harpsichord; so that the same sound may serve for different degrees of different scales.

These instruments have twelve sounds in every octave; that is, they have the eight natural degrees and four intercalary sounds, viz. between C and D, D and E, F and G, G and A, and A and B.

The purpose of these intercalary sounds is, that an air may be performed in any pitch; that is, that any sound may be taken for a key note, and that other sounds may be found to form the scale of that key note, at intervals corresponding to those of the natural scale.

Thus, if instead of C, the key note of the natural scale, we take B for the key note required; A, which is the seventh to B, will by no means answer for the seventh of the assumed scale; for the interval between A and B is a major tone, of which the ratio is 9 : 8, whereas the interval between the seventh of the scale and the octave, can only be a hemitone, the ratio of which is 16 : 15. We must therefore employ the intercalary sound between A and B, which in this employment we call A✻, or A sharp. But we shall presently see that we cannot tune even this sound in the ratio of 16 : 15 with B. For, let us take F for the key note of another scale, we find that B will not serve for the fourth of that scale, being a major tone above A the third; whereas the fourth of the scale is only a hemitone above the third. We must therefore have recourse to our intercalary sound between A and B, which

(c) The logarithmic measures of these intervals, and of the compound intervals determined in the way which we have described, are

Comma, - -	54
Hemitone, - -	280
Minor tone, - -	458
Major tone, - -	512
Minor third, - -	792
Major third, - -	969
Fourth, - -	1249
Fifth, - -	1761
Minor sixth, - -	2041
Major sixth, - -	2219
Seventh, - - -	2730
Octave, - - -	3010

The octave being thus divided into 3010 equal parts, a circle of which the circumference is divided into 301 degrees, and a concentric moveable circle having a nonius subdividing each into ten parts, will form a convenient instrument for examining all temperaments of the scale.

which we must here call B♭, or B flat, and which ought in this state to be tuned a hemitone above A, or in the ratio of 16 : 15 with that note. Now, this intercalary sound cannot be both in the ratio of 16 : 15 with A, and in the same ratio of 16 : 15 with B. This would extend the whole interval between A and B, to the ratio of about 8 : 7; whereas it should only be in that of 9 : 8. We must therefore tune the intercalary sound in such a diminished relation to A and to B, that it may serve either for A ※ or B ♭.

But, even independent of these intercalary notes, some temperament of the natural scale is necessary.

Let the four-fifths, 'c g', 'g' *d*, '*d a*', and '*a* $\bar{e}$', be tuned all perfect. Then tune the two perfect octaves from '$\bar{e}$' downwards, '$\bar{e}$ *e*', '*e* : e'. The major third 'c e' resulting from this process, will be too sharp, by a comma, or 81 : 80, and will beat 15 times in a second. The minor third 'e g' and the major sixth 'c a' will be still more discordant.

It is therefore impossible to have perfect fifths, and at the same time perfect thirds and sixths. Now, although a perfect fifth, occasionally employed, be pleasing, yet the ear does not relish a succession of perfect fifths; such a succession not only renders the harmony languid, but creates a doubt as to the key, which is unsatisfactory. On the other hand, an alternate succession of major and minor thirds and sixths constitutes the chief and most brilliant part of our harmonics. We therefore find it necessary to sacrifice somewhat of the perfect harmony of the fifths to that of the third and sixths.

It is this accommodation which is properly called TEMPERAMENT; and to this system of it, by which the fifths are diminished, and the thirds and sixths preserved perfect, we give the preference.

We have just seen that four consecutive perfect fifths compose an interval, greater, by a comma, than two octaves and a major third. But in the tuning of our instruments requiring temperament, these intervals must be rendered equal. Because, as we have seven hemitonic intervals in the fifth, twelve in the octave, and four in the major third; so the interval of four-fifths contains twenty-eight hemitonic intervals, and that of two octaves and major third contain also twenty-eight, being twenty-four for the two octaves, and four for the major third. The real difference being, however, a comma, it is plain, that if we keep the major thirds perfect, we must diminish or flatten each of the four-fifths one-fourth of a comma.

It is not easy to ascertain with perfect exactness the quarter comma by which the first fifth 'c g' is to be diminished. We shall, however, be sufficiently accurate for practical purposes if we flatten 'g' till a beating of 9 beats in four seconds is produced (D).

Having in this manner tuned 'g', we diminish the next fifth 'g' *d*, one-fourth of a comma, by flattening *d* till 'g' *d* beat half as fast again as 'c g', or $13\frac{1}{2}$ beats in four seconds (E).

The next fifth, *d a*, must be diminished in the same proportion by flattening *a* till '*d a*' beat 15 times in six seconds.

Instead of tuning upward the fifth *a* $\bar{e}$, tune downward (F) the octave *a* 'a', and then tune upward the fifth 'a' *e*, and flatten it till it beat 15 times in eight seconds.

If we take 15 seconds for the common period of all these beats, we shall find

The beats of 'c g' = 34
G 'd' = 25
'd a' = $37\frac{1}{2}$
'a *e*' = 28

On tuning downwards the octave *e* 'e' we have the major third 'c e' perfect without any beating; and we proceed, tuning upwards a fifth flattened by one-fourth of a comma, and when the beating becomes too quick, tuning downward an octave. We may do this till we reach 'b' ※, which should be the same with *c*, a perfect octave above 'c'.

It will be better, however, to stop at 'g' ※, and then to tune fifths downward from 'c' and octaves upwards, when we get too low. Thus we have 'c' F, F 'f', 'f' B♭, 'B

(D) If any concord, whose perfect ratio is $\frac{m}{n}$ (m being the greatest term of the smallest integers expressing that ratio), be tempered sharp by the fraction $\frac{p}{q}$ of a comma, and if M and N be the pulses made by the acute and grave notes of the concord during any number of seconds, the number b of beats made in the same time by this concord will be $= \frac{2\,q\,m\,N}{161\,p-q}$, or $\frac{2\,q\,n\,M}{161\,p+q}$; and if it be tempered flat, then $b = \frac{2\,q\,m\,N}{161\,p+q}$, or $\frac{2\,q\,n\,M}{161\,p-q}$. (Smith's Harm. 2d edit. p. 82, &c.). Now, let $\frac{m}{n}$ be $=\frac{3}{2}$, the ratio of the fifth; $q=1$, $p=4$; therefore, $\frac{p}{q}$ = one-fourth of a comma, and N='c' or 240 pulses in a second. Therefore, $\frac{2\,q\,m\,N}{161 \times p+q} = \frac{2 \times 3 \times 240}{161 \times 4+5} = \frac{1440}{645} = 2.25$ beats in four seconds very nearly.

(E) Because fifths, being in the ratio to each other of 3 : 2, N in this fifth = 360.

(F) The grave octaves of the upper terms of each of these tempered fifths may be determined with perfect accuracy, by making the grave octave beat with the lower term of the tempered fifth as often as the upper term does with it; for instance, by making G 'c' beat as often as 'c g', &c. For, it has been demonstrated by Dr Smith, that the upper term of a minor concord beats equally with the lower term, and with the acuter octave of that term; but that the upper term of a major concord beats twice as fast with the acuter octave of the lower term, as it does with the lower term itself. Therefore, as 'g' beats twice as fast with *c* as with 'c', and is with its grave octave G in the ratio of 2 : 1, G 'c' beats precisely as often as 'c g'.

'B♭ 'b♭', 'b♭e♭'; and this method is preferable, because the notes marked ✻ or ♭, are, when tuned in this way, in the best relation to those with which they are most frequently employed as major thirds, and the major third is the harmonic interval most in use (G).

Another system of temperament is that which divides the

(G) The process of temperament thus recommended, will be greatly facilitated by employing a pendulum made of a ball of about two ounces weight, sliding on a light deal rod, having at one end a small ring. Let this pendulum be hung by the ring on a peg, and the ball adjusted so as to make 20 vibrations in 15 seconds. This done, mark the rod at the upper edge of the ball, and adjust it in the same manner for 24, 28, 32, 36, 40, 44, and 48 vibrations. Then having calculated the beats of the different fifths, set the ball at the corresponding mark, and temper the sound till the beats keep pace exactly with the pendulum.

In order to discover, should it be necessary, the number of pulses made in a second by the tuning fork, by which we tune the tenor 'c' of our instrument, let a wire be stretched by a weight till it be unison or octave below the fork; let $\frac{1}{40}$th then be added to the weight. Being thus tempered by a comma, the contemporaneous sounding of the fork and wire will produce a beating; and on multiplying the beats by 80, the product gives the number of pulses of the fork, and consequently of the 'c' of the instrument tuned from it. But the common 'c' tuning forks are so nearly consonant to 240 pulses, that this process is scarcely necessary.

On the system of temperament now proposed, Dr Smith makes the following useful observation and deduction.

The octave consisting of five mean tones and two limmas, it is obvious that by enlarging the tones we diminish the limmas, and that the increment of the tone is two-fifths of the contemporaneous diminution of the limma. Let v represent any minute variation of this temperament: the increment of a mean tone is $2\,v$, and the contemporaneous diminution of the limma $-5\,v$. Again, if the tone be diminished by $-2\,v$, the limma will increase by $-5\,v$. Let us observe the variations of the intervals in the latter case.

The perfect fifth consisting of three tones and a limma, its variation will be $-6\,v+5\,v$ or $-v$. That is, the fifth is flattened by the quantity v. Consequently the fourth is sharpened by that quantity.

The second, being a tone above the key note, and being therefore flattened by $-2\,v$, the minor seventh is increased by $2\,v$.

The minor third consisting of a tone and a limma, its variation is $-2\,v+5\,v$ or $3\,v$. Accordingly, that of the major sixth is $-3\,v$.

The major third, or two tones, is therefore diminished by $-4\,v$. Consequently the minor sixth is increased by $4\,v$.

The major seventh, being the inversion of the limma, is therefore varied by $-5\,v$.

The tritone being diminished $-6\,v$, the false fifth is accordingly $6\,v$.

On this observation, Dr Smith has founded the following geometrical construction: Divide the straight line CE (fig. 2.) into six equal parts C*g*, *g d*, *d a*, *a* E, E *b*, *b t*, and intersect the points of division with the six parallel lines *g* G, *d* D, &c. representing the intervals arranged according to the system of mean tones and limmas.

Let any length *g* G, on the first line to the right of the line CE, represent a quarter of a comma, G will thus mark the place of the perfect fifth, and *g* that of the tempered fifth, flattened by a comma.

Take *d* D, double of *g* G, on the second parallel also on the right hand; D will mark the place of the perfect second, and *d* that of the tempered second, flattened by the half comma *d* D.

By setting off *a* A on the third parallel to the left, equal to *g* G, we have A' the perfect major sixth, and *a* the transferred major sixth, sharpened by the quarter comma A *a*.

The major third being in the system of mean tones kept perfect, the place of that degree will be *e*.

By taking *b* B on the fifth line, on the right, equal to *g* G, we find B to be the place of the perfect major seventh, and *b* to be that of the tempered major seventh flattened by the quarter comma *b* B.

And by making *t* T on the sixth line, to the right, equal to *d* D, we have the contemporaneous temperament of the tritone flattened by the half comma *t* T, and of the false fifth, sharpened by that quantity.

Any other straight line C *t'* drawn from C, across these parallels, will represent, by the intervals *g'* G, *d'* D, &c. the temperaments of another system of mean tones and limmas. Since it is plain that the simultaneous variations *g g' d d*, &c. from the former temperament are in the just proportions to each other. The straight line thus employed, (C *e'*, or C *e''*), has therefore been termed the *temperer*.

As the arrangement of the sounds of keyed instruments having only twelve keys for an octave, and meant to be used in different scales, must approach nearly to a system of mean tones, or rather mean limmas, this construction of Dr Smith's is very useful. The temperer points out, not only all the temperaments of the notes with the key note, but also the temperaments of the harmonic concords. Thus it will be seen, that the temperament of the minor third forming the interval between the major third and fifth, is in all cases the same with that of the major sixth and octave, and that the temperament of the major third forming the interval between the fourth and major sixth, is equal to that of the key and major third of the scale.

It has been proposed, in order to render Dr Smith's construction still more useful, that it should be drawn of such a size as to admit of the following supplementary scales.

1. A scale of *g* G divided into thirteen parts and a half, expressing the logarithmic measures of the temperaments mentioned in the note (C), a comma being $=54$.

2. A scale of *g* G divided into 36 parts, giving the beats made in 16 seconds by the notes *c*, *g*, when tempered by any quantity G *g'*.

3. A

the alterations between the fifths and major thirds, flattening the fifths and sharpening the major thirds; and making both beat equally fast along with the key: and since enlarging the fifth increases the tone, and consequently diminishes the limma, the intercalary sounds become thus better suited for their double service of the sharp of the note below, and the flat of the note above. Much, however, is lost in the brilliancy of the major thirds, which are the most effective concords. The fifths are not much improved, and the sixths are evidently hurt by this temperament (H).

These methods of tuning by beats are incomparably more exact than by the ear. We cannot mistake above one beat, that is, in the fifth $\frac{5}{108}$th, and in the major third $\frac{5}{180}$th of a comma.

We have offered a short view of what appears to us to be the preferable system of temperament. It has been deduced from the observations of the most able theorists, and will greatly assist a tuner; but to him there are farther necessary, as to a musical performer, a correct ear, patient attention, and long practice.

TEMPERANCE, that virtue which a man is said to possess who moderates and restrains his sensual appetites. It is often, however, used in a much more general sense, as synonymous with moderation, and is then applied indiscriminately to all the passions.

Temperance (says Mr Nelson) is the virtue that bridles our irregular desires; it is nearly allied to prudence, and has a close connection with justice; it calms revenge, and quenches the fire of unjust resentment; it checks the epicure, and stops the riotous hand of the Bacchanalian; it extinguishes or abates the flames of lust, and banishes every lawless action; it silences the flippant detracting tongue, and gives in its stead a pleasing moderation of speech; it shuts the door against avarice, and proves experimentally, that happiness does not consist in the eager pursuit or acquisition of riches, but in a contented mind; it curbs the strongest of all other passions, gaming, and distinguishes justly the absurdity and folly of making that a dangerous trade, which was only designed as a relaxation and an amusement: temperance, in a word, is the parent of many virtues; the parent of peace, prosperity, health, and joy.

Nothing can be more strange to all observation than the practice of forsaking temperance; since every day's experience proves to us, that intemperance produces the opposite to what we seek. Suppose, when a child is born, we ask the parents what it is they wish in that child; they will answer, life. But as life alone, that is, mere existence, may, by infirmity or other accidents, be very wretched, they will naturally wish for health and happiness. Well then, life, health, and happiness, are the general wishes of parents for their children. Now let us see how their wishes are likely to succeed. Their first step is usually a shameful neglect of the food of nature, the breast; the next, a blind gratification of their will; the third, an almost total neglect of their manners; and a fourth, the cherishing them in every irregular affection. Where then is the wonder that parents are disappointed? Life and health depend on proper food and other judicious management on one part; and if sick, an obedience to remedies on the other part: and happiness essentially depends in the first place on health; in the next, on the due government of our senses, affections, and passions. See here how much mankind deviate from themselves; how far they depart from their own

3. A scale of g G divided into 60 parts, for the beats of the major third C e.
4. A scale of g G divided into 72 parts, for the beats of the minor third C $e\ b$.
5. A scale of g G divided into 48 parts, for the beats of the fourth $c\,f$.
6. A scale of g G divided into 89 parts, for the beats of the minor third $g\ e$.
7. And, g G divided into 80 parts, for the beats of the major third $f\,a$.

Thus provided, and having determined by Dr Smith's construction, the temperament of 'g' 'd', 'a', 'e', 'b', and 'f', the accurate tuning of the whole octave as a system of mean tones with perfect major thirds may be completed as follows.

Let 'f ✱' be tuned a perfect major third above 'd'; 'g ✱' a perfect major third above 'e', and c ✱ a perfect major third above 'a'.

Let 'b ♭' be tuned a perfect major third below 'd' and 'e ♭' a perfect major third below 'g'.

(H) To adjust the temperer to this mode, let EG (fig. 2.) be divided in p, so that E p may be to p G, as 3 to 5. Then draw C p, cutting g C in g', and C t' shall be the temperer required. It will be found that E e' and G g' are each of them 32 of their respective scales.

Let therefore 'c g' beat 32 times in 16 seconds

G 'c'	32;
G 'd'	24;
G 'b'	24, and tune 'b' b;
'd' a	36, and tune a 'a'
'd' 'f ✱'	36;
'a' e	27;
'a' c ✱	27;
$e\ b$	$40\frac{5}{8}$, proving 'b' b;
$e\ g$ ✱	$40\frac{5}{8}$;
F 'c'	$21\frac{5}{7}$, and tune F 'f';
FA	$21\frac{5}{7}$, proving A 'a';
B ♭ 'f'	$28\frac{5}{8}$, and tune B ♭ 'b ♭'
'e ♭ b ♭'	$38\frac{1}{8}$;
'C' c	perfect.

own principles. But what is the remedy? Nothing more obvious. Let parents exercise their reason in all the steps they take for their children's welfare; let them examine right and wrong; let them not only avoid passion, but labour to correct their own errors of judgement, that they may be the better enabled to prevent them in their children; but, particularly, let them fix in them the knowledge, love, and habit, of temperance.

TEMPERING, in the mechanic arts, the preparing of steel and iron, so as to render them more compact, hard, and firm; or even more soft and pliant, according to their respective occasions.

TEMPLARS, TEMPLERS, or *Knights of the Temple*, a religious order instituted at Jerusalem in the beginning of the 12th century, for the defence of the holy sepulchre and the protection of Christian pilgrims. They were first called *The poor of the Holy City*, and afterwards assumed the appellation of *Templars*, because their house was near the temple. The order was founded by Baldwin II. then king of Jerusalem, with the concurrence of the pope; and the principal articles of their rule were: That they should hear the holy office throughout every day; or that, when their military duties should prevent this, they should supply it by a certain number of pater nosters: that they should abstain from flesh four days in the week, and on Fridays from eggs and milk-meats: that each knight might have three horses, and one esquire: and that they should neither hunt nor fowl. After the ruin of the kingdom of Jerusalem about 1186, they spread themselves through Germany and other countries of Europe, to which they were invited by the liberality of the Christians. In the year 1228, this order acquired stability, by being confirmed in the council of Troyes, and subjected to a rule of discipline drawn up by St Bernard. In every nation they had a particular governor, called *master of the Temple*, or of the *militia of the Temple*. Their grand-master had his residence at Paris.

The order of Templars flourished for some time, and acquired, by the valour of its knights, immense riches and an eminent degree of military renown: but as their prosperity increased, their vices were multiplied, and their arrogance, luxury, and cruelty rose at last to such a monstrous height, that their privileges were revoked, and their order suppressed with the most terrible circumstances of infamy and severity. Their accusers were two of their own body, and their chief prosecutor Philip the Fair of France, who addressed his complaints to Clement V. The pope, though at first unwilling to proceed against them, was under a necessity of complying with the king's desire; so that, in the year 1307, upon an appointed day, and for some time afterwards, all the knights, who were dispersed throughout Europe, were seized and imprisoned, and many of them, after trials for capital crimes, were convicted and put to death. In 1312 the whole order was suppressed by the council of Vienne. A part of the rich revenues they possessed was bestowed upon other orders, especially on the knights of St John, now of Malta, and the rest confiscated to the respective treasuries of the sovereign princes in whose dominions their possessions lay.—The knights Templars, in order to justify the severity with which they were treated, were charged with apostasy to the Saracens, and holding correspondence with them, with insulting the majesty of God, turning into derision the gospel of Christ, and trampling upon the obligation of all laws human and divine. Candidates, it is said, upon admission to this order, were commanded to spit, in token of contempt, upon an image of Christ, and after admission to worship either a cat or a wooden head crowned with gold. It is farther affirmed, that, among them, the odious and unnatural act of sodomy was a matter of obligation; and they are charged with other crimes too horrible to be mentioned, or even imagined. However, though there be reason to believe, that in this order, as well as others of the same period, there were shocking examples of impiety and profligacy; yet that the whole order was thus enormously corrupt, there is no reason to believe. The pope indeed, though he acted with severity, acted with justice. He sent two cardinals to Paris, who, publishing his bull against the order, condemned those Templars who had made the voluntary confession to be burnt by a slow fire. The criminals recanted their former confessions, but acknowledged themselves worthy of death, because they had unjustly accused the order of crimes of which they were innocent. Several authors of those times wrote in defence of the order; and Boccace alleges, that its extirpation was owing to the avarice of the king of France, who coveted the rich possessions the Templars then enjoyed in France.

The king of Arragon was much pressed to treat the Templars in his kingdom as they had been treated in France; but his constant answer was, "We must be first convinced of their guilt, and it will be then time enough to talk of their punishment." The people, however, were in general so provoked against them, that they were compelled to shut themselves up in the fortresses belonging to their order, to prevent their being torn in pieces; which precaution was represented to the king of Arragon as an act of rebellion. He marched, therefore, with a corps of troops against one of these fortresses. The knight who commanded surrendered immediately, and told the king the truth, assuring him that they desired nothing but a fair trial; with which declaration the king was extremely moved, took the whole order into his protection, and forbade any to abuse or insult them under the heaviest penalties. At the same time he declared he was ready to receive any informations against them that were supported by proofs; but if the informers failed therein, he would punish them as they deserved.

These facts plead strongly for the innocence of the Templars, or at least they prove that their guilt must have been exaggerated; and if we add, that many of the accusations advanced against them flatly contradict each other, and that many members of this unfortunate order solemnly avowed their innocence while languishing under the severest tortures, and even with their dying breath—it would seem probable, that King Philip set on foot this bloody tragedy, with a view to gratify his avarice, and glut his resentment against the Templars, and especially against their grand-master, who had highly offended him. The principal cause of his invincible hatred against them was, that in his quarrel with Boniface VIII. the knights espoused the cause of the pope, and furnished him with money to carry on the war. They originally wore a white habit, with red crosses sewed upon their cloaks as a mark of distinction.

TEMPLE, SIR WILLIAM, was born in London in the

Temple.

the year 1628. The family from which he sprung was ancient, and is said to have assumed the surname of Temple from the manor of Temple, in the hundred of Sparken-Hall, in Leicestershire. He was first sent to school at Penschurst, in Kent, under the care of his uncle, the celebrated Dr Hammond, then minister of that parish; but at the age of ten he was removed thence to a school at Bishop-Stortford, in Hertfordshire. When he had acquired a sufficient knowledge of the Greek and Latin, he returned home at the age of fifteen; and, two years after, he went to Cambridge, where he was placed under the tuition of the learned Dr Cudworth, then fellow of Emanuel college. His father, Sir John Temple, being a statesman, seems to have designed him for the same way of life; and on this account, after residing at Cambridge two years, which were principally spent in acquiring a competency of French and Spanish, both languages exceedingly useful for his intended pursuits, he was sent abroad to finish his education.

Mr Temple began his travels by visiting France in 1648. As he chose to pass through the Isle of Wight, where his majesty was detained a prisoner, he there accidentally met with the second daughter of Sir Peter Osborn of Chicksand, in Bedfordshire, then governor of Guernsey for the king; and his lady being on a journey with her brother to St Maloes, where their father then was, our young traveller joined their party. This gave rise to an honourable attachment, which, at the end of seven years, concluded in a happy marriage. Having resided two years in France, and learned the French language perfectly, Mr Temple made a tour through Holland, Flanders, and Germany, during which he became completely master of the Spanish. In 1654 he returned from the continent, and, marrying Miss Osborn, passed his time in retirement with his father, his two brothers, and a sister, then in Ireland, happy in that perfect harmony which has been so often remarked in their family.

As he rejected all offers made him of employment under Cromwell, the five years which he lived in Ireland were spent chiefly in improving himself in history and philosophy; but at the Restoration, in 1660, being chosen a member of the convention there, while others were trying to make their court to the king, Mr Temple opposed the poll-bill with so much spirit, that his conduct soon attracted the attention of the public, and brought him into notice. In the succeeding parliament, in 1661, he was elected with his father for the county of Carlow; and in the year following, he was chosen one of the commissioners to be sent from that parliament to the king, which gave him an opportunity of waiting on the duke of Ormond, the new lord lieutenant, then at London. Soon after he went back to Ireland, but with a resolution of quitting that kingdom, and of removing with his family to England.

On his return he met with a very favourable reception from the duke of Ormond; and soon acquired such a considerable share in his esteem, that the duke complained of him as the only man in Ireland that had never asked any thing from him. When he mentioned his design of carrying his family to England, his grace said, that he hoped he would at least give him leave to write in his favour to the two great ministers, Clarendon then lord chancellor, and the earl of Arlington, who was secretary of state. This the duke did in such strong terms, as procured him the friendship of these two noblemen, as well as the good opinion of the king. Mr Temple, however, made no other use of this advantage than to tell Lord Arlington, that if his majesty had any employment abroad, which he was fit for, he should be happy to undertake it; but, at the same time, he requested that he might not be sent into any of the northern climates, to which he had a very great aversion. Lord Arlington replied, he was very sorry he had made such an objection, as there was no other employment then undisposed of except that of going envoy to Sweden. However, in 1665, about the beginning of the first Dutch war, Lord Arlington sent a messenger to acquaint him that he must immediately come to his house; which he did, and found that his lordship's business was to tell him, that the king had occasion to send some person abroad upon an affair of the utmost importance, and that he had resolved to make him the first offer; but that he must know, without delay, and without telling him what it was, whether he would accept of it, and that he must be ready to set out in two or three days, without mentioning it to any of his friends. After a little consideration, Mr Temple told his lordship, that, as he took him to be his friend, and as he had advised him not to refuse, as it would be an entrance into his majesty's service, he should consult no farther. This business was to carry a secret commission to the bishop of Munster; which he set out with on the second of August, and executed it so much to the satisfaction of Charles II. that, on his return to Brussels, his majesty appointed him resident there, and created him a baronet. As Brussels was a place which he had long wished to reside at, in April 1666 he sent for his family; but, before their arrival, he had been again obliged to depart upon business to the prelate's court: for the bishop having listened to terms of accommodation with France, Sir William wrote two letters to dissuade him from that alliance; and these not having the desired effect, he went in disguise to Munster, where, though he arrived too late to secure the prince in his first engagement, yet he prevailed on him to permit five or six thousand of his best troops to enter into the Spanish service. In this journey he passed for a Spanish envoy, having twenty Spanish guards to attend him. In this manner he first went to Dusseldorp, where the duke of Newburgh, though in the French interest, gave him a guard to Dortmund; but when he reached that place, finding the gates shut, he was forced to proceed to a village, at the distance of a league, which being full of Brandenburgh troops, he was under the necessity of lodging in a barn, upon a straw bed, with his page for a pillow. Next day he was entertained at a castle belonging to the bishop of Munster, by one Gorges a Scotch lieutenant-general in that prelate's service, with what he calls a very episcopal way of drinking. The general coming to the large hall, in which stood a great many flaggons ready charged, he called for wine to drink the king's health. A silver bell, that might hold about two quarts, was upon this brought him; and, as soon as he received it, he pulled out the clapper, and giving it to Sir William, to whom he intended to drink, ordered the bell to be filled. When he was done, he drank off the contents to his majesty's health; and asked Sir William for the clapper, put it on, and turning down the bell, rang it, to show that he had drank fair, and

Temple.

and left nothing in it. He then took out the clapper, desired Sir William to give it to whomsoever he pleased; and, ordering the bell to be filled again, presented it to Sir William: but as the latter seldom used to drink, he had generally some gentleman with him to supply his place in this respect whenever it might be necessary. Having finished his business at Munster, he returned to Brussels, where he passed a year with great pleasure and satisfaction.

Two months after the conclusion of the peace with the Dutch at Breda, Sir William's sister, who resided with him at Brussels, being very desirous of seeing Holland, he went thither incognito to gratify her desire; but while he was at the Hague, he paid a private visit to Mr De Witt, in which he laid the foundation of that close intimacy which afterwards subsisted between them.

In the spring of 1667, a new war breaking out between France and Spain, which exposed Brussels to the danger of falling into the hands of the former, Sir William sent his lady and family to England; but he himself remained there with his sister till the Christmas following, when he was ordered by the king to come over privately to London. Taking the Hague in his way, he paid another visit to De Witt, and, pursuant to his instructions, proposed those overtures to him which produced the triple alliance. Soon after his arrival at the British court, he returned, on the 16th of January 1668, with the character of envoy extraordinary and plenipotentiary to Holland; where a conference being opened, he brought that treaty to a perfect conclusion in the short space of five days. The ratifications of this alliance being exchanged on the 15th of February, he repaired to Brussels; and a treaty being set on foot between France and Spain at Aix-la-Chapelle, he set out for that place on the 24th of April in quality of his majesty's ambassador extraordinary and mediator. Here he arrived on the 27th: and it was chiefly owing to his assistance that the Spaniards were brought to sign the articles of that peace on the second of May. This service being completed, he returned to Brussels, with a view of remaining there in his former station of resident; but he received letters from the earl of Arlington, with the king's order to continue as ambassador, and to serve his country in that quality in Holland, as on account of the late alliances, his majesty was resolved to renew a character which the crown of England had discontinued there since the time of King James. Sir William being now left at liberty to return to England, embraced the opportunity; and, upon his arrival at London, he was received with every possible demonstration of favour both by the king and the court.

Setting out again for Holland, with his new character of the king's ambassador, he arrived at the Hague in the end of August 1668. Here he enjoyed the confidence of that great minister De Witt, and lived in great intimacy with the prince of Orange, who was then only eighteen years of age; but, in September 1669, he was hurried back to England by Lord Arlington, who ordered him to put his foot in the stirrup as soon as he should receive his letter. When Sir William waited on the earl, he found that he had not one word to say to him; for, after making him attend a long time, he only asked a few indifferent questions respecting his journey. Next day he was received as coolly by the king; but the secret soon came out, and he pressed to return to the Hague, and pave the way for a war with Holland. This, however, he excused himself from having any hand in; which so much provoked the lord treasurer Clifford, that he refused to him an arrear of two thousand pounds due from his embassy. Disgusted with Arlington's behaviour, which was so unlike the friendship he had formerly professed, Sir William now retired to his house at Sheen near Richmond, in Surry; and in his retreat, when free from the hurry of business, he wrote his Observations on the United Provinces, and one part of his Miscellanies, in the time of the second Dutch war. About the end of summer, however, 1673, the king wishing to put an end to the war, sent for Sir William, and desired him to go to Holland to negociate a peace; but powers having been sent from thence at this time to the Marquis de Fresno, the Spanish ambassador at London, Sir William was ordered to confer with him; and a treaty was accordingly concluded in three days, and the point carried respecting the superiority of the British flag, which had been so long contested. In June 1674 he was again sent ambassador to Holland to offer the king's mediation between France and the confederates, then at war, which was accepted not long after; Lord Berkeley, Sir William Temple, and Sir Leoline Jenkins, being declared ambassadors and mediators; and Nimeguen, which Sir William had proposed, was at length agreed upon by all parties to be the place of treaty. During his stay at the Hague, the prince of Orange, who was fond of the English language, and of the plain English way of eating, constantly dined and supped once or twice a week at his house; and by this familiarity he so much gained the prince's confidence and esteem, that he had a considerable hand in his marriage with the Princess Mary, daughter of James II.

In July 1676 he removed his family to Nimeguen, where he spent the remainder of that year without making any progress in the treaty; and the year following his son was sent over with letters from the lord treasurer, ordering him to return, and succeed Mr Coventry as secretary of state. In consequence of this order, Sir William came over to England in the spring of 1677; and though the affair of the secretary's place was dropped at his desire, he did not return to Nimeguen that year. About this time, the prince having the king's leave to come over, he soon after married the Princess Mary; and this gave occassion for a new coolness between Lord Arlington and Sir William, as he and the lord-treasurer Osborn, who was related to Sir William's lady, were only privy to that affair. After the prince and princess were gone to Holland, as the court always seemed inclined to favour France, the king wished to engage Sir William in some negociations with that crown: but he was so ill satisfied with this proposal, that he offered to give up all pretensions to the office of secretary; and desiring the lord-treasurer to acquaint his majesty with his intentions, retired to Sheen, in hopes of being taken at his word. Upon a discovery, however, of the French designs not to evacuate the Spanish towns agreed by the treaty to be delivered up, the king commanded him to go upon a third embassy to the states; with whom he concluded a treaty: by which England engaged, in case France refused to evacuate the towns in forty days, to declare war immedi-

 ately

ately against that nation; but before half that time was elapsed, one Du Cross was sent from the English court to Holland upon a business which damped all the good humour excited by the treaty there, and which produced such sudden and astonishing changes in this country, as gave Sir William a distaste for all public employments.

In 1679 he went back to Nimeguen, where the French delayed to sign the treaty till the last hour; but having concluded it, he returned to the Hague, whence he was soon after sent for to enter upon the secretary's office, which Mr Coventry at length resolved to resign. He accordingly come over, and went to court, as all his friends hoped, with a full intention of assuming his office; but he started some difficulty, because he had not a seat in the house of commons, thinking that, by his not being a member, the public business would suffer at such a critical time, when the contests between the two parties ran so high that the king thought fit to send the duke of York into Flanders, and the parliament to put the lord-treasurer Danby into the Tower. After this his majesty still pressed Sir William to be secretary of state; using as an argument for his compliance, that he had nobody to consult with at a time when he had the greatest need of the best advice. Notwithstanding all this, Sir William declined the king's offer, advising him to choose a council in whom he could confide, and upon whose abilities he could depend. This advice the king followed; and the choice of the persons being concerted between his majesty and Sir William, the old council was dissolved four days after, and the new one established, of which the latter was a member.

In 1680 the councils began again to be changed, on the king's illness, at the end of summer, and the duke of York's return privately to court. In this juncture Sir William, endeavouring to bring to the king's favour and business some persons to whom his majesty had taken a dislike, if not an aversion, he met with such treatment from them as gave him a fresh distaste to the court, at which he seldom made his appearance; so that he resided principally at Sheen. Soon after this the king sent for him again; and having proposed that he should go as ambassador into Spain, Sir William consented: but when his equipage was almost ready, and part of the money paid down for it, the king changed his mind, and told him that he would have him defer his journey till the end of the session of parliament, in which he was chosen a member for the university of Cambridge. In this session the spirit of party ran so high that it was impossible to bring the house to any kind of temper. The duke was sent into Scotland; but this would not satisfy them, nor any thing but a bill of exclusion; which Sir William strenuously opposed, saying, that "His endeavour ever should be to unite the royal family, and that he would never enter into any councils to divide them." Not long after this period, the parliament being dissolved by his majesty, without the advice of his privy council, and contrary to what he had promised, Sir William made a bold speech against it; for which he was very ill used by some of those friends who had been most earnest in promoting the last change in the ministry. Upon this he grew quite tired of public business, declined the offer he had of again serving for the university in the next parliament, that was soon after called, and met at Oxford; and seeing his majesty resolved to govern without his parliament, and to supply his treasury through another channel, he retired to Sheen a few days after, whence he sent word by his son, that "he would pass the rest of his days like a good subject, but would never more meddle with public affairs." From that time Sir William lived at this place till the end of that reign and for some time in the next; when having purchased a small seat, called *Moor Park*, near Farnham in Surry, which he conceived a great fondness for, on account of its solitude and retirement, and its healthy and pleasant situation, and being much afflicted with the gout, and broken with age and infirmities, he resolved to spend the remainder of his life in this agreeable retreat. In his way thither, therefore, he waited on King James, who was then at Windsor, and begged his favour and protection to one "that would always live as a good subject, but, whatever might happen, never again enter upon any public employment;" desiring his majesty to give no credit to any thing he might hear to the contrary. The king, who used to say that Sir William Temple's character was always to be believed, promised him whatever he desired, gently reproached him for not entering into his service, which, he said, was his own fault; and kept his word as faithfully to Sir William as Sir William did to his majesty, during the surprising turn of affairs that soon after followed by the arrival of the prince of Orange. At the time of this happy revolution, in 1688, Moor Park becoming unsafe, as it lay in the way of both armies, he went back to the house at Sheen, which he had given up to his son; to whom he refused leave, though importunately begged, to go and meet the prince of Orange at his landing: but after King James's abdication, when the prince reached Windsor, he went thither to wait upon his highness, and carried his son along with him. The prince pressed him to enter into his service, and to be secretary of state; but his age and infirmities confirming him in the resolution he had made not to meddle any more with public affairs, he was satisfied that his son alone should enjoy his majesty's favour. Mr John Temple was upon this appointed secretary at war; but he had hardly been a week in that office, when he resolved to put an end to his own existence; which he did on the 14th of April 1689, by throwing himself out of a boat, hired for that purpose, in shooting London-bridge; having first put stones into his pocket to make him sink speedily.

In 1694 Sir William had the misfortune to lose his lady, who was a very extraordinary woman, as well as an affectionate wife. He was then considerably turned of sixty; at which age he practised what he had so often declared to be his opinion, that "an old man ought then to consider himself of no farther use in the world except to himself and his friends." After this he lived four years very much afflicted with the gout; and his strength and spirits being worn out by the infirmities of age, he expired in the month of January 1698. He died at Moor-Park, where his heart was buried in a silver box under the sun dial in his garden, opposite to a window from which he used to contemplate and admire the works of nature, with his sister, the ingenious Lady Gifford. This was according to his will; in pursuance of which his body was privately interred in Westminster Abbey, and a marble monument erected in 1722, after the

the death of Lady Gifford, who resembled him in genius as well as in person, and left behind her the character of one of the best and most constant friends in the world.

Sir William Temple's principal works are, 1. Memoirs from 1672 to 1692: They are very useful for those who wish to be acquainted with the affairs of that period. 2. Remarks upon the State of the United Provinces. 3. An Introduction to the History of England: This is a Sketch of a General History. 4. Letters written during his last embassies. And, 5. Miscellanies, which contain a great many curious pieces that display considerable depth of thought. He was an accomplished gentleman, a sound politician, a patriot, and a great scholar. And if this great idea should perchance be shaded by some touches of *vanity* and *spleen*, the reader will be so candid as to consider, that the greatest, wisest, and the best of men, have still some failings and imperfections which are inseparable from human nature.

TEMPLE, *Templum*, a public building, erected in honour of some deity, either true or false; and wherein the people meet to pay religious worship to the same. The word is formed from the Latin *templum*, which some derive from the Greek τιμενος, signifying the same thing; and others from τεμνω, *abscindo*, "I cut off, I separate," in regard a temple is a place separated from common uses; others with more probability derive it from the old Latin word *templare*, "to contemplate." It is certain the ancient augurs gave the name *templa* to those parts of the heavens which were marked out for the observation of the flight of birds. Their formula was this: *Templa tesqua sunto.* Temples were originally all open, and hence received their name. See Phil. Trans. N° 471. sect. 5. where we have an account of an ancient temple in Ireland of the same sort as our famous Stonehenge. The word *templum*, in its primary sense among the old Romans, signified nothing more than a place set apart and consecrated by the augurs, whether inclosed or open, in the city or in the fields.

Clemens Alexandrinus and Eusebius refer the origin of temples to the sepulchres built for the dead. This notion has been lately illustrated and confirmed by a variety of testimonies by Mr Farmer in his Treatise on the Worship of Human Spirits, p. 373, &c. Herodotus and Strabo will have the Egyptians to have been the first who built temples to the gods. The first erected in Greece is ascribed to Deucalion, by Apollonius, Argonaut. lib. iii. In antiquity we meet with many people who would not build any temples to their gods for fear of confining them to too narrow bounds. They performed their sacrifices in all places indifferently, from a persuasion that the whole world is the temple of God, and that he required no other. This was the doctrine of the magi, followed by the Persians, the Scythians, the Numidians, and many other nations mentioned by Herodotus, lib. i. Strabo, lib. xv. and Cicero in his second oration against Verres.

The Persians, who worshipped the sun, believed it would wrong his power to inclose him in the walls of a temple, who had the whole world for his habitation; and hence, when Xerxes ravaged Greece, the magi exhorted him to destroy all the temples he met with.

The Sicyonians would build no temple to their goddess Coronis; nor the Athenians, for the like reason, erect any statue to Clemency, who, they said, was to live in the hearts of men, not within stone walls.

The Bithynians had no temples but the mountains to worship on; nor had the ancient Germans any other but the woods.

Even some philosophers have blamed the use and building of temples, particularly Diogenes, Zeno, and his followers the Stoics. But it may be said, that if God hath no need of temples, men have need of places to meet in for the public offices of religion: accordingly temples may be traced back even into the remotest antiquity. See *Hospinian de Origine Templorum.*

The Romans had several kinds of temples; whereof those built by the kings, &c. consecrated by the augurs, and wherein the exercise of religion was regularly performed, were called, by way of eminence, *templa*, "temples." Those that were not consecrated, were called *ædes*. The little temples, that were covered or roofed, they called *ædiculæ*. Those open, *sacella*. Some other edifices, consecrated to particular mysteries of religion, they called *fana* and *delubra*.

All these kinds of temples, Vitruvius tells us, had other particular denominations, according to the form and manner of their construction, as will be hereafter specified.

Indeed the Romans outdid all nations with regard to temples: they not only built temples to their gods, to their virtues, to their diseases, &c. but also to their emperors, and that in their life time; instances whereof we meet with in medals, inscriptions, and other monuments. Horace compliments Augustus hereupon, and sets him above Hercules and all the heroes of fable; because those were admitted into temples only after their death, whereas Augustus had his temples and altars while living.

Præsenti tibi maturos largimur honores;
Jurandasque tuum per nomen ponimus aras.
Epist. ad Aug.

Suetonius, on this occasion, gives an instance of the modesty of that emperor, who would allow of no *temples* being erected to him in the city; and even in the provinces, where he knew it was usual to raise temples to the very proconsuls, refused any but those erected in the name of Rome as well as his own.

The most celebrated temples among the Romans were the Capitol and Pantheon. They had also the temple of Saturn, which served for the public treasury; and the temple of Janus.

The temple at Jerusalem was similar in its plan to the TABERNACLE. The first temple was begun by Solomon about the year of the world 2992, and before Christ 1012 according to some chronologers, and finished in eight years. Great mistakes have been committed respecting the dimensions of this temple, by confounding the emblematical description of Ezekiel with the plain account of it in the books of Kings and Chronicles. It consisted of the holy of holies, the sanctuary, and a portico. The holy of holies was a square room of 20 cubits; the sanctuary, or holy place, was 40 cubits long and 20 broad, consequently the length of both these together was 60 cubits. The portico, which stood before the sanctuary, was 20 cubits long and 10 cubits broad. Whether the portico was separated by a wall from

Temple.

from the rest of the temple or not, is not mentioned in scripture. If it was, the whole length of the temple, computing the cubit at 22 inches, did not exceed 110 feet in length and 36 feet 8 inches in breadth. In the portico stood the two brazen pillars called *Jachin* and *Boaz*, which, upon comparing and reconciling the seemingly different accounts in different places, appear to have been 40 cubits high and about 4 cubits diameter. The court probably at first extended all round the temple. Now we are told, that the court about the tabernacle was 100 cubits long and 50 broad; and as Solomon made every part of the temple about twice as large as the corresponding part in the tabernacle, we have reason to conclude, that the court around the temple was 200 cubits long and 100 broad. According to this description, which is taken from the scripture history, the temple of Solomon was by no means so large, as it is commonly represented. Still, however, it was very magnificent in size and splendid in ornament. It was plundered of its treasures in the reign of Rehoboam, and repaired by Joash; it was again spoiled in the time of Ahaz and of Hezekiah; and after being restored by Josiah, was demolished by Nebuchadnezzar in the year of world 3416, after it had stood 476 years according to Josephus, and according to Usher 428 years.

The second temple was built by the Jews, after their return from the Babylonish captivity, under the direction and influence of Zerubbabel their governor, and of Joshua the high-priest, with the leave and encouragement of Cyrus the Persian emperor, to whom Judea was now become a tributary kingdom. According to the Jews, this temple was destitute of five remarkable appendages, which were the chief glory of the first temple; viz. the ark and mercy-seat, the Shechinah, the holy fire on the altar, which had been first kindled from heaven, the urim and thummim, and the spirit of prophecy. This temple was plundered and profaned by Antiochus Epiphanes, who also caused the public worship in it to cease; and afterwards purified by Judas Maccabæus, who restored the divine worship; and after having stood 500 years, rebuilt by Herod, with a magnificence approaching to that of Solomon's. Tacitus calls it *immensæ opulentiæ templum*; and Josephus says, it was the most astonishing structure he had ever seen, as well on account of its architecture as its magnitude, and likewise the richness and magnificence of its various parts and the reputation of its sacred appurtenances. This temple, which Herod began to build about 16 years before the birth of Christ, and so far completed in nine years and a half as to be fit for divine service, was at length destroyed by the Romans on the same month and day of the month on which Solomon's temple was destroyed by the Babylonians.

Maurice's Indian Antiquities, vol. iii. p. 352.

The Indian temples, or pagodas, are sometimes of a prodigious size. They are commonly erected near the banks of the Ganges, Kistna, or other sacred rivers, for the benefit of ablution in the purifying stream. Where no river flows near the foot of the pagoda, there is invariably in the front of it a large tank or reservoir of water. These are, for the most part, of a quadrangular form, are lined with freestone or marble, have steps regularly descending from the margin to the bottom, and Mr Crauford observed many between three and four hundred feet in breadth. At the entrance of all the more considerable pagodas there is a portico, supported by rows of lofty columns, and ascended by a handsome flight of stone steps; sometimes, as in the instance of Tripetti *, to the number of more than a hundred. Under this portico, and in the courts that generally inclose the whole building, an innumerable multitude assemble at the rising of the sun; and, having bathed in the stream below, and in conformity to an immemorial custom over all the East, having left their sandals on the border of the tank, impatiently await the unfolding of the gates by the ministering brahmin. The gate of the pagoda universally fronts the east, to admit the ray of the solar orb; and, opening, presents to the view an edifice partitioned out, according to Mr Thevenot in his account of Chitanagar, in the manner of the ancient cave-temples of Elora, having a central nave or body; a gallery ranging on each side; and, at the farther end, a sanctuary, or chapel of the deity adored, surrounded by a stone balustrade to keep off the populace. Those who wish to peruse a more particular account of the Indian temples may consult Maurice's Indian Antiquities. See also PAGODA and SERINGHAM.

Crauford's Sketches, vol. i. p. 106.

* *Voyage des Indes*, tom. iii.

TEMPLE, in *Architecture*. The ancient temples were distinguished, with regard to their construction, into various kinds; as, *Temple in antæ*, *Ædes in antis*. These, according to Vitruvius, were the most simple of all temples, having only angular pilasters, called *antæ* or *parastatæ*, at the corners, and two Tuscan columns on each side of the doors. *Temple tetrastyle*, or simple *tetrastyle*, was a temple that had four columns in front, and as many behind. Such was the temple of Fortuna Virilis at Rome. *Temple prostyle*, that which had only columns in its front or foreside; as that of Ceres at Eleusis in Greece. *Temple amphiprostyle*, or *double prostyle*, that which had columns both before and behind, and which was also tetrastyle. *Temple periptere*, that which had four rows of insulated columns around, and was hexastyle, i. e. had six columns in front; as the temple of Honour at Rome. *Temple diptere*, that which had two wings and two rows of columns around, and was also octostyle, or had eight columns in front; as that of Diana at Ephesus.

TEMPLES, among us denote two inns of court in London, thus called, because anciently the dwelling-house of the knights templars. At the suppression of that order, they were purchased by the professors of the common law, and converted into *hospitia* or inns. They are called the *inner* and *middle temple*, in relation to Essex-house; which was also a part of the house of the templars, and called the *outer temple*, because situated without Temple-Bar. In the middle temple, during the time of the templars, the king's treasure was kept; as was also that of the kings of France in the house of the templars at Paris. The chief officer was the master of the temple, who was summoned to parliament in 47 Hen. III. and from him the chief minister of the temple-church is still called *master of the temple*.

TEMPLES, in *Anatomy*, a double part of the head, reaching from the forehead and eyes to the two ears. The temples are chiefly formed of two bones called *ossa temporis*. These parts, according to physicians, were called *tempora*, from their showing the age or time of a man by the colour of the hair, which turns white in this part before any other; which Homer seems to have been aware of, by his calling men *poliocrotaphi*, q. d. "grey-templed."

TEMPORAL,

Temporal, Temporalities.

TEMPORAL, a term generally used for secular, as a distinction from ecclesiastical. Thus we say temporal lords, and spiritual or ecclesiastical lords.

TEMPORALITIES *of Bishops*, are the revenues, lands, tenements, and lay-fees, belonging to bishops, as they are barons and lords of parliament.

The custody of the temporalities of bishops forms a branch of the king's ordinary revenues (see REVENUE). These, upon the vacancy of the bishopric, are immediately the right of the king, as a consequence of his prerogative in church matters: whereby he is considered as the founder of all archbishoprics and bishoprics, to whom, during the vacancy, they revert. And for the same reason, before the dissolution of abbeys, the king had the custody of the temporalities of all such abbeys and priories as were of royal foundation (but not of those founded by subjects), on the death of the abbot or prior. Another reason may also be given why the policy of the law hath vested this custody in the king; because, as the successor is not known, the lands and possessions of the see would be liable to spoil and devastation if no one had a property therein. Therefore the law has given the king, not the temporalities themselves, but the custody of the temporalities, till such time as a successor is appointed; with power of taking to himself all the intermediate profits, without giving any account to the successor; and with the right of presenting (which the crown very frequently exercises) to such benefices and other preferments as fall within the time of vacation. This revenue is of so high a nature, that it could not be granted out to a subject, before or even after it accrued: but now, by the statute 15 Edw. III. stat. 4. cap. 4. and 5. the king may, after the vacancy, lease the temporalities to the dean and chapter; saving to himself all advowsons, escheats, and the like. Our ancient kings, and particularly William Rufus, were not only remarkable for keeping the bishoprics a long time vacant, for the sake of enjoying the temporalities, but also committed horrible wastes on the woods and other parts of the estate; and to crown all, would never, when the see was filled up, restore to the bishop his temporalities again, unless he purchased them at an exorbitant price. To remedy which, King Hen. I. granted a charter at the beginning of his reign, promising neither to sell, nor let to farm, or take any thing from, the domains of the church, till the successor was installed. And it was made one of the articles of the great charter, that no waste should be committed in the temporalities of bishoprics, neither should the custody of them be sold. The same is ordained by the statute of Westminster the first; and the statute 14 Edward III. stat. 4. cap. 4. (which permits a lease to the dean and chapter) is still more explicit in prohibiting the other exactions. It was also a frequent abuse, that the king would, for trifling or no causes, seize the temporalities of bishops, even during their lives, into his own hands: but this is guarded against by statute 1 Edw. III. stat. 2. cap. 2.

Blackst. Comment. vol. i.

This revenue of the king, which was formerly very considerable, is now by a customary indulgence almost reduced to nothing; for, at present, as soon as the new bishop is consecrated and confirmed, he usually receives the restitution of his temporalities quite entire and untouched from the king; and then, and not sooner, he has a fee-simple in his bishopric, and may maintain an action for the profits.

Temporalities ‖ Tenedos.

TENACITY, in *Natural Philosophy*, that quality of bodies by which they sustain a considerable pressure or force of any kind without breaking. It is the quality opposite to fragility or brittleness. See STRENGTH *of Materials*.

TENACULUM, in *Surgery*, an instrument used in amputation, for pulling out bleeding vessels that are to be tied by ligatures. See SURGERY.

TENAILLES and TENAILLIONS. } See FORTIFICATION, Sect. I. § 3. and 5.

TENANT, one that holds lands or tenements of some lord or landlord, by rent, fealty, &c. See TENURE.

TENAWIT. See LOXIA, ORNITHOLOGY *Index*.

TENCH. See CYPRINUS, ICHTHYOLOGY *Index*.

TENDER, a small ship in the service of men of war, for carrying men, provisions, or any thing else that is necessary.

TENDONS, in *Anatomy*, are white, firm, and tenacious parts, contiguous to the muscles, and usually forming their extremities. See ANATOMY, N° 85.

TENEBRIO, in *Natural History*, a genus of insects belonging to the order of coleoptera. See ENTOMOLOGY *Index*.

TENEDOS, in *Ancient Geography*, an island on the coast of Troas, at the distance of 40 stadia from the continent, and 80 in compass; with a cognominal Æolian town, and a temple of Apollo Smintheus. Its origin is derived from Tennes or Tenes, who being exposed in a coffer or bog by his father Cygnus the Thracian, at the instigation of the mother-in-law, was by fate carried to this island, made king of it, and at length worshipped as a god on account of his virtues. The island was famous for its earthen ware, for which purpose it had an excellent red clay; and hence Bochart would derive the appellation from *tinedom*, a "red clay." *Tenedia securis*, is a proverbial saying to denote severity; from a law there passed, that persons found in the act of adultery should be put to death; a severity executed on the king's son; and therefore, in the coins of Tenedos, on one side are two heads, in memorial of the king and his son, and on the reverse an axe, (Aristotle). This island still retains its ancient name; and is one of the smallest islands of the Archipelago, situated near the coast of Lesser Asia, west of the ruins of Troy. It is chiefly rocky, but fertile, being remarkable for producing the best Muscadine wine in the Levant; and its position, thus near the mouth of the Hellespont, has given it importance in all ages; vessels bound towards Constantinople finding shelter in its port, or safe anchorage in the road, during the Etesian or contrary winds, and in foul weather. The emperor Justinian erected a magazine to receive the cargoes of the corn ships from Alexandria, when detained there. This was a lofty building, 280 feet long, and 90 broad. The voyage from Egypt was rendered less precarious, and the grain preserved until it could be transported to the capital. Afterwards, during the troubles of the Greek empire, Tenedos experienced a variety of fortune. The pirates, who infested these seas, made it for many years their place of rendezvous; and Othman seized it in 1302, procured vessels, and thence subdued the other islands of the Archipelago.

In

Tenedos, Teneriff.

It has continued in the possession of the Turks ever since: and on the eastern side is a pretty large town, seated at the foot of a mountain, with a fine harbour commanded by a castle. E. Long. 26. 0. N. Lat. 39. 42.

TENERIFF, an island of Africa, and one of the Canaries, being the most considerable for riches, trade, and extent. It lies to the south of the island of Salvages, to the west of the Grand Canary, to the north of the island of Gomera, and to the east of that of Palma. It is of a triangular form, being about 45 miles in length and 20 in breadth; and in the centre is the famous *peak*, called by the natives *El Pico de Teyde*, which in clear weather may be seen at the distance of 120 or even 140 miles, like a thin blue vapour very little darker than the sky.

The most frequented harbour is called *Santa Cruz*, which is on the south side of the island, and where ships with good anchors and cables may be safe in all weathers. At this port is the principal commercial town in the island, called also *Santa Cruz*, in the middle of which is a mole, built at a vast expence, for the convenience of landing; between the mole and the town is a fort called *St Philip's*, and near it is a steep rocky den or valley, beginning at the sea shore, and running far inland, which would render the attack of an enemy very difficult; there are also other forts for its defence, all joined together by a thick stone wall, and mounted with cannon.

Glas's Historical Account of the Canary Islands.

Santa Cruz is a large town, containing several churches and convents, an hospital, and the best constructed private buildings of any in the Canary islands. It contains about 7000 inhabitants; it is not fortified on the land side, and all the country near it is dry, stony, and barren.

About four leagues to the south of Santa Cruz, close to the sea, there is a cave, with a church called the *chapel of our Lady of Candelaria*, in which is an image of the Virgin Mary, that is held in as much reverence here as that of Diana was at Ephesus. This chapel is endowed with so many ornaments that it is the richest place in all the seven islands. At a certain season of the year almost all the inhabitants go thither on pilgrimage, and innumerable and incredible stories are related and universally believed concerning this image.

About four miles inland from Santa Cruz stands the city of St Chrystobal de la Laguna, which is the metropolis of the island, and contains two parish churches and five convents, but has no trade, being inhabited principally by the gentry of the island. It contains, according to Humboldt, about 9000 inhabitants, and stands in a plain 2200 feet above the sea, in which however wheat is cultivated, There are many other towns in the island which contain a great number of people, but none are more than three leagues from the sea.

All the fertile ground within a league of the sea is covered with vines; that of the next league is sown with corn, the third is adorned with woods, and above the woods are the clouds, for the island gradually ascends from the sea, rising on all sides till it terminates in the peak, which is the centre.

On the south-east of the island inland from *Candelaria* is a town called *Guimar*, where there are some families which know themselves to be the genuine unmixed offspring of the original natives; but they know nothing of the manners of their ancestors, nor have they preserved any remains of their language. They are fairer than the Spaniards of Andalusia.

Teneriff.

Teneriff contains about 96,000 persons, supposed to be equal to the number of inhabitants of all the rest of the seven islands put together. The peasants in general are wretchedly clothed; when they do appear better, they are habited in the Spanish fashion. The men, in a genteeler line, dress very gayly, and are seldom seen without long swords. It is remarked, that few of them walk with dignity and ease; which may be attributed to the long cloaks they usually wear. The women wear veils; those worn by the lower ranks are of black stuff, those of the higher of black silk; and such among the latter as have any claim to beauty are far from being over careful in concealing their faces by them. The young ladies wear their fine long black hair plaited, and fastened with a comb or a ribband on the top of the head.

White's Voyage to New South Wales, p. 13.

The common people, and in this they resemble the inhabitants of most of the islands in the Pacific ocean lately discovered, have in them a strong tendency to thieving; they are besides lazy, and the most importunate beggars in the world. "I observed likewise (says Mr White) that the itch was so common among them, and had attained such a degree of virulence, that one would almost be led to believe it was epidemic there. Some of the women are so abandoned and shameless, that it would be doing an injustice to the prostitutes met with in the streets of London to say they are like them. The females of every degree are said to be of an amorous constitution, and addicted to intrigue; for which no houses could be better adapted than those in Teneriff.

"The manufactures carried on here are very few, and the product of them little more than sufficient for their own consumption. They consist of taffeties, gauze, coarse linens, blankets, a little silk, and curious garters. The principal dependence of the inhabitants is on their wine (their staple commodity), oil, corn, and every kind of stock for shipping. With these the island abounds; and, in their season, produces not only the tropical fruits, but the vegetable productions of the European gardens, in the greatest plenty."

The height of the peak of Teneriff has been variously estimated and calculated by different travellers and geographers. Dr Halley allows but two miles and a quarter from the level of the sea to the summit of the sugar-loaf, whilst the Spanish account of the Canary islands, translated by Mr Glas in 1763, makes it no less than five miles. Borda, however, found its height by trigonometrical measurement to be 1905 toises, or 12,181 feet. Humboldt has described the different zones characterised by certain vegetables on the sides of this mountain. At the bottom lies a plain 3320 feet above the sea, covered chiefly with arborescent heaths, in which there is a spring whose temperature is 60° Fahrenheit. Above this is the region of arborescent ferns, which is succeeded by one of junipers and pines. Next to this, at the height of 9100 feet, is a sandy plain, characterised by the *spartium nubigenum*, a species of broom. All above this the surface is nearly covered with masses of obsidian and pumice; and a little higher, traces of vegetation

Rye's Excursion to the Peak of Teneriff.

getation almost entirely disappear. Near the summit, and before sunrise, the travellers observed a singular phenomenon; luminous points floating and moving in the air, which proved to be the images of several stars, magnified by vapours. Humboldt saw the sun rise from a place near the summit, and found that the upper limb of that luminary was visible 12 minutes 55 seconds sooner than it should be in the plain by calculation. The crater is surrounded by a parapet of compact lava, and is of an elliptical form, 300 feet long by 200 broad. At the bottom the heat was perceptible only at a few crevices, from which the aqueous vapours issued with a buzzing noise. When thrust into these the thermometer rose to 122 or 135 of Fahrenheit. The vapours consist of pure water. The depth of the crater is about 110 feet. The temperature at the summit was 37° in the middle of June. The air was extremely clear, the sky of the deepest blue, and prospect most magnificent.

TENESMUS, in *Medicine*, is a continual desire of going to stool, but without any stool being ready to be voided. See MEDICINE, N° 111.

TENIERS, DAVID, the Elder, a Flemish painter, born at Antwerp in 1582. He received the first rudiments of his art from the famous Rubens, who highly esteemed him for his promising genius, and with great satisfaction examined and commended his designs. From the school of that celebrated painter Teniers went to finish his studies at Rome. He attached himself to Adam Elsheimer for six years; and from the instructions of two such incomparable masters, he formed to himself a peculiar style, which his son cultivated so happily afterward as to bring it to the utmost perfection. His pictures were small; and his subjects usually shops, elaboratories, humorous conversations, and rural festivities. The demand for his pieces was universal; and even his master Rubens thought them an ornament to his cabinet. He died at Antwerp in 1640.

TENIERS, *David*, the Younger, also an admirable painter, was the son of the former, and was born at Antwerp in 1610. He obtained the name of *Ape of Painting*, from his imitating the manner of different painters with such exactness as to deceive even the nicest judges. He improved greatly under his father, and obtained such reputation as introduced him to the favour of the great. The archduke Leopold William made him gentleman of his bedchamber; and all the pictures of his gallery were copied by Teniers, and engraved by his direction. The king of Spain and Don Juan of Austria set so high a value on his pictures, that they built a gallery on purpose for them. William prince of Orange honoured him with his friendship; and Rubens not only esteemed his works, but assisted him with his advice. His principal talent lay in landscapes, adorned with small figures. He also painted men drinking and smoking, chemists elaboratories, country fairs, and the like. His small figures are superior to his large ones. He died in 1694.

The works of the father and son are thus distinguished: The latter discover a finer touch and fresher pencil, greater variety of attitudes, and a better disposition of the figures. The father retained something of the tone of Italy in his colouring, which was stronger than the son's; besides, the son used to put at the bottom of his pictures, David Teniers, junior.

Abraham, another son of David the Elder, was equal, if not superior, to his father and brother in the expression of his characters, and his understanding the *claro obscuro;* though he was inferior in the sprightliness of his touch, and the lightness of his pencil.

TENISON, DR THOMAS, archbishop of Canterbury, was born at Cottenham in Cambridgeshire in 1636; and studied at Corpus Christi college in Cambridge. In his youth, while the fanatical government lasted, he applied himself to physic; but afterward went into orders, and was some time minister of St Andrew's church, Cambridge; where he attended the sick during the plague in 1665, which his parishioners acknowledged by the present of a piece of plate. He showed himself very active against the growth of Popery, by his writings both in King Charles's and in King James's reigns: in 1680 he was presented to the vicarage of St Martin's in the Fields, London, to which parish he made several donations; and among others, endowed a free school, and built a handsome library, which he furnished with useful books. King William and Queen Mary, in 1689, presented him to the archdeaconry of London; in 1691, he was nominated to the see of Lincoln, and in 1694 he succeeded Dr Tillotson as archbishop of Canterbury. He performed all the duties of a good primate for 20 years, and died in 1715.

TENNIS, a play at which a ball is driven by a racket.

Hoyle's Games improved by Beaufort.

As many persons would become players at tennis, provided they could easily understand the rudiments of the game, so as to form some judgment of the players, or at least to know who wins and who loses, we have here attempted to give so plain a description of it, that no one can be at a loss, if ever he should bett or play. As to the executive part, it requires great practice to make a good player, so that nothing can be done without it; all we presume to do is to give an insight into the game, whereby a person may not seem a total stranger to it when he happens to be in a tennis court.

The game of tennis is played in most capital cities in Europe, particularly in France, from whence we may venture to derive its origin. It is esteemed with many to be one of the most ancient games in Christendom, and long before King Charles I.'s time it was played in England.

This game is as intricate as any game whatever; a person who is totally ignorant of it may look on for a month together, without being able to make out how the game is decided. Therefore we shall begin by describing the court in which it is played.

The size of a tennis court is generally about 96 or 97 feet by 33 or 34, there being no exact dimension ascribed to its proportion, a foot more or less in length or width being of no consequence. A line or net hangs exactly across the middle, over which the ball must be struck, either with a racket or board to make the stroke good. Upon the entrance of a tennis-court, there is a long gallery which goes to the dedans, that is, a kind of front gallery, where spectators usually stand, into which, whenever a ball is struck, it tells for a certain stroke. This long gallery is divided into different compartiments or galleries, each of which has its particular name, as follows; from the line towards the dedans are the *first gallery*, *door*, *second gallery*, and the *last gallery*, which is called the *service side*. From the dedans to the last gallery

Tennis.

gallery are the figures 1, 2, 3, 4, 5, 6, at a yard distance each, by which the chaces are marked, and is one of the most essential parts of the game, as will appear in the following description.

On the other side of the line are also the *first gallery*, *door*, *second gallery*, and *last gallery;* which is called the *hazard-side*. Every ball struck into the last gallery on this side reckons for a certain stroke the same as the dedans. Between the second and this last gallery are the figures 1, 2, to mark the chaces on the hazard-side. Over this long gallery, or these compartiments, is a covering, called the pent-house, on which they play the ball from the service-side, in order to begin a set of tennis, from which it is called a *service*. When they miss putting the ball (so as to rebound from the pent-house) over a certain line on the service side, it is deemed a fault, two of which are reckoned for a stroke. If the ball rolls round the pent-house, on the opposite side of the court, so as to fall beyond a certain line described for that purpose, it is called *passe*, reckons for nothing on either side, and the player must serve again.

On the right-hand side of the court from the dedans is what they call the *tambour*, a part of the wall which projects, and is so contrived in order to make a variety in the stroke, and render it more difficult to be returned by the adversary; for when a ball strikes the *tambour*, it varies its direction, and requires some extraordinary judgment to return it over the line. The last thing on the right hand side is called the *grill*, wherein if the ball is struck, it is also 15, or a certain stroke.

The game of tennis is played by what they call *sets;* a set of tennis consists of six games: but if they play what is called an advantage-set, two above five games must be won on one side or the other successively, in order to decide; or, if it comes to six games all, two games must still be won on one side to conelude the set; so that an advantage-set may last a considerable time; for which kind of sets the court is paid more than for any other.

We must now describe the use of the chaces, and by what means these chaces decide or interfere so much in the game. When the player gives his service at the beginning of a set, his adversary is supposed to return the ball; and wherever it falls after the first rebound untouched, the chace is called accordingly; for example, if the ball falls at the figure 1, the chace is called at a yard, that is to say, at a yard from the dedans: this chace remains till a second service is given; and if the player on the service side lets the ball go after his adversary returns it, and if the ball falls on or between any of these figures or chaces, they must change sides, there being two chaces; and he who then will be on the hazard side, must play to win the first chace; which if he wins by striking the ball so as to fall, after its first rebound, nearer to the dedans than the figure 1, without his adversary's being able to return it from its first hop, he wins a stroke, and then proceeds in like manner to win the second chace, wherever it should happen to be. If a ball falls on the line with the first gallery door, second gallery, or last gallery, the chace is likewise called at such or such a place, naming the gallery, door, &c. When it is just put over the line, it is called a chace at the line. If the player on the service-side returns a ball with such force as to strike the wall on the hazard-side so as to rebound, after the first hop over the line, it is also called a chace at the line.

The chaces on the hazard-side proceed from the ball being returned either too hard or not quite hard enough; so that the ball after its first rebound falls on this side of the blue line, or line which describes the hazard-side chaces; in which case it is a chace at 1, 2, &c. provided there is no chace depending. When they change sides, the player, in order to win this chace, must put the ball over the line anywhere, so that his adversary does not return it. When there is no chace on the hazard-side, all balls put over the line from the service-side, without being returned, reckon for a stroke.

As the game depends chiefly upon the marking, it will be necessary to explain it, and to recommend those who play at tennis to have a good and unbiassed marker, for on him the whole set may depend: he can mark in favour of the one and against the other in such a manner, as will render it two to one at starting, though even players. Instead of which the marker should be very attentive to the chaces, and not be anyway partial to either of the players.

This game is marked in a very singular manner, which makes it at first somewhat difficult to understand. The first stroke is called 15, the second 30, the third 40, and the fourth game, unless the players get four strokes each; in that case, instead of calling it 40 all, it is called *deuce;* after which, as soon as any stroke is got, it is called *advantage;* and in case the strokes become equal again, *deuce* again, till one or the other gets two strokes following, which win the game; and as the games are won, so they are marked and called; as one game love, two games to one, &c. towards the set, of which so many of these games it consists.

Although but one ball at a time is played with, a number of balls are made use of at this game to avoid trouble, and are handed to the players in baskets for that purpose; by which means they can play as long as they please, without ever having occasion to stoop for a ball.

There are various methods of giving odds at tennis, in order to make a match equal; and that they may be understood, we shall give the following list of them, with their meanings, so that any person may form a judgement of the advantage received or given.

The lowest odds that can be given, excepting the choice of the sides, is what they call a *bisque*, that is, a stroke to be taken or scored whenever the player, who receives the advantage, thinks proper: for instance, suppose a critical game of the set to be forty thirty, by taking the *bisque*, he who is forty becomes game, and so in respect of two *bisques*, &c.

The next greater odds are *fifteen*, that is, a certain stroke given at the beginning of each game.

After these, *half thirty*, that is, fifteen one game, and thirty the next. Then follow the whole *thirty*, *forty*, &c.

There are also the following kind of odds which are given, viz.

Round services; those are services given round the pent-house, so as to render it easy for the *striker out* (the player who is on the hazard side) to return the ball.

Half court, that is, being obliged or confined to play into the adversary's half-court; sometimes it is played straightwise, and at other times across; both which are great advantages given by him so confined, but the strait half-court is the greatest.

Touch no-wall, that is, being obliged to play within the compass of the walls, or sides of the court. This is

a

a considerable advantage to him who receives it; as all the balls must be played gently, and consequently they are much easier to take than those which are played hard, or according to the usual method of play.

Barring the hazards, that is, barring the dedans, tambour, grill, or the last gallery on the hazard-side, or any particular one or more of them.

These are the common kind of odds or advantages given; but there are many others, which are according to what is agreed by the players: such as playing with *board* against *racket*, *cricket-bat* against *racket*, &c.

The game of tennis is also played by four persons, two partners on each side. In this case, they are generally confined to their particular quarters, and one of each side appointed to serve and strike out; in every other respect, the game is played in the same manner as when two only play.

Any thing more to be said upon this subject would be needless, as nothing can be recommended after reading this short account of tennis, but practice and attention, without which no one can become a proficient at the game.

TENOR, or TENOUR, the purport or content of a writing or instrument in law, &c.

TENOR, in *Music*, the first mean, or middle part, or that which is the ordinary pitch of the voice, when neither raised to a treble nor lowered to a bass.

TENNESSEE, one of the United States of North America. It is bounded on the north by Kentucky and Virginia; south by the states of Mississippi and Georgia, and the territory of Alibama; east by North Carolina; and west by the river Mississippi. The parallel of 35° and 36° 30′ forms the southern and northern boundaries. The area is about 40,000 square English miles. In point of soil and climate this is one of the most favoured states in the Union. In the eastern parts the country is mountainous, in the western it is finely diversified with low hills; and every where it is well watered, covered with excellent wood, and affording when broken up most productive crops. Wheat, barley, rye, maize, flax, hemp, tobacco, indigo, rice, and cotton, thrive luxuriantly. Lands of the first and second quality are too rich for wheat till they have been reduced by other crops. On Cumberland river the common produce of Indian corn is 60 to 70 bushels an acre; that of cotton is usually 800 pounds an acre. Vegetation is six or seven weeks earlier than in the eastern states. The rivers are scarcely ever frozen, and the snow seldom continues more than ten or twelve days. In some of the low grounds bilious fever prevails; but in general this state is one of the healthiest in North America.

The principal rivers are the Tennessee with its branches, and the Cumberland. The former is navigable for boats 500 miles, with one interruption, and by its branches a considerable way farther. The latter is navigable for boats of 20 tons to Nashville, 200 miles up, and for small craft 150 miles farther.

Iron ores are abundant in this state, and lead ore is also found. Limestone is common; gypsum and slate exist in some places. Nitre is found in prodigious quantities in vast natural caves of a wonderful extent, some of which have large streams running through them. The natural forests furnish wood of all kinds and of excellent quality. The wild animals consist of deer, bears, panthers, wolves, wild cats, racoons, foxes, beavers, &c. The animals of prey are seldom seen near cultivated tracts.

This state was first settled in 1774, and was admitted into the union in 1796. Its population in 1791 was only 35,691; but in 1810 had increased to 261,727, of whom 44,535 were slaves. The inhabitants are good horsemen, expert in the use of the rifle, active and enterprising, but addicted to gaming and fighting. The legislature consists of a senate and house of representatives, elected by all the free citizens of 21 years of age, who have resided six months in the state. The executive power is vested in a governor elected for two years. The judges are appointed by the legislature during good behaviour. The religious denominations are Presbyterians, Baptists, Roman Catholics, Methodists, and Episcopalians. There are four colleges in the state, none of which have yet acquired much celebrity. The value of lands and houses in this state, as ascertained by the assessment, in 1799 was 6,134,108 dollars; and in 1814 it was 24,233,750, exclusive of slaves. The value of the manufactures of this state, which are chiefly domestic, was found to be 3,611,029 in 1810. Tennessee being entirely an inland state, its commerce is carried on chiefly through New Orleans, and hence the value of its exports does not appear. They consist principally of saltpetre, tobacco, corn, hogs, and cattle. The imports are dry goods, groceries, &c. Maple sugar is generally made by the farmers themselves. A single tree on an average yields from 15 to 25 gallons of sap, from which four or five pounds of sugar is extracted. The quantity made in the state in 1810 amounted to 162,340 pounds.

TENSE, in *Grammar*, an inflection of verbs, whereby they are made to signify or distinguish the circumstance of time in what they affirm. See GRAMMAR.

TENT, in *War*, a pavilion or portable house. Tents are made of canvas, for officers and soldiers to lie under when in the field. The size of the officers tents is not fixed; some regiments have them of one size and some of another; a captain's tent and marquee is generally $10\frac{1}{2}$ feet broad, 14 deep, and 8 high: the subalterns are a foot less; the major's and lieutenant-colonel's a foot larger; and the colonel's two feet larger. The subalterns of foot lie two in a tent, and those of horse but one. The tents of private men are $6\frac{1}{2}$ feet square, and 5 feet high, and hold five soldiers each. The tents for horse are 7 feet broad and 9 feet deep: they hold likewise five men and their horse accoutrements.—The word is formed from the Latin *tentorium*, of *tendo*, "I stretch," because tents are usually made of canvas stretched out, and sustained by poles, with cords and pegs.

TENT, in *Surgery*, a roll of lint made into the shape of a nail with a broad flat head, chiefly used in deep wounds and ulcers. They are of service, not only in conveying medicines to the most intimate recesses and sinuses of the wound, but to prevent the lips of the wound from uniting before it is healed from the bottom; and by their assistance grumous blood, sordes, &c. are readily evacuated.

TENTER, TRIER, or *Prover*, a machine used in the cloth manufactory, to stretch out the pieces of cloth, stuff, &c. or only to make them even and set them square.

It is usually about $4\frac{1}{2}$ feet high, and for length exceeds that of the longest piece of cloth. It consists of several long square pieces of wood, placed like those which form the barriers of a manege; so, however, as that

Tenter ‖ Tenths.

that the lower cross pieces of wood may be raised or lowered as is found requisite, to be fixed at any height by means of pins. Along the cross pieces, both the upper and the under one, are hooked nails, called *tenter-hooks*, driven in from space to space.

To put a piece of cloth on the TENTER. While the piece is yet quite wet, one end is fastened to one of the ends of the tenter; then it is pulled by force of arms towards the other end, to bring it to the length required: that other end being fastened, the upper list is hooked on to the upper cross-piece, and the lowest list to the lowest cross piece, which is afterwards lowered by force till the piece have its desired breadth. Being thus well stretched, both as to length and breadth, they brush it with a stiff hair brush, and thus let it dry. Then they take it off; and, till they wet it again, it will retain the length and breadth the tenter gave it.

TENTHREDO, the SAW-FLY; a genus of insects belonging to the order of *hymenoptera*. See ENTOMOLOGY *Index*.

TENTHS, and *First Fruits of Spiritual Preferments*, a branch of the king's revenue. See REVENUE.

These were originally a part of the Papal usurpations over the clergy of this kingdom; first introduced by Pandulph the pope's legate, during the reigns of King John and Henry III. in the see of Norwich; and afterwards attempted to be made universal by the popes Clement V. and John XXII. about the beginning of the 14th century. The first fruits, *primitiæ* or *annates*, were the first year's whole profits of the spiritual preferment, according to a rate or *valor* made under the direction of Pope Innocent IV. by Walter bishop of Norwich in 38 Hen. III. and afterwards advanced in value by commission from Pope Nicholas III. A. D. 1202, 20 Edw. I.; which valuation of Pope Nicholas is still preserved in the exchequer. The tenths, or *decimæ*, were the tenth part of the annual profit of each living by the same valuation; which was also claimed by the holy see, under no better pretence than a strange misapplication of that precept of the Levitical law, which directs, that the Levites "should offer the tenth part of their tithes as a heave offering to the Lord, and give it to Aaron the highpriest." But this claim of the pope met with vigorous resistance from the English parliament; and a variety of acts were passed to prevent and restrain it, particularly the statute 6 Hen. IV. c. 1. which calls it a *horrible mischief and damnable custom*. But the Popish clergy, blindly devoted to the will of a foreign master, still kept it on foot; sometimes more secretly, sometimes more openly and avowedly: so that in the reign of Henry VIII. it was computed, that in the compass of 50 years 800,000 ducats had been sent to Rome for first fruits only. And as the clergy expressed this willingness to contribute so much of their income to the head of the church, it was thought proper (when in the same reign the papal power was abolished, and the king was declared the head of the church of England) to annex this revenue to the crown; which was done by statute 26 Hen. VIII. c. 3. (confirmed by statute 1 Eliz. c. 4.); and a new *valor beneficiorum* was then made, by which the clergy are at present rated.

Blackst. Comment. vol. i.

By these last-mentioned statutes all vicarages under ten pounds a-year, and all rectories under ten marks, are discharged from the payment of first fruits: and if, in such livings as continue chargeable with this payment, the incumbent lives but half a year, he shall pay only one quarter of his first fruits; if but one whole year, then half of them; if a year and a half, three quarters; and if two years, then the whole, and not otherwise. Likewise by the statute 27 Hen. VIII. c. 8. no tenths are to be paid for the first year, for then the first fruits are due: and by other statutes of Queen Anne, in the fifth and sixth years of her reign, if a benefice be under 50l. per annum clear yearly value, it shall be discharged of the payment of first fruits and tenths.

Tenths, Tenure.

Thus the richer clergy being, by the criminal bigotry of their Popish predecessors, subjected at first to a foreign exaction, were afterwards, when that yoke was shaken off, liable to a like misapplication of their revenues through the rapacious disposition of the then reigning monarch; till at length the piety of Queen Anne restored to the church what had been thus indirectly taken from it. This she did, not by remitting the tenths and first fruits entirely; but, in a spirit of the truest equity, by applying these superfluities of the larger benefices to make up the deficiencies of the smaller. And to this end she granted her royal charter, which was confirmed by the statute 2 Ann. c. 11. whereby all the revenue of first fruits and tenths is vested in trustees for ever, to form a perpetual fund for the augmentation of poor livings. This is usually called *Queen Anne's bounty;* which has been still farther regulated by subsequent statutes.

TENURE, in *Law*, signifies the manner whereby lands or tenements are held, or the service that the tenant owes to his lord.

Of this kingdom almost all the real property is by the policy of our laws supposed to be granted by, dependent upon, and holden of, some superior lord, by and in consideration of certain services to be rendered to the lord by the tenant or possessor of this property. The thing holden is therefore styled a *tenement*, the possessors thereof *tenants*, and the manner of their possession a *tenure*. Thus all the lands in the kingdom are supposed to be holden, mediately or immediately, of the king; who is styled the *lord paramount*, or above all. Such tenants as held under the king immediately, when they granted out portions of the lands to inferior persons, became also lords with respect to those inferior persons, as they were still tenants with respect to the king; and thus partaking of a middle nature, were called *mesne* or *middle lords*. So that if the king granted a manor to A, and he granted a portion of the land to B, now B was said to hold of A, and A of the king; or, in other words, B held his lands immediately of A, but mediately of the king. The king therefore was styled *lord paramount:* A was both tenant and lord, or was a mesne lord; and B was called *tenant paravail* or the *lowest tenant*, being he who was supposed to make avail or profit of the land. In this manner are all the lands of the kingdom holden which are in the hands of subjects: for, according to Sir Edward Coke, in the law of England we have not properly *allodium*, which is the name by which the feudists abroad distinguish such estates of the subject as are not holden of any superior. So that at the first glance we may observe, that our lands are either plainly feuds, or partake very strongly of the foedal nature.

Blackst. Comment. vol. ii.

All tenures being thus derived, or supposed to be derived, from the king, those that held immediately under him, in right of his crown and dignity, were called his *tenants in capite*, or *in chief;* which was the most honourable species of tenure, but at the same time subjected the tenants to greater and more burdensome services

services than inferior tenures did. And this distinction ran through all the different sorts of tenure.

There seem to have subsisted among our ancestors four principal species of lay-tenures, to which all other may be reduced: the grand criteria of which were the natures of the several services or renders that were due to the lords from their tenants. The services, in respect of their quality, were either *free* or *base* services: in respect of their quantity and the time of exacting them, were either *certain* or *uncertain*. Free services were such as were not unbecoming the character of a soldier or a freeman to perform; as to serve under his lord in the wars, to pay a sum of money, and the like. Base services were such as were fit only for peasants or persons of a servile rank; as to plough the lord's land, to make his hedges, to carry out his dung, or other mean employments. The certain services, whether free or base, were such as were stinted in quantity, and could not be exceeded on any pretence; as, to pay a stated annual-rent, or to plough such a field for three days. The uncertain depended upon unknown contingencies; as, to do military service in person, or pay an assessment in lieu of it when called upon; or to wind a horn upon the appearance of invaders; which are free services; or to do whatever the lord should command; which is a base or villein service.

From the various combinations of these services have arisen the four kinds of lay-tenure which subsisted in England till the middle of the last century; and three of which subsist to this day. Of these Bracton (who wrote under Henry III.) seems to give the clearest and most compendious account of any author ancient or modern; of which the following is the outline or abstract: "Tenements are of two kinds, *frank-tenement*, and *villenage*. And of frank-tenements, some are held freely in consideration of homage and knight-service; others in free-socage, with the service of fealty only. And again, of villenages, some are *pure*, and others *privileged*. He that holds in pure villenage shall do whatsoever is commanded him, and always be bound to an uncertain service. The other kind of villenage is called *villein-socage;* and these villein-socmen do villein services, but such as are certain and determined." Of which the sense seems to be as follows; first, where the service was free, but uncertain, as military service with homage, that tenure was called the *tenure in chivalry*, *per servitium militare*, or by knight-service. Secondly, where the service was not only free, but also certain, as by fealty only, by rent and fealty, &c. that tenure was called *liberum socagium*, or *free socage*. These were the only free holdings or tenements; the others were villenous or servile: as, thirdly, where the service was base in its nature, and uncertain as to time and quantity, the tenure was *purum villenagium*, absolute or pure villenage. Lastly, where the service was base in its nature, but reduced to a certainty, this was still villenage, but distinguished from the other by the name of *privileged villenage*, *villenagium privilegiatum;* or it might be still called *socage* (from the certainty of its services), but degraded by their baseness into the inferior title of *villanum socagium*, villein-socage.

1. The military tenure, or that by knight-service, was done away by stat. 12 Car. II. For an account of this species of tenure see *Feodal System*, and *Knight-Service;* and for its incidents, see Relief, Primer-seisin, Wardship, Marriage, Fines, and Escheat.

2. The second species of tenure or free-socage, not only subsists to this day, but has in a manner absorbed and swallowed up (since the statute of Charles the Second) almost every other species of tenure. Se Socage.

The other grand division of tenure, mentioned by Bracton, is that of villenage, as contradistinguished from *liberum tenementum*, or frank-tenure. And this (we may remember) he subdivides into two classes, pure and privileged villenage: from whence have arisen two other species of our modern tenures.

3. From the tenure of pure villenage have sprung our present copyhold tenures, or tenure by copy of court-roll at the will of the lord; in order to obtain a clear idea of which, it will be previously necessary to consult the articles Manor and Villenage.

As a farther consequence of what has been there explained, we may collect these two main principles, which are held to be the supporters of a copyhold-tenure, and without which it cannot exist: 1. That the lands be parcel of and situate within that manor under which it is held. 2. That they have been demised, or demisable, by copy of court-roll immemorially. For immemorial custom is the life of all tenures by copy; so that no new copyhold can, strictly speaking, be granted at this day.

In some manors, where the custom hath been to permit the heir to succeed the ancestor in his tenure, the estates are styled *copyholds of inheritance;* in others, where the lords have been more vigilant to maintain their rights, they remain copyholds for life only; for the custom of the manor has in both cases so far superseded the will of the lord, that, provided the services be performed or stipulated for by fealty, he cannot in the first instance refuse to admit the heir of his tenant upon his death; nor, in the second, can he remove his present tenant so long as he lives, though he holds nominally by the precarious tenure of his lord's will.

The fruits and appendages of a copyhold-tenure, that it hath in common with free tenures, are fealty, services (as well in rents as otherwise), reliefs, and escheats. The two latter belong only to copyholds of inheritance; the former to those for life also. But, besides these, copyholds have also heriots, wardship, and fines. Heriots, which are agreed to be a Danish custom, are a render of the best beast or other good (as the custom may be) to the lord on the death of the tenant. This is plainly a relic of villein tenure; there being originally less hardship in it, when all the goods and chattels belonged to the lord, and he might have seized them even in the villein's lifetime. These are incident to both species of copyhold; but wardship and fines to those of inheritance only. Wardship, in copyhold-estates, partakes both of that in chivalry and that in socage. Like that in chivalry, the lord is the legal guardian, who usually assigns some relation of the infant tenant to act in his stead: and he, like guardian in socage, is accountable to his ward for the profits. Of fines, some are in the nature of primer-seisms, due on the death of each tenant, others are mere fines for alienations of the lands; in some manors, only one of those sorts can be demanded, in some both, and in others neither. They are sometimes arbitrary and at the will of the lord, sometimes fixed by custom; but, even when arbitrary, the courts of law, in favour of the liberty of copyholders, have tied them down to be reasonable in their extent; otherwise they might amount to disherison of of the estate. No fine therefore is allowed to be taken upon descents and alienations (unless in particular circumstances) of more than two years improved values of the estate. From this instance we may judge of the favourable disposition that the law of England (which is a law of liberty) hath always shown to this species of tenants, by removing, as far as possible, every real badge of slavery from them, however some nominal ones may continue. It suffered custom very early to get the better of the express terms upon which they held their lands; by declaring that the will of the lord was to be interpreted by the custom of the manor; and, where no custom has been suffered to grow up to the prejudice of the lord, as in this case of arbitrary fines, the law itself interposes in an equitable method, and will not suffer the lord to extend his power so far as to disinherit the tenant.

4. There is yet a fourth species of tenure, described by Bracton, under the name sometimes of *privileged villenage*, and sometimes of *villein socage*. See *Privileged* VILLENAGE.

Having in the present article, and those referred to, taken a compendious view of the principal and fundamental points of the doctrine of tenures, both ancient and modern, we cannot but remark the mutual connection and dependence that all of them have upon each other. And upon the whole it appears, that, whatever changes and alterations these tenures have in process of time undergone, from the Saxon era to the 12 Car. II. all lay-tenures are now in effect reduced to two species; free tenure in common socage, and base tenure by copy of court-roll. But there is still behind one other species of tenure, reserved by the statute of Charles II. which is of a spiritual nature, and called the tenure in *FRANK-Almoign;* see that article.

A particular account of the ancient tenures would to many persons be highly amusing. We can only select a few of the most singular, referring the curious reader for more information to Anderson's Origin of Commerce, Henry's History of Britain, and Blount's *Fragmenta Antiquitates.*

In the 19th of Henry III. Walter Gately held the manor of Westcourt, in Bedington in Surry, yielding yearly to the king one cross-bow, *balistam*, value twelve pence.

Anno tertio Edw. I. Osbert de Lonchamp, knight, held his lands of Ovenhelle, in Kent, for personally guarding the king forty days into Wales at his own expence, with one horse of five shillings value, one sack worth sixpence, and one broch for that sack. N. B. All personal services, or attendances on our kings in those times, were limited to forty days, at their own expence.

The like the same year of Laurence de Broke, who for his hamlet of Renham in Middlesex, found the king one soldier, a horse worth five shillings, a sack worth fivepence, and a broch worth twopence (this broch was a kind of cup, jug, pot, or bason), for forty days, at his own expence, wherever his army shall be within the four seas. This was settled (says Mr Blount) at the Stone Cross, which stood near the May-pole in the Strand, London, where the judges-itinerant used in old times to sit.

Robert Maunsel's tenure of lands in Peverel paid the same service, and the horse, sack, and broch of the same prices.

13mo Edw. I. Henry de Averning's tenure of the manor of Morton in Essex, was to find a man, a horse worth ten shillings, four horse-shoes, a leather sack, and an iron broch.

The year following three persons held thirty acres of land in Carleton in Norfolk, by the service of bringing the king, whenever he shall be in England, twenty-four pasties of fresh herrings at their first coming in.

Another held his manor in Norfolk of that king, by annually supplying him at his exchequer with two vessels, called *mues*, of wine made of pearmains. "Here (says our author) it is worth observing, that in King Edward the First's time pearmain cyder was called *wine.*" This therefore seems to account for the mention of vineyards in old times in Kent, Sussex, and other parts of England, which has so often puzzled many people to elucidate.

Another person, in the 21st of the said king, held thirty acres of land, valued at ten shillings yearly in the exchequer, or four-pence per acre, in Cambridgeshire, for furnishing a truss of hay for the king's necessary-house or privy, whenever he shall come into that county.

Another, in the 34th of that king, held a manor in Kent for providing a man to lead three greyhounds when the king shall go into Gascony, so long as a pair of shoes of fourpence should last.

And that we may not again recur to these old tenures, we shall further add, from the same author, that in the first year of King Edward II. Peter Spileman made fine to the king for his lands by serjeanty, to find one to serve as a soldier for forty days in England, with a coat of mail; also to find straw for the king's bed, and hay for his horse.

This article of straw for the king's bed we did not so much wonder at, when we found it in an article in William the Conqueror's time; but it is somewhat more remarkable so late as the days of King Edward II.

Several others, we find, held their lands of the crown in those times by very different tenures. One, by paying two white capons annually; another, by carrying the king's standard whenever he happens to be in the county of Sussex; another, by carrying a rod or batoon before the king on certain occasions; another, by serving the office of chamberlain of the exchequer, a very good place at present; another, by building and upholding a bridge; another, by being marechal (*meretricum*), i. e. as Mr Blount translates it, of the laundresses in the king's army; another, by acting as a serjeant at arms for the king's army whilst in England; one supplies a servant for the king's larder; another, for his wardrobe; others, to find servants for this or that forest; another, a hawk; one presents the king a pair of scarlet hose annually; others are bound to supply soldiers with armour for certain days, for the keeping this or that castle; one, viz. for the manor of Elston in Nottinghamshire, pays yearly rent of one pound weight of cummin seed, two pair of gloves, and a steel needle; another, is to repair the iron-work of the king's ploughs; Ela countess of Warwick, in the 13th year of King Edward I. held the manor of Hokenorton in Oxfordshire, in the barony of D'Oyly, by the serjeanty of of carving at the king's table on his birth-day, and she to have the knife the king then uses at table.

TEOS, one of the twelve Ionian cities, was situated on the south side of the Ionian peninsula, and distinguished by being the place where the poet Anacreon and the historian Hecatœus were born.

TERAPHIM, or THERAPHIM, a word in the Hebrew language, which has exercised much the ingenuity of the critics. It occurs 13 or 14 times in the Old Testament, and is commonly interpreted *idols*. We will not trouble our readers with the numerous conjectures which have been formed respecting the meaning of this word. The only way to determine it, if it be at all possible, would be to examine and compare all the passages in which it occurs, and to consult the ancient translations. Conjectures are useless; every man may make a new one, which will have just as good a title to belief as those which have been already proposed.

TERCERY, or TERCERA, one of the largest islands of the Azores, or Western islands, lying in the Atlantic ocean. It is about 40 miles in circumference; and surrounded with craggy rocks, which render it almost inaccessible. The soil is fertile, abounding in corn, wine, and fruits; and they have plenty of cattle to supply the ships which call there. Their principal trade is wood. The inhabitants are lively, addicted to gallantry, and are said to be extremely revengeful. It is subject to Portugal; and Angra is the capital town. W. Long. 27. 1. N. Lat. 28. 45.

TEREBELLA, the PIERCER, a genus of insects belonging to the class of vermes, and order of mollusca. See HELMINTHOLOGY *Index*.

TEREBINTHUS. See PISTACIA, BOTANY *Index*.

TEREDO, a genus of vermes belonging to the order of testacea. See CONCHOLOGY *Index*.

TERENCE, or PUBLIUS TERENTIUS AFER, a celebrated comic poet of ancient Rome, was born at Carthage in Africa. He was slave to Terentius Lucanus the senator; who gave him his liberty on account of his wit, his good mien, and great abilities. Terence, on his becoming a freed man, applied himself to the writing of comedies; in the execution of which he imitated Menander and the other celebrated comic poets of Greece. Cicero gives him the most pompous eulogiums, both for the purity of his language and the perspicuity and beauty of his compositions, which he considers as the rule and standard of the Latin tongue; and observes, that they were esteemed so fine and elegant, that they were thought to have been written by Scipio and Lelius, who were then the greatest personages and the most eloquent of the Roman people. Terence died while on a voyage into Greece, about the 15th year before the Christian era. There are six of his comedies extant, of which the best editions are the Elzevir one 1635, 12mo; that *cum integris notis Donati, et selectis variorum*, 1686, 8vo; Westerhovius's, in two vols 4to, 1726; and that of Bentley the same year, 4to. Madame Dacier has given a beautiful French version of this author; and a very good English translation was published in 4to, 1768, by Mr Colman.

TERM, in *Law*, is generally taken for a limitation of time or estate; as, a lease for term of life or years.

Term, however, is more particularly used for that time wherein our courts of justice are open; in opposition to which, the rest of the year is called *vacation*.

TERM, in *Grammar*, denotes some word or expression in a language.

The word *term*, *terminus*, is borrowed metaphorically, by the grammarians and philosophers, from the measurers or surveyors of lands: as a field is defined and distinguished by its *termini*, or limits, so is a thing or matter spoken of by the word or term it is denoted by.

TERM in the Arts, or *TERM of Art*, is a word, which, besides the literal and popular meaning which it has or may have in common language, bears a further and peculiar meaning in some art or science.

TERMS, the several times or seasons of the year, wherein the tribunals, or courts of judicature, are open to all who think fit to complain of wrong, or to seek their rights by due course of law, or action; and during which the courts in Westminster-hall sit and give judgement. But the high court of parliament, the chancery, and inferior courts, do not observe the terms; only the courts of king's-bench, common-pleas, and exchequer, which are the highest courts at common law. In contradistinction to these, the rest of the year is called *vacation*.

Of these terms there are four in every year, during which time matters of justice are dispatched. *Hilary-term*, which, at London, begins the 23d day of January, or if that be Sunday, the next day after; and ends the 12th of February following. *Easter-term*, which begins the Wednesday fortnight after Easter-day, and ends the Monday next after Ascension-day. *Trinity-term*, beginning the Friday next after Trinity-Sunday, and ending the Wednesday fortnight after. *Michaelmas-term*, which begins the sixth day of November, and ends the 28th of November following. Each of these terms have also their returns. These terms are supposed by Mr Selden to have been instituted by William the Conqueror; but Sir H. Spelman hath shewn, that they were gradually formed from the canonical constitutions of the church; being no other than those leisure seasons of the year which were not occupied by the great festivals or fasts, or which were not liable to the general avocations of rural business. Throughout all Christendom, in very early times, the whole year was one continual term for hearing and deciding causes. For the Christian magistrates, in order to distinguish themselves from the heathens, who were very superstitious in the observation of their *dies fasti* and *nefasti*, administered justice upon all days alike; till at length the church interposed, and exempted certain holy seasons from being profaned by the tumult of forensic litigations; as, particularly, the time of Advent and Christmas, which gave rise to the winter vacation; the time of Lent and Easter, which created that in the spring; the time of Pentecost, which produced the third; and the long vacation, between midsummer and Michaelmas, which was allowed for the hay-time and harvest. All Sundays also, and some peculiar festivals, as the days of the purification, ascension, &c. were included in the same prohibition, which was established by a canon of the church, A. D. 517, and fortified by an imperial constitution of the younger Theodosius, comprised in the Theodosian code. Afterwards, when our own legal constitution was established, the commencement and duration of our law-terms

terms were appointed, with a view to these canonical prohibitions; and it was ordered by the laws of King Edward the Confessor, that from Advent to the octave of the Epiphany, from Septuagesima to the octave of Easter, from the Ascension to the octave of Pentecost, and from three in the afternoon of all Saturdays till Monday morning, the peace of God and holy church shall be kept throughout the whole kingdom.

And so extravagant was afterwards the regard paid to these holy times, that though the author of the Mirror mentions only one vacation of considerable length, containing the months of August and September, yet Britton says, that in the reign of King Edward I. no secular plea could be held, nor any man sworn on the Evangelists, in the time of Advent, Lent, Pentecost, harvest, and vintage, the days of the great litanies, and all solemn festivals. He adds, that the bishops and prelates granted dispensations for taking assizes and juries in some of these holy seasons, upon reasonable occasions; and soon after a general dispensation was established in parliament by stat. Westm. 1. 3 Edw. I. cap. 51. that assizes of novel disseisin, *mort d'ancestor*, and darrein presentment, should be taken in Advent, Septuagesima, and Lent, as well as inquests; at the special request of the king to the bishops. The portions of time that were not included within these prohibited seasons fell naturally into a fourfold division; and from some festival, or saint's day, that immediately preceded their commencement, were denominated the terms of *St Hilary*, of *Easter*, of the *Holy Trinity*, and of *St Michael*: which terms have been since regulated and abbreviated by several acts of parliament; particularly Trinity-term by stat. 32 Hen. VIII. cap. 2. and Michaelmas-term by stat. 16 Car. I. cap. 6. and again by stat. 24 Geo. II. cap. 48.

Terms, *Oxford*. Hilary or Lent-term begins January 14th, and ends the Saturday before Palm-Sunday. Easter term begins the tenth day after Easter, and ends the Thursday before Whitsunday. Trinity-term begins the Wednesday after Trinity-Sunday, and ends after the act, or 6th of July, sooner or later, as the vice-chancellor and convocation please. Michaelmas-term begins October the 10th, and ends December the 17th.

Terms, *Cambridge*. Lent-term begins January the 14th, and ends Friday before Palm-Sunday. Easter-term begins the Wednesday after Easter-week, and ends the week before Whitsunday. Trinity-term begins the Wednesday after Trinity-Sunday, and ends the Friday after the commencement, or 2d of July. Michaelmas-term begins October the 10th, and ends December the 16th.

Terms, *Scottish*. The court of session has two terms, the winter and summer. The winter begins on 12th November, and ends 11th March, only there is a recess of three weeks at Christmas. The summer term commences 12th May, and ends 11th July. The court of exchequer has four terms: 1. Candlemas term begins 15th January, and ends 3d February; 2. Whitsuntide term begins 12th May, and ends 2d June; 3. Lammas term begins 17th June, and ends 5th July; 4. Martinmas term begins 24th November, and ends 20th December.

Terms, *Irish*. In Ireland the terms are the same as at London, except Michaelmas term, which begins October the 13th, and adjourns to November the 3d, and thence to the 6th.

TERMES, a genus of insects belonging to the order of aptera. See Entomology *Index*.

TERMINALIA, in antiquity, feasts celebrated by the Romans in honour of the god Terminus.

Terminalia, a genus of plants belonging to the class polygamia. See Botany *Index*.

TERMINI, in *Architecture*, denote a kind of statues or columns, adorned on the top with the figure of a man's, woman's, or satyr's head, as a capital; and the lower part ending in a kind of sheath or scabbard.

TERMINUS, in Pagan worship, an ancient deity among the Romans, who presided over the stones or landmarks, called *termini*, which were held so sacred, that it was accounted sacrilege to move them; and as the criminal became devoted to the gods, it was lawful for any man to kill him. The worship of this deity was instituted by Numa Pompilius, who, to render landmarks, and consequently the property of the people, sacred, erected a temple on the Tarpeian mount to Terminus.

TERN. See Sterna, Ornithology *Index*.

TERNATE, the most northerly of the Molucca or Clove islands in the East Indies. It abounds in cocoa-nuts, bananas, citrons, oranges, and other fruits peculiar to the torrid zone; but cloves are the most valuable produce. It is in the possession of the Dutch. Malaya is the capital town. E. Long. 129. 0. N. Lat. 1. 0.

TERNI, a town of Italy in the pope's territories, and in the duchy of Spoletto, with a bishop's see. It is but a small place; though there are very beautiful ruins of antiquity, it having been a very considerable Roman colony. It is situated on the top of a high mountain, and to the west of it are fields which are extremely fertile. E. Long. 12. 40. N. Lat. 42. 34.

TERNSTROMIA, a genus of plants belonging to the class polyandria. See Botany *Index*.

TERPANDER, a celebrated Greek poet and musician. The Oxford marbles tell us that he was the son of Derdeneus of Lesbos, and that he flourished in the 381st year of these records; which nearly answers to the 27th Olympiad, and 671st year B. C. The marbles inform us likewise, that he taught the *nomes*, or airs, of the lyre and flute, which he performed himself upon this last instrument, in concert with other players on the flute. Several writers tell us that he added three strings to the lyre, which before his time had but four; and in confirmation of this, Euclid and Strabo quote two verses, which they attribute to Terpander himself.

> The tetrachord's restraint we now despise,
> The seven-string'd lyre a nobler strain supplies.

Among the many signal services which Terpander is said to have done to music, none was of more importance than the notation that is ascribed to him for ascertaining and preserving melody, which before was traditional, and wholly dependent on memory. The invention, indeed, of musical characters has been attributed by Alypius and Gaudentius, two Greek writers on music, and upon their authority by Boethius, to Pythagoras, who flourished full two centuries after Terpander. But Plutarch, from Heraclides of Pontus, assures us that Terpander, the inventor of nomes for the cithara, in hexameter

hexameter verse, set them to music, as well as the verses of Homer, in order to sing them at the public games: And Clemens Alexandrinus, in telling us that this musician wrote the laws of Lycurgus in verse, and set them to music, makes use of the same expression as Plutarch; which seems clearly to imply a written melody.

After enumerating the airs which Terpander had composed and to which he had given names, Plutarch continues to speak of his other compositions; among which he describes the proems, or hymns for the cithara, in heroic verse. These were used in after-times by the rhapsodists, as prologues or introductions to the poems of Homer and other ancient writers. But Terpander rendered his name illustrious, no less by his performances upon the flute and cithara than by his compositions. This appears by the marbles already mentioned; by a passage in Athenæus, from Hellanicus, which informs us that he obtained the first prize in the musical contests at the Carnean games; and by the testimony of Plutarch, who says, that "no other proof need be urged of the excellence of Terpander in the art of playing upon the cithara, than the register of the Pythic games, from which it appears that he gained four prizes successively at those solemnities. Of the works of this poet only a few fragments now remain.

TERRA AUSTRALIS INCOGNITA, a name for a large unknown continent, supposed to lie towards the south pole, and which for a long time was sought after by navigators. The voyages of Captain Cook have ascertained this matter as much as it probably ever will be. (See *South Sea; Cook's Discoveries*, N° 47, 48, 68, 69; and AMERICA, N° 4). On this subject Captain Cook expresses himself as follows: "I had now made the circuit of the Southern ocean in a high latitude, and traversed it in such a manner as to leave not the least room for the possibility of there being a continent, unless near the pole, and out of the reach of navigation. By twice visiting the tropical sea, I had not only settled the situation of some old discoveries, but made there many new ones, and left, I conceive, very little more to be done even in that part. Thus I flatter myself, that the intention of the voyage has in every respect been fully answered; the southern hemisphere sufficiently explored; and a final end put to the searching after a southern continent, which has at times engrossed the attention of some of the maritime powers for near two centuries past, and been a favourite theory amongst the geographers of all ages. That there may be a continent, or large tract of land near the pole, I will not deny: on the contrary, I am of opinion there is; and it is probable that we have seen a part of it. The excessive cold, the many islands, and vast floats of ice, all tend to prove that there must be land to the south; and for my persuasion that this southern land must lie or extend farthest to the north, opposite to the southern Atlantic and Indian oceans, I have already assigned some reasons; to which I may add, the greater degree of cold experienced by us in these seas than in the Southern Pacific ocean under the same parallels of latitude."

Terra Firma, in *Geography*, is sometimes used for a continent, in contradistinction to islands.

Terra Firma, otherwise called *New Castile*, or *Castella del Oro*, a country of America, bounded on the north by the North sea and part of the Atlantic ocean, by the same sea and Guiana on the east, by the country of the Amazons and Peru on the south, and by the Pacific ocean and Veragua on the west, including the provinces better known under the name of Caraccas, Venezuela, Santa Martha, and Santa Fe, &c. It lies between 62 and 82 degrees of west longitude, and between the equator and 12 degrees of north latitude. It had the name of *Castella del Oro* from the quantity of gold found in the districts of Uraba and other parts; and was first discovered by the celebrated Columbus in his third voyage.

The climate is neither pleasant nor healthy; the inhabitants one part of the year being scorched by the most intense and burning heat, and the other almost drowned with perpetual floods of rain, pouring from the sky with such violence as if a general deluge was to ensue.

In so large a tract of country the soil must necessarily vary. Accordingly, in some parts it is a barren sand, or drowned mangrove land, that will scarce produce any kind of grain; in others it yields Indian corn, balms, gums, and drugs, almost all manner of fruits as well of Old as of New Spain, sugar, tobacco, Brasil wood, and several other kinds of dyeing woods; a variety of precious stones, particularly emeralds and sapphires; venison and other game. The plantations of cacao, or chocolate nuts, in the district of the Caraccas, are esteemed the best in America. The mountains abound with tygers, and, according to some, with lions, and great numbers of other wild beasts. The rivers, seas, and lakes, teem with fish, and also with alligators; and the bowels of the earth were once furnished with the richest treasures, now almost exhausted. The same may be said of the pearl fisheries on the coast, which are far from being so profitable now as formerly.

Terra Firma is a very mountainous country. Terra Firma Proper, in particular, consists of prodigious high mountains, and deep valleys flooded more than half the year. The mountains in the provinces of Carthagena and St Martha, according to Dampier, are the highest in the world: being seen at sea 200 miles off: from these runs a chain of hills of almost equal height, quite through South America, as far as the straits of Magellan, called the *Cordilleras des Andes*. The province of Venezuela also, and district of the Caraccas, the most northerly parts of South America, are almost a continued chain of hills, separated by small valleys, pointing upon the coast of the North sea. A chain of barren mountains, almost impassable, runs through the province of Popayan from north to south, some whereof are volcanoes; but towards the shores of the Pacific ocean it is a low country, flooded great part of the year.

The principal rivers of Terra Firma are, the Darien, Chagre, Santa Maria, Conception, Rio Grande or Magdalena, Maricaibo, and Oroonoko.

Terra Firma contains the provinces of Terra Firma Proper or Darien, of Carthagena, St Martha, Rio de la Hacha, Venezuela, Comana, New Andalusia or Paria, New Granada, and Popayan.

Terra Firma Proper lies in the form of a crescent, about the spacious bay of Panama, being the isthmus which joins South and North America; and extending in length between the two seas 300 miles, but in breadth, where the isthmus is narrowest, only 60. Here are found gold mines, gold sands, and fine pearls; and many fruitful valleys. The chief places are Panama and Porto Bello.

This country has been the scene of a bloody contest, since 1810, between the Spanish authorities and the inhabitants. The struggle has been greatest in the eastern parts, in the province of Caraccas, but is now

(1819) extended to Santa Fe, and may be expected soon to issue in the total subversion of the Spanish power. See CARACCAS, SUPPLEMENT.

TERRA Japonica, or *Cutechu*, a drug which, was formerly supposed to be an extract from the seeds of the areca catechu, is obtained from the mimosa catechu. See MATERIA MEDICA *Index*.

TERRA Puzzolana. See PUZZOLANA.

TERRÆ Filius, Son of the Earth, a student of the university of Oxford, formerly appointed in public acts to make satirical and jesting speeches against the members thereof, to tax them with any growing corruptions, &c.

TERRACE, a walk or bank of earth, raised in a garden or court to a due elevation for a prospect. The name is also given to the roofs of houses that are flat, and whereon we may walk.

TERRAQUEOUS, in *Geography*, a name given to our globe, because consisting of land and water.

Kirwan's Mineralogy.

TERRAS, or TARRAS, in *Mineralogy*, a species of argillaceous earth, differing little from puzzolana, but in being more compact and hard, porous and spongy. It is generally of a whitish yellow colour, and contains more heterogeneous particles, as spar, quartz, shoerl, &c. and something more calcareous earth; it effervesces with acids, is magnetic, and fusible *per se*. When pulverized, it serves as a cement, like puzzolana. It is found in Germany and Sweden.

Society for Arts, &c. vol. v.

A species of red earth has been found in the parish of St Elizabeth in Jamaica, which turns out to be an excellent substitute for terras or puzzolana earth, and may therefore be of great value to the inhabitants of the West Indies.

One measure of this earth, mixed with two of well slaked lime, and one of sand, forms a cement that answers extremely well for buildings in water, for it soon hardens and becomes like a stone.

TERRASON, ABBE JOHN, a French writer, born at Lyons in 1669. He distinguished himself in the dispute concerning Homer, between La Motte and Madame Dacier, by writing a *Dissertation contre l'Iliade*. He wrote a political and moral romance called *Sethos*, full of learning and philosophy; and another capital work of his is a French translation of Diodorus Siculus. He died in 1750.

TERRE *Verte*, in the colour-trade, the name of a green earth much used by painters, both singly for a good standing green, and in mixture with other colours. The name is French, and signifies, "green earth."

It is an indurated clay, of a deep bluish green colour, and is found in the earth, not in continued strata or beds, as most of the other earths are, but in large flat masses of different sizes, imbedded in other strata; these break irregularly in the cutting, and the earth is generally brought out of the pit in lumps of different sizes. It is of a fine, regular and even structure, and not very hard. It is of an even and glossy surface, very smooth to the touch, and in some degree resembling the morochthus or French chalk, but adhering firmly to the tongue. It does not stain the hand in touching it; but being drawn along a rough surface, it leaves an even white line, with a greenish cast.

It does not effervesce with acids, and burns to a dusky brown colour. It is dug in the island of Cyprus, and in many parts of France and Italy. That from the neighbourhood of Verona has been esteemed the best in the world; but of late there has been some dug in France that equals it. There is also an earth dug on Mendip Hills, in the sinking for coal, which, though wholly unobserved, is nearly, if not wholly, of equal value. When scraped, and the finer parts separated, it is ready to be made up with oil for the use of the painters, and makes the most true and lasting green of any simple body they use.

TERRESTRIAL, something partaking of the nature of earth, or belonging to the globe of earth; thus we say, the terrestrial globe, &c.

TERRIER, a small hound to hunt the fox or badger; so called because he creeps into the ground, as ferrets do into the coney-burrows, after the fox, &c.

TERRITORY, in *Geography*, denotes an extent or compass of land, within the bounds or belonging to the jurisdiction of any state, city, or other subdivision of a country.

TERROR. See FEAR and FRIGHT.

TERTIAN FEVER. See MEDICINE, N° 126.

TERTULLIAN, or QUINTUS SEPTIMUS FLORENS TERTULLIANUS, a celebrated priest of Carthage, was the son of a centurion in the militia, who served as proconsul of Africa. He was educated in the Pagan religion; but being convinced of its errors, embraced Christianity, and became a zealous defender of the faith. He married, it is thought, after his baptism. Afterwards he took orders, and went to Rome; where, during the persecution under the emperor Severus, he published his Apology for the Christians, which is, in its kind, a masterpiece of eloquence and learning; and at the beginning of the third century he embraced the sect of the Montanists. He lived to a very great age, and died under the reign of Antoninus Caracalla, about the year 216. Many of his works are still extant, in all of which he discovers a great knowledge of the Holy Scriptures, a lively imagination, a strong, elevated, and impetuous style, great eloquence and strength of reasoning; but is sometimes obscure. His Apology and Prescriptions are most esteemed. The best editions of his works are those of Rigault: especially that of Venice in 1746, folio. Pamelius and Alix, Mr Thomas, and the Sieur du Fossé, have written his life; and Rigault, M. de l'Aube Epine, Father Petau, and other learned men, have published notes on his works.

TERUNCIUS, in antiquity, a very small brass coin in use among the Romans.

The inconvenience of such very small pieces being soon found, the teruncius became disused, but its name is still retained in reckoning, and thus it became a money of account. The teruncius at first was a quarter of the as, or libra; hence, as the as contained twelve ounces, the teruncius contained three, whence the name, which is formed of the Latin *tres unciæ*. Teruncius was also used for the quarter of the denarius; so that when the denarius was at ten ases, the teruncius was worth two and a half; and when the denarius was risen to sixteen, the teruncius was worth four. See DENARIUS.

TESSELATED PAVEMENTS, those of rich mosaic work, made of curious square marbles, bricks, or tiles, called *tesselæ* from their resembling dice.

TESSERA, in Roman antiquity, denoted in its primary sense a cube or dye; so called from the Greek word τετταρα or τεσσερα *four*; respect being had to its number

number of sides, distinct from the two horizontal planes above and below. And it was thus distinguished from the talus, which being round at each end, contained only four planes or faces on which it could stand; and therefore when thrown had no more than two side faces in view. Hence *ludere talis et ludere tesseris*, are spoken of by Roman writers as two different games. The syllable TES occurs often in Roman inscriptions. The word *tessera* was applied to many other things, not so much from a similitude in the figure, as from the relation they bore to some other things of which they were the sign or token; as the points on the upper plane of the dye denoted the good or ill success of the cast.

The *tessera hospitalis* was either public or private. As to the former, we find among the inscriptions published by Gruter instances of two municipal towns which put themselves under the patronage of the Roman governor; and the reciprocal engagement between them, engraved on two copperplates, in the form of an oblong square, with a pediment at the top is called in both *tessera hospitalis*. The design of it was to cultivate or maintain a lasting friendship between private persons and their families; and gave a mutual claim to the contracting parties and their descendants of a reception and kind treatment at each other's houses, as occasion offered. For which end these tesseræ were so contrived as best to preserve the memory of that transaction to posterity. And one method of doing this was by dividing one of them lengthwise into two equal parts; upon each of which one of the parties wrote his name, and interchanged it with the other. From this custom came the prevailing expression *tesseram hospitalem confringere*, applied to persons who had violated their engagements.

The *tesseræ frumentariæ* were small tallies given by the emperors to the populace at Rome, entitling them to the reception of a quantity of corn from the public at stated seasons. The person who had the inspection of these was called *tesserarius*. They were made of wood and of stone.

There was another kind of tessera which intitled persons to a sight of the public games and other diversions, usually made in the form of an oblong square.

The *tessera militaris* was a signal given by the general or chief commander of an army, as a direction to the soldiers for executing any duty or service required of them. This, upon urgent occasions, was only vocal; but, in ordinary cases, it was written on a tablet, commonly made of wood. Besides these civil and military tesseræ, there are others which relate to religious affairs, and may be called *sacred*.

TESSON, or TESTON. See TESTER.

TESSOUWA, a considerable town in Africa, situated east of Mourzouk, the capital of the kingdom of Fezzan. Near this town a deep and rapid stream is said to have existed, but was overwhelmed by the moving sands so frequent in Africa.

TEST, a vessel used in metallurgy for absorbing the scoriæ of metallic bodies when melted. See CUPEL, under ORES, *Reduction of*.

Test-Act, in *Law* is the statute 25 Car. II. cap. 2. which directs all officers, civil and military, to take the oaths, and make the declaration against transubstantiation, in the court of King's Bench, or Chancery, the next term, or at the next quarter-sessions, or (by subsequent statutes) within six months after their admission; and also within the same time to receive the sacrament of the Lord's Supper, according to the usage of the church of England, in some public church, immediately after divine service or sermon, and to deliver into court a certificate thereof signed by the minister and churchwarden, and also to prove the same by two credible witnesses, upon forfeiture of 500l. and disability to hold the said office.

The avowed object of this act was to exclude from places of trust all members of the church of Rome; and hence the dissenters of that age, if they did not support the bill when passing through the two houses of parliament, gave it no opposition. For this part of their conduct they have been often censured with severity, as having betrayed their rights from resentment to their enemies. But is this a fair state of the case? Were any rights in reality betrayed? That the dread of a popish successor and of popish influence was the immediate and urgent cause of passing the *test-act*, is indeed true; but that the legislature, when guarding against an impending evil, had not likewise a retrospect to another from which they had so recently been delivered, is not so evident. If it be proper to support an established church as a branch of the constitution, and if the test-act be calculated to afford that support to the church of England, it is probable that the deliberations of parliament were as much influenced by the dread of puritanic fury, and a renewal of the covenant, as by apprehensions of a persecution from a popish king and popish councils. That the members of the church established by law in England had as much reason to dread the effects of power in the hands of Puritans as in the hands of Papists, no impartial man will controvert, who is not a stranger to that period of our national history; and that it was the duty of the legislature by every method in their power to provide for the security of the constitution against the machinations of both its enemies, will be admitted by all but such as are in love with anarchy on the one hand, or with despotism on the other.

Many people, when they talk or write of the *test-act*, seem to think that it was framed in opposition to the *religious* opinions of the church of Rome; and finding the Protestant dissenters, who abhor these opinions, deprived by it of their civil *rights*, they speak with indignation of a law which confounds the innocent with the guilty. But all this proceeds from a palpable mistake of the purpose of the test. As the legislature had no authority to make laws against *any opinions whatever*, on account of their being false in theology; so it is not to be supposed that, in their deliberations on the TEST-ACT, the members of that august body took into their consideration the comparative orthodoxy of the distinguishing tenets of the Catholics and Puritans. As a religious sect they might esteem the latter much more than the former; but if they found that both had combined with their theological doctrines opinions respecting civil and ecclesiastical government, inconsistent with the fundamental principles of the English constitution, they had an undoubted right to enact a law, by which none should be admitted to offices, in the execution of which they could injure the constitution, without previously giving security that their administration should support it in all its branches. It had not then been doubted, nor is there reason to doubt yet, but that an established religion is necessary, in conjunction with civil govern-

Test.

ment, to preserve the peace of society; and therefore in every well regulated state an established religion must be supported, not because it is the duty of the civil magistrate to conduct his subjects to future happiness, but because he cannot without such an establishment preserve among them present tranquillity. The establishment which must best answer this purpose, is that which, teaching the great and unchangeable duties of morality, is most acceptable in its government and forms of worship to the majority of the people; and therefore in giving a legal establishment to one constitution of the church in preference to all others, it is only this circumstance, and not the comparative purity of the rival churches, viewed merely as ecclesiastical corporations, to which it is the business of the legislature to pay attention. At the time when the *test act* passed the two houses of parliament, the established church of England was certainly more acceptable to the great body of the people and to all ranks in the state, than any one of the sects, whether Catholic or Protestant, which dissented from her; and therefore it was the duty of the legislature to preserve to that church all her privileges and immunities, and to prevent those hostile sectaries from doing her injury in the discharge of any civil office with which they might be entrusted. It was with this view that the *test-act* was formed; and it is with the same view that the legislature has hitherto rejected every petition for its repeal. In doing so, it deprives no man of his *rights*, far less of rights which *conscience* calls upon him to maintain at every hazard; for the rights of individuals to hold civil offices are not inherent, but derived from the legislature, which of course must be the judge upon what terms they are to be held. The legislature of England has excluded from many offices, civil and military, every man who will not give security, that in the discharge of his public duty he will support the church established by law; and as the test of his intention it requires him, before he enters upon his office, to renounce the doctrine of transubstantiation, and receive the sacrament of the Lord's Supper in some public church, according to the liturgy of the church of England. Whether this be the most proper test that could have been enacted, may well be questioned; but that in a country abounding with sectaries of various denominations, who agree in nothing but venomous hostility to the religious establishment, *some* test is necessary, seems incontrovertible, if it be the business of the legislature to preserve the public peace.

To this it will be replied, That the public peace in Scotland is preserved without a test, and that therefore a test cannot be necessary in England. This is plausible, but not conclusive. For 40 years after the Revolution, there was in Scotland no denomination of Christians but those of the Presbyterian church, established by law, the Protestant Episcopalians, whose church had been established prior to that event, and the adherents to the church of Rome. The Episcopalians and Papists were effectually excluded from every office in which they could injure the ecclesiastical establishment, by the several restrictions under which they were laid, on account of their attachment, real or supposed, to the abdicated family of Stuart. The penal laws operated upon them more powerfully than a religious test. It is to be observed too that in the church of Scotland, though her clergy are better provided for than any other parochial clergy perhaps in Europe (A), there is nothing of that splendour and temporal power which in England excite envy to clamour against the establishment, under the pretence of maintaining the cause of religious liberty. Yet even in Scotland a religious test is occasionally exacted of civil officers. In the royal boroughs of that part of the united kingdom, no man can hold the office of a magistrate without previously swearing the burgess-oath (see SECEDER, N° 8.); and every instructor of youth, whether in schools or colleges, may be called upon to qualify himself for his office, by subscribing the established Confession of Faith. The burgess-oath is a more effectual test than that which is required of magistrates in England; for a man might with a safe conscience receive the sacrament of the Lord's Supper occasionally in a church "at which he would not swear to abide and defend the same to his *life's end*." This test appears to us to be necessary in boroughs, where faction is commonly blended with fanaticism; and if those sectaries which, at their first appearance in 1732, were insignificant, if not contemptible, continue to multiply, and to imbibe principles much more pernicious than those which were held by their fathers, it may perhaps be found expedient to extend some test over the whole country.

We do not, however, by any means, wish to see the sacramental test introduced into Scotland. A test may be necessary to secure to the church all her rights and immunities; but to receive the sacrament can give her no such security, whilst it leads inevitably to the profanation of a sacred ordinance. A much better test would be, to require every man, before he be admitted to an executive office, to swear that in the discharge of it he will be careful to maintain all the rights and privileges of the church established by law. Such an oath no sensible and peaceable dissenter could refuse; for it would not bind him to communicate with the established church; and he cannot be ignorant that it belongs not to the executive government, but to the legislature, to determine what shall be the religion of the state. On this account, we cannot help thinking that the members of

(A) There are indeed many livings in the church of England, and probably in other churches, to which nothing in the church of Scotland can be compared in respect of emolument; but these rich benefices bear no proportion to the number of those which, in this age of unavoidable expence, cannot afford to the incumbents the means of decent subsistence as gentlemen. In the church of Scotland many livings amount to 200l. each annually; and we have reason to hope, that when the present plan for augmenting the stipends of the clergy has been extended over Scotland, very few will be below 100l.; whilst in England the vicarages and small rectories, from which we have reason to believe that the incumbents reap not 80l. a-year, greatly exceed in number all the livings in Scotland. Nay we doubt if there be not upwards of a thousand livings in England and Wales from which the rector or vicar derives not above 50l. annually.

of the legislative body should be subjected to no religious test whatever, that they may be at freedom to reform the corruptions of the church, or to exchange one establishment for another, should they find such exchange expedient. If this reasoning be just, it will be difficult to vindicate that clause of 25 Car. II. and of 1 Geo. I. in which it is enacted, that no member shall vote or sit in either house of parliament, till he hath, in the presence of the house, subscribed and repeated the declaration against transubstantiation, the invocation of saints, and the sacrifice of the mass. The church of Rome is indeed a very corrupt society; but if it be not for the purity of her doctrines and government that any church is established in preference to all others, why should that particular church be precluded from the possibility of obtaining a legal establishment in Great Britain, even though she were to become most acceptable to the majority of all ranks in the kingdom? The English Catholics have unquestionably greater reason to complain of this test, than either they or the dissenters have to complain of the law which requires every civil and military officer to receive the Lord's Supper in the established church.

Test for Acids and Alkalies. See CHEMISTRY.

Test Liquors for Wines. See WINE.

TESTACEA, in the Linnæan system, comprehends the third order of vermes, or shell-fish. See CONCHOLOGY *Index*.

TESTACEOUS, in *Natural History*, an epithet synonymous with TESTACEA. See above.

TESTAMENT, or LAST WILL. Testaments both Justinian and Sir Edward Coke agree to be so called, because they are *testatio mentis*: an etymon which seems to savour too much of conceit; it being plainly a substantive derived from the verb *testari*, in like manner as *juramentum*, *incrementum*, and others, from other verbs. The definition of the old Roman lawyers is much better than their etymology; *voluntatis nostræ justa sententia de eo, quod quis post mortem suam fieri velit*: which may be thus rendered into English, "the legal declaration of a man's intentions, which he wills to be performed after his death." It is called *sententia*, to denote the circumspection and prudence with which it is supposed to be made: it is *voluntatis nostræ sententia*, because its efficacy depends on its declaring the testator's intention, whence in English it is emphatically styled his *will*; it is *justa sententia*; that is, drawn, attested, and published, with all due solemnities and forms of law: it is *de eo, quod quis post mortem suam fieri velit*, because a testament is of no force till after the death of the testator.

Blackst. Comment. vol. ii.

These testaments are divided into two sorts; written, and verbal or nuncupative; of which the former is committed to writing: the latter depends merely upon oral evidence, being declared by the testator in *extremis*, before a sufficient number of witnesses, and afterwards reduced to writing.

But as nuncupative wills and CODICILS (which were formerly more in use than at present when the art of writing is become more general) are liable to great impositions, and may occasion many perjuries, the statute of frauds, 29 Car. II. c. 3. enacts, 1. That no written will shall be revoked or altered by a subsequent nuncupative one, except the same be in the lifetime of the testator reduced to writing, and read over to him, and approved; and unless the same be proved to have been so done by the oaths of three witnesses at the least, who, by statute 4 and 5 Anne, c. 16. must be such as are admissible upon trials at common law. 2. That no nuncupative will shall in anywise be good, where the estate bequeathed exceeds 30l. unless proved by three such witnesses, present at the making thereof (the Roman law requiring seven), and unless they or some of them were specially required to bear witness thereto by the testator himself; and unless it was made in his last sickness, in his own habitation or dwelling-house, or where he had been previously resident ten days at the least, except he be surprised with sickness on a journey, or from home, and dies without returning to his dwelling. 3. That no nuncupative will shall be proved by the witnesses after six months from the making, unless it were put in writing within six days. Nor shall it be proved till fourteen days after the death of the testator, nor till process hath first issued to call in the widow, or next of kin, to contest it if they think proper. Thus hath the legislature provided against any fraud in setting up nuncupative wills, by so numerous a train of requisites, that the thing itself has fallen into disuse; and hardly ever heard of, but in the only instance where favour ought to be shown to it, when the testator is surprised by sudden and violent sickness. The testamentary words must be spoken with an intent to bequeath, not any loose idle discourse in his illness; for he must require the by-standers to bear witness of such his intention; the will must be made at home, or among his family or friends, unless by unavoidable accident, to prevent impositions from strangers: it must be in his last sickness; for if he recovers, he may alter his dispositions, and have time to make a written will: it must not be proved at too long a distance from the testator's death, lest the words should escape the memory of the witnesses; nor yet too hastily and without notice, lest the family of the testator should be put to inconvenience or surprise.

As to written wills, they need not any witness of their publication. We speak not here of devices of lands, which are entirely another thing, a conveyance by statute, unknown to the feodal or common law, and not under the same jurisdiction as personal testaments. But a testament of chattels, written in the testator's own hand, though it has neither his name nor seal to it, nor witnesses present at its publication, is good; provided sufficient proof can be had that it is his hand-writing. And though written in another man's hand, and never signed by the testator, yet if proved to be according to his instructions and approved by him, it hath been held a good testament of the personal estate. Yet it is the safer and more prudent way, and leaves less in the breast of the ecclesiastical judge, if it be signed or sealed by the testator, and published in the presence of witnesses; which last was always required in the time of Bracton; or rather he in this respect has implicitly copied the rule of the civil law.

No testament is of any effect till after the death of the testator: *Nam omne testamentum morte consummatum est, et voluntas testatoris est ambulatoria usque ad mortem.* And therefore, if there be many testaments, the last will overthrows all the former; but the republication of a former will revoke one of a later date, and establishes the first again.

Regularly, every person hath full power and liberty to make a will, that is not under some special prohibition by law or custom: which prohibitions are principally upon three accounts; for want of sufficient discretion; for want of sufficient liberty and free-will; and on account of criminal conduct.

1. In the first species are to be reckoned infants, under the age of 14 if males, and 12 if females; which is the rule of the civil law For though some of our common lawyers have held that an infant of any age (even four years old) might make a testament, and others have denied that under 18 he is capable; yet as the ecclesiastical court is the judge of every testator's capacity, this case must be governed by the rules of the ecclesiastical law. So that no objection can be admitted to the will of an infant of 14, merely for want of age; but if the testator was not of sufficient discretion, whether at the age of 14 or 24, that will overthrow his testament. Madmen, or otherwise *non compotes*, idiots or natural fools, persons grown childish by reason of old age or distemper, such as have their senses besotted with drunkenness,—all these are incapable, by reason of mental disability, to make any will so long as such disability lasts. To this class also may be referred such persons as are born deaf, blind, and dumb; who, as they have always wanted the common inlets of understanding, are incapable of having *animum testandi*, and their testaments are therefore void.

2. Such persons as are intestable for want of liberty or freedom of will, by the civil law are of various kinds; as prisoners, captives, and the like. But the law of England does not make such persons absolutely intestable; but only leaves it to the discretion of that court to judge upon the consideration of their particular circumstances of duress, whether or no such persons could be supposed to have *liberum animum testandi*. And with regard to feme-coverts, our laws differ still more materially from the civil. Among the Romans there was no distinction; a married woman was as capable of bequeathing as a feme-sole. But with us a married woman is not only utterly incapable of devising lands, being excepted out of the statute of wills, 34 and 35 Hen. VIII. c. 5. but also she is incapable of making a testament of chattels, without the license of her husband. For all her personal chattels are absolutely his own; and he may dispose of her chattels real, or shall have them to himself, if he survives her: it would be therefore extremely inconsistent to give her a power of defeating that provision of the law, by bequeathing those chattels to another. The queen-consort is an exception to this general rule, for she may dispose of her chattels by will, without the consent of her lord; and any feme-covert may make her will of goods which are in her possession *in auter droit*, as executrix or administratrix; for these can never be the property of the husband: and if she has any pin-money or separate maintenance, it is said she may dispose of her savings thereout by testament, without the controul of her husband. But if a female sole makes her will, and afterwards marries, such subsequent marriage is esteemed a revocation in law, and entirely vacates the will.

3. Persons incapable of making testaments on account of their criminal conduct, are in the first place all traitors and felons, from the time of conviction; for then their goods and chattels are no longer at their own disposal, but forfeited to the king. Neither can a *felo de se* make a will of goods and chattels, for they are forfeited by the act and manner of his death; but he may make a devise of his lands, for they are not subject to any forfeiture. Outlaws also, though it be but for debt, are incapable of making a will so long as the outlawry subsists, for their goods and chattels are forfeited during that time. As for persons guilty of other crimes, short of felony, who are by the civil law precluded from making testaments (as usurpers, libellers, and others of a worse stamp), at the common law their testaments may be good. And in general the rule is, and has been so at least ever since Glanvil's time, *quod libera sit cujuscunque ultima voluntas*.

Testaments may be avoided three ways: 1. If made by a person labouring under any of the incapacities before-mentioned; 2. By making another testament of a later date; and, 3. By cancelling or revoking it. For though I make a last will and testament irrevocable in the strongest words, yet I am at liberty to revoke it; because mine own act or words cannot alter the disposition of law, so as to make that irrevocable which is in its own nature revocable. For this, saith Lord Bacon, would be for a man to deprive himself of that which, of all other things, is most incident to human condition; and that is, alteration or repentance. It hath also been held, that, without an express revocation, if a man, who hath made his will, afterwards marries and hath a child, this is a presumptive or implied revocation of his former will which he made in his state of celibacy. The Romans were also wont to lay aside testaments as being *inofficiosa*, deficient in natural duty, if they disinherited or totally passed by (without assigning a true and sufficient reason) any of the children of the testator. But if the child had any legacy, though ever so small, it was a proof that the testator had not lost his memory or his reason, which otherwise the law presumed; but was then supposed to have acted thus for some substantial cause: and in such case no *querela inofficiosi testamenti* was allowed. Hence probably has arisen that groundless vulgar error of the necessity of leaving the heir a shilling, or some other express legacy, in order to disinherit him effectually; whereas the law of England makes no such wild supposition of forgetfulness or insanity; and therefore, though the heir or next of kin be totally omitted, it admits no *inofficiosi* to set aside such a testament.

TESTAMENT, in *Scots Law*. See LAW, N° clxxxi. 2. &c.

TESTAMENT, *Old* and *New*. See BIBLE and SCRIPTURE.

TESTATOR, the person who makes his will and testament.

TESTER, TESTON, the name of a coin struck in France by Louis XII. in 1513, and in Scotland in the time of Francis II. and Mary queen of Scotland, so called from the head of the king, which was engraved upon it. The silver it contained was 11 deniers 18 grains, its weight seven deniers $11\frac{1}{3}$ grains, and its value 10 sols. The coinage of it was prohibited by Henry III. in 1575, when the value of it was augmented to 14 sols six deniers. The teston or tester among us was rated at 12d. in the reign of Henry VIII. and afterwards reduced to 6d.

TESTES, in *Anatomy*, the testicles. See the next article.

TESTICLE (*testis*), a double part in animals of the male kind, serving for the office of generation. See ANATOMY, N° 107.

TESTIMONY. See LOGIC, N° 29. and METAPHYSICS, N° 135—138.

TESTIMONY, in *Law*. See EVIDENCE.

TESTUDO, the TORTOISE, a genus of animals, belonging to the class of amphibia, and order of reptilia. See ERPETOLOGY *Index*.

TESTUDO, in antiquity, was particularly used among the poets &c. for the ancient lyre; because it was originally made by its inventor Mercury, of the back or hollow of the testudo aquatica, or sea-tortoise, which he accidentally found on the banks of the river Nile. See LYRE.

TESTUDO, in the military art of the ancients, was a kind of cover or screen which the soldiers, *e. gr.* a whole company, made themselves of their bucklers, by holding them up over their heads, and standing close to each other. This expedient served to shelter them from darts, stones, &c. thrown upon them, especially those thrown from above, when they went to the assault.

TESTUDO, was also a kind of large wooden tower which moved on several wheels, and was covered with bullock-hides, serving to shelter the soldiers when they approached the walls to mine them, or to batter them with rams. It was called *testudo*, from the strength of its roof, which covered the workmen as the shell does the tortoise.

TETANUS, a dreadful spasmodic disorder, in which the whole body becomes rigid and inflexible. It most commonly proves mortal. See MEDICINE, N° 279.

TETHYS, a genus of insects belonging to the class of vermes, and order of mollusca. See HELMINTHOLOGY *Index*.

TETRACERA, a genus of plants belonging to the class polyandria; and in the natural system ranging under the doubtful. See BOTANY *Index*.

TETRADYNAMIA, (τισσαρες "four," and δυναμις "power"), four powers; the name of the 15th class in Linnæus's Sexual System. See BOTANY *Index*.

TETRAGONIA, a genus of plants belonging to the class icosandria; and in the natural method ranging under the 13th order, *succulentæ*. See BOTANY *Index*.

TETRAGRAMMATION, τιτραγραμματον, a denomination given by the Greeks to the Hebrew name of God יהוה, "*Jehova*," because in the Hebrew it consists of four letters.

TETRAGYNIA, (τισσαρες, "four," and γυνη, "a woman"); the name of an order, or secondary division, in the Sexual System. See BOTANY *Index*.

TETRANDRIA, (τισσαρες, "four," and ανηρ, "a man or husband"); the name of the fourth class in the Linnæan System. See BOTANY *Index*.

TETRAO, a genus of birds belonging to the order of gallinæ. See ORNITHOLOGY *Index*.

TETRODON, a genus of fishes arranged by Linnæus under the class of *amphibia*, and order of *nantes*; but placed by Gmelin under the class of *pisces*, and order of *branchiostegi*. See ICHTHYOLOGY *Index*.

TETRARCH, a prince who holds and governs a fourth part of a kingdom. Such originally was the import of the title *tetrarch*; but it was afterwards applied to any petty king or sovereign; and became synonymous with ethnarch, as appears from the following considerations: 1. That Pliny makes mention of six tetrarchies within the city of Decapolis. 2. That Herod's kingdom was only divided into three parts, which yet were called *tetrarchies*, and the sovereigns thereof, Luke iii. 1. *tetrarchs*. 3. Josephus tells us, that, after the battle of Philippi, Antony, going into Syria, constituted Herod *tetrarch*; and on medals the same Herod is called *ethnarch*.

Josephus's Antiq. b. xiv. c. 23.

TETRASTYLE, in the ancient architecture, a building, and particularly a temple, with four columns in its front.

TETUAN, an ancient and pleasant town of Africa, in the kingdom of Fez, and in the province of Habata. It is pretty well built, and the inhabitants are about 15,000 in number, who call themselves *Andalusians*, and almost all speak Spanish, but they are great pirates. Some say there are 30,000 Moorish inhabitants, and 5000 Jews. W. Long. 5. 26. N. Lat. 35. 27.

TEUCRIUM, GERMANDER, a genus of plants belonging to the class didynamia; and in the natural system ranging under the 42d order, *Verticillatæ*. See BOTANY *Index*.

TEUTHIS, a genus of fishes belonging to the order of abdominales. See ICHTHYOLOGY *Index*.

TEUTONES, or TEUTONI, in *Ancient Geography*, a people always by historians joined with the Cimbri; both seated, according to Mela, beyond the Elbe, on the Sinus Codanus, or Baltic; and there, it is supposed, lay the country of the Teutones, now *Ditmarsh*; diversity of dialects producing the different terms *Teu*, *Tut*, *Dit*, *Tid*, and *Thod*, which in the ancient German language signified *people*. Of these Teutones, Virgil is to be understood in the epithet *Teutonicus*, an appellation which more lately came to be applied to the Germans in general, and later still the appellation *Alemanni*.

The Teutones, in conjunction with the Cimbri and Ambrones, made war on the Romans, and marched towards Italy in the year 101 B. C. We are told, that the Teutones alone were so numerous, that they were six whole days without intermission in passing by the Roman camp. In Transalpine Gaul they engaged the Roman consul Marius; but were defeated with incredible slaughter; 100,000 of them, according to the lowest calculations, being killed on the spot. According to others, the number of those killed and taken prisoners amounted to 290,000. The inhabitants made fences for vineyards of their bones. Their king Teutobochus, said to be a monstrous giant, was taken prisoner and carried to Rome. See GIANT.

TEUTONIC, something belonging to the Teutones. The Teutonic language is supposed to have been the language of the ancient Germans, and hence is reckoned amongst the mother-tongues. See PHILOLOGY N° 219.

TEUTONIC *Order*, an order of military knights, established towards the close of the twelfth century, on the following occasion.—When the emperor Barbarossa engaged in a crusade for the recovery of the Holy Land out of the hands of Saladin, he was followed by great numbers of German volunteers, who from various motives enlisted under his banners. After the death of Barbarossa, the Germans, who had signalized themselves before Acre or Ptolemais, resolved to choose another leader; and at last fixed their choice upon Frederic duke

duke of Suabia, second son to the emperor, and Henry duke of Brabant. Under these generals they behaved with so much bravery, that Henry king of Jerusalem, the patriarch, and several other princes, determined to reward their valour by instituting an order of knighthood in their favour. This was accordingly done; and our new knights had at first the title of the *knights of St George;* afterwards it was thought proper to put them under the tutelage of the Virgin Mary, to whom there was already an hospital dedicated on Mount Zion, for the relief of German pilgrims. From this time they were called *Equites Mariani*, or knights of St Mary. Laws, regulations, and statutes, were drawn up for them by the Christian kings in Syria and the patriarch; and among other obligations it was required, that every person admitted to the privileges of the order should be of noble parentage; that the order should defend the Christian religion and the Holy Land; that they should exercise hospitality towards the Christians in general, but particularly those of their own country; and that they should with all their power endeavour to propagate and extend the Christian faith and the religion of Jesus. In the year 1190, having become rich by donations from the superstitious, they elected their first grand-master, Henry Walpot, a German, who had distinguished himself by his zeal and valour; and their choice was confirmed by the emperor. The following year, Pope Celestine III. confirmed their privileges already granted, giving them the title of the *Teutonic knights of the hospital of St Mary the Virgin*. By the conditions of this bull, they vowed perpetual continence, obedience, and poverty; obligations which it may well be imagined were not very strictly kept. See Poland, N° 59, 61, 67—69, and Prussia, N° 3, 4.

TEWIT. See Tringa, Ornithology *Index*.

TEWKESBURY, a town in Gloucestershire, formerly noted for its monastery, and containing 4820 inhabitants in 1811, with a magnificent church. It is seated at the confluence of the rivers Severn and Avon, has a cotton manufactory, and sends two members to parliament. W. Long. 2. 13. N. Lat. 52. 0.

TEXEL, a town of the United Provinces, in North Holland, seated at the mouth of the Zuyder-Zee, with a good harbour, and a strong fort. It is seated in a fruitful island, known all over the world by the great number of ships that pass this way every day from all parts; it is about six miles long and five broad, lying a little northward of the continent of Holland, between which and the island is one of the principal passages out of the Zuyder-Zee into the ocean. It is defended from the sea by sand hills and strong banks. Most of the soil is applied to feed sheep, of which they have great flocks; and the cheese made of their milk is said to vie with the Parmesan. This island contains several fair villages, and a town on the east side, called *Burch*, strongly fortified and garrisoned, and inhabited chiefly by fishermen. N. Lat. 53. 8. E. Long. 4. 51.

Nugent's Grand Tour, vol. i.

TEXT, a relative term, contradistinguished to gloss or commentary, and signifying an original discourse exclusive of any note or interpretation. This word is particularly used for a certain passage of Scripture, chosen by a preacher to be the subject of his sermon.

TEXTURE, properly denotes the arrangement and cohesion of several slender bodies or threads interwoven or entangled among each other, as in the webs of spiders, or in the cloths, stuffs, &c.

Texture is also used in speaking of any union or constituent particles of a concrete body, whether by weaving, hooking, knitting, tying, chaining, indenting, intruding, compressing, attracting, or any other way. In which sense we say, a close compact texture, a lax porous texture, a regular or irregular texture, &c.

THABOR. See Tabor.

THALES, a celebrated Greek philosopher, and the first of the seven wise men of Greece, was born at Miletus about 640 B. C. In order to improve himself in the knowledge of the sciences, he travelled into Egypt, where he discoursed with the priests and other learned men. Some say that he married; but others observe, that he eluded the solicitations of his mother on this head, by telling her, when he was young, that it was too soon; and afterwards that it was too late. Thales acquired great reputation by his wisdom and learning: he was the first among the Greeks who foretold eclipses of the sun, and made extraordinary discoveries in astronomy. Thales was the author of the Ionian sect of philosophers, who were thus called from his being born at Miletus, a city of Ionia. He maintained that water was the principle of which all the bodies in the universe are composed; that the world was the work of God; and that God sees the most secret thoughts in the heart of man. He said, "That the most difficult thing in the world is to know ourselves; the most easy to advise others; and the most sweet to accomplish our desires. That, in order to live well, we ought to abstain from what we find fault with in others. That the bodily felicity consists in health, and that of the mind in knowledge. That the most ancient of beings is God, because he is uncreated: that nothing is more beautiful than the world, because it is the work of God; nothing more extensive than space, quicker than spirit, stronger than necessity, wiser than time." It was also one of his sentences, "That we ought never to say that to any one that may be turned to our prejudice; and that we should live with our friends as with persons that may become our enemies." He thanked God for three things; that he was born of the human, not of the brute species; a man, and not a woman; a Greek, and not a barbarian. None of the ancient philosophers ever applied themselves more earnestly to the study of astronomy than Thales. Diogenes Laertius reports, that leaving his lodging with an old woman to contemplate the stars, he fell into a ditch; on which the good woman cried, "How canst thou know what is doing in the heavens, when thou canst not perceive what is at thy feet?" He went to see Crœsus, who was marching with a powerful army into Cappadocia, and enabled him to pass the river Halys without making a bridge. Thales died soon after, at about 90 years of age. He composed several treatises in verse, on meteors, the equinoxes, &c. but they are all lost.

THALIA, in Pagan mythology, one of the nine muses. She presided over Comedy; and is represented crowned with a garland of ivy, holding a mask in her hand, and wearing buskins on her feet.

Thalia, a genus of plants belonging to the class monandria; and in the natural system ranging under the 8th order, *Scitamineæ*. See Botany *Index*.

THALICTRUM,

Thalictrum, Thames

THALICTRUM, Meadow-Rue, a genus of plants belonging to the class polyandria; and in the natural system ranging under the 26th order, *Multisiliquæ*. See Botany *Index*.

THAMES, the finest river in Great Britain, which takes its rise from a copious spring, called *Thames Head*, two miles south-west of Cirencester in Gloucestershire. It has been erroneously said, that its name is Isis till it arrives at Dorchester, 15 miles below Oxford, when, being joined by the Thame or Tame, it assumes the name of the Thames, which, it has been observed, is formed from a combination of the words Thame and Isis. What was the origin of this vulgar error, cannot now be traced. Poetical fiction, however, has perpetuated this error, and invested it with a kind of classical sanctity. "It plainly appears (says Camden), that the river was always called *Thames* or *Tems*, before it came near the Thame; and in several ancient charters granted to the abbey of Malmsbury, as well as that of Ensham, and in the old deeds relating to Cricklade, it is never considered under any other name than that of *Thames*." He likewise says, that it occurs nowhere under the name of Isis. All the historians who mention the incursions of Ethelwold into Wiltshire in the year 905, or of Canute in 1016, concur likewise in the same opinion, by declaring, that they passed over the Thames at Cricklade in Wiltshire. It is not probable, moreover, that Thames Head, an appellation by which the source has usually been distinguished, should give rise to a river of the name of Isis; which river, after having run half its course, should reassume the name of Thames, the appellation of its parent spring. About a mile below the source of the river is the first corn-mill, which is called *Kemble Mill*. Here the river may properly be said to form a constant current; which, though not more than nine feet wide in the summer, yet in the winter becomes such a torrent as to overflow the meadows for many miles around. But, in the summer, the Thames Head is so dry, as to appear nothing but a large dell, interspersed with stones and weeds. From Somerford the stream winds to Cricklade, where it unites with many other rivulets. Approaching Kemsford, it again enters its native county, dividing it from Berkshire at Inglesham. It widens considerably in its way to Lechlade; and being there joined by the Lech and Coln, at the distance of 138 miles from London, it becomes navigable for vessels of 90 tons. At Ensham, in its course north-east, to Oxford, is the first bridge of stone; a handsome one, of three arches, built by the earl of Abingdon. Passing by the ruins of Godstow nunnery, where the celebrated Fair Rosamond was interred, the river reaches Oxford, in whose academic groves its poetical name of Isis has been so often invoked. Being there joined by the Charwell, it proceeds south-east to Abingdon, and thence to Dorchester, where it receives the Tame. Continuing its course south-east by Wallingford to Reading, and forming a boundary to the counties of Berks, Bucks, Surry, Middlesex, Essex, and Kent, it washes the towns of Henley, Marlow, Maidenhead, Windsor, Eton, Egham, Staines, Laleham, Chertsey, Weybridge, Shepperton, Walton, Sunbury, East and West Moulsey, Hampton, Thames Ditton, Kingston, Teddington, Twickenham, Richmond, Isleworth, Brentford, Kew, Mortlake, Barnes, Chiswick, Hammersmith, Putney, Fulham, Wandsworth, Battersea, Chelsea, and Lambeth. Then, on the north bank of the river, are Westminster and London, and, on the opposite side, Southwark; forming together one continued city, extending to Limehouse and Deptford; and hence the river proceeds to Greenwich, Erith, Greenhithe, Gray's Thurrock, Gravesend, and Leigh, into the ocean. It receives in its course from Dorchester the rivers Kennet, Loddon, Coln, Wey, Mole, Wandle, Lea, Roding, Darent, and Medway. The jurisdiction of the lord mayor of London over the Thames extends from Coln ditch, a little to the west of Staines, to Yendal or Yenleet to the east, including part of the rivers Medway and Lea; and he has a deputy, named the water bailiff, who is to search for and punish all offenders against the laws for the preservation of the river and its fish. Eight times a-year the lord mayor and aldermen hold courts of conservance for the four counties of Surry, Middlesex, Essex, and Kent. Though the Thames is said to be navigable 138 miles above the bridge, yet there are so many flats, that in summer the navigation westward would be entirely stopped, when the springs are low, were it not for a number of locks. But these are attended with considerable expence; for a barge from Lechlade to London pays for passing through them 13l. 15s. 6d. and from Oxford to London 12l. 18s. This charge, however, is in summer only, when the water is low; and there is no lock from London bridge to Bolter's lock; that is, for $51\frac{1}{2}$ miles above the bridge. The plan of new cuts has been adopted, in some places, to shorten and facilitate the navigation. There is one near Lechlade, which runs nearly parallel to the old river, and contiguous to St John's bridge; and there is another a mile from Abingdon, which has rendered the old stream toward Culham bridge useless. But a much more important undertaking has lately been accomplished; namely, the junction of this river with the Severn. A canal had been made, by virtue of an act of parliament in 1730, from the Severn to Wallbridge, near Stroud. A new canal now ascends by Stroud, through the vale of Chalford, to the height of 343 feet, by means of 28 locks, and thence to the entrance of a tunnel near Sapperton, a distance of near eight miles. The canal is 42 feet in width at top and 30 at the bottom. The tunnel (which is extended under Sapperton hill, and under that part of Earl Bathurst's grounds called *Halleywood*, making a distance of two miles and three furlongs) is near 15 feet in width, and can navigate barges of 70 tons. The canal descending hence 134 feet, by 14 locks, joins the Thames at Lechlade, a distance of above 20 miles. In the course of this vast undertaking, the canal, from the Severn at Froomlade to Inglesham, where it joins the Thames, is a distance of more than 30 miles. The expence of it exceeded the sum of 200,000l. of which 3000l. are said to have been expended in gunpowder alone, used for the blowing up of the rock. This new canal was completed in 1789, in less than seven years from its commencement. A communication, not only with the Trent, but with the Mersey, has likewise been effected by a canal from Oxford to Coventry; and an act of parliament has passed to extend another canal from this, at Braunston, to the Thames at Brentford. This is to be called *The Grand Junction Canal*. On the extensive advantages resulting from these navigable communications from the metropolis with the ports of Bristol, Liverpool, Hull, &c. and

Brooke's Gazetteer.

Thames, Thane.

and the principal manufacturing towns in the inland parts of the kingdom, it is needless to expatiate. The tide flows up the Thames as high as Richmond, which, following the winding of the river, is 70 miles from the ocean; a greater distance than the tide is carried by any other river in Europe. The water is esteemed extremely wholesome, and fit for use in very long voyages, during which it will work itself perfectly fine.

THAMES is also the name of a river in the state of Connecticut in America. See the article CONNECTICUT.

THANE, or THANUS, a name given to the nobility in Britain before the time of William the Conqueror. It signifies a minister or honourable retainer, from the verb *thenian*, "to minister." There were several degrees of nobility among the Anglo-Saxons; but those most commonly mentioned are the king's thanes and the alderman's thanes. The king's thanes seem to have been of three different degrees, according to their different degrees of wealth or favour at court. The alderman's thanes seem to have been of the lowest degree of nobility, and next to them those who were promoted to that dignity from their advancement in the church, from their valour, success in agriculture or commerce: for if a ceorl or farmer applied to learning and attained to priests orders; if he acquitted himself so well as to obtain from a nobleman five hythes of land, or a gilt sword, helmet, and breast-plate, the reward of his valour; or if by his industry he had acquired the property of five hythes of land; or if he applied to trade, and made three voyages beyond sea in a ship of his own, and a cargo belonging to himself, he was denominated a *thane*.

The thanes, who were the only nobility among the Anglo-Saxons, were a very numerous body of men, comprehending all the considerable landholders in England, and filling up that space in society between the ceorls or yeomanry on the one hand, and the royal family on the other; which is now occupied both by the nobility and gentry. In times of war, they constituted the flower of their armies, and in times of peace they swelled the trains of their kings, and added greatly to the splendour of their courts, especially at the three great festivals of Christmas, Easter, and Whitsuntide. From this body all the chief officers, both civil and military, as aldermen, greeves, earls, heretogens, &c. were taken; and to obtain some of these offices was the great object of their ambition. Before they obtained an office, their lands were their only support; and they lived in greater or less affluence, according to the extent of their estates. These they divided into two parts; one of which they called their *inlands*, and the other their *outlands*. Their inlands they kept in their own immediate possession, and cultivated them by the hands of their slaves and villains, in order to raise provisions for their families; their outlands they granted to ceorls or farmers, either for one year, or for a term of years; for which they received a certain stipulated proportion of their produce annually. These customs had long prevailed among their ancestors in Germany, and were adhered to by their posterity in England till the conquest.

Henry's History of Great Britain, vol. ii.

The thanes were under no obligations on account of their lands, except the three following, which were indispensably necessary to the defence and improvement of their country: To attend the king with their followers in military expeditions, to assist in building and defending the royal castles, and in keeping the bridges and highways in proper repair. To these obligations all proprietors of land (even the churchmen for a long time not excepted) were subjected; and these services were considered as due to their country, rather than to the persons of their kings; and were agreed to by all as being necessary to their own preservation and conveniency.

Thane || Theatre.

This title of thane was abolished in England at the conquest, upon the introduction of the feudal system by William. The titles of earl and baron were about the same period introduced into Scotland by Malcolm Canmore, when the title of thane fell into disuse.

THANET, an island of the county of Kent, surrounded by the sea except on the north-east side, where it is bounded by the branches of the river Stour, now inconsiderable to what they were formerly. It contains several villages, and the sea port towns of Margate and Ramsgate, and has the title of an earldom. It is celebrated for being the spot through which arts, sciences, and divine knowledge, came into this happy isle. The Britons called it *Richborough*, from its vicinity to the city of that name, now only a venerable ruin; but the Saxons called it *Thanet*, from fire, having so many beacons erected on it. It is in the north-east part of the county, lies open to the sea on the north and east, with the river Wantsum on the west and south, is about 10 miles long from the North Foreland to Sarre-Bridge, and about 8 broad from Westgate to Sandwich-Ferry. The north part of it is chiefly arable; and the south and west parts consist of marsh or pasture-lands. The soil is generally very fertile, especially in producing the best barley, of which it is computed above 20,000 quarters are annually sent to London.

THEA. See TEA.

THEATINES, a religious order in the Romish church, so called from their principal founder John Peter Caraffa, then bishop of Theate, or Chieti, in the kingdom of Naples, and afterwards pope, under the name of Paul IV. The names of the other founders were Gaetan, Boniface, and Consiglieri. These four pious men desiring to reform the ecclesiastical state, laid the foundation of an order of regular clerks at Rome in the year 1524. Pope Clement VII. approved the institution, and permitted the brethren to make the three religious vows, to elect a superior every three years, and to draw up statutes for the regulation of the order. They were the first who endeavoured, by their example, to revive among the clergy the poverty of the apostles and first disciples of our Saviour, and were also the first who assumed the title of *regular clerks*.

THEATRE, a place in which shows or dramatic representations are exhibited.

For the origin of the dramatic art we always turn our eyes to Greece, the nursery of the arts and sciences. It may indeed have been known among more ancient nations, Theatre.

nations, but no records remain sufficient to support this opinion. The different states of Greece asserted their claim to the honour of having given it birth, but the account of the Athenians is most generally received. It derived its origin from the hymns which were sung in the festivals of Bacchus in honour of that deity. While these resounded in the ears of the multitude, choruses of Bacchants and Fauns, ranged round certain obscene images which they carried in triumphal procession, chanted lascivious songs, and sometimes sacrificed individuals to public ridicule.

This was the practice in the cities; but a still greater licentiousness reigned in the worship paid to the same divinity by the inhabitants of the country, and especially at the season when they gathered the fruits of his beneficence. Vintagers, besmeared with wine-lees, and intoxicated with joy and the juice of the grape, rode forth in their carts, and attacked each other on the road with gross sarcasms, revenging themselves on their neighbours with ridicule, and on the rich by publishing their injustice.

Anacharsis's Travels, vol. i.

Among the poets who flourished at that time, some celebrated the great actions and adventures of gods and heroes, and others attacked with asperity the vices and absurdities of individuals. The former took Homer for their model, and supported themselves by his example, of which they made an improper use. Homer, the most tragic of poets, the model of all who have succeeded him, had in the Iliad and the Odyssey brought to perfection the heroic poem, and in his Margites had employed pleasantry. But as the charm of his works depends in a great measure on the passions and motion with which he knew to animate them, the poets who came after him endeavoured to introduce into theirs an action which might excite emotion or mirth in the spectators: some even attempted to produce both, and ventured certain rude essays, which have since been styled indifferently either tragedies or comedies, because they unite the characters of those two dramas. The authors of these sketches have been distinguished by no discovery; they only form in the history of the art a succession of names which it would be useless to recal to light.

The necessity and power of theatrical interest was already known. The hymns in honour of Bacchus, while they described his rapid progress and splendid conquests, became imitative; and in the contests of the Pythian games, the players on the flute who entered into competition were enjoined by an express law to represent successively the circumstances that had preceded, accompanied, and followed the victory of Apollo over Python.

Some years after this regulation, Susarion and Thespis, both born in a small borough of Attica, named *Icaria*, appeared each at the head of a company of actors, the one on a kind of stage, the other in a cart (A). The former attacked the vices and absurdities of his time; and the latter treated more noble subjects, which he took from history.

The comedies of Susarion were in the same taste with those indecent and satirical farces which were afterwards performed in some of the cities of Greece. They were long the favourite entertainment of the country people. Athens did not adopt this species of exhibition until after it was brought to perfection in Sicily.

Thespis had more than once seen in the festivals, in which as yet hymns only were sung, one of the singers, mounted on a table, form a kind of dialogue with the chorus. From this hint he conceived the idea of introducing into the tragedies an actor who, by simple recitals introduced at intervals, should give relief to the chorus, divide the action, and render it more interesting. This happy innovation, together with some other liberties in which he had allowed himself, gave alarm to the legislator of Athens, who was more able than any other person to discern the value or danger of the novelty. Solon condemned a species of composition in which the ancient traditions were disguised by fictions. "If we applaud falsehood in our public exhibitions (said he to Thespis), we shall soon find that it will insinuate itself into our most sacred engagements."

The excessive approbation and delight with which both the city and country received the pieces of Thespis and Susarion, at once justified and rendered useless the suspicious foresight of Solon. The poets, who till then had only exercised their genius in dithyrambics and licentious satire, struck with the elegant forms which these species of composition began to assume, dedicated their talents to tragedy and comedy. Soon after a greater variety was introduced in the subjects of the former of these poems. Those who judged of their pleasures only from habit, exclaimed, that these subjects were foreign to the worship of Bacchus; but the greater number thronged with still more eagerness after the new pieces.

Phrynichus, the disciple of Thespis, made choice of that kind of verse which is most suitable to the drama, was the author of some other changes, and left tragedy in its infancy.

Æschylus received it from his hands enveloped in a rude vestment, its visage covered with false colours, or a mask inexpressive of character, without either grace or dignity in its motions, inspiring the desire of an interest which it with difficulty excited, still attached to the buffooneries which had amused its infant years, and expressing its conceptions sometimes with elegance and dignity, but frequently in a feeble and low style, polluted with gross obscenities.

In his first tragedies he introduced a second actor; and afterwards, copying the example of Sophocles, who had just entered on his theatrical career, he admitted a third, and sometimes even a fourth. By this multiplicity of personages, one of his actors became the hero of the piece, and attracted to himself the principal interest; and as the chorus now held only a subaltern station, Æschylus took care to shorten its part, and perhaps even carried this precaution too far.

He is censured for having admitted mute characters into his drama. Achilles, after the death of his friend, and Niobe, after the destruction of her children, appear on

(A) Susarion represented his first pieces towards the year 580 before Christ. Some years after, Thespis made his first attempts in tragedy, and acted his Alcestis in 536.

on the stage, and remain during several scenes motionless, with their heads covered with a veil, and without uttering a word; but if their eyes had overflown with tears, and they had poured forth the bitterest lamentations, could they have produced an effect so terrible as this veil, this silence, and this abandonment to grief?

It was not sufficient that the noble and elevated style of tragedy should leave in the minds of the auditors a strong impression of grandeur; to captivate the multitude, it was requisite that every part of the spectacle should concur to produce the same effect. It was then the general opinion that nature, by bestowing on the ancient heroes a more lofty stature, had impressed on their persons a majesty which procured them as much respect from the people as the ensigns of dignity by which they were attended. Æschylus therefore raised his actors on high stilts or buskins. He covered their features, which were frequently disagreeable, with a mask that concealed their irregularity. He clothed them in flowing and magnificent robes, the form of which was so decent, that the priests of Ceres have not blushed to adopt it. The inferior actors were also provided with masks and dresses suited to their parts.

Instead of those wretched scaffolds which were formerly erected in haste, he obtained a theatre furnished with machines, and embellished with decorations. Here the sound of the trumpet was reverberated, incense was seen to burn on the altars, the shades of the dead to arise from the tomb, and the furies to rush from the gulfs of Tartarus. In one of his pieces these infernal divinities appeared, for the first time, with masks of a horrid paleness, torches in their hands, serpents intertwined in their hair, and followed by a numerous retinue of dreadful spectres. It is said that, at the sight of them, and the sound of their terrific howlings, terror seized on the whole assembly, women miscarried, and children expired with fear; and that the magistrates, to prevent similar accidents in future, commanded that the chorus should consist only of fifteen actors instead of fifty.

The effect of so many new objects could not but astonish the spectators; nor were they less surprised and delighted at the intelligence displayed in the performance of the actors, whom Æschylus almost always exercised himself. He regulated their steps, and taught them to give additional force to the action by new and expressive gestures.

The progress of the art was extremely rapid. Æschylus was born 525 years before Christ, 11 years after Thespis had acted his Alcestis. He had for competitors Chœrilus Pratenas, and Phrynichus, whose glory he eclipsed, and Sophocles, who rivalled his own. Sophocles was born about the year 497 B. C. about 14 years before Euripides. These carried tragedy to the highest perfection to which it attained among the Greeks. Æschylus painted men greater than they can be, Sophocles as they ought to be, and Euripides as they are.

Invented towards the 50th Olympiad (about 580 B. C.) and adapted to the rude manners of the rustics, comedy ventured not to approach the capital; and if by chance some companies of actors, who were unconnected with any others, found their way into the city, and performed their indecent farces, they were less authorised than tolerated by the government. It was not till after a long infancy that this species of drama began suddenly to make a rapid improvement in Sicily. Instead of a succession of scenes without connection or tendency, the philosopher Epicharmus introduced an action, all the parts of which had a dependence on each other; and conducted his subject, without wandering from it, through a just extent to a determinate end. His pieces, subjected to the same laws of tragedy, were known in Greece, where they were considered as models; and comedy soon shared with her rival the suffrages of the public, and the homage due to genius. The Athenians, especially, received her with the same transports as they would have testified at the news of a victory: many of their poets exercised their genius in this novel species of composition; and their names adorn the numerous list of writers who have been distinguished in comedy from the time of Epicharmus. Such were, among the more ancient, Magnes, Cratinus, Crates, Pherecrates, Eupolis, and Aristophanes. They all flourished in the age of Pericles.

If we peruse the comic pieces which have come down to us, we shall be convinced that the sole object of the authors was to please the multitude. The gods and heroes were travestied, gross and obscene language was often employed, and virulent invectives were often thrown out against individuals of the first rank for genius and virtue. Towards the end of the Peloponnesian war the licentiousness of comedy was restrained. The chorus was laid aside, because the rich citizens were alarmed, and would no longer contribute money to support it, nor provide masks with portraits for exposing individuals.

The poets being thus restrained from mentioning names of living persons on the stage, invented false names. They still exposed real and known characters; and thus gave a more exquisite gratification to the spectators, who were highly amused with finding out the persons intended. The consequence of the law was only to make that done with delicacy which was formerly done in the most indecent and scurrilous manner. Aristophanes, in some of his latest pieces, has given us some good examples of this kind of comedy, which is sometimes called the middle comedy.

Comedy was still liable to abuse, and therefore required farther reformation. As the use of real names had formerly been prohibited, real subjects were also forbidden; and comedy from that time was no longer a fury armed with torches, or a firebrand scattering mischief, but a pleasing and instructive companion. This is called the new comedy. The most eminent among the Greeks in this improved species was Menander. His writings are now lost; but we may form a good estimate of their merit from the comedies of Terence, which are said to have been borrowed from Menander, and to have nearly resembled the original, though inferior in that *vis comica* by which the elegant Grecian was distinguished. The comedy of Menander is that which has been cultivated in modern times.

To give some idea of a Grecian theatre, we shall describe very shortly the theatre of Bacchus in Athens, which was built by the famous architect Philos in the time of Pericles. The part intended for the spectators was of a simicircular form, at the diameter of which was erected the stage. The orchestra occupied the space where the pit in modern theatres is situated, where the

Theatre.

the music, the chorus, and the mimi were placed. It was four feet elevated above the ground. The spectators were arranged in three galleries round all the sides of the orchestra except that next the stage, each gallery containing eight rows of seats. At the farther end of the orchestra, where the stage is erected in modern theatres, stood the thymele or logeon, but projecting a little towards the audience. It was a little higher than the orchestra, and did not extend the whole breadth of it. In some theatres it was only six feet square. Here the principal part of the chorus made their recitations, and in comical interludes the mimi performed. Behind the thymele appeared the stage or proscenion, considerably elevated. No part of this theatre was covered except the stage, and a high gallery called *circys* set apart for the women. The Athenians, being exposed to the weather, came usually with great cloaks, to secure them from the rain or the cold; and for defence against the sun they had the *sciadion*, a kind of parasol, which the Romans used also in the theatres by the name of *umbellæ;* but when a sudden storm arose, the play was interrupted, and the spectators dispersed.

Gentleman's Magazine for 1760.

A sort of tent-work over the entire area of the edifice might have been contrived as a shelter from the rain and a shade from the sun. Such a covering would have obviated the inconveniences of roofed theatres, which obstruct the free communication of the air, and of unroofed theatres, which do not keep out the weather. At Athens the plays were always represented in the daytime, which made the unroofed theatres less inconvenient.

Plays were represented only during the three festivals solemnized in honour of Bacchus. The first of these was celebrated at the Piræus, where some of Euripides's pieces were first performed. The second, which lasted only one day, was kept at the end of January or beginning of February. The third, called the greater *Dionysia*, was celebrated a month after. It continued several days, and attracted a great multitude of spectators. In the festivals which lasted only one day, five or six dramatic pieces, either tragedies or comedies, were performed. But in the greater Dionysia, which continued longer, 12 or 15, and sometimes more, were acted. The performance began early in the morning, and sometimes lasted the whole day.

The chorus, according as the subject demanded, was composed of men and women, old men or youths, citizens or slaves, priests, soldiers, &c. to the number of 15 in tragedy, and 24 in comedy. The chorus came upon the stage preceded by a flute-player, who regulated their steps; sometimes one after the other, but in tragedy more frequently three in front and five in depth, or five in front and three in depth.

The same persons performed both in tragedy and comedy; but, as among ourselves, it was rare to meet with any who excelled in both. The pay of those who had acquired great reputation was considerable. Polus gained a talent in two days (equal to 225l. sterling *). Players of eminence were solicited by different actors of Greece to attend their festivals. If, after making an engagement, they failed, they were obliged to pay a certain sum of money; and if they were absent during the festivals of their own republic, they were condemned to a heavy fine.

* *Plut. in X. Rhet.*

The actors had habits and symbols suited to their parts. Kings wore a diadem, leaned on a sceptre which supported an eagle on its top, and were dressed in long robes of purple or other splendid colours ornamented with gold. Heroes, besides having their stature frequently increased to six feet English †, and their bulk in proportion, were frequently covered with the skin of a lion or a tyger, and armed with swords, quivers, and clubs. All who suffered misfortunes wore a black, brown, or dirty white garment, which frequently hung in tatters. There were various kinds of masks for tragedy, comedy, and satire. These certainly took away the pleasure arising from the expression of the countenance; but at any rate, little pleasure could be derived from this circumstance in a Grecian theatre, from its immense size, and the great distance of the audience from the stage.

† *Arist. in Ran.* v. 1046. *Athen.* lib. v. cap. 7.

Dramatic entertainments were introduced at Rome in the year of the city 391. They were called *ludi scenici*, because they were first acted in a shade formed by the branches and leaves of trees. They were borrowed immediately from Etruria, whence also they received their first players. These Etrurians at first only danced to a flute, without either singing or acting. The Roman youth soon imitated them at their solemn festivals, adding raillery in rude verses, and gestures adapted to the subject. These verses were called *Fescennini*, from Fescennia, a city of Etruria. Livius Andronicus was the first poet who wrote a regular play in Latin. This happened in the year of Rome 512 or 514, about 160 years after the death of Sophocles and Euripides, and 52 after that of Menander. The Grecian model was afterwards introduced and cultivated much by succeeding dramatic writers. This was the model of Menander, for the old and middle comedy was unknown at Rome. As the Romans were only imitators of the Greeks in the dramatic art, as well as in most of the arts and sciences, nothing more is necessary to be said in addition to the account which we have already given of the Grecian stage.

The origin of the English stage is hid in obscurity. It was not, however, copied from the Grecian or Roman; for it was evidently different in form as well as in matter, and may with more propriety be deduced from a Gothic original. It appears that there were theatrical entertainments in England almost as early as the conquest; for we are told by William Stephanides or Fitz-Stephen, a monk, who in the reign of Henry II. wrote his *Descriptio Nobilissimæ Civitatis Londoniæ*, that "London, instead of the common interludes of the theatre, had plays of a more holy kind; representations of the miracles of confessors, and the sufferings of martyrs." At this time there were also certain sets of idle people, who travelled the countries, and were called *Mummers*, a kind of vagrant comedians, whose excellence consisted altogether in mimickry and humour.

Gentleman's Magazine for 1761.

It is probable that, soon after this time, the dramatic representations called *Mysteries* were exhibited: These mysteries were taken from scripture-history: some represented the creation of the world, with the fall of Adam and Eve; some the story of Joseph; and others even the incarnation and sufferings of the Son of God. These pieces were exhibited in a manner so ridiculous as to favour libertinism and infidelity, as appears by a petition of the chaunters of St Paul's Cathedral to Richard II. in 1378, praying, that "some unexpert people might be-

Theatre. be prohibited from representing the history of the Old Testament to the prejudice of the said clergy, who had been at great expence to represent it publicly at Christmas."

In the year 1390, the parish clerks of London are said to have played interludes at Skinner's-well on three successive days in July; and, in 1409, to have acted for eight days successively a play concerning the creation of the world, at the same place which thence acquired the name of *Clerkenwell.*

These Mysteries were succeeded by Moralities, in which there were some rude traces of a fable and a moral; and some also of poetry, the virtues, vices, and other affections of the mind being frequently personified.

After these Moralities came what were called Interludes, which made some approaches to wit and humour. Many of these pieces were written by John Heywood, jester to Henry VIII.

In the time of Henry VIII. one or two pieces had been published under the classical names of *Comedy* and *Tragedy*, but they appear not to have been intended for popular use. It was not till the religious ferments had subsided that the public had leisure to attend to dramatic poetry. In the reign of Elizabeth, tragedies and comedies began to appear in form, and could the poets have persevered, the first models were good. *Gorboduc*, a regular tragedy, was acted in 1561; and Gascoigne, in 1566, exhibited *Jocasta*, a translation from Euripides, as also *The Supposes*, a regular comedy, from Ariosto, near 30 years before any of Shakespeare's were printed.

Percy's Relics of Ancient English Poetry.

The people, however, still retained a relish for their old mysteries and moralities, and the popular dramatic poets seem to have made them their models. The graver sort of moralities appear to have given birth to our modern tragedy; as our comedy evidently took its rise from the lighter interludes of that kind. And as most of these pieces contain an absurd mixture of religion and buffoonery, an eminent critic has well deduced from thence the origin of our unnatural tragi-comedies. Even after the people had been accustomed to tragedies and comedies, moralities still kept their ground. One of them, intitled *The New Custom*, was printed so late as 1573. At length they assumed the name of *masques*, and, with some classical improvements, became in the two following reigns the favourite entertainments of the court.

As for the old mysteries, which ceased to be acted after the reformation, they seem to have given rise to a third species of stage exhibition; which, though now confounded with tragedy or comedy, was by our first dramatic writers considered as quite distinct from them both: these were historical plays, or histories; a species of dramatic writing which resembled the old mysteries in representing a series of historical events simply in the order of time in which they happened, without any regard to the three great unities. These pieces seem to differ from tragedy just as much as historical poems do from epic: as the Pharsalia does from the Æneid. What might contribute to make dramatic poetry take this turn was, that soon after the mysteries ceased to be exhibited, there was published a large collection of poetical narratives, called *the Mirror for Magistrates*, wherein a great number of the most eminent characters in English history are drawn relating their own misfortunes. This book was popular and of a dramatic cast; and therefore, as an elegant writer has well observed, might have its influence in producing historic plays. These narratives probably furnished the subjects, and the ancient mysteries suggested the plan. Theatre.

That our old writers considered historical plays as somewhat distinct from tragedy and comedy, appears from numberless passages of their works. "Of late days (says Stow in his Survey of London), instead of those stage plays have been used comedies, tragedies, interludes, and histories, both true and fained." Beaumont and Fletcher, in the prologue to the *Captain*, say,

> "This is nor comedy, nor tragedy,
> "Nor *history*."

Polonius in Hamlet commends the actors as the best in the world, either for tragedie, comedie, historie, pastoral, &c. And Shakespeare's friends, Heminge and Condell, in the first folio edition of his plays, in 1623, have not only intitled their book "Mr William Shakespeare's Comedies, Histories, and Tragedies," but, in their table of contents, have arranged them under those three several heads; placing in the class of histories, "King John, Richard II. Henry IV. two parts, Henry V. Henry VI. three parts, Richard III. and Henry VIII."

This distinction deserves the attention of the critics: for if it be the first canon of sound criticism to examine any work by those rules the author prescribed for his first observance; then we ought not to try Shakespeare's histories by the general laws of tragedy and comedy. Whether the rule itself be vicious or not, is another inquiry; but certainly we ought to examine a work only by those principles according to which it was composed. This would save much impertinent criticism.

Not fewer than 19 playhouses had been opened before the year 1633, when Prynne published his *Histriomastix*. From this writer we learn that tobacco, wine, and beer, were in those days the usual accommodations in the theatre, as now at Sadlers Wells. With regard to the ancient prices of admission, the playhouse called the *Hope* had five different priced seats, from sixpence to half-a-crown. Some houses had penny benches. The two-penny gallery is mentioned in the prologue to Beaumont and Fletcher's *Woman-hater;* and seats of threepence and a groat in the passage of Prynne last referred to. But the general price of what is now called the *Pitt* seems to have been a shilling. The time of exhibition was early in the afternoon, their plays being generally acted by day-light. All female parts were performed by men, no actress being ever seen on the public stage before the civil wars. And as for the playhouse furniture and ornaments, they had no other scenes nor decorations of the stage, but only old tapestry, and the stage strewed with rushes, with habits accordingly; as we are assured in a short Discourse on the English Stage, subjoined to Flecknoe's *Love's-Kingdom*, 1674, 12mo.
