Those who were blessed with the light of revelation undoubtedly looked forward to that state with a holy joy; but the rest worshipped superior powers from worldly motives. How many of those powers there might be, or how far their influence might reach, they knew not. Uncertain whether there be one Supreme Governor of the whole world, or many co-ordinate powers presiding each over a particular country, climate, or place — gods of the hills and of the valleys, as they were afterwards distinguished — they thought that the more of these they could engage in their interest the better. Like the Samaritans therefore, in after times, they sought, wherever they came, the "manner of the god of the land," and served him, together with their own gods.

Thus was the world ready to lose all knowledge of the true God and his worship, had not he been graciously pleased to interpose, and take effectual care to preserve that knowledge in one nation, from which it might be conveyed to the rest of mankind at different times, and in greater or less degrees, as they should be capable of receiving it. To this purpose he made way for the removal of Jacob and his family to one of the most improved and polished countries of the world; and introduced them into it in a manner so advantageous, as to give them an opportunity of imparting much religious knowledge to the natives. The natives, however, were gross idolaters; and that his chosen people might be as far as possible from the contagion of their example, he placed them upon the borders of Egypt, where, though they multiplied exceedingly, they were by their very occupation still kept a separate people, and must have been rendered, by a long and severe oppression, in a great degree averse to the manners and religion of their neighbours. This aversion, however, seems to have gradually become less and less; and before they were miraculously redeemed from their house of bondage, they had certainly lost all correct notions of the unity of God, and the nature of his worship, and had adopted the greater part of the superstitions of their task-masters. Of this we need no other proof than what is implied in the words of Moses, "when he said unto God, "Be hold, when I come unto the children of Israel, and say unto them, the God of your fathers hath sent me unto you; and they shall say unto me, What is his name? and I shall say unto them, "I am a God"."

Had not the destined law-giver of the Hebrews been aware that his countrymen had adopted a plurality of gods, this difficulty could not have occurred to him; for some are more apt from each other beings of the same kind; and he must have remembered, that in Egypt, where the multitude of goods was marshalled into various classes, the knowledge of their names was deemed of great importance. This we learn likewise from Herodotus, who informs us, "that the Pelasgi, after settling in Greece, thought it necessary to consult the oracle of Dodona, whether it would be proper to give to their own gods the names of the Egyptian divinities, and that the oracle, as might have been supposed, assured them that it would. Indeed the Hebrews during their residence in Egypt had acquired such an attachment to the idolatrous worship of the country, that it appears never to have left them entirely till many ages afterwards, when they were carried captive into Babylon, and severely punished for their repeated apostasies; and so completely were they infatuated by these superstitions at the era of their exodus, that, as the prophet Ezekiel informs us, they rebelled against God, and would not cast away their abominations, or forsake the idols of Egypt, even in the very day that the hand of Omnipotence was lifted up to bring them forth of that land in which they had been so long and so cruelly oppressed. In such a state of things, to have suffered them to remain longer in Egypt, could have served no good purpose; and therefore to fulfill the promise which he had given to Abraham, God determined to deliver them out of the hands of the Egyptians by means which should convince both them and their offspring of his own supremacy over heaven and earth.

As Moses was the person appointed to deliver God's message to Pharaoh, and to demand of him leave for the Israelites to go three days journey into the wilderness to serve the God of their fathers, it was necessary that he should be endowed with the power of working miracles to evince the reality of his divine mission. Without a conviction that his claims were well founded, neither Pharaoh nor his own countrymen could reasonably have been expected to listen to the proposals of a man who, though blessed in his youth with a princely education, had come directly on his embassy from the humble employment.
Theology seems to have been likewise acknowledged to be the finger of God, if not by the magicians, at least by Pharaoh; for in a fit of terror he agreed that the Israelites should go and serve the Lord. That he was terrified at the swarms of flies which infested the whole country, except the land of Goshen, will excite no wonder when it is known that the worship of the fly originated in Egypt; whence it was carried by the Captorim to Palestine; by the Pharnicians to Sidon, Tyre, and Babylon; and from these regions to other parts of the world. The denunciation of this plague was delivered to Pharaoh early in the morning, when he was on the banks of the Nile, probably paying his accustomed devotion to his greatest god; and when he found himself and his people tormented by a swarm of subordinate divinities, who executed the judgment of Jehovah in defiance of the power of the supreme numen of Egypt, he must have been convinced, had any candour remained in his mind, that the whole system of his superstitious was a mass of absurdities, and that his gods were only humble instruments at the disposal of a Superior Power. He was not, however, convinced; he was only alarmed, and quickly relapsed into his wonted obstinacy. The fifth plague therefore, the murmur among the cattle, brought death and destruction on his most revered gods themselves. Neither Osiris, nor Isis, nor Ammon, nor Pan, had power to save his brute representatives. The sacred bull, and heifer, and ram, and goat, were carried off by the same malady which swept away all the other herds of deities, these div stercorees, who lived on grass and hay. The impression of this punishment must have been awful on the minds of the Egyptians, but perhaps not equal to that which succeeded it.

In Egypt there were several altars on which human sacrifices were offered; and from the description of the persons qualified to be victims, it appears that those unhappy beings must have been foreigners, as they were required to have bright hair and a particular complexion. The hair of the Israelites was much brighter than that of the Egyptians, and their complexions fairer; and therefore there can be little doubt but that, during their residence in Egypt, they were made to furnish the victims demanded by the bloody gods. These victims being burnt alive on a high altar, and thus sacrificed for the good of the nation, their ashes were gathered together by the priest, and scattered upwards in the air, that a blessing might be entailed on every place to which an atom of this dust should be wafted. Moses too, by the direction of the true God, took ashes of the furnace, probably of one of those very furnaces in which some of his countrymen had been burnt, and sprinkling them towards heaven in the sight of Pharaoh, brought boils and blains upon all the people, of so malignant a nature, that the magicians and the other ministers of the medical gods, with which Egypt abounded beyond all other countries, could not themselves escape the infection.

The powers of darkness were thus foiled; but the heart of the monarch was still hardened. Destruction was therefore next brought on him and his country by the elements, which were among the earliest idol deities not
Theology.

not only of the Egyptians, but of every other polytheistic nation. "The Lord rained hail on the land of Egypt; so that there was hail, and fire mingled with the hail, such as there was none like it in all the land of Egypt since it became a nation. And the hail smote the field of the field, and broke every tree of the field." This was a dreadful calamity in itself; and the horror which it excited in the minds of the people must have been greatly aggravated by the well-known fact, that Egypt is blessed with a sky uncommonly serene; that in the greatest part of it rain has never been seen at any other time since the creation of the world; and that a slight and transient shower is the utmost that in the ordinary course of nature falls anywhere throughout the country. The small quantity of vegetables which was left undestroyed by the fire and the hail was afterwards devoured by locusts, which by a strong east wind were brought in such numbers from Arabia, where they abounded at all times, that they covered the whole face of the earth, and did eat every herb of the land, and all the fruit of the trees, so that there remained not any green thing in the trees or in the herbs of the field through all the land of Egypt.

The ninth plague which the obstinacy of Pharaoh brought upon his country, whilst it severely punished the Egyptians for their cruelty to the Hebrews, struck at the very foundation of all idolatry. We have elsewhere shown, that the first objects of idolatrous worship were the contending powers of light and darkness (see POLYTHEISM); and that the benevolent principle, or the power of light, was everywhere believed to maintain a constant superiority over the power of darkness. Such was the faith of the ancient Persians; and such, as a very learned writer has lately proved, was likewise the faith of the earlier Egyptians. It was therefore with wisdom truly divine, that God, to show the vanity of their imaginations, brought upon these votaries of light, who fancied themselves the offspring of the sun, a preternatural darkness, which, for three days, all the powers of their supreme deity, and his subordinate agents, could not dispel.

The tenth and last plague brought on this idolatrous people was more universally and severely felt than any which had preceded it. It was likewise, in some sense, an instance of the lex talionis, which requires an eye for an eye, and a tooth for a tooth, &c. Moses was commanded, at his first interview with Pharaoh, to say, "Thus saith the Lord, Israel is my son, even my first-born. Let my son go that he may serve me: and if thou refuse to let him go, behold, I will slay thy son, even thy first-born." Before this threat was put in execution, every attempt was made to soften the hardened heart of the obstinate tyrant. The waters of his sacred river were turned into blood, and all the fishes that it contained slain; frogs were brought over all the land to pollute the people; the ministers of religion were rendered so impure by vermin, that they could not discharge their wonted offices; the animals most revered as gods, or emblems of gods, were cut off by a murrain; the elements, that were everywhere worshipped as divinities, carried through the land a devastation, which was completed by swarms of locusts; the ashes from the sacred furnace, which were thought to convey blessings wheresoever they were wafted, were made to communicate incurable disease; a thick and preternatural darkness was spread over the kingdom, in defiance of the power of the great Osiris; and when the hearts of the people and their sovereign continued still obdurate, the eldest son in each family was slain, because they refused to let go Israel, God's first-born. From this universal pestilence the Israelites were preserved by sprinkling the door-posts of their houses with the blood of one of the animals adored in Egypt; a fact which, as it could not be unknown to Pharaoh or his subjects, ought to have convinced that people of the extreme absurdity of their impious superstitions. This effect it seems not to have had; but the death of the first-born produced the deliverance of the Hebrews; for when it was found that there was not a house where there was not one dead, "Pharaoh called for Moses and Aaron by night, and said, Rise up, and get you forth from among my people, both you and the children of Israel; and bless me also. And the Egyptians were urgent upon the people, that they might send them out of the land in haste; for they said, We be all dead men (x)." The wanted obstinacy of the monarch indeed very soon returned; and his subjects, forgetting the loss of their children, joined with him in a vain attempt to bring back to bondage the very people whom they had been thus urgent to send out of the land; but their attempt was defeated by Jehovah, and all who engaged in it drowned in the Red sea.

The God of Israel having thus magnified himself over the Egyptians and their gods, and rescued his people from bondage by such means as must not only have struck terror and astonishment into the whole land, but also have spread his name through all the countries which had any communication with that far-famed nation, proceeded to instruct and exercise the Hebrews for many years in the wilderness. He inculcated upon them the unity of the Godhead; gave them statutes and ideas of the unity of the Godhead; gave them statutes and judgments more righteous than those of any other nation; and by every method consistent with the freedom of moral agency guarded them against the contagion of idolatry and polytheism. He sent his angel before them to keep them in the way, took upon himself the office of their supreme civil governor, and by his presence directed them in all their undertakings. He led them with repeated signs and wonders through the neighbouring nations, continued to try and discipline them.

(x) For this account of the plagues of Egypt, we are indebted to the very valuable Observations on the subject published by Mr. Bryant. We have not quoted the authorities by which the learned and pious author supports his opinions; because it is to be hoped, that for a fuller account of these important transactions the reader will have recourse to his work, of which we have given only a very brief abstract. For much of the preceding parts of this section, we acknowledge our obligations to Bishop Law's admirable discourse on the Several Dispensations of Revealed Religion.
Part II.

THEOLOGY.

them till they were tolerably attached to his government and established in his worship, and introduced them into the Promised Land when its inhabitants were ripe for destruction. At their entrance into it, he gave them a summary repetition of their former laws, with more such ordinances, both of a ceremonial and moral kind, as were both suited to their temper and circumstances, as well as to prejudice, and by degrees to prepare them for, a more perfect dispensation under the Messiah.

The Jewish law had two great objects in view; of which the first was to preserve among them the knowledge of the true God, a rational worshipspring from that knowledge, and the regular practice of moral virtue: and the second was to fit them for receiving the accomplishment of the great promise made to their ancestors, by means analogous to those which a schoolmaster employs to fit his pupils for discharging the duties of master years. Every thing in that law peculiar to itself, its various ceremonies, modes of sacrificing, sanctions by which it was enforced, and the theocratic government by which it was administered, had a direct tendency to promote one or other of these ends; and keeping these ends in view, even the minutest laws, at which impious ignorance has affected to make itself merry, will be discovered by those who shall study the whole system, and are at the same time acquainted with the genius of ancient polytheism, to have been enacted with the most consummate wisdom.

It is not easy for us, who have been long blessed with the light of revelation, to conceive the propriety of all nations, in that early age of the world, to the worship of false gods, of which they were daily adding to the number. It is indeed probable, from many passages of Scripture, as well as from profane authors of the greatest antiquity, that one supreme numen was everywhere acknowledged: but he was considered as an extramundane being, too highly exalted to concern himself with the affairs of this world, the government of which, it was believed, he had delegated to various orders of subordinate deities. Of those deities, some were supposed to have the charge of one nation and some of another. Hence it is, that we read of the gods of Egypt, the gods of the Amorites, and the gods of the different nations around Palestine. None of those nations denied the existence of their neighbour's gods; but all agreed, that while the Egyptians were the peculiar care of Osiris and Isis, the Amorites might be the favourites of Moloch, the Phoenicians of Cronus, and the Philistines of Dagon; and they had no objection occasionally to join with each other in the worship of their respective tutelary deities. Nay, it was thought impious in foreigners, while they sojourned in a strange country, not to sacrifice to the gods of the place. Thus Sophocles makes Antigone say to her father, that a stranger should both reverence and abhor those things which are venerated and abhorred in the city where he resides; and another author, who, though comparatively late, drew much of his information from ancient writings which are now lost, assures us, that this complaisance proceeded from the belief that the several parts of the world were from the beginning distributed to several powers, of which each had his peculiar allotment and residence.

From this notion of local divinities, whose power or partial fondness was confined to one people, the Israelites, on their departure from Egypt, appear not to have been free (2). Hence it is, that when the true God first tells them, by their leader Moses, that if they would obey his voice indeed and keep his covenant, then they should be a peculiar treasure to him above all people: to prevent them from supposing that he shared the earth with the idols of the heathen, and had from partial fondness chosen them for his portion, he immediately adds, for all the earth is mine. By this declaration he gave them plainly to understand that they were chosen to be his peculiar treasure for some purpose of general importance; and the very first article of the covenant which they were to keep, that they should have no other gods but him. So inveterate, however, was the principle which led to an intercommunion of the objects of worship, that they could not have kept this article of the covenant but in a state of separation from the rest of mankind; and that separation could neither have been effected nor continued without the visible providence of the Almighty watching over them as his peculiar treasure. This we learn from Moses himself, who, when interceding for the people after their idolatrous worship of the golden calf, and intreating that the presence of God would still accompany them, adds these words: “For wherein shall it be known here that I and thy people have found grace in the eyes of thy sight? Is it not in that thou goest with us? So shall we be separated, I and thy people, from all the people that are on the face of the earth.” On this separation every thing depended; and therefore to render it the more secure, Jehovah was graciously pleased to become likewise their supreme Magistrate, making them a “kingdom of priests and a holy nation,” and delivering to them a digest as well of their civil as of their religious laws.

The Almighty thus becoming their King, the government of their nation was properly a THEOCRACY, in theocracy which the two societies, civil and religious, were of course incorporated. They had indeed after their settlement in the Promised Land, at first, temporary judges occasionally raised up; and afterwards permanent magistrates called kings, to lead their armies in war, and to give vigour to the administration of justice in peace; but neither those judges nor those kings could abrogate a single law of the original code, or make the smallest addition to it but by the spirit of prophecy. They cannot.

(2) It is not indeed evident that they had got entirely quit of this absurd opinion at a much later period. Jephtha one of their judges, who, though half pagenated (as Warburton observes) by a bad education, had probably as correct notions of religion as an ordinary Israelite, certainly talked to the king of Ammon as if he had believed the different nations of the earth to be under the immediate protection of different deities: “Wilt not thou (says he) possess that which Che摩sh thy God giveth thee to possess? So whomsoever the Lord our God shall drive out from before us, them will we possess.” (Judges xi. 24.)

Vol. XX. Part I.
THEOLOGY.

To keep them warmly attached to their public worship that worship was loaded with opulence and magnificence from the rites, and so completely incorporated with their civil policy as to make the same things at once duties of religion and acts of state. The service of God was indeed so ordered as to be the constant business as well as entertainment of their lives, supplying the place of all other entertainments; and the sacrifices which they were commanded to offer on the most solemn occasions; were of such animals as the Egyptians and other Heathens deemed sacred.

Thus a heifer without blemish was in Egypt held sacred to the goddess Isis, and worshipped as the representative of that divinity; but the same kind of heifer by the ritual law of the Hebrews commanded to be burnt without the camp, as the vilest animal, and the water of separation to be prepared from her ashes. The goat was by the Egyptians held in great veneration as emblematical of their ancient god Pan, and sacrifices of the most abominable kind were offered to the impure animal (see Pasht); but God, by his servant Moses, enjoined the Israelites to offer goats themselves as sacrifices for sin, and on one occasion to dismiss the live animal loaded with malefactions into the wilderness. The Egyptians, with singular zeal, worshipped a calf without blemish as the symbol ofApis, or the god of fertility; and it appears from the book of Exodus, that the Israelites themselves had been infected with that superstition. They were, however, so far from being permitted by their Divine lawgiver to consider that animal as sacred, that their priests were commanded to offer for themselves a young calf as a sin-offering. No animal was in Egypt held in greater veneration than the ram, the symbol of their god Ammon, one of the constellations. It was therefore with wisdom truly divine, that Jehovah, at the institution of the passover, ordered his people to kill and eat a young ram on the very day that the Egyptians began their annual solemnities in honour of that animal as one of their greatest gods; and that he enjoined the blood of this divinity to be sprinkled as a sign on the two side-posts and upper door-post of the house in which he was eaten. Surely it is not in the power of imagination to conceive a ritual better calculated to cure the Israelites of their propensity to idol worship, or to keep them separate from the people who had first given them that propensity, than one which enjoined them to offer in sacrifice the very creatures which their superstitious masters had worshipped as gods." Shall we (said Moses) sacrifice the abominations of the Egyptians before their eyes, and will they not stone us? But it was not against Egyptian idolatry only that the ritual law was framed: the nations of Syria, in the midst of whom the Israelites were to dwell, were addicted to many cruel and absurd superstitions, against which it was as necessary to guard the people of God as against the brute-worship of Egypt. We need not inform any reader of the book of Moses that those nations worshipped

(A) Of these precepts we think it not necessary, in an abstract so short as this, to waste the reader's time with a formal and laboured defence. To the decalogue no objection can be made by any man who admits the obligations of natural religion; for, except the observation of the Sabbath-day, it enjoins not a single duty which does not by the confession of all men result from our relations to God, ourselves, and our fellow-creatures.
Part II. Theology from the fall of Adam to the coming of Christ.

THEOLOGY.

Theology from the fall of Adam to the coming of Christ.

Thou shalt not wear a garment of divers sorts, or of woolen and linen together. But his wonder will cease when he knows that all these were practices from which the Sabian idolators of the east expected the greatest advantages. Their belief in magic and judicial astrology led them to imagine, that by sowing different kinds of corn among their vines they should propitiate the gods which were afterwards known in Rome by the names of Bacchus and Ceres; that, by yoking animals so heterogeneous as the ox and the ass in the same plough, they should by a charm secure the favour of the deities who presided over the affairs of husbandry; and that a garment composed of linen and woollen, worn under certain conjunctions of the stars, would protect its owner, his flocks, his herds, and his field, from all malign influences, and render him in the highest degree prosperous through the whole course of his life. But magical ceremonies were always performed in order to secure propitious good or evil; see MAGIC, p. 31. 33. and therefore such ceremonies, however unimportant in themselves, were in that age most wisely prohibited in the Mosaic law, as they naturally led those who were addicted to them to the worship of idols and impure spirits.

If the whole ritual of the Jewish economy be examined in this manner, every precept in it will be found to be directed against some idolatrous practice of the age in which it was given. It was therefore admirably calculated to keep the Israelites separate people, and to prevent too close an intercourse between them and their Gentile neighbours. The distinction made by their law between clean and unclean animals (see SLAVERY, N. 33.) rendered it impossible for them, without a breach of that law, to eat and drink with their idolatrous neighbours; their sacred and civil ceremonies being directly levelled against the Egyptian, Zabian, and Canaanitish superstitions, had a tendency to generate in their minds a contempt of those superstitions; and that contempt must have been greatly increased by their yearly, monthly, and daily sacrifices, of the very animals which their Egyptian masters had worshipped as gods.

That these laws might have the fuller effect on minds the most gross and carnal, they were all enforced by temporal and spiritual sanctions. Hence it is that Moses assured them that if they would hearken to God's judgments, and keep them, and do them, they should be blessed above all nations; people; threatening them at the same time with utter destruction if they should at all walk after other gods, and serve them, and worship them. Nor were these temporal rewards and punishments held out only to the nation as a collective body; they were promised and threatened to every individual in his private capacity for the certain consequences of his obedience or disobedience. Every particular Hebrew was commanded to honour his father and mother, that it might go well with him, and that his days might be prolonged; whilst he who cursed his father or his mother was surely to be put to death. Against every idolater, and even against the willful transgressor of the ceremonial law, God repeatedly declared that he would set his face, and would cut off that man from among his people: and that individuals, as well as the nation, were in this life actually rewarded and punished according to their deserts, has been proved by Bishop Warburton. Indeed the Mosaic...
THEOLOGY.

Theology from the fall of Adam to the coming of Christ.

Theologic law, taken in its literal sense, holds out no other prospects to the Israelites than temporal happiness; such as health, long life, peace, plenty, and dominion, if they should keep the covenant; and temporal misery, viz. diseases, immature death, war, famine, want, subjection, and captivity, if they should break it. "See (says Moses), I have set before thee this day life and good death, and evil; in that I command thee this day to love the Lord thy God, to walk in his ways, and to keep his commandments, and his statutes, and his judgments, that thou mayest live and multiply; and the Lord thy God shall bless thee in the land whither thou goest to possess it. But if thine heart turn away, so that thou wilt not hear, but shalt be drawn away, and worship other gods, and serve them; I denounce unto you this day, that ye shall surely perish, and that ye shall not prolong your days upon the land whither thou passest over Jordan to possess it." And elsewhere, having informed them that, upon their apostasy, their land should be rendered like Sodom and Gomorrah, he adds, that all men should know the reason of such barrenness being brought upon it, and should say, "Because ye have forsaken the Lord God of your fathers, which made them with him when he brought them forth out of the land of Egypt, the anger of the Lord was kindled against this land, to bring upon it all the curses that are written in this book." From this fact, which scarcely any man of letters will venture to deny, some divines have concluded, that the ancient Israelites had no hope whatever beyond the grave; and that in the whole Old Testament there is not a single intimation of a future state. That many of the lower classes, who could neither read nor write, were in this state of darkness, may be true; but it is impossible that those who understood the book of Genesis could be ignorant that death came into the world by the transgression of their first parents, and that God had repeatedly promised to redeem mankind from every consequence of that transgression. They must likewise have known that, before the deluge, Enoch was translated into heaven without tasting death; that afterwards Elijah had the same exemption from the common lot of humanity; and that, as God is no respecter of persons, every one who served him with the zeal and fidelity of these two prophets would, by some means or other, be made capable of enjoying the same rewards. The God of Abraham, Isaac, and Jacob, was not the God of the dead, but of the living.

In the earliest periods of their commonwealth, the Israelites could, indeed, only infer, from different passages of their sacred books, that there would be a general resurrection of the dead, and a future state of rewards and punishments; but from the writings of the prophets it appears, that before the Babylonish captivity that doctrine must have been very generally received. In the Psalms, and in the prophecies of Isaiah, Daniel, and Ezekiel, there are several texts which seem to us to prove incontrovertibly, that, at the time these inspired books were written, every Israelite who could read the scripture must have had some hopes of a resurrection from the dead. We shall consider two of these texts, because they have been quoted by a very learned and valuable writer in support of an opinion the reverse of ours.

In a sublime song, composed with a view to incite the people to confidence in God, the prophet Isaiah has these remarkable words: "Thy dead men shall live; together with my dead body shall they arise. Awake and sing, ye that dwell in the dust: for thy dew is as the dew of herbs, and the earth shall cast out the dead." We agree with Bishop Warburton that these words are figurative, and that they were uttered to give the Israelites consolation in very disastrous times. This opinion is confirmed by the purpose of the prophet was to assure them, that though their community should, in Babylon, be as completely dissolved as a dead body reduced to dust, yet God would restore them to their own land, and raise that community again to life. This was indeed a prophecy only of a temporal deliverance; but as it is expressed in terms relating to the death and resurrection of man, the doctrine of a resurrection must then have been well known, and generally received, or such language would have been altogether unintelligible.

The prophet Ezekiel, when the state of things was most desperate, is carried by the Spirit into a valley full of dry bones, and asked this question: "Son of man, can these bones live?" To which he answers: "O Lord God, thou knowest." He is not asked if all the dead would rise at the last day; but only if the particular bones then presented to him could live at that time, and while other bones were mouldering in corruption: and to such a question we cannot conceive any answer that a man brought up in the belief of a general resurrection could have given, but—"O Lord God, thou knowest." Had Ezekiel been a stranger to the doctrine of a general resurrection, or had he not believed that doctrine, he would doubtless have answered the question that was put to him in the negative; but convinced that all men are at some period to rise from the dead, "that every one may receive the things done in his body, according to that he hath done, whether it be good or bad," he very naturally said, that God alone knew whether the bones then exhibited to him in the valley would rise before the general resurrection.

But though the more intelligent and righteous Israelites certainly "all died in faith, and not having received the promises, but having seen them afar off, themselves were persuaded of them and embraced them, confessing that they were strangers and pilgrims on earth, who desired a better country, that is, a heavenly one," we are not to suppose that this heavenly desire arose from anything taught in the law of Moses. That law, when taken by itself, as unconnected with prior and subsequent revelations, makes no mention whatever of a heavenly inheritance, which St Paul assures us was given 160 years before to Abraham by a promise which may be traced back to the first ray of comfort vouchsafed to fallen man in the sentence passed on the original deceiver. "Wherefore then served the law? It was added (says the apostle), because of transgressions, till the Seed should come to whom the promise was made." The transgressions here alluded to were polytheism and idolatry, which, with a train of cruel and detestable vices, had overspread the whole world; and the primary attention of the law was to stem the torrent of these corruptions, for which we have seen it was admirably calculated; and, like a schoolmaster, to instruct the Israelites in the unity and worship of Jehovah, and thus by degrees bring them to Christ.

But
THEOLOGY.

But though it is apparent that a future state of rewards and punishments made no part of the Mosaic dispensation, yet the law had certainly a spiritual meaning to be understood when the fulness of time should come. Every Christian sees a striking resemblance between the sacrifice of the paschal lamb, which delivered the Israelites from the destroying angel in Egypt, and the sacrifice of the Lamb of God, which taketh away the sin of the world. Indeed the whole ritual of sacrifice must have led the more intelligent of them to faith in a future sacrifice; by which, while the head of the seed of the woman should be bruised, the head of the serpent should be completely crushed (see SACRIFICE) and as prophets were raised up from time to time, to prepare them for the coming of the Messiah, and to foretell the nature of his kingdom, there can be no doubt but that those inspired teachers would lay open to them, as far as was expedient, the temporary duration of the Mosaic law, and convince them that it was only the shadow of better things to come. From the nature of their ritual, and the different prophecies vouchsafed them, which became more and more evident as they approached the accomplishment, they must surely have been led to expect redemption from the curse of the fall by the sufferings of their Messiah; but that any one of them knew precisely the manner in which they were to be redeemed, and the nature of that religion which was to supersede their own, is wholly incredible. Such knowledge would have made them impatient under the yoke of ordinances to which they were subjected; for after the Christian faith came into full splendour, mankind could be no longer under the tutelage of such a schoolmaster as the law, which "had only a shadow of good things; and so far from their reality, not even the very image of them."

Through these shadows, however, the Jews, aided by the clearer light of prophecy, though it too shone in a dark place, might have seen enough of God's plan of redemption to make them acknowledge Jesus of Nazareth, when he came among them working miracles of mercy, for the Messiah so long promised to their forefathers, and in whom it was repeatedly said, that all the nations of the earth should be blessed. Much care was taken to prepare the descendents of Abraham for the coming of the Prince of Peace, and it must not suppose that God was a respecter of persons, and that the rest of the world was totally neglected. The dispersion of the ten tribes certainly contributed to spread the knowledge of the true God among the eastern nations. The subsequent captivity of the tribes of Judah and Benjamin must have confirmed that knowledge in the great empires of Babylon and Persia; and that particular providence of God which afterwards led Ptolemy Philadelphus to have the Jewish scriptures translated into the Greek language, laid the divine oracles open to the study of every accomplished scholar. At last, when the arms of Rome had conquered the civilized world, and rendered Judea a province of the empire; when Augustus had given peace to that em-

pire, and men were at leisure to cultivate the arts and sciences; when the different sects of philosophers had by their disputations whetted each other's understandings, so that some of them was disposed to submit to an imposture; and when the policy of the Roman government was such that intelligence of every thing important was quickly transmitted from the most distant provinces to the capital of the empire; "when that fulness of time was come, God sent forth his Son made of a woman, made under the law, to redeem them that were under the law, that we might receive the adoption of sons," and be restored to that inheritance of which the forfeiture introduced the several dispensations of revealed religions into the world.

SECT. V. View of Theology more peculiarly Christian.

MANKIND being trained by various dispensations of providence for the reception of Jesus Christ, and the time fixed by the prophets for his coming being arrived, "a messenger was sent before his face to prepare the way before him by preaching the baptism of repentance for the remission of sins." This messenger was John the Baptist, a very extraordinary man, and the greatest of all the prophets. His birth was miraculous, the scene of his ministry the wilderness, his manners austere, and his preaching upright, without respect of persons. He frankly told his audience that he was not the Messiah, that the Messiah would soon appear among them, that he was mightier than himself, and that he would baptize them with the Holy Ghost and with fire."

Mightier indeed he was; for though born of a woman the Messiah was not the son of a human father; and though living for the first thirty years of his life in obscurity and poverty, he was the lineal descendant of David, and heir to the throne of Israel. But the dignity of his human descent, great as it was, vanishes from consideration when compared with the glory which he had with his Father before the world was. The Jewish dispensation was given by the ministry of Moses, and illustrated by subsequent revelations vouchsafed to the prophets; the immediate author of the Christian religion is the AION or the second person of the blessed Trinity, of whom St John declares, that he was in the beginning with God, and was God; that all things were made by him; and that without him was not anything made that was made."

We have already proved that in the one Godhead there is a Trinity of persons; and that the AION is one of the three, is apparent from these words of the apostle, and from many other passages of sacred scripture. Thus he is called the Lord of hosts himself; the first and the last, besides whom there is no God; the most high God; God blessed for ever; the mighty God, the everlasting Father, Jehovah our righteousness; and the only wise God our Saviour (b).

This great Being, as the same apostle assures us, was made flesh, and dwelt among men; not that the divine nature was or could be changed into humanity, for God is immutable, the same almighty and incomprehensible

(b) Isaiah viii. 13, 14. compared with 1 Peter ii. 7, 8.; Isaiah vi. 5. compared with John xii. 41.; Isaiah lixiv. 6. compared with Revelation xxii. 13.; Psalm lxxviii. 56. compared with 1 Corinthians x. 9.; Romans ix. 5.; Isaiah ix. 6.; Jeremiah xxiii. 6.; Jude.
Theology

The Spirit yesterday, to-day, and for ever; but the Word or second person in the godhead, assuming a human soul and body into a personal union with himself, dwelt upon earth as a man, veiling his divinity under mortal flesh. Hence he is said elsewhere to have been "manifested in the flesh," and "to have taken upon him the nature of man," phrases of the same import with that which asserts the Word to have been made flesh.

This incarnation of the Son of God is perhaps the greatest mystery of the Christian faith, and to which ancient and modern heretics have offered the most plausible objections. The doctrine of the Trinity is indeed equally incomprehensible; but the nature of God and the mode of his subsistence, as revealed in scripture, no man, who thinks, can be surprised that he does not comprehend; for a revelation which should teach nothing mysterious on such a subject would be as incredible and as useless as another which contained nothing but mystery. The difficulty respecting the incarnation, which forces itself on the mind, is not how two natures so different as the divine and human can be so intimately united as to become one person; for this union in itself is not more inconceivable than that of the soul and body in one man; but that which at first is apt to stagger the faith of the reflecting Christian is the infinite distance between the two natures in Christ, and the comparatively small importance of the object, for the attainment of which the eternal Son of God is said to have taken on him our nature.

Upon mature reflection, however, much of this difficulty will vanish to him who considers the ways of Providence, and attends to the meaning of the words in which this mystery is taught. The importance of the object for which the Word descendened to be made flesh, we cannot adequately know. The oracles of truth indeed inform us, that Christ Jesus came into the world to save sinners; but there are passages scattered through the New Testament, which indicate, not obscurely, that the influence of his sufferings extends to other worlds besides this: and if so, who can take upon us to say, that the quantity of good which they may have produced was not of sufficient importance to move even to this condescension a Being who is emphatically styled love?

But let us suppose that every thing which he did and taught, and suffered was intended only for the benefit of man, we shall, in the daily administration of providence, find other instances of the divine condescension; which, though they cannot be compared with the incarnation of the second person in the blessed Trinity, are yet sufficient to reconcile our understandings to that mystery when revealed to us by the Spirit of God. That in Christ there should have dwelt on earth "all the fulness of the Godhead bodily," is indeed a truth by which the devout mind is overwhelmed with astonishment; but it is little less astonishing that the omnipotent Creator should be intimately present at every instant of time to the meanest of his creatures, "upholding all things, the vilest reptile as well as the most glorious angel, by the word of his power." Yet it is a truth self-evident, that without this constant presence of the Creator, nothing which had a beginning could continue one moment in being; that the visible universe would not only crumble into chaos, but vanish into nothing; and that the souls of men, and even the most exalted spirits of creation, would instantly lose that existence, which, as the Word was not of itself, and is not necessary, must depend more peculiarly on the will of Him from whom it was originally derived. See Metaphysics, No. 272—276, and Providence, No. 3.

In what particular way God is present to his works, we cannot know. He is not diffused through the universe like the anima mundi of the ancient Platonists, or that modern idol termed the substratum of space (Metaphysics, No. 329, 340): but that he is in power as intimately present to every atom of matter as when he first brought it into existence, is equally the dictate of sound philosophy and of divine revelation; for "in him we live and move and have our being," and power without substance is inconceivable. If then the divine nature be not debased, if it cannot be debased by being constantly present with the vilest reptile on which we tread, why should our minds recoll from the idea of a still closer union between the second person of the ever blessed Trinity and the body and soul of Jesus Christ? The one union is indeed different from the other, but we are in truth equally ignorant of the nature of both. Reason and revelation assure us that God must be present to his works to preserve them in existence; and revelation informs us farther, that one of the persons in the Godhead assumed human nature into a personal union with himself, to redeem myriads of rational creatures from the miserable consequences of their own folly and wickedness. The importance of this object is such, that, for the attainment of it, we may easily conceive that he who condescends to be potentially present with the worms of the earth and the grass of the field, would condescend still farther to be personally present with the spotless soul and body of a man. Jesus Christ lived indeed a life of poverty and suffering upon earth, but his divine nature was not affected by his sufferings. At the very time when, as a man, he had not a place where to lay his head; as God, he was in heaven as well as upon earth, dwelling in light inaccessible; and while, as a a man, he was increasing in wisdom and stature, his divinity was the fulness of him who filleth all in all, and from whom nothing can be hid.

Perhaps the very improper appellation of mother of God, which at an early period of the church was given to the Virgin Mary, may have been one cause of the reluctance with which the incarnation has been admitted; for we have elsewhere observed (see Nestorius), such language, in the proper sense of the words, implies what those, by whom it is used, cannot possibly believe to be true; but it is not the language of scripture. We are there taught, that "Christ being in the form of God, thought it no robbery to be equal with God; but made himself of no reputation, and took upon him the form of a servant, and was made in the likeness of man+;" that "God sent his Son made of a woman, made under the law, to redeem them that were under the law, that we might receive the adoption of sons;" and that "the word who was in the beginning with God, and was God, by whom all things were created, was made flesh, and dwelt among men (who beheld his glory);" and that, "the word who was in the beginning with God, and was God, by whom all things were created, was made flesh, and dwelt among men (who beheld his glory, the glory as of the only begotten of the Father), full of grace and truth." But we are now taught, that, as God, he had a mother! It was the very principle of personality and individual existence in the universe.
Part II.

THEOLOGY.

Mary's son, was union with the uncreated Word; and this doctrine is thought to imply the miraculous conception, which is recorded in the plainest terms by two of the evangelists; for he was conceived by the Holy Ghost and born of a virgin; but, as God, he had been begotten from all eternity of the Father, and in order of nature was prior to the Holy Ghost. This is evident from the appellation of \( \text{\textit{Logos}} \) given to him by St. John; for the term being used in that age, both by the Jewish rabbis and the heathen philosophers, to denote the second divine subsistence, which they considered as an eternal and necessary emanation from the first, sometimes called \( \text{\textit{Himeros}} \) and sometimes \( \text{\textit{Physis}} \); and the apostle giving no intimation of his using the word in any uncommon sense, we must necessarily conclude, that he meant to inform us that the divinity of Christ is of eternal generation. That term the \( \text{\textit{Logos}} \) was used in this sense by the later Platonists, and in all probability by Plato himself, we have sufficiently shewn in another place (see PLATONISM); and that a similar mode of expression prevailed among the Jews in the time of St. John, is apparent from the Chaldee paraphrase; which, in the 10th psalm, instead of the words "the Lord said unto my Lord," has, "the Lord said unto his word.

Again, where we are told in the Hebrew that Jehovah said to Abraham, "I am thy shield and thy exceeding great reward," we read in the Chaldee, "my word is thy shield, and thy exceeding great reward." Where it is said, "your new moons and your appointed feasts your soul hateth," the paraphrast hath it, "my word hateth," and where it is said, that "Israel shall be saved in the Lord with an everlasting salvation," it is in the same paraphrase it is, "Israel shall be saved by the word of the Lord with everlasting salvation." But there is a passage in the Jerusalem Targum which puts it beyond a doubt, that by the \( \text{\textit{Logos}} \) the Jews understood a divine person begotten of his Father before all worlds; for commenting on Genesis iii. 22. the authors of that work thus express themselves: "The word of the Lord said, behold Adam, whom I created, is the only begotten upon earth, as I AM THE ONLY BEGOTTEN IN HEAVEN!" in conformity with which, Philo introduces \( \text{\textit{Logos}} \) speaking thus of himself: \( \text{\textit{Kos ygap}} \) is \( \text{\textit{logos}} \) \( \text{\textit{hēmēra}} \), \( \text{\textit{gēs}} \), \( \text{\textit{anagōs}} \). I AM NEITHER UNBEGOTTEN, AS GOD, NOR BEGOTTEN AFTER THE SAME MANNER AS YOU ARE.

From these quotations we may justly conclude, that the Nicene fathers expressed themselves properly when they declared that the only begotten Son of God was begotten of his Father before all worlds, and is God of God; for if St. John had believed the \( \text{\textit{Logos}} \) or \( \text{\textit{Word}} \) to be unbegotten, contrary to the belief of all who made more sense of the phrase at the time when he wrote, he would not have expressed his dissent from the generally received opinion. This however he is so far from doing, that he gives the plainest confirmation of that opinion, by declaring, that "behold the glory of the Word incarnate as the glory of the only begotten of the Father;" for this declaration is true only of the divinity of Christ, his human nature not being begotten of the Father, but conceived by the Holy Ghost of the Virgin Mary. Hence our blessed Lord assures us, that "as the Father has life in himself, so hath he given the Son to have life in himself;" that "the Son can do nothing of himself, but what he seeth the Father do;" and that "he knew the Father, because he was from him and sent by him;" We must therefore agree with Bishop Pearson (c), that "though the Father and Son are both truly God, and therefore equal in respect of nature, yet the one is greater than the other, as being the fountain of the Godhead. The Father is God, but not of God; Light, but not of Light. Christ is God, but of God; Light, but of Light. There is no difference or inequality in the nature or essence, because in both; but the Father of our Lord Jesus Christ hath that essence of himself, from none; Christ hath the same essence, not of himself, but from him."

The great purpose for which this divine person was sent into the world, was to bruise the head of the serpent, and restore mankind to the inheritance which had been forfeited by Adam's transgression. Every dispensation of Providence from the fall had been preparatory to this restoration. Prophets had been raised from time to time to preserve in the early ages of the world the knowledge and worship of the true God: the children of Abraham had been separated from the surrounding nations for the same purpose; and by the dispersion of the ten tribes, the captivity of the other two in Babylon, and the translation of the Hebrew scriptures into the Greek language, much of the knowledge which had been revealed to the Israelites was gradually diffused over the eastern world.

But while the Jews were thus rendered the instruments of enlightening the heathen nations of antiquity, their intercourse with those nations made them almost unavoidably acquainted with the philosophy which was cultivated among the Chaldeans, the Persians, and the Egyptian Greeks; and ingrafting many of the opinions derived from those schools upon the doctrines of Moses and the prophets, they corrupted their own religion while
Theology

while they improved that of their neighbours. Hence, by the time that Christ came among them, they had made the word of God of none effect through a number of idle fancies which they inculcated on the people; for the traditions of the elders; and as they had attached themselves to different masters in philosophy, their unauthorised opinions were of course different according to the different sources whence they were drawn. The peculiar tenets of the Essenes seem to have been a species of mystic Platonism. The Pharisees are thought to have derived their origin from a Jewish philosopher of the Peripatetic school; and the resemblance between the doctrines of the Sadducees and the philosophy of Epicurus has escaped no man's observation.

Though these sects maintained mutual communion in public worship, they abhorred each other's distinguishing tenets; and their wranglings had nearly banished from them every sentiment of true religion. They agreed, however, in the general expectation of the Messiah promised to their fathers; but, unhappily for themselves, expected him as a great, and temporal prince. To this mistake several circumstances contributed: some of their prophets had foretold his coming in lofty terms, borrowed from the ritual law, and the splendour of earthly monarchs. The necessity of casting this veil over those living oracles we have shown in another place (see Prophecy, No. 17.). At the time when the predictions were made, the Mosaic system had not run out half its course, and was therefore not to be exposed to popular contempt by an information, that it was only the harsh rudiment of one more easy and perfect. To prevent, however, all mistakes in the candid and impartial, when the Messiah should arrive with the credentials of miraculous powers, other prophets had described him in the clearest terms as having no form nor comeliness, as a sheep dumb before his shearsers, and as a lamb brought to the slaughter; but the Jews had suffered so much from the Chaldeans, the Greeks, and other nations by whom they had been conquered, and were then suffering so much from their masters the Romans, that they could think of no deliverance greater than that which should rescue their nation from every foreign yoke.

What men earnestly wish to be true, they readily believe. Hence that people, losing sight of the yoke under which they and the whole human race were brought by the fall of Adam, mistaking the sense of the blessing promised to all nations through the seed of Abraham, and devoting their whole attention to the most magnificent descriptions of the Messiah's kingdom, expected in him a prince who should conquer the Romans, and establish on earth a universal monarchy, of which Jerusalem was to be the metropolis.

As our Saviour came for a very different purpose, the first object of his mission was to rectify the notions of his erring countrymen, in order to fit them for the deliverance which they were to obtain through him. Accordingly, when he entered on his office as a preacher of righteousness, he embraced every opportunity of inveighing against the false doctrines taught as traditions of the elders; and by his knowledge of the secrets of all hearts, he exposed the vile hypocrisy of those who made a gain of godliness. The Jews had been led, by their separation from the rest of the world, to consider themselves as the peculiar favourites of Jehovah; and the consequence was, that, contrary to the spirit of their own law, and the explicit doctrines of some of their prophets, they looked on all other nations with abhorrence, more particularly on people physically impure. These prejudices the Lord laboured to eradicate. Having desired a lawyer, by whom he was tempted, to read that part of the law of Moses which commanded the Israelites to love their neighbours as themselves, he compelled him, by means of a parabolical account of a compassionate Samaritan, to acknowledge, that under the denomination of neighbour the divine lawgiver had comprehended all mankind as the objects of love. The importance of St. Luke in which Moses held the ritual law, and to which, as 2. 21. 35., the means of preserving its votaries from the contagion of idolatry, it was justly intimated, had led the Jews to consider every ceremony of it as of intrinsic value and perpetual obligation: but Jesus brought to their recollection God's declared preference of mercy to sacrifice; he showed them that the weightier matters of the law, judgment, mercy, and faith, called to their regard in the first place, and its ceremonial observances only in the second; and taught them, in conformity with the predictions of their own prophets, that the hour was about to come when the worship of God should not be confined to Jerusalem, but that "true worshipers" should everywhere worship the Father in spirit and in truth.

It being the design of Christ's coming into the world to break down the middle wall of partition between the Jews and Gentiles, and to introduce a new dispensation of religion which should unite all mankind as brethren in the worship of the true God, and fit them for the enjoyment of heaven; he did not content himself with merely restoring the moral part of the Mosaic law to its primitive purity, disencumbered of the corrupt glosses of the Scribes and Pharisees, but added to it many spiritual precepts, which, till they were taught by him, had never occurred either to Jew or Gentile. The Hebrew lawgiver had prohibited murder under the penalty of death; but Christ extended the prohibition to causeless anger, and to contemptuous treatment of our brethren, commanding his followers, as they valued their everlasting salvation, to forgive their enemies, and to love all mankind. Adultery was forbidden by the law of Moses as a crime of the deepest dye; but Jesus said to his disciples, "that whosoever looketh on a woman to lust after her, hath committed adultery with her already in his heart," and is of course liable to the Divine vengeance. The lex talionis was in force among the Jews, so that the man who had deprived his neighbour of an eye or a tooth, was to suffer the loss of an eye or a tooth himself; but this mode of punishment, which inflicted blemish for blemish, though suited to the hardness of Jewish hearts, being inconsistent with the mild spirit of Christianity, was abolished by our blessed Lord, who severely prohibited the indulgence of revenge, and commanded his followers to love even their enemies. Perjury has in every civilized nation been justly considered as a crime of the highest atrocity, and the Mosaic law doomed the false witness to bear the punishment, whatever it might be, which he intended by swearing falsely to bring on his brother; but the Author of the Christian religion forbade not only false swearing, but swearing at all, except on solemn occasions, and when an oath should be required by legal authority. See OATH.

By thus restoring the law to its original purity, and in
Part II.

Theology

in many cases extending its sense, the blessed Jesus executed the office of a Prophet to the lost sheep of the house of Israel; but had he not been more than an ordinary prophet, he could not have abrogated the most trivial ceremony of it, nor even extended the sense of any of its moral precepts; for their great lawgiver had told them, that “the Lord their God would raise up unto them but one Prophet, like unto him, to whom they should hearken.” That Prophet was by themselves understood to be the Messiah, whom they expected to tell them all things. It was necessary therefore that Jesus, as he taught some new doctrines, and therefore plainly indicated that greater changes would soon be introduced, should vindicate his claim to that exalted character which alone could authorize him to propose innovations. This he did in the simplest manner, by fulfilling prophecies and working miracles (See Miracle and Prophecy); so that the unprejudiced part of the people readily acknowledged him to be of a truth “that prophet which should come into the world—the Son of God, and the King of Israel.” He did not, however, make any change in the national worship, or assume to himself the smallest civil authority. He had submitted to the rite of circumcision, and strictly performed every duty, ceremonial as well as moral, which that covenant made incumbent on other Jews; thus fulfilling all righteousness. Though the religion which he came to propagate was in many respects contrary to the ritual law, it could not be established, or that law abrogated, but in consequence of his death, which the system of sacrifices was appointed to prefigure; and as his kingdom, which was not of this world, could not commence till after his resurrection, he yielded during the whole course of his life a cheerful obedience to the civil magistrate, and wrought a miracle to obtain money to pay the tribute that was exacted of him. Being thus circumstanced, he chose from the lowest and least corrupted of the people certain followers, whom he treated with the most endearing familiarity for three years, and commissioned at his departure to promulgate such doctrines as, consistently with the order of the divine dispensations, he could not personally preach himself. With these men, during the course of his ministry on earth, he went about continually doing good, healing the sick, casting out devils, raising the dead, reproving vice, preaching righteousness, and instructing his countrymen, by the most perfect example which was ever exhibited in the world, of whatsoever things are true, or honest, or just, or pure, or lovely, or of good report. The Scribes and Pharisees, however, finding him not that conqueror whom they vainly expected, becoming envious of his reputation among the people, and being filled with rancour against him for detecting their hypocritical arts, delivered him up to the Roman governor, who, though convinced of his innocence, yielded to the popular clamour, and crucified him between two thieves, as an enemy to Caesar.

Just before he expired, he said, It is finished, intimating that the purpose was now fulfilled for which he had come into the world, and which, as he had formerly told his disciples, “was not to be ministered unto, but to minister, and to give his life a ransom for many.” For his blood, as he assured them at the institution of the Eucharist, “was to be shed for the remission of sins.” That Christ died voluntarily for us, the just for the unjust, and that “there is none other name under heaven” Vol. XX. Part I. 

ven given among men whereby we must be saved,” in Theology, the uniform doctrine of the prophets who foretold his coming, of John the Baptist who was his immediate herald, and of the apostles and evangelists who preached the gospel after his ascension into heaven. Thus Isaiah says of the Messiah, that “he was wounded for our transgressions, and bruised for our iniquities; the chastisement of our peace was upon him, and with his stripes we are healed; that we all like sheep gone astray, turning every one to his own way, and that the Lord laid on him the iniquity of us all; that he was cut off out of the land of the living, and stricken for the transgression of God’s people; and his soul or life was made an offering for sin; and that he bore the sin of many, and made intercession for the transgressors.” The Baptist, “when he saw Jesus coming unto him, said to the people, Behold the Lamb of God, which taketh away the sin of the world; plainly intimating that his death was to be a sacrifice, since it was only as a sacrifice that the Jews could form any conception of a lamb taking away sin. The epistles of St Paul are so full of the doctrine of Christ’s satisfaction, that it is needless to quote particular texts in proof of it. He tells the Romans, that Jesus Christ was set forth to be a propitiation through faith in his blood; he was delivered for our offences, and raised again for our justification; that he died for the ungodly; and that God commendeth his love towards us, in that while we were yet sinners Christ died for us.” He assures the Corinthians that Christ died for all; that “they who live should not henceforth live unto themselves, but to him who died for them and rose again; and that God made him to be sin for us, who knew no sin, that we might be made the righteousness of God in him.” He informs the Galatians, that Christ “gave himself for our sins, that he might deliver us from this present evil world, according to the will of God and our Father; and that he redeemed us from the curse of the law, being made a curse for us.” St Peter and St John speak the very same language; the former teaching us, that “Christ suffered for us, and bare our sins in his own body on the tree; the latter, that the blood of Jesus Christ cleanseth us from all sin, and he is the propitiation for our sins; and not for our sins only, but also for the sins of the whole world.” That John says, he came into the world for the purpose of suffering, and of giving proofs from his own words: for “no man (said he) taketh my life from me, but I lay it down of myself.” If I have power to lay it down, and I have power to take it again. This commandment have I received from my Father.” And that he voluntarily laid it down for mankind, is evident from his calling himself the Good Shepherd, and adding, that “the Good Shepherd giveth his life for the sheep.”

That Christ died for the benefit of the human race, is a truth so apparent from these texts, that no man professing Christianity has hitherto called it in question. Very different opinions have been formed indeed concerning the nature and extent of that benefit, and the means by which and extent which it is applied; but that the passion and death of the blessed Jesus were essential parts of his ministry on earth, next to which has seldom been controverted. That on the cross he was made satisfaction to his Father for the sins of the world, is the general belief of Christians; but presumptuous men, aiming at being wise beyond what is written, have started a thousand idle questions concerning the necessity of
THEOLOGY.

Part II.

Of such satisfaction, and the manner in which it was made. Some limiting the power and mercy of the Omnipotent, have dared to affirm that God could not have pardoned man without receiving full satisfaction for his offences; that nothing but the shedding of the blood of Christ could make that satisfaction; that his death was indeed sufficient to atone for a thousand worlds; that, however, he did not die for all mankind, but only for a chosen few, ordained to eternal life by a secret decree before the foundation of the world; and that the rest of the race are passed by, and doomed to eternal perdition, for the glory of God's justice. Others, convinced by every thing around them that the Creator and Governor of the universe is a being of infinite benevolence, whose only end in giving life must have been to communicate happiness, have contended, that no atonement whatever could be necessary to obtain from him the forgiveness of sin on sincere repentance; that it is contrary to all our notions of justice to punish the innocent for the guilty; and that therefore the death of Christ, though the essential part of his ministry, could not be necessary, but at the most expedient.

We enter not into these debates. The Scriptures have nowhere said what God could or could not do; and on this subject we can know nothing but what they have taught us. That "we are reconciled to God by the death of his Son," is the principal doctrine of the New Testament; and without presuming to limit the power, the mercy, or the wisdom, of him who created and sustains the universe, we shall endeavour to show that it is a doctrine worthy of all acceptation. In doing this, we shall state impartially the opinions which pious men have held respecting the form or manner in which Christ by his death made satisfaction to God for the sins of the world; and we hope that our readers will embrace that opinion which shall appear to them most consonant to the general sense of sacred Scripture.

The strictest adherents to the theological system of Calvin, interpreting literally such texts of Scripture as speak of his being made sin for us, of his bearing our sins in his own body on the tree, and of the Lord's laying on him the iniquity of us all, contend, that the sins of the elect were lifted off from them and laid on Christ by imputation, much in the same way as they think the sin of Adam is imputed to his posterity. "By bearing the sins of his people (says Dr Gill + ) he took them off from them, and took upon himself, bearing or carrying them, as a man bears or carries a burden on his shoulders. There was no sin in him inherently, for if there had, he would not have been a fit person to make satisfaction for it; but sin was put upon him by his Divine Father, as the sins of the Israelites were put upon the scape-goat by Aaron. No creature (continues he) could have done this; but the Lord had laid on him, or made to meet on him, the iniquity of us all, not a single iniquity, but a whole mass and lump of sins collected together; and laid as a common burden upon him; even the sins of all the elect of God. This phrase of laying sin on Christ is expressive of the imputation of it to him; for it was the will of God not to impute the transgressions of his elect to themselves, but to Christ, which was done by an act of his own; for he hath made him to be sin for us that is, by imputation, in which literally Christ became sin for us, and we being imputed to him as our sins were to Christ. The sense (says our author) is, a charge of sin was brought against him as the surety of his people. He was numbered with the transgressors; for bearing the sins of many, he was reckoned as if he had been a sinner himself, sin being imputed to him; and he was dealt with as such. Sin being found upon him by imputation, a demand of satisfaction for sin was made, and he answered it to the full. All this was with his own consent. He agreed to have sin laid upon him, and imputed to him, and a charge of it brought against him, to which he engaged to be responsible; yes, he himself took the sins of his people upon him; so the Evangelist Matthew has it, 1 He himself took our infirmities, and bore our sicknesses. As he took the nature of men, so he took; Chap. their sins, which made his flesh to have the likeness of sin. 6 that flesh, though it really was not sinful. What Christ bore being laid upon him, and imputed to him, were sins of all sorts, original and actual; sins of every kind, open and secret, of heart, lip, and life; all acts of sin committed by his people, for he has redeemed them from all their iniquities; and God, for Christ's sake, forgives all trespasses, his blood cleanses from all sin, and his righteousness justifies from all; all being imputed to him as that is to them. Bearing sin supposes it to be a burden; and indeed it is a burden too heavy to bear by a sensible sinner (x). When sin is charged home upon the conscience, and a saint grooms, being burdened with it, what must that burden be, and how heavy the load which Christ bore, consisting of all the sins of all the elect from the beginning of the world to the end of it; and yet he sunk not, but stood up under it; failed not, nor was he discouraged, being the mighty God, and the Man of God's right hand, made strong for himself."

To the Arminians or Remonstrants, this doctrine of imputation is as absurd as the similar doctrine of the imputation of the sin of Adam to his unborn posterity; and it is certainly attended with consequences which have alarmed serious Christians of other denominations.

Were it possible in the nature of things, says the Arminian, to transfer the guilt of one person to another, and to lay it upon him as a burden, it could not be done without violating those laws of equity which are established in the scripture and engraven on the human heart. But this is not possible. To talk of lifting lumps of sin, or transferring them like burdens from the guilt to the innocent, is to utter jargon, says he, which has no meaning; and we might with as much propriety speak of lifting a scarlet colour from a piece of cloth and laying it on the sound of a trumpet, as of literally lifting the sins of the elect from them and laying them on Christ. Guilt is seated on the mind; and no man can become a sinner but by an act of volition. If Christ therefore really took upon him the sins of his people, he must have deliberately formed a wish to have actually committed them.
Part II.

THEOLOGY.

Theology committed all these sins; but such a wish, though it more peculiarly Christ.

ian, would have made him inherently guilty, and therefore incapable of satisfying for sin, could not have cancelled deeds that were done before he was born, or have made those innocent who really had been sinners. A deed once done cannot be undone; a volition which has been formed cannot be annihilated. By sincere repentance, the habitual dispositions are indeed changed, and those who have been sinners become objects of mercy; but no power can recall the hours that are past, or make those actions which have been performed to have been not performed. To remove guilt from the sinner and lay it on the innocent may therefore be safely pronounced impossible even for Omnipotence itself, for it implies that a thing may be and not be at the same instant of time; and the doctrine which teaches that this removal was made from the elect to Christ, is an imagination of yesterday, which has no countenance from scripture, and is contrary to the established constitution of things. Those who imagine that guilt may be propagated from father to son, have something like an argument to urge for the imputation of Adam's sin to his numberless posterity; for all the men and women who have by ordinary generation been introduced into the world, have undoubtedly derived their nature from the primal pair. But Christ did not derive his nature from the elect, that their sins should be communicated to him; nor, as he was miraculously conceived by the Holy Ghost, can we attribute to him any degree of that taint which is supposed to have been conveyed from Adam to all the other generations of men.

Nothing more, therefore, can be meant by “Christ's being made sin for us,” and “bearing our sins in his own body on the tree,” or by God's “laying upon him the iniquity of us all,” than that by his sufferings we are freed from the pollution of our sins: it being in scripture a common figure of speech, as even Dr. Gill has somewhere acknowledged, to denote by the word sin the consequences of sin. That this figure is used in those texts from which he infers that Christ took the sins of the elect on himself, is evident from the verse which he quotes from the gospel of St. Matthew; in which it is said, that “himself took our infirmities and bore our sicknesses.” The sicknesses and infirmities there alluded to are the leprosy, the palsy, the fever, and demoniacal possession: but when our blessed Lord cured these diseases, surely he did not by his omnipotent word lift them off from the patients and take them on himself, so as actually to become a leper, a paralytic, and a demoniac, or even to be reckoned as such either by the multitude, or by the priest, whose duty it was to take cognizance of every illegal uncleanness. And if his inveterate enemies did not impute to him the leprosy when he removed that plague from others, why should it be supposed that his own Father, to whom he was at all times well-pleasing, imputed to him the sins of which, by his sufferings, he removed the punishment from those who were guilty? To impute to a person any action, whether virtuous or vicious, which he did not perform, can proceed only from ignorance or malice, or partiality; but God is no respecter of persons, and from ignorance and malice he is removed to an infinite distance. It is indeed an undoubted truth, that “the Lord Jesus, by his perfect obedience and sacrifice of himself, which he through the eternal spirit once offered up unto God, hath fully satisfied the justice of his Father; and purchased not only reconciliation, but an everlasting inheritance in the kingdom of heaven for all those whom the Father hath given him;” but that he actually took on himself the sins of mankind, or that those sins were imputed to him by God, who punished him as a person whom he considered as guilty, is a doctrine equally injurious to the justice of the Father and to the immaculate purity of the Son.

The earnestness with which this doctrine was inculcated by some of the earliest reformers, and the impossibility of admitting it, which every reflecting and unprejudiced mind must feel, was probably one of the causes which drove Socinus and his followers to the other extreme of denying Christ's satisfaction altogether, and considering his death as nothing more than that of an ordinary martyr, permitted for the purpose of attesting the truth of his doctrine, and paving the way for his resurrection, to confirm the great promise of immortality. According to these men, forgiveness is freely dispensed to those who repent, by the essential goodness of God, without regard to the merit or sufferings of any other being; and the gospel is said to save from sin, because it is the most perfect lesson of righteousness. The great objection of Crelina to the doctrine of the satisfaction is, that it is a hindrance to piety; for if Christ has paid the whole debt, he thinks that he must have nothing to do, as nothing more can be required of us. And if it were indeed true that our sins are imputed to Christ, and his righteousness imputed to us, this objection would be insurmountable; for God could not justly exact a double punishment for the same sin, or inflict misery on those to whom he imputes perfect righteousness. But as to this imaginary transference of virtues and vices from one person to another, the scriptures give no countenance; so they nowhere call the death of Christ a satisfaction for the sins of men. The term has indeed been long in use among divines, and when properly explained it may be retained without any danger; but in treating of this subject, it would perhaps be more prudent to restrict ourselves to the use of scripture language, as the word satisfaction carries in it the ideas of a debt paid and accepted; whereas it is said by St. Paul, that “eternal life is the gift of God through Jesus Christ our Lord; and that we are justified freely by his grace through the redemption that is in Jesus Christ, whom God hath set forth to be a propitiation through faith in his blood.”

To clear up this matter, and attain adequate notions of the death redemption and justification, it will be necessary to look Christ back to the fall of our first parents; for the great purpose of mankind for which Christ was promised, and for which he came into the world, was, by bruising the head of the serpent, to restore mankind to the inheritance which they had lost through the transgression of Adam. This is apparent not only from the original promise made to the woman, but also from different passages in the epistles of St. Paul, who expressly calls Christ the second Adam, and says, that, as by the offence of one, judgment came upon all men to condemnation; even so by the righteousness of one, the free gift came upon all men unto justification of life;” that “as by one man's disobedience many were made sinners, so by the obedience of one shall many be made righteous;” and that, “as in Adam all die, even so in Christ shall all be made alive.”
THEOLOGY

Part II.

Theology of nature can secure to themselves the favour of their more perfect Creator, or recover it when accidentally lost. The moral virtue, comprehending piety, was the condition of that favour and protection which man, in his original state, could claim from his Maker; but obedience to a positive command was the condition of the free gift of immortality conferred on Adam on his introduction into paradise. The claim arising from the relation between the creature and the Creator is indissoluble, because that relation cannot be dissolved: so that the man who, by a transgression of the moral law, has forfeited the favour of God may reasonably hope to recover it by sincere repentance and a return to his duty; and nothing but such repentance and reformation can recover it; because, in a moral agent, nothing can be agreeable to God but moral dispositions, which cannot be transferred from one person to another, and for the want of which nothing can atone. Our virtues are not restored nor our vices procribed, as if the one could profit and the other injure him who created us; for "is it any pleasure to the Almighty that we are righteous? or is it gain to him that we make our ways perfect? Will he reprove us for fear of us?" No! He commands us to be virtuous, and forbids us to be vicious, only because virtue is necessary to our own happiness, and vice productive of everlasting misery.

There was an immoral man to be introduced into the society of angels and just men made perfect, he would not experience in that society what we are taught to expect from the joys of heaven; because to such joys his acquired dispositions would be wholly repugnant. Nor could the sufferings of any person whatever, or the imputation of any extrinsic righteousness, make that mind which had long been immersed in the grossest sensuality relish the intellectual and refined enjoyments of heaven; or the man who had been the habitual slave of envy, malice, and duplicity, a fit inhabitant of that place where all are actuated by mutual love. On the other hand, say the divines whose doctrine we are now detailing, it is impossible to suppose that the Father of mercies, who knows whereof we are made, should have doomed to eternal misery any moral agent who had laboured through life to serve him in sincerity and in truth; or that any atonement could be necessary to redeem from the pains of hell the man whose pious and virtuous dispositions have through penitence and prayer become suited to the society of heaven. Uninspiring perfection never was nor ever could be expected in man. He is brought into the world free indeed from vice, but equally destitute of virtue; and the great business of his life is to guard his mind from being polluted by the former, and to acquire dispositions habitually leading to the practice of the latter. Till these habits be fairly formed, it seems impossible that he should not sometimes deviate from the paths of rectitude, and thereby incur a temporary forfeiture of the divine favour; but the very constitution of his mind, and the purpose for which he is placed in a state of probation, show that the divine favour thus forfeited can be recovered only by repentance and reformation.
Part II.

Theology

Widely different, however, is the case with respect to the forfeiture and recovery of a free gift, to which man has no natural claim. When the condition is broken on which such a gift was bestowed, repentance can be of no avail; it must be either irrecoverably lost or restored by the mere good pleasure of the giver. Immortality or perpetual existence is a gift which upon certain terms was freely bestowed upon the human race, and forfeited by the transgression of their first parent violating those terms. It was restored by the free grace of God, who was pleased to ordain, that “since by man came death, by man should also come the resurrection of the dead; for as in Adam all die, even so in Christ shall all be made alive.” Hence the apostle, writing to the Romans of the benefits of being the children of God, and joint-heirs with Christ, summethe up those benefits with resurrection from the dead.” For the creature, i.e. mankind, was made subject (says he §) to vanity or death, not willingly, but by reason of him who hath subjected the same in hope: because the creature itself also shall be delivered from the bondage of corruption into the glorious liberty of the children of God. For we know that the whole creation groaneth, and travaileth in pain together until now: and not only they, but ourselves also, who have the first fruits of the spirit, even we ourselves groan within ourselves, waiting for the adoption, viz. “The redemption of our body (r).” That this the redemption of our body is the consequence of the sacrifice of Christ, is taught in the most explicit terms in the epistle to the Hebrews; of which the inspired author informs us, that “forasmuch as the children are partakers of flesh and blood, he himself also took part of the same; that through death he might destroy him that had the power of death, that is the devil; and deliver them, whom through fear of death were all their lifetime subject to bondage.” A vicarious atonement made with this view, the divines, whose theory we are now considering, acknowledge to be perfectly rational and consistent with the strictest justice. “The law of nature (say they) allows not of vicarious atonements; but ordains that the man who transgresseth shall himself bear the punishment of his iniquity; a punishment which no man deserves for the faults of another, unless he be partaker of the guilt by joining in the transgression.” And in proof of this their opinion, they appeal to the words of God himself, declaring to Moses,—“Whosoever hath sinned against me, him will I blot out of my book.” But when the free gift of immortality was lost, it was with great wisdom, say they, that God restored it through a Mediator who should make atonement by his blood for the breach of the first covenant; since such a mediation implies that the gift restored is merely of grace, to the attainment of which man could no further cooperate than by his hopes and wishes.

To this view of redemption, and indeed to every view of it which we have yet taken, an objection forces itself. Theology upon the mind. Throughout the New Testament itself, and the doctrine of immortality are considered as a free gift, and so called in express words by St Paul* to the scheme under consideration it is essential to consider them as such; and yet we know that a large price was paid for them, as St Paul likewise acknowledges, when he twice tells the Corinthians that they were bought with a price †. To clear up this matter (says Bishop Warburton) it is to reconcile the apostle to himself, who certainly was not defective either in natural sense or artificial logic, let us once again remind the reader, that life and immortality bestowed on Adam in paradise was a free gift, as appears from the history of his creation. As a free gift, it was taken back by the Donor when Adam fell; to which resumption our original natural rights are not subject, since natural religion teacheth, that sincere repentance alone will reanimate us in the possession of those rights which our crimes had suspended. So that when this free gift, forfeited by the first Adam, was recovered by the second, its nature continuing the same, it must still remain a free gift—a gift to which man, by and at his creation had no claim; a gift which natural religion did not bestow. But if misled by measuring this revealed mystery of human redemption by the scant idea of human transactions, where a free gift and purchased benefit are commonly opposed to one another, yet even here we may be able to set ourselves right, since, with regard to man, the character of a free gift remains to immortality restored. For the price paid by forfeited man was not paid by him, but by a Redeemer of divine extraction, who was pleased, by participating of man’s nature, to stand in his stead. Hence the sacred writers seeing, in this case, the perfect agreement between a free gift and a purchased possession, call it sometimes by the one and sometimes by the other name ‡. A restoration to life and immortality from that state the death of unconsciousness or extinction, to which all mankind of Christ were doomed in consequence of the fall, is that great and solemn salvation which we have obtained through the blood of our Redeemer; and according to the theologians whose actual theory we are now considering, it was the only thing in the divine intention when the promise was given to the first mother that the seed of the woman should bruise the head of the serpent. But though they contend that the death of Christ does not operate, directly as atonement for the actual sins of men, they admit that it does so indirectly and by necessary consequence, since it gives opportunities for repentance and newness of life, which under the first covenant they did not enjoy. Had a man under that covenant transgressed any moral precept, he would have forfeited the favour of his God, and either been subjected to punishment or to a long course of repentance; but supposing the efficacy of repentance under

According to the Calvinists, Christ died only for the elect. It is well known to be one of the fundamental doctrines of the Calvinistic school, that "no one are redeemed by Christ, effectually called, justified, adopted, sanctified, and saved, but the elect only;" and if the notions of redemption, which, in the end of the 17th century, were very generally embraced, be admitted as just, it will not be easy to overturn the arguments by which that doctrine is supported. Such of them as are connected with the great question of election and reprobation, and enter into the decision of it, we have stated in another place (see Predestination, No. 44); but it is further argued, that the doctrine of universal redemption reflects on the wisdom, the justice, and the power of God, and robs him of his glory.

The scriptures assure us that all men shall not be saved; but how can this be, if Christ died for all, and the scheme of salvation, by his death was formed by infinite wisdom? The Arminians indeed say, that those who fail of salvation, fail through their own fault in not performing the conditions required of them; but God either knew or knew not that such men would not perform those conditions. If he knew it not, his knowledge is limited; if he knew it, where was his wisdom in providing a scheme of redemption for all men, in whom he was aware that it would be of no benefit? "God, we are told, is righteous in all his ways, and holy in all his works;" but there is no righteousness in making Christ bear the sins of all men, and suffer the punishment due to them, if any one of those men shall be afterwards punished everlasting. If Christ has already paid the debts of the whole world, it cannot be just to cast a single inhabitant of the whole world into the prison of hell, there to be detained till he shall again have paid the uttermost farthing. "The Lord's hand is not shortened that it cannot save," for he is and always will be the same Almighty power that he was from eternity; but if by the divine decree Christ died for all men, and yet all men shall not be saved, it would appear that man is mightier than his Maker! The ultimate end of God in the redemption of man is admitted to have been his own glory; but if any individual of the human race, who was redeemed by Christ, shall not be saved, God will so far lose his end, and be deprived of his glory. For, if this were the case, where would be the glory of God the Father in forming a theological scheme which, with respect to multitudes, does not succour those, and where would be the glory of the Son of man, by the redemption of men who are yet not to be saved by him? and where would be the glory of the spirit of God, if redemption were not by him effectually applied to every individual for whom it was wrought? By such arguments as these do the Calvinists oppose the scheme of universal redemption, and contend that Christ died only for the elect, or such as shall be placed on his right hand at the day of judgment. This notion of a limited redemption, as they think it more worthy of the sovereignty of God, they believe to be taught by our Saviour himself, when he saith, "All that the Father giveth me shall come to me;" and him that cometh to me, I will in no wise cast out. For I came down from heaven, not to do mine own will, but the will of him that sent me. And this is the Father's will whom hath sent me, that of all which he hath given me I should lose nothing, but should raise it up again at the last day." (John 14:14). The Arminians, on the other hand, contend, that it is impious to limit the effects of Christ's death to a chosen number, and that it is not true to say that every man, that all, without exception, might through his own merit obtain remission of their sins. Thus our Lord himself told Nicodemus, that as Moses lifted up the serpent in the wilderness, even so must the Son of Man be lifted up, that whosoever believeth in him, should not perish, but have everlasting life. For God so loved the world, that he gave his only begotten Son, that whosoever believeth in him should not perish, but have everlasting life. For God sent not his Son into the world to condemn the world, but that the world through him might be saved. In perfect conformity with the doctrine of his divine Master, St. Paul teaches, that "Christ died for all; that God was in Christ reconciling the world to himself, not imputing their trespasses unto them;" that "he will have all men to be saved, li. 47; and to come into the knowledge of the truth;" that "Christ gave himself a ransom for all;" and that "If Jesus was made a little lower than the angels, that by the grace of God he should taste death for every man." The very same thing is taught in St. Peter and St. John, when the former says, that "the Lord is not willing that any should perish, but that all should come to repentance;" and the latter, that "Jesus Christ the righteous is the propitiation for our sins; and not for our's only, but for the whole world." On these texts, without any commentary, the Arminians are willing to rest their doctrine of universal redemption; though they think that a very strong additional argument for its truth arises from the numberless absurdities which flow from the contrary opinion. Thus, say they, the apostles were commanded by our Saviour to "go into all the world and preach the gospel amongst every creature," and all who hear it preach it are required to believe it: but no man, as the Calvinists themselves confess, believe the gospel as a Christian; without believing that Christ died for him; and therefore, if it be true that Christ died only for the elect, it is plain that the great part of mankind are required to believe a lie, and are not to be saved.
Part II.

Theology

he is bound to believe in Christ when preached to him: nor can any man be justly condemned for infidelity: which is not only absurd in itself, but directly contrary to what we are taught by our blessed Lord, who assures us*, that unbelief is the cause of condemnation. Lastly, if Christ died not for all, then is it certain that he cannot claim dominion over all in consequence of his death and resurrection; but St Paul says expressly†, that "this end Christ both died, and rose, and revived, that he might be the Lord of the dead and living." The Arminians acknowledge, that though Christ died for all, there are many who will not be saved; for, say they ‡, the death of Christ did not literally pay the debts incurred by sinners, but only obtained for them the gracious covenant of the gospel, by which all who believe in him, and sincerely endeavour to work out their own salvation with fear and trembling, are entitled to forgiveness of sins and eternal life.

Such is the state of this controversy as it was agitated between the Calvinists and Arminians of the 17th century; but the present leaders of this latter school are of opinion, that it never could have been started, had not both parties mistaken the purpose for which Christ died. It is not conceivable, say they, that any thing for which the eternal Son of God took upon him human nature, and in that nature suffered a cruel and ignominious death, shall not be fully accomplished; and therefore, if in the divine intention he died to make atonement for the sins of man actual as well as original, we must of necessity conclude, that those for whom he died shall certainly be saved. Yet we learn from scripture that many shall go away into everlasting punishment, though the same scripture repeatedly assures us that Christ gave his life a ransom for all, and that he is the propitiation for the whole world. To reconcile those different passages of scripture is impossible, if we suppose that he laid down his life to atone for the actual transgressions of men; but if the direct purpose of the Godhead in forming this stupendous plan of redemption was, that the death of Christ should be the ransom of all from the grave or utter extinction, every difficulty is removed; for we know that all, the wicked as well as the righteous, shall through him be raised to life at the last day. That this was the purpose for which he died, they think apparent from the very words quoted by the Calvinists to prove that redemption was not universal; for he declares that it was his Father's will, that "of all which had been given him he should lose nothing." not that he should save it all from future punishment, but only that he "should raise it up at the last day." When St John calls him a propitiation for our sins, which, as we have seen, the divines whose doctrine we are now stating hold him to be indirectly, he does not add, as in our translation, for the sins of the whole world, but πολλοὶ προσόν τοῦ σώματός, for the whole world, which, by his death, he redeemed from that vanity and corruption under which, according to St Paul, it had remained from the fall till the preaching of the gospel. Hence it is that our blessed Lord calls himself "the resurrection and the life," and always promises to those who should believe in him, that though they were dead, yet should they live, and that he would raise them up at the last day.

Among these various opinions respecting the destination of the death of Christ, it belongs not to us to de-

cide. The serious reader, divesting himself of prejudice, and more peculiarly of those of the Arminian persuasion, will search the scriptures, and apply the theories which he shall find most explicitly taught in that sacred volume; but as in every system it is admitted, that one purpose for which Christ died was to redeem mankind, one purpose of the everlasting power of the grave, and bring to pass for the light life and immortality, it is of the utmost importance to know whether that purpose has been fully attained. Was to Death we see still triumphing over all the generations brought to light, and immortality, some sensible evidence seems necessary to evince that a general resurrection shall actually take place. This we are promised as one great benefit purchased for us by the sufferings of Christ sacrificed on the cross. And since the price has been paid, and paid thus visibly, the nature of the covenant requires that the benefit should be as visibly enjoyed by the person whose sufferings obtained it for his brethren. "If the Redeemer himself had not been seen to enjoy the fruits of the redemption procured, what hopes could have remained for the rest of mankind? Would not the natural conclusion have been, that the expiatory of redemption, by the death and sacrifice of Jesus, had proved inefficacious?" This is the conclusion which St Paul himself draws: "If Christ be not risen (says he *), then is our faith vain, and your faith also, yea are yet xm. 15:13; in your sins. Then they also, who are fallen asleep in Christ, are perished—αιτω—lost, as if they had never existed. But now (adds he) is Christ risen from the dead, and become the first fruits of them that slept. For since by man came death, by man came also the resurrection of the dead: For as in Adam all die, even so in Christ shall all be made alive."—So necessarily connected, in the opinion of the apostle, is the resurrection of Christ with the very essence of Christianity. 

We have in another place (see RESURRECTION, No. 50.) stated such arguments for the truth of this fundamental article of our common faith, as must carry conviction to every mind capable of estimating the force of evidence; we shall not here resume the subject.

Archbishop King has supposed †, that the human will is a faculty distinct from the understanding, and the appen-
tites; that activity is essential to it; and that previous sec. 1. sub-
to an election formed, it is equally indifferent to all ob-
bects. He thence infers, that a man may choose, and even take delight in, what is not naturally agreeable to the object of his appetites; because when the choice is made, a relation begins, between the will and the object of the choice, which, from being originally indifferent, now becomes a favourite object. But neither his Grace, nor any other asserter of human liberty, has ever affir-
med or supposed, that any man or body of men could de-
liberately choose evil for its own sake, or enter zealously upon a tedious and difficult enterprise, from which no good could possibly arise, and from which unmixed mis-
sery was clearly foreseen as the necessary result of every step of the progress." Such, however, must have been the choice and the conduct of the apostles, when they resolved to preach a new religion founded on the resurrection of Jesus, if they did not certainly know that Jesus had risen from the dead. And this conduct must have been adopted, and, in opposition to every motive which can influence the human mind, have been persevered.
Theology more peculiarly Christian. vered in by a great number of men and women, without the smallest contradiction having ever appeared in the various testimonies, which at different times, and under the cruellest tortures, they all gave to a variety of circumstances, of which not one had its foundation in truth. He who can admit this supposition, will not surely object to the incredibility of miracles. The resurrection of a man from the dead is an event so different indeed from the common course of things, that nothing but the most complete evidence can make it an object of rational belief; but as the resurrection of Jesus has always been said to have had God for its Author, it is an effect which does not exceed the power of the cause assigned, and is therefore an event possible in itself and capable of proof. It is a deviation from the laws of nature, but it is not contradictory to any one of those laws. That a great number of men and women should deliberately form a plan of ruin and misfortune to themselves, without a prospect of the smallest advantage either in this world or in the next, is as different from the common course of things as the resurrection from the dead; and therefore in itself at least as great a miracle; for that they should persist in prosecuting this plan in the midst of torments; that they should spread themselves over the whole world, and everywhere publish a number of falsehoods, without any one of them contradicting the rest; that truth should never escape them either in an unguarded moment, or when lingering on the rack, and yet that all their lies should be in perfect agreement with each other; that they should every one of them court sufferings for a person whom they knew to be an impostor; that not one of the number—not even a single woman—should have so much compassion for a fellow-creature, as to rescue him from the flames by confessing a truth which could injure nobody—not even the suffering deceivers themselves;—all this is not only different from the common course of things, but directly contrary to the most known laws of nature, and is therefore not miraculous, but may be pronounced impossible. Yet this impossibility we must admit, or acknowledge, that as Christ died for our sins, according to the Scriptures, and was buried, and was restored again the third day according to the Scriptures; that he was seen of Cephas, then of the twelve; after that of above five hundred brethren at once; after that of James; then of all the apostles; and that he was last of all seen of St. Paul, who was converted by the vision to preach the faith which till then he had persecuted.

Thus we are assured, that those who have fallen asleep in Christ are not lost, since he is risen from the dead, and become the first fruits of them that slept. For since by man came death, by man came also the resurrection of the dead. For as in Adam all die, even so in Christ shall all be made alive. But every man in his own order: Christ the first-fruits, afterwards they that are Christ's at his coming; for all that are in the graves shall hear his voice, and shall come forth; they that have done good unto the resurrection of life, and they that have done evil to the resurrection of damnation."

Our blessed Lord having conversed familiarly with the eleven apostles for forty days after his resurrection, instructing them in the things pertaining to the kingdom of God; having extended their authority as his ministers, by giving them a commission to teach all nations, and make them his disciples, by baptizing them in the name of the Father, and of the Son, and of the Holy Ghost; and having promised them power from on high to enable them to discharge the duties of so laborious an office—led them on as far as Bethany, that they might be witnesses of his ascension into heaven. When they therefore came together, they asked of him, saying, Lord, wilt thou at this time restore again the kingdom to Israel? And he said, it is not for you to know the times and the seasons, which the Father hath put in his own power. But ye shall receive power after that the Holy Ghost is come upon you; and ye shall be witnesses unto me, both in Jerusalem, and in all Judea, and in Samaria, and unto the uttermost parts of the earth. But tarry ye in the city of Jerusalem, until ye be endued with power from on high; and he lift up his hands and blessed them; and it came to pass while he blessed them, he was parted from them, and a cloud received him out of their sight. And while they looked steadfastly towards heaven, as he went up, behold, two men stood by them in white apparel; who also said, Ye men of Galilee, why stand ye gazing up into heaven? This same Jesus, who is taken up from you into heaven, shall so come, in like manner as ye saw him go into heaven. And they went forth from that place into minister.
Part II.

Theology

since Christ had told to his disciples that he was to ascend to his Father and their Father, to his God and their God, and that he was going to prepare a place for them, that where he is there they might be likewise; he can hardly doubt but that all who believed in him as the Redeemer of the world would take care to be present, not only to view their Master's triumph over all his enemies, but also to have a sight of that glory which awaited themselves. It was on this occasion probably that he was seen after his resurrection by above five hundred brethren at once, of whom the greater part were alive at the writing of St Paul's first epistle to the Corinthians.

But though such multitudes of people saw Jesus lifted up from the mount, and gradually vanished out of their sight, some other evidence seemed necessary to certify them of the place to which he had gone. Two angels therefore appear, and attest what human eyes could not see, but what was indeed the consequence of what they had seen. They attest that Christ had ascended to heaven, not to descend again till the last day; and surely, with respect to this point, the citizens of heaven were the most unexceptionable witnesses. We must therefore acknowledge and confess, against all the wild heresies of old, that Jesus Christ the Son of God, who died and rose again, did with the same body and soul with which he had lived upon earth ascend up "into heaven, there to appear in the presence of God for us." Having in the outward tabernacle of this world once offered up himself a pure and perfect sacrifice for the expiation of our sins, he entered within the veil into the most holy place, there to present his blood before God himself, in order to obtain mercy for us, and restore us to the Divine favour. So that, "If any man sin, we have an advocate with the Father, Jesus Christ the righteous, who is the propitiation for our sins, and not for ours only, but also for the sins of the whole world; and he is able to save to the uttermost those that come to God by him, seeing he ever liveth to make intercession for us." "Seeing then that we have a great high-priest, who is passed into the heavens, Jesus the Son of God, we may through him boldly unto the throne of grace, that we may obtain mercy and find grace to help us in time of need."

But it is not the office of a priest only that our Lord discharges in heaven; he is represented as sitting on the right hand of God, to denote that regal authority with which he is now vested; angels, and authorities, and powers, being made subject to him. "Hence it is, that after his resurrection, he said of himself, "all power is given unto me in heaven and in earth; for, as St Paul informs us, "because he humbled himself and became obedient unto death, even the death of the cross, therefore God hath highly exalted him, and given him a name which is above every name: that at the name of Jesus every knee should bow, of things in heaven, and things on earth, and things under the earth." And this submission is due to him, because "God raised him from the dead, and set him at his own right hand in the heavenly places, far above all principalities and powers, and might, and dominion, and every name that is named, not only in this world, but also in that which is to come; and hath put all things under his feet, and gave him to be head over all things to the church," "As God, Christ possessed a kingdom, which, as it had not a beginning, can never have an end: but the dominion, of which the apostle is here treating, was conferred upon him as the mediator of the new covenant, and will no longer continue than till his enemies shall be subdued; for we are told, that "he must reign till he hath put all enemies under his feet; and that the last enemy which shall be destroyed is death." He will ransom his subjects from the power of the grave; he will redeem them from death. O death, he will be thy plague; O grave, he will be thy destruction." The trumpet shall sound, the graves shall be opened, and the sons and daughters of Adam shall return to life, and death shall be swallowed up in victory. Then cometh the end, when the office of mediator ceasing, he shall have delivered up the kingdom to God, even the Father, when he shall have put down all rule and all authority and power. For when all things shall be subdued unto him, then shall the Son also himself be subject unto him that put all things under him, that God may be all in all."

The first conspicuous proof which our blessed Lord gave of being vested with supreme power, and made head over all things to the church, was on the day of Pentecost. He had told the apostles that he would pray the Father to give them another comforter, who should abide with them for ever, even the Spirit of the apostles, which should teach them all things, and bring all things to their remembrance which he had said unto them. He had assured them, that it was expedient for them that he himself should go away; "for if I go not away (said he*), the Comforter will not come unto you; but if I depart, I will send him unto you." At his last interview with them, just before his ascension, he had desired them to tarry at Jerusalem till they should be endued with power from on high, before they entered upon their great work of converting the nations. These promises were amply fulfilled; for "when the day of Pentecost was fully come, they were all with one accord in one place. And suddenly there came a sound from heaven as of a rushing mighty wind, and it filled all the house where they were sitting. And there appeared unto them cloven tongues, like as of fire, and it sat upon each of them. And they were all filled with the Holy Ghost, and began to speak with other tongues, as the Spirit gave them utterance. And there dwelling

(n) There was one Apelles in the primitive church, who was condemned as a heretic for teaching that Christ's body was dissolved in the air, and that he ascended to heaven without it. The opinions of this man and his followers are stated at large and confused by Tertullian, Gregory Nazianzen, and Epiphanius; and the reader who thinks such ridiculous notions worthy his notice, will find enough said of them in the Notes to the sixth article of Pearson's Exposition of the Creed. Perhaps it may be from a hint communicated in these Notes, that our great modern corrector of the evangelists has discovered, if it be indeed true that he pretends to have discovered, that Jesus Christ is still upon earth.
Theology more peculiarly Christian, dwelling at Jerusalem Jews, devout men, out of every nation under heaven. Now when this was noised abroad, the multitude came together, and were convinced, because that every man heard them speak in his own language. And they were all amazed, and marvelling, saying one to another, Behold, are not all these who speak Galileans? And how hear we every man in our own tongue, wherein we were born? Parthians, and Medes, and Elamites, and dwellers in Mesopotamia, and Judæa, and Cappadocia, in Pontus and Asia, Phrygia, and Pamphylia, in Egypt and in the parts of Libya about Cyrene, and strangers of Rome, Jews, and proselytes, Cretes and Arabians—do we hear them speak in our tongues the wonderful works of God? And they were all amazed, and were in doubt, saying one to another, What meaneth this? 192

Certainty of that miracle.

That those who heard the apostles speak so many different languages were amazed, is what we should naturally suppose; but that a single individual among them remained unconvinced, is astonishing; for the gift of tongues on the day of Pentecost is one of the most palpable miracles that was ever wrought. It is likewise one of the best authenticated miracles; for the book entitled The Acts of the Apostles was written not more than 30 years after the event took place (see Scripture, No. 168.); and it is not conceivable that, within so short a period, St Luke, or any man of common sense, would have appealed for the truth of what he recorded to so many inveterate enemies of the Christian name, had he not been aware that the miraculous gift of tongues was a fact incontrovertible. We all know how desirous the Jewish rulers were to stop the progress of the faith, by whatever means; but if this miracle was not really performed, they had now an opportunity of doing it effectually by means to which truth and honour would give their approbation. Thousands must have been alive in the city of Jerusalem who were men and women at the time when the apostles were said to have been thus suddenly inspired with the tongues of the Parthians, Medes, and Elamites, &c.; and as these foreigners were themselves either Jews by descent, or at least proselytes to the Jewish religion, surely the priests would have found multitudes ready, both at home and abroad, to contradict this confident appeal of St Luke's if contradiction had been possible. We read however of no objection whatever being made to this miracle. Some of the audience, indeed, when the apostles addressed people of so many nations in all their respective languages, not understanding what was said, and taking it for jargon which had no meaning, concluded, not unnaturally, that the speakers were full of new wine, and mocked them for being drunk so early in the day; but this is a circumstance which, so far from rendering the miracle doubtful, adds much to the credit of the historian, as it would hardly have occurred to the writer of a narrative wholly false, and would certainly not have been mentioned, had he known that the apostles really attempted to impose on the multitude unmeaning sounds for foreign languages.

As it is thus certain that the apostles were miraculously furnished with the gift of tongues, so the elegance and propriety of that miracle to attest the real descent of the Spirit of truth, who was to teach them all things, and endue them with power from on high to convert the nations, can never be enough admired by the pious Christians; for words being the vehicle of knowledge, Theology an ability to speak the different languages of the earth was absolutely necessary to enable those who had been largely Christian originally fishermen to go into all the world and preach the gospel to every creature. Yet that we have been writers, who, though unable to call in question the reality of the gift of tongues on the day of Pentecost, have contended, that it was a gift, not lasting, but temporal, instantaneous and transitory; not bestowed upon them for the constant work of the ministry, but as an occasional sign only, that the person endowed with it was a chosen minister of the gospel; which sign, according to them, ceased and totally vanished as soon as it had served that particular purpose. The chief argument was, upon which this opinion is attempted to be built, is drawn from the scripture Greek, which is said to be "utterly rude and barbarous, and abounding with every fault which can possibly deform a language; whereas we should naturally expect to find an inspired language pure, clear, noble, and affecting, even beyond the force of common speech; since nothing can come from God but what is perfect in its kind. In short, we should expect, says the objector, the purity of Plato and the eloquence of Cicero."

Middleton's Essay on the Gift of Tongues, that it supposes what is called the purity, elegance, and sublimity, of language, to be something natural and essential to human speech, and inherent in the constitution of things. But the matter is far otherwise. The Greek qualities are accidental and arbitrary, and depend on the different climes of the earth; and as inconstant as the tempers, genius, and circumstances, of its inhabitants. For what is purity, but the use of such terms and combinations as the caprice of a writer or speaker of authority hath preferred to their equals? what is elegance, but such a turn of idiom as a fashionable fancy hath brought into credit; and what is sublimity, but the application of such images as arbitrary and casual connections, rather than their own native grandeur, have dignified and ennobled? The consequence of this is, that the mode of composition which is a model of perfection to one nation or people, has always appeared either extravagant or mean to another. Asiatic and Indian eloquence was esteemed hyperbolical and unnatural by the Greeks and Romans, and is so esteemed by us; whilst the Greek and Roman eloquence in its turn appeared cold and insipid to the warm inhabitants of the east; and ours would appear perhaps still colder. But the New Testament was designed for the rule of life to all mankind. Such a rule required inspiration; and inspiration, say the objectors, implies the most perfect eloquence. What human model then was the Holy Ghost to follow? for a human model it must have been, because there was no other; and if there had, no other would have answered the purpose, which was to make a due impression on the mind and affections. Should the eastern eloquence have been employed? But it would have been too swelling and animated for the west. Should the western? This would have been too still and inactive for the east. Or suppose us only solicitous for what we best understand; which species of latter genus should the sacred writers have preferred? The dissonant sofness of the Asiatic Greeks, or the dry conciseness of the Spartans? The flowing exuberances
Part II.  

THEOLOGY.

Theology is the study of the nature and attributes of God, and the principles and laws governing the universe. It is the foundation of all knowledge and is concerned with understanding the divine nature and the relationship between humanity and divinity.

A. But are there not some general principles of eloquence in common to all the species? There are. Why then should not these have been employed to credit the apostolic inspiration? Because the end even of these (replies our author) is to mislead reason, and inflame the passions; which being abhorrent to the truth and purity of our holy religion, were very fitly rejected by the inspired penman. Besides, it might easily be known to have been the purpose of Providence, though such purpose had not been expressly declared, that the gospel should bear all possible marks of its divine original, as well in the course of its progress as in the circumstances of its promulgation. To this end, the human instruments of its conveyance were mean and illiterate, and chosen from among the lowest of the people, that when the world saw itself converted by the foolishness of preaching, as the only learned apostle thinks fit to call it, unbelievers might have no pretense to ascribe its success to the parts, or stations, or authority, of the preachers. Now had the language inspired into these illiterate men been the eloquence of Plato or Tully, Providence would have appeared to counteract its own measures, and to defeat the purpose best calculated to advance its glory. But God is wise, though man is a fool. The course of Providence was uniform and constant: It not only chose the weakest instruments, but carefully kept out of their hands that powerful weapon of words which their adversaries might so easily have wrested to the dishonour of the gospel. Common sense tells us, that the style of an universal law should retain what is common to all languages, and neglect what is peculiar to each. It should retain nothing but CLEARNESS and PRECISION, by which the mind and sentiments of the writer are intelligibly conveyed to the reader. This quality is essential, invariably the same, and independent of custom and fashion. It is the consequence of syntax, the very thing in language which is least positive, as being formed on the principles of philosophy and logic; whereas all besides, from the very power of the elements and signification of the terms to the tropes and figures in composition, are arbitrary; and, as deviating from these principles, frequently vicious. But this quality of clearness and precision eminently distinguishes the writings of the New Testament; insomuch that it may be easily shown, that whatever difficulties occur in the sacred books do not arise from any imperfect information caused by this local or nominal barbarity of style; but either from the sublime or obscure nature of the things treated of, or from the intentional conciseness of the writers; who, in the casual mention of anything not essential to the dispensation, always observe a studied brevity.

After much ingenious and sound reasoning on the nature of language in general, our author concludes, that the STYLE of the New Testament, even on the truth of what has been said to its discredit, is so far from proving the language not to be divinely inspired, that it bears one certain mark of that original. "Every language consists of two distinct parts, the single terms, and the phrases and idioms. Suppose now a foreign language to be instantaneously introduced into the minds of illiterate men like the apostles; the impression must be made either by fixing in the memory the terms and

single words only with their signification, as, for instance, Greek words corresponding to such or such Syriac or Hebrew words; or else, together with that simple impression, by enriching the mind with all the phrases and idioms of the language so inspired. But to enrich the mind with the peculiar phrases and idiom of a foreign language, would require a previous impression to be made of the manners, notions, fashions, and opinions, of the people to whom that language is native; because the idiom and phrases arise from, and are dependent on, these manners. But this would be a waste of miracles without sufficient cause or occasion; for the Syriac or Hebrew idiom, to which the Jews were of themselves enabled to adapt the Greek or any other words, abundantly served the useful purposes of the gift of tongues, which all centered in those tongues, being so spoken and written as to be CLEARLY UNDERSTOOD. Hence it follows, that if the style of the New Testament were indeed derived from that language which was miraculously impressed upon the apostles on the day of Pentecost, it must be just such a one as in reality we find it to be; that is, it must consist of Greek words in the Syriac or Hebrew idiom:"  

The immediate author of this gift, so necessary to the Divinity of the propagation of the gospel, was the Spirit of truth, or the Holy Ghost. The Spirit of truth is the third person in the blessed Trinity. That there are three persons in the one Godhead, has been shown at large in a former section of this article; and that the Holy Ghost is one of these three, might be safely concluded from the form of baptism instituted by Christ himself. But as more plausible objections have been urged against his divinity than any that we have met with against the divinity of Christ, it may not be improper to consider these before we proceed to give an account of the graces which he imparted to the infant church, and of the apostles preaching under his influence. By the Arians the Holy Ghost is considered as a creature; by the Socinians and modern Unitarians, as they call themselves, the words Holy Ghost are supposed to express, not a person or spiritual subsistence, but merely an energy or operation, a quality or power, of the Father, whom alone they acknowledge to be God. If this doctrine can be confuted, the Arian hypothesis will fall to the ground of itself; for it is not conceivable that any inspired teacher should command his followers to be baptized in the name of the self-existent God and two creatures.

It is admitted by the Socinians themselves, that in Objections the Scriptures many things are spoken of the Holy Ghost which can be properly predicated only of a person; but the inference drawn from this concession they endeavour to invalidate by observing, that in scripture there are likewise expressions in which things are predicated of abstract virtues, which can be literally true only of such persons as practise these virtues. Thus when St Paul says, "Charity suffereth long and is kind; charity envieth not, charity vaunteth not itself, is not puffed up," &c., we cannot suppose his meaning to be, that these actions are performed by charity in the abstract, but that every charitable person, in consequence of that one Christian grace, suffereth long and is kind, envieth not, vaunteth not himself, and is not puffed up, &c. In like manner, say they, personal actions are attributed to the Holy Ghost, which itself is

more peculiarly Christian.

* Acts x.

19, 20.

no person, but only the virtue, power, or efficacy, of God the Father; because God the Father, who is a person, performs such actions by that power, virtue, or efficacy, in himself, which is denominated the Holy Ghost. Thus when we read that "the Spirit said unto Peter, Behold three men seek thee; arise therefore and get thee down, and go with them, doubting nothing, for I have sent them;" we must understand that God the Father was the person who spoke these words and sent the three men; but because he did it by that virtue in him which is called the Spirit, therefore the Spirit is said to have spoken the words and sent the men. Again, when "the Holy Ghost said to those at Antioch, Separate me Barnabas and Saul for the work wherein I have called them;" we are to conceive that it was God the Father who commanded the two apostles to be separated for the work to which he had called them; but because he had done all this by that power within him which is called the Holy Ghost, therefore his words and actions are attributed to the Holy Ghost, just as long-suffering in men is attributed to charity.

Answered.

† Acts viii.

26.

This reasoning has a plausible appearance, and would be much more force all the actions which in scripture are attributed to the Holy Ghost of such a nature as that they could be supposed to have proceeded from the person of God the Father in consequence of any particular power or virtue in him; but this is far from being the case. Thus "Spirit is said to make intercession for us;" but with whom can we suppose God the Father, the fountain of divinity, to intercede? Our Saviour assured his disciples, that the Father would, in his name, send to them the Holy Ghost, who is the Comforter; that he would himself send the Comforter unto them from the Father; that the Comforter should not speak of himself, but speak only what he should hear; and that he should receive of Christ's, and shew it unto them. But we cannot, without blasphemy and absurdity, suppose that the Father would, in the name of Christ, send himself; that the Son would send the Father from the Father; and the Father would not speak of himself, but speak only what he heard; or that either the Father in person, or a quality of the Father, should receive any thing of Christ to shew unto the apostles.

The sanctity of Socinus perceived the force of such objections as these to his notion of the Holy Ghost being nothing more than the power of the Father personified; and therefore he invented another prosopopoeia to serve his purpose in the interpretation of those texts to which this one cannot be applied. "The Spirit of God (says he) may be considered either as a property or power in God, or as the things on which that power is working. When taken in the former sense, the Spirit, where any personal attribute is given to it, means God the Father; when taken in the latter sense, it means the man on whom the power of the Father is working; who, as long as he is affected by that power, is therefore called the Spirit of God;" and he quotes, we think most absurdly, the tenth verse of the second chapter of the first epistle to the Corinthians, as a text in which the Spirit is meant an inspired man who could search all things, yea, even the deep things of God.

How his modern followers, who deny the plenary inspiration even of Christ, will relish such a degree of inspiration as this, which raises mere men to a temporary equality with God, we know not; but leaving them to settle the dispute with their master, we shall produce one or two passages in which personal attributes are given to the Spirit of God, when it is impossible to conceive that Spirit, either as a power inherent in the Divine Father, or as the person on whom that power is operating. We need not bring new texts into view, as some of those already quoted will serve our purpose. When our Saviour promises that the Holy Ghost, the Comforter, the Spirit of truth, should be sent by the Father and the Son to the apostles, we have seen, that by this Spirit he could not mean the Father or a property of the Father; neither could he possibly mean the apostles themselves, unless we are to suppose that the Father and the Son sent St Peter to St Peter, and that St Peter, so sent, came to St Peter! Again, when Christ saith of the Holy Ghost, "he shall receive of mine, and shall show it unto you," he could not, for the reason already assigned, mean by the Holy Ghost the Father or the power of the Father; and surely his meaning was not, that the apostles, under the influence of the power of the Father, should receive something and shew it each to himself! The Holy Ghost therefore is unquestionably a person; for though there are many passages of scripture in which the gifts of the Holy Ghost are called the Holy Ghost, they are so called by a very common figure of speech, in which the effect receives the name of its cause: and since this person is joined with the Father and the Son in the formula of Christian baptism; since they who lied to the Holy Ghost are said to have lied unto God; since blasphemy Acts v. against him is a more heinous offence than the same sin against even the Father or the Son; and since it was Mark iii. the operation of the Holy Ghost that Jesus Christ was conceived of the Virgin Mary, and even on that account called the Son of God—it follow that the Holy Ghost is God, of the same substance with the Father and Son.

It was this Divine Spirit which, on the day of Pentecost, inspired the apostles with the knowledge of different languages; and as these were given only to enable them to preach the gospel to every creature, it can be admitted of no doubt but that he, who so amply provided tribes of the means of preaching, would take care that the gospel should be preached in purity. Our Saviour had told his apostles, that the Comforter would guide them into all the truth (υπερηναι την οθονην), and bring all things to their remembrance, whatsoever he had said unto them; but if they had not comprehended the meaning of what he said, the bare remembrance of his sayings would have been of little importance. That before this omnious shedding abroad of the Spirit they had but a very imperfect knowledge of his doctrines, and of the purpose for which he had come into the world, is apparent from that unseasonable question which they put to him when assembled to witness his glorious ascension: "Lord, wilt thou at this time restore again the kingdom to Israel?" Their minds still cherished with fondness the vain prospect of temporal power; but after the day of Pente-"cost they were directed to nobler objects. From the same Spirit they received diversities of gifts besides that of language; for we are assured by St Paul, when speaking of the early converts to Christianity in gene-
Part II.

T H E O L O G Y.

Theology, that "to one was given by the Spirit the word of Wisdom; to another the word of Knowledge by the same Spirit; to another Faith by the same Spirit; to another the gifts of Healing by the same Spirit; to another the working of Miracles; to another Prophecy; to another Discerning of Spirits; to another Gifts kinds of Tongues; to another the Interpretation of Tongues;" and these gifts, which were severally divided either among private Christians or among the inferior orders of ministers in the church, we have reason to believe were all bestowed in a greater or less degree upon each of the apostles.

Men thus endowed were well qualified to declare unto the world all the counsel of God. By the word of Wisdom they communicated to the Gentile nations a pure system of what is called Natural Religion; turning them from the vanity of idols to the worship of the living God: by the word of knowledge, they preached the great doctrines of revelation both to Jews and Gentiles, shewing them that there is none other name under heaven given unto men whereby they may be saved than the name of Jesus Christ (L); and by their gifts of healing and of miracles, &c.; they were enabled to prove unanswerably, that their doctrines were divine. They taught everywhere the unity of God, the creation of the world, the fall of man, the necessity of redemption, the divinity of the Redeemer, his sacrifice on the cross to restore mankind to their forfeited immortality, and the terms of the new covenant into which they had through him been graciously admitted by God.

Such a view as our limits would admit of we have given of all these doctrines, except that which respects the terms of the gospel covenant; but these being explicitly stated only by St Paul and St James, we could not till now investigate them, without violating the historical order into which, for the sake of perspicuity, we have digested the several parts of this short system. Our Saviour himself has indeed taught with great plainness the necessity of faith and baptism to the salvation of those who have an opportunity of hearing the gospel preached with power (see Baptism): and in his sermon on the mount, which is such a lecture of ethics founded on religion as the Son of God only could have delivered, we learn, that "unless our righteousness shall exceed the righteousness of the Scribes and Pharisees, we shall in no case enter into the kingdom of heaven; that not every one who saith unto Christ, Lord, Lord, shall enter into the kingdom of heaven, but he who doth the will of the Father who is in heaven: and that many will say to him at the day of judgment, Lord, Lord, have we not prophesied in thy name, and in thy name done many wonderful works?" which could not be done without faith; to whom he will, notwithstanding, say, "Depart from me, ye that work iniquity." St Paul, however, seems to attribute our justification to the bare act of believing; for he repeatedly assures us, "that a man is justified by faith without the deeds of the law," while St James, on the other hand, affirms, "that by works a man is justified, and not by faith only." This apparent difference in the language of the two apostles, has produced among divines opinions really different respecting the justification of Christians; and the principal of these opinions it is our duty to state.

Between pardon of sin and justification there is so close a connection, that many writers seem to consider the terms as synonymous, and to infer, that he who is pardoned is ipso facto justified. That every Christian, who shall be pardoned at the judgment of the great day, will likewise be justified, is indeed true; but in propriety of speech, justification is a word of very different import from pardon, and will entitle the Christian to what mere pardon could not lead him to expect. An innocent person, when falsely accused and acquitted, is justified but not pardoned; and a criminal may be pardoned, though he cannot be justified or declared innocent. A man whose sins are pardoned is free from punishment; but the justified Christian is entitled to everlasting life, happiness, and glory. If we were only pardoned through Christ, we should indeed escape the pains of hell, but could have no claim to the enjoyments of heaven; for these, being more than the most perfect human virtue can merit, must be, what in the scriptures they are always said to be, the gift of God through Jesus Christ our Lord." Hence it is that St Paul, distinguishing, as we have done upon his authority, between mere remission of sins and justification of life, declares, that Romans 4:25-27.

The word justification, as used both by St Paul and St James, has been very generally considered as a forensic term expressing the sentence of a judge. The most eminent reformed divines of all denominations, &c., Limborch, Bull, Waterland, Warburton, Beveridge, saucification; and if so, it will signify God's pronouncing a person just, either as being perfectly blameless, or guilt, &c., as having fulfilled certain conditions required of him in the Christian covenant. But that "there is not a just man upon earth, who doth good and sinneth not," is made known to us by the most complete evidence possible, the joint dictates of our own consciences and of divine

(1.) It is not perhaps easy to determine what is here meant by the word of Wisdom and the word of Knowledge, as distinguished from each other. By the former (αριτον), Bishop Warburton understands all the great principles of natural religion. "The ancients (says he) used the word σοφία in this peculiar sense; it is used in the same sense by St Paul in Col. iv. 5; and we can hardly give it any other in the place before us, where we see the word of wisdom distinguished from the word of knowledge (αληθειας γνωσεως), which evidently means all the great principles of revelation; the term γνωσις being as peculiarly applied by Christian writers to revealed religion as σοφια is by the Gentiles to the natural. St Paul uses the word in this sense in 2 Cor. xi. 6, where he says, Εί δέ καὶ μιματίς τιν ομοιός ελαχρον τα γνωσις; and St Peter in his first epistle, chap. iii. verse 7. Hence those early heretics who so much deformed the simplicity and purity of the Christian faith by visionary pretences to superior knowledge of revelation, took from this word the name of Gnostics." See Warburton's Sermon on the Office and Operation of the Holy Ghost.
THEOLOGY.

Theology is more properly Christian doctrine.

It is a forensic term.

Rom. iii. 26.

For, if, after the publication of the law, sin had dominion over men, not by reason of the law, but by reason of sin, which by the law is not conceived, so we die.

Omnis causa instrumentalis (says Bishop Bull), suo modo in effectuum infinit, eique effectu producit proprii attributi potest. Jam vero, cum justificatio nihil aliquid sit quam gratiosum Dei actus, quos praecepera nostra nobis condonet, ac nos ad salutem acceptet, vel absuendum esse dicere, vel fidem, vel opera nostra, vel quidvis aliquid, nostri aut remittere praecepera nostra, aut personas nostras acceptare: quod tamen, si instrumentalis causa justificationis, fides sit, plena dicitum esse."

In this sentiment of the bishop of St. David's some of the most eminent divines both among the Calvinists and Arminians agree. Many, however, have chosen to treat of justification not only in the active sense, as it is the act of God, for all admit that it is he who justifies; but likewise in a passive sense, as it means our privilege or possession of him, when we are said to be justified by his grace. In this view of the subject they may talk with sufficient propriety, of an instrument of justification, not as the mean by which it is conveyed, but as the medium through which it is received by the true Christian. And hence it follows, that Waterland and Warburton strenuously maintain in the doctrine of the Westminster Catechism, that faith receiving and resting on Christ is the alone instrument of justification; though it cannot be alone in the person justified, but must ever be accompanied with all other saving graces, and be a faith which worketh by love.

A notion (says Dr. Gill) obtained some years ago, that a relaxation of the law and the severities of it has been obtained by Christ; and a new law, a remedial law, a law of milder terms, been introduced by him, which is the gospel: the terms of which are, faith, repentance, and new obedience; and though these he imperfect, yet, being sincere, they are accepted by God in the room of perfect righteousness. But every article of this scheme (continues he) is wrong; for the law is not relaxed, nor any of its severities abated; Christ came not to destroy, but to fulfil it; and therefore it requires the same holy, just, and good things, as ever. Nor is the gospel a new law. There is nothing in it (he says) which looks like a law; for it has no commands in it, but all promises, being a pure declaration of grace and salvation by Christ: nor are faith, repentance, and a new thing in obedience, required by it as conditions of man's acceptance with God. Faith and repentance are gospel doctrines, and parts of the gospel ministry: they are graces, and not terms required to be performed by men themselves. Faith is the gift of God, and repentance is a grant from him. It is not true (continues our author) that God will accept of an imperfect righteousness in the room of a perfect one; nor can any thing more highly reflect upon the justice and truth of God, who is the judge of all the earth, than to suppose that he can ever account that as a righteousness which is not one.

Having thus proved by arguments which were almost in the same words stated long before by Bishop Beveridge, that the gospel is no relaxation of the law, he proceeds to lay down his own notions of justification, of which (he says) "the sole matter, or that for the sake of which a sinner is justified before God, is the righteousness of Christ—that which he did and suffered on earth, in our nature, in our stead, and as our representative. This is commonly called his active and passive obedience; and when the purity and holiness of his own nature was added to it, the whole made up the imputation of the righteousness of the law, which was fulfilled by him as the head and representative of his people: for whatever the law required is necessary to a sinner's justification before God, and it required of sinners more than it did of man in innocence. Man was created with a pure and holy nature, conformable to the pure and holy law of God; and it was incumbent on him to continue so, and to yield in it perfect and sinless obedience, in the failure whereof he was threatened with death. Man did fail, by which his nature was vitiated and corrupted, and his obedience became faulty and imperfect. He thereby became liable to the penalty of the law, and still perfect obedience was required him. To the justification of a sinner therefore is required the most complete obedience, active and passive; or, in other words, purity of nature, perfect obedience, and the sufferings of death; all which meet in Christ, the representative of his people, in whom they are justified. There are indeed some divines (continues our author) who exclude the active obedience of Christ from being any part of the righteousness by which men are justified. They allow it to have been a condition requisite in him as a Mediator, qualifying him for his office; but deny that it is the matter of justification, or reckoned for righteousness to man. But without the active obedience of Christ the law would not be satisfied; the language which is, Do and live; and unless its precepts be obeyed, as well as its penalty endured, it cannot be satisfied; and unless it be satisfied there can be no justification. If therefore men are justified by the righteousness of Christ, it must be by his active obedience imputed and made over to them, so as to become their's, even as David describeth the blessedness of the man unto whom God imputeth righteousness without works. That this is really the way in which men are justified, our author thinks evident,
THEOLOGY.

Father, believe not only in the doctrine of Christ, but also in himself, trusting in him alone for everlasting life and salvation.

Were it not that this author, in every thing that he writes, has an eye to the doctrine of election and reprobation, which he carries to a greater height than almost any other divine with whose works we are acquainted, he would differ little in his notions of justification from the more moderate Armenians. "Justification (says Limborch) is the merciful and gracious act of God, whereby he fully absoles from all guilt the truly penitent and believing soul, through, and for the sake of Christ apprehended by a true faith; or gratuitously imputes that faith for righteousness." Here indeed the imputation of Christ's righteousness is expressly denied; but Dr Waterland, who can hardly be considered as a Calvinist, seems to contend for the imputation of that righteousness to the sinner, as well as for faith being the instrument by which it is received.

It cannot be for nothing (says that able writer *) that St Paul so often and so emphatically speaks of man's being justified by faith, or through faith in Christ's blood, and that he particularly notes how Abraham, that he believed, and that his faith was counted to him for justification, when he might as easily have said that Abraham, to whom the gospel was preached, was justified by gospel-faith and obedience, had he thought faith and obedience equally instruments of justification. Besides, it is on all hands allowed, that though St Paul did not directly oppose faith to evangelical works, yet he comprehended the works of the moral law under those which he excluded from the office of justifying, in his sense of the word justification. He even used such arguments as extended to all kinds of works; for Abraham's works were excluded. Faith then, he interprets the apostle's doctrine fairly, our author of it. quotes, from the genuine epistle of Clemens of Rome, a passage, in which it appears beyond a doubt that this fellow-labourer of St Paul so understood the doctrine of justifying faith as to oppose it even to evangelical works, however exalted. It is true (continues our author), Clemens elsewhere, and St Paul almost everywhere, insists upon true holiness of heart and obedience of life as indispensable conditions of salvation or justification; and of that, one would think, there could be no question among men of any judgment or prudence. But the question about conditions is very distinct from the other question about instruments; and therefore both parts may be true, viz. that faith and obedience are equally conditions, and equally indispensable where opportunities permit; and yet faith over and above is emphatically the instrument both of receiving and holding justification, or a title to salvation.

To explain this matter more distinctly, let it be remembered, that God may be considered either as a party contracting with man on very gracious terms, or as a Judge to pronounce sentence on him. Man can enter into the covenant, supposing him adult, only by assenting to it, and accepting it, to have and to hold it on such kind of tenure as God proposes: that is to say, upon a self-denying tenure, considering himself as a guilty man standing in need of pardon, and of borrowed merits, and at length resting upon mercy. So here, the previous question is, Whether a person shall consent to hold a privilege upon this submissive kind of tenure or not?
THEOLOGY.

Part II.

not? Such assent or consent, if he comes into it, is the very thing which St Paul and St Clemens call faith.

And this previous and general question is the question which both of them determine against any proud claimants who would hold by a more self admiring tenure.

"Or if we next consider God as sitting in judgment, and man before the tribunal going to plead his cause; here the question is, What kind of plea shall a man reconcile to trust his salvation upon? Shall he stand upon his innocence, and rest upon strict law? or shall he plead guilty, and rest in an act of grace? If he chooses the former, he is proud, and sure to be cast: if he chooses the latter, he is safe so far in throwing himself upon an act of grace. Now this question also, which St Paul has decided, is previous to the question, What conditions even the act of grace itself finally insists upon? A question which St James in particular, and the general tenure of the whole Scripture, has abundantly satisfied; and which could never have been made a question by any considerate or impartial Christian. None of our works are good enough to stand by themselves before him who is of purer eyes than to behold iniquity. Christ only is pure enough for it at first hand, and they that are Christ's at second hand in and through him. Now because it is by faith that we thus interpose, as it were, Christ between God and us, in order to gain acceptance by him; therefore faith is emphatically the instrument whereby we receive the grant of justification. Obedience is equally a condition or qualification, but not an instrument, not being that act of the mind whereby we look up to God and Christ, and whereby we embrace the promises."

But though our author contends that faith is the instrument of justification, he does not, like the Antinomians, teach that it will save men without works. "The covenant of grace (says he) has conditions annexed to it of great importance, for without them no instruments can avail. These are faith and obedience, as St James hath particularly maintained. St Paul had before determined the general and previous question respecting the plea by which we ought to abide; and when some libertines, as is probable, had perverted his doctrine of faith and grace, St James showed that the very faith which rests in a covenant of grace implies a cordial submission to the conditions of that covenant, otherwise it would be nothing but an empty ceremony. The perfect agreement between St Paul and St James in the article of justification, appears very clear and certain. St Paul declares, that in order to come at justification, it is necessary to stand upon grace, not upon merit; which St James does not deny, but rather confirms, in what he says of the perfect law of liberty (James i. 25, ii. 12.). St Paul makes faith the instrument of receiving that grace; which St James does not dispute, but approves by what he says of Abraham (ii. 23.); only he maintains also, that in the conditionate sense, justification depends equally upon faith and good works; which St Paul also teaches and inculcates in effect, or, in other words, through all his writings. If St Paul had had precisely the same question before him which St James had happened to have, he would have decided just as St more prudently did; and if St James had had precisely the same question before him which St Paul had, he would have determined just as St Paul did. Their principles were exactly the same, but the questions were diverse; and they had different adversaries to deal with, and opposite extremes to encounter, which is a common case.

"It may be noted, that that faith which is here called a condition, is of much wider compass than that particular kind of faith which is precisely the instrument of justification. For faith as a condition means the whole complex of Christian belief, as expressed in the creeds; while faith as an instrument means only the laying hold on grace, and resting in Christ's merits, in opposition to our own deservings: though this also, if it is a vital and operative principle (and if it is not, it is nothing worth), must of course follow after it an hearty submission to, and observance of, all the necessary conditions of that covenant of grace wherein we repose our whole trust and confidence. So that St Paul might well say, "Do we then make void the law (the moral law) through faith? God forbid. Yea, we establish the law."

We ex. Rom ii. emptor no man from religious duties; which are duties still, though they do not merit nor are practicable to such a degree as to be above the need of pardon: they are necessary conditions in their measure of justification, though not sufficient in themselves to justify, nor perfect enough to stand before God or to abide trial: therefore Christ's merits must be taken to supply their defects: and so our resting in Christ's atonement by an humble self-denying faith is our last resort, our anchor of salvation both sure and steadfast, after we have otherwise done our utmost towards the fulfilling of God's sacred laws, towards the performing of all the conditions required.

"That good works, internal and external, are according as opportunities offer and circumstances permit, conditions properly so called, is clear from the whole tenor of Scripture, as hath been often and abundantly proved by our own divines (m), and is admitted by the most judicious among the foreign Reformed (s). Yet some have been very scrupulous as to this innocent name, even while they allow the absolute necessity of good works as indispensable qualifications for future blessedness. Why not conditions therefore as well as qualifications? Perhaps because that name might appear to strike at absolute predestination, or unconditional election; and there may lie the scruple; otherwise the difference appears to lie rather in words than in things.

"Some will have them called not conditions, but fruits or consequents of justification. If they mean by justification the same as the grace of the Holy Spirit, and the first grace of faith springing from it, they say true; and then there is nothing more in it than an improper use of the word justification, except that from abuse of words very frequently arises some corruption of doctrine. If they mean only, that outward acts of righteousness are fruits of inward habits or dispositions; that

---

Theology that also is undoubtedly true: but that is no reason why internal acts, virtues, graces (good works of the mind), should not be called conditions of justification; or why the outward acts should not be justly thought as conditions of preserving it. But if they mean that justification is ordinarily given to adults, without any preparatory or previous conditions of faith and repentance, that indeed is a very new doctrine and dangerous, and opens a wide door to carnal security and to all ungodliness. Such is the doctrine of Christian justification as it has been taught by the followers of Calvin, and by some of the most eminent Arminians who flourished in the end of the 17th and beginning of the 18th century. They appear not, from this view of their opinions, to differ so widely as some of them have wished the world to believe. It is evident that Dr. Waterland, though he rejects some of the distinguishing tenets of Calvinism, lays greater stress upon faith in his scheme of justification than Dr. Gill himself, and that they both consider it as the instrument by which the adult Christian must receive the imputed righteousness of Christ. The greater part of modern Arminians, however, exclaim against the imputation of Christ's righteousness, as a doctrine false in itself, and fraught with the most pernicious consequences; and they would be ready to tell Dr. Gill, in his own words, that of his scheme every article is wrong. It is not true (say they) that God exacts of man, or ever did exact of him, an obedience absolutely perfect; for under every dispensation man was in a state of discipline, and had habits of virtue and piety to acquire; and it is probable that his progress in piety, virtue, and wisdom, will continue for ever, as none but God is perfect and stationary, and incapable of deviating from the line of rectitude. Most of them, after Bishop Bull, disbelieve the use of such unscriptural phrases as instrument of justification, applied either to faith or to works; and think, that by considering God as the sole justifier of man, upon certain conditions, they can more precisely ascertain the distinct provinces of faith and obedience in the scheme of justification, than either their brethren of the old school of Arminians, or their rivals of the school of Calvin.

By the very constitution of man, piety and virtue are duties which, if he do not sincerely perform, he must of course forfeit the favour of his Maker; but the most perfect performance of his natural duties would not entitle him to a supernatural and eternal reward. Eternal life is the gift of God through Jesus Christ; and it is surely reasonable that we should acknowledge it to be so, and not claim it as a debt due to our merits. The pious and virtuous man has a natural claim to more happiness than misery during the period of his existence, a claim founded on the attributes of that God who calls him into being; but he has no natural claim to a future life, and still less to a perpetuity of existence. This is a truth not more clearly taught in the holy scripture than consonant to the soundest philosophy: and yet, by not attending to it, have St. Paul and St. James been set at variance, and the most opposite doctrines taught respecting the justification of Christians.

Because faith in Christ cannot entitle a wicked man to eternal happiness, one class of divines seem to infer that such faith is not necessary to Christian justification, and that "his faith cannot be wrong whose life is in the right." They proceed upon the supposition that man is naturally immoral; that piety and virtue are entitled to reward; and that therefore the pious and virtuous man, whatever be his belief, must undoubtedly inherit an eternal reward. But this is very fallacious reasoning. That piety and virtue are through the divine justice and benevolence entitled to reward, is indeed a truth incontrovertible; but that man who is of yeasty day is naturally immortal; that a being who began to exist by the mere good will of his Maker, has in himself a principle of perpetual existence independent of that will—is a direct contradiction. Whatever began to be, can be continued in being only by the power, and according to the pleasure, of the infinite Creator; but it pleased the Creator of his free grace at first to promise mankind eternal life, on the single condition of their first father's observing one positive precept. That precept was violated, and the free gift lost: but the covenant was renewed in Christ, who "by his death hath abolished death, and by his death and by his blood he hath brought faith to light life and immortality." The condition annexed to the gift thus restored was faith: for "being justified by faith, we have peace with God through our Lord and Saviour Jesus Christ; by whom also we have access by faith equally into this grace wherein we stand, and rejoice in the Christian hope of the glory of God." Faith therefore is in the Son of God and Saviour of the world, is not only a condition, but the sole condition, of that justification which is peculiarly Christian; for since Christ, without any co-operation of ours, hath purchased for us the free gift of eternal life, we shall be guilty of the grossest ingratitude to our Divine Benefactor, and improperly claim an independence on God, if we look upon that gift either as a right inherent in our nature, or as a debt due to our meritorious deeds.

But though faith be the condition of justification, as but not of that implies the inheritance of eternal life, there are other conditions to be performed before a man can be put in possession of eternal felicity. By a law long prior to the promulgation of the gospel—a law interwoven with our very being—no man can enjoy the favour of his Maker, who does not make it his constant endeavour to do justly, to love mercy, and to walk humbly with his God. This law was in force before man fell; it continues to be in force now that he is redeemed; and it will not be abrogated even at that period when faith shall give place to vision, and hope to enjoyment. By the grace of the Christian covenant, all mankind are rendered immortal in consequence of the death and resurrection of Christ, who is the Lamb slain, in the divine decree, from the foundation of the world; but to obtain immortal happiness, they must observe the conditions both of nature and of revealed religion, which are repose from death, works, and faith in Christ the Redeemer. The former is that condition upon which alone we can retain the Divine favour, and of course enjoy either present or future happiness; the latter is a most equitable acknowledgement required of us, that perpetual conscious existence is neither a right inherent in our nature, nor a debt due to our virtuous obedience, but merely the gift of God through Jesus Christ our Lord.

To make the distinct provinces of faith and works in the business of justification clear, let us suppose (says Bishop Warburton), that, at the publication of the gospel, all to whom the glad tidings of immortality were

Part II.

THEOLOGY.

A third office of the Holy Spirit is to lead, direct, and govern us through all the periods of our lives, more peculiarly Christians. Without such a leader and guide, the temptations with which we are surrounded would certainly overcome us, and we should faint long before we arrive at the end of our journey. By the very constitution of our nature we are subjected in some degree to the influence of sense, of which the objects are present, whilst the enjoyment of heaven is future, and seen, as at a distance, only by the eye of faith; but "the law of the Spirit of life, in Christ Jesus, hath made us free from the law of sin and death," for God worketh in us both to will and to do of His good pleasure; and as many as are thus led by the spirit of God, they are the sons of God; and while they walk in the Spirit, they do not fulfil the lusts of the flesh. Without the aid of the same Spirit, we could not even make our prayers acceptable; for since our confidence in God is, that He heareth us only when we ask any thing according to His will; and since we know not what we should pray for as we ought, the Spirit itself maketh intercession for us with groanings which cannot be uttered.

A fourth operation of the Holy Ghost, as He is the sanctifier of Christians, is to join them to Christ, and make them members of that one body of which He is the head. For by one Spirit are we all baptized into one body; and as the body is one and hath many members, and all the members of that one body being one, so also is Christ. Hereby we know that God abideth in us, by the Spirit which He hath given us; and as, in the ordinary course of His dealings with Christians, this Spirit is first given in baptism, so is it continued to the faithful by the instrumentality of the Lord's supper. That ordinance we have elsewhere (see Supper of the Lord) proved to be a federal rite; and surely no time can be supposed so highly sanctified for the reception of the graces of the Holy Spirit, as that in which we renew our federal union with our Lord and Master in the communion of His body and blood.

It is likewise the office of the Holy Ghost to give us an earnest of our everlasting inheritance, to create in us a sense of the paternal love of God, and thereby to assure us of the adoption of sons. As many as are led by the Spirit of God, they are the sons of God; and because we are sons, God hath sent forth the spirit of His Son into our hearts. For we have not received the spirit of bondage again to fear; but we have received the Spirit of adoption, whereby we cry, Abba Father; the Spirit itself bearing witness with our spirit, that we are the children of God.

As the gifts of grace are generally annexed to means, Rom. viii., to the proper use of the word and sacraments, it is a fifth and sixth office of the same Spirit to sanctify such persons as are regularly set apart for the work of the ministry, and ordained to offer up the public prayers of the people; to bless them in the name of God; to teach the doctrines of the gospel; to administer the sacraments instituted by the ministers of the Church; and to perform all things necessary for the perfecting of the saints, for the work of the ministry, of the gospel, for the edifying of the body of Christ. The same Spirit which illuminated the apostles, and endowed them with power from above to perform personally their apostolic functions, fitted them also for sending others, as they were sent by their Divine Masters; and for establishing the church.

† Clarke and Waterland.
THEOLOGY.

Part II.

Theology more peculiarly Christian.

Adapted for preserving Christians in the unity of the Spirit and bond of peace. They committed a standing power to a successive ministry to be conveyed down to the end of the world; and those who are vested with that power are obliged to take heed unto themselves, and to all the flock over which the Holy Ghost hath made them overseers, to feed the church of God, and to contend earnestly for the faith which was once delivered unto the saints. See Episcopacy, Independents, Presbyterians, Popes, and Quakers.

By these, and the like means, doth the Spirit of God sanctify the sons of men; and in consequence of this sanctification proceeding immediately from his office, he is called the Holy Spirit and the Comforter. This is such a provision for renewing us in the spirit of our minds, and enabling us to put on the new man, which, after God, is created in righteousness and true holiness, as, when made known by revelation, appears to have been expedient, may be conceived to have been even necessary, and though reason could hardly be urged for it, is contradicted by none of our natural notions either of God or of man. Many, however, are the controversies to which it has given rise in the church of God; some contending that it is given only unto the elect, upon whom it operates with resistless efficacy; others affirming that it is offered to all, but in such a manner as that, by the abuse of their free will, it may be resisted, grieved, and quenched; and some few, still intoxicated with the pride of Pelagius, think it is not necessary, and of course is not bestowed.

The questions concerning election, the efficacy of grace, and the final perseverance of the saints, we have stated elsewhere, and given a summary view of the arguments by which the contending parties maintain their respective opinions (see Predestination); and the texts of Scripture which we have just quoted, under the different heads of sanctification, show sufficiently that the opinion of Pelagius is directly contrary to the doctrine of the apostles. It may not be improper to enquire whether it be as agreeable to reason and experience as its patrons seem to imagine.

If it be unreasonable to expect any assistance from the Spirit of God in carrying on the work of our own salvation, how came so many of the wisest and best of men in all ages to believe, that he who sincerely endeavours to discharge his duty is supported in that endeavour by assistance from heaven? That such was the popular belief of the early Greeks, is evident from the poems of Homer; in which we everywhere find some god calming the passions of the heroes, altering their determinations when improper, and inspiring them with wisdom. Nor was this the sentiment of the poets only. Socrates, it is well known, professed to believe that his own conduct was under the direction of a superior spirit, which he called a daemon; and Plutarch, as we find him quoted by Wollaston, speaks of the gods assisting men, by exciting the powers or faculties of the soul; by suggesting secret principles, imaginations, or thoughts; or, on the contrary, by diverting or stopping them.

Of the same opinion must Cicero have been, when he said, "statibus illis quidem, quod locum hinc cum instanter, de quo agimus, esse Deos, et eorum providentia munere, nec semper universis, verum etiam singulis," for it is not conceivable that a particular providence can be administered without the influence of the Deity on the more present minds of men. That the poets and philosophers of the early heathen world derived these notions from primitive tradition, cannot be too much questioned; but if they were absurd in themselves, or apparently contradictory to the laws of nature, it would not have been so universally embraced; for it will scarcely be denied, that Socrates and Cicero were men of as great natural sagacity as Pelagius or any of his followers. It is indeed so far from being incredible that the Father of spirits occasionally directs the thoughts and actions of men, that we believe there are very few who have made observations on themselves and their own affairs, who have not found, on reflection, many instances in which their usual judgment and sense of things were overruled, they know not how, or why; and that the actions which they performed in those circumstances have had consequences very remarkable in their general history. See Providence, No. 18, 19.

In this being the case, why should the pride of Christians make them hesitate to admit, on the authority of divine revelation, what Socrates, and Plutarch, and Cicero, and all the virtuous and wise men of antiquity, admitted in effect, on no better evidence than that of oral tradition, supported by their own meditations on their own thoughts, and the principles of their own conduct? Is it that they see not such beneficial effects of Christianity as to induce them to believe the professors of that religion to be indeed "chosen to salvation through the sanctification of the Spirit?" Let them study the practical precepts of the gospel, consider the consequences which they have had on the peace and happiness of society, and compare the general conduct of Christians with that of the Jews, Pagans, and Mahometans (see Religion), and they will doubtless find reason to alter their opinion; and let those who embrace the truth remember, that as they are the temple of God, if the Spirit of God dwell in them, it is their indispensable duty to cleanse themselves from all filthiness of the flesh and spirit; to follow peace with all men, and holiness, without which, no man shall see the Lord; and to work out their own salivation with fear and trembling, since it is God who worketh in them both to will and to do of his good pleasure.

Opinions of the heathens concerning it.

† De Div. i. sect. "dum administrari, coelestisque consilioris, rebus humanis, nec solum universis, verum etiam singulis." It is evident that the gospel is not only the best but the last gift of the kind which man has to expect from his Maker; that the scheme of revelation is completed; and that the pretences of Mahomet and of more modern enthusiasts to divine inspiration are not only false, but fraught with contradictions. All these men admit the divine origin of the Mosaic and Christian religions; but it appears from the scriptures, in which those religions are taught, that the system of revealed truths which constitute the Patriarchal, Mosaic, and Christian revelations, commenced with the fall of man, and that it must therefore necessarily end with his restoration to life and immortality by the sacrifice of Christ upon the cross. A new revelation therefore like that of Mahomet cannot be admitted without rejecting the whole Bible, though the impostor himself everywhere acknowledges the inspiration of Abraham, of Moses, and of Christ. Nor is greater regard due to the claims of Christian enthusiasts. Such as pretend to
Part II.

Theology

THEOLOGY, something relating to theory, or that terminates in speculation.

THEORY, in general, denotes any doctrine which terminates in speculation, without considering the practical uses or application thereof.

THEOSOPHISTS, a sect of men who pretend to derive all their knowledge from divine illumination. They boast that, by means of this celestial light, they are not only admitted to the intimate knowledge of God, and of all divine truth, but have access to the most sublime secrets of nature. They ascribe to it the singular manifestation of divine benevolence, that they are able to make such a use of the element of fire, in the chemical art, as enables them to discover the essential principles of bodies, and to disclose stupendous mysteries in the physical world. They even pretend to an acquaintance with those Celestial beings which form the medium of intercourse between God and man, and to a power of obtaining from them, by the aid of magic, astrology, and other similar arts, various kinds of information and assistance.

To this class belonged Paracelsus, Robert Fludd, Jacob Boehmen, Van Helmont, Peter Poiret, and the Rosicrucians. They are also called FIRE-Philosophers.

THERAPEUTÆ, a term applied to those that are wholly in the service of religion. This general term has been applied to particular sects of men, concerning whom there have been great disputes among the learned.

THERAPEUTICS, that part of medicine which acquaints us with the rules that are to be observed, and the medicines to be employed, in the cure of diseases.

THERMÆ, hot baths or baths. Luxury and extravagance were in nothing carried to such heights as in the thermæ of the Roman emperors. Ammian complains, that they were built to such an extent as to equal whole provinces; from which Valesius would date, by reading piscina instead of praecinctus. And yet after all, the remains of some still standing are sufficient testimonies for Ammian's censure; and the accounts transmitted of their ornaments and furniture, such as being laid with precious stones (Seneca), set round with seats of solid silver (Pliny), with pipes and cisterns of the same metal (Statius), add to, rather than take from, the censure. The most remarkable baths were those of Dioscletian and Caracalla at Rome, great part of which remains at this day; the lofty arches, stately pillars, variety of foreign marble, curious vaulting of the roofs, great number of spacious apartments, all attract the curiosity of
THE [ 398 ]

Thermometer.

Invention of the thermometer.

The thermometer was invented about the beginning of the 17th century; but, like many other useful inventions, it has been found impossible to ascertain to whom the honour of it belongs. Boecharne * ascribes it to Cornelius Drebble of Alcmar, his own countryman. Fulgenzio † attributes it to his master Paul Sarpi, the great oracle of the Venetian republic; and Viviani gives the honour of it to Galileo ‡. But all these are posthumous claims. Sanctorio § claims this honour to himself; and his assertion is corroborated by Borelli ‡ and Malpighi * of the Florentine academy, whose partiality is not to be suspected in favour of a member of the Patavian school.

Perhaps the best way to reconcile these different claims would be, to suppose that the thermometer was really invented by different persons about the same time.

We know that there are certain periods in the progress of knowledge, when the stream of human genius runs in the same direction, and moves towards the same object. That part of the current which reaches the object first may possess the title; but the other parts follow so rapidly and arrive so soon after, that it is impossible for a spectator to decide which is first in point of time.

The first form of this instrument for measuring the degrees of heat and cold, was the air-thermometer. It is a well known fact that air expands with heat so as to occupy more space than it does when cold, and that it is condensed by cold so as to occupy less space than when warmed, and that this expansion and condensation is greater or less according to the degree of heat or cold applied. The principle then on which the air-thermometer was constructed is very simple. The air was confined in a tube by means of some coloured liquor; the liquor rose or fell according as the air became expanded or condensed. What the first form of the tube was, cannot now perhaps be well known; but the following description of the air-thermometer will fully explain its nature.

The air-thermometer consists of a glass tube BE, fig. 1, connected at one end with a large glass ball A, and at the other end immersed in an open vessel, or terminating in a ball DE, with a narrow orifice at D; which vessel, or ball, contains any coloured liquor that will not easily freeze. Aquafortis tinged of a fine blue colour with a solution of vitriol or copper, or spirit of wine tinged with cochineal, will answer this purpose. But the ball A must be first moderately warmed so that a part of the air contained in it may be expelled through the orifice D; and then the liquor pressed by the weight of the atmosphere will enter the ball DE, and rise, for example, to the middle of the tube at C, at a mean temperature of the weather; and in this state the liquid by its weight, and the air included in the ball A, &c. by its elasticity, will counterbalance the weight of the atmosphere. As the surrounding air becomes warmer, the air in the ball and upper part of the tube, expanding by heat, will drive the liquor into the lower ball, and consequently its surface will descend; on the contrary, as the ambient air becomes colder, that in the ball is condensed, and the liquor pressed by the weight of the atmosphere will ascend; so that the liquor in the tube will ascend or descend more or less according to the state of the air contiguous to the instrument. To the tube is affixed a scale of the same length, divided upwards and downwards from the middle, into 100 equal parts, by means of which the ascent and descent of the liquor in the tube, and consequently the variations in the cold or heat of the atmosphere, may be observed.

This instrument was extremely defective; for the air in its defects in the tube was not only affected by the heat and cold of the atmosphere, but also by its weight.

The air being found improper for measuring with accuracy the variations of heat and cold according to the form of the thermometer which was first adopted, another thermometer fluid was proposed about the middle of the 17th century by the Florentine academy. This fluid was spirit of wine, or alcohol, as it is now generally named. The alcohol being coloured, was inclosed in a very fine cylindrical glass tube previously exhausted of its air, having a hollow ball at one end A, fig. 2. and hermetically sealed at the other end D. The ball and tube are filled with rectified spirit of wine to a convenient height, as to C, when the weather is of a mean temperature, which may be done by inverting the tube into a vessel of stagnant coloured spirit, under a receiver of the air-pump, or in any other way. When the thermometer is properly filled, the end D is heated red hot by a lamp, and then hermetically sealed, leaving the included air of about one-third of its natural density, to prevent the air which is in the spirit from dividing it in its expansion. To the tube is applied a scale, divided from the middle, into 100 equal parts, upwards and downwards.

As spirit of wine is capable of a very considerable degree of rarefaction and condensation by heat and cold, when the heat of the atmosphere increases the spirit dilates, and consequently rises in the tube; and when the heat decreases, the spirit descends, and the degree or quantity of the motion is shown by a scale.

The spirit of wine thermometer was not subject to the defects of some of the inconveniences which attended the air thermometer. In particular, it was not affected by variations in the weight of the atmosphere: accordingly it Manner's soon came into general use among philosophers. It was, Exemp at an early period, introduced into Britain by Mr Boyle. To this instrument, as then used, there are, however, many objections. The liquor was of different degrees of strength, and therefore different tubes filled with it, when exposed to the same degree of heat, would not correspond. There was also another defect: The scale which was adjusted to the thermometer did not commence at any fixed point. The highest term was adjusted to the great sunshine heats of Florence, which are too variable and undetermined; and frequently the workman formed the scale according to his own fancy. While the thermometer laboured under such disadvantages it could not be of general use.

To obtain some fixed unalterable point by which a determined scale might be discovered, to which all thermometers might be accurately adjusted, was the subject of many propositions by which next drew the attention of philosophers. Mr Boyle, who seems at an early period to have studied this subject with much anxiety, proposed the freezing of the essential oil of aniseeds as a convenient point for graduating thermometers; but this opinion has been laid aside. Dr Halley next proposed that thermometers should

Thermometer.

should be graduated in a deep pit under ground, where the temperature both in winter and summer is pretty uniform; and that the point to which the spirit of wine should rise in which was named place should be the point from which the scale should commence. But this proposal was evidently attended with such inconveniences that it was soon abandoned. He made experiments on the boiling point of water, of mercury, and of spirit of wine; and he seems rather to give a preference to the spirit of wine

* Phil. Trans. Abr. II. 34. 7

Sir Isaac Newton's oil thermometer.

It seems to have been reserved to the all-conquering genius of Sir Isaac Newton to determine this important point, on which the accuracy and value of the thermometer depends. He chose, as fixed, those points at which water freezes and boils; the very points which the experiments of succeeding philosophers have determined to be the most fixed and convenient. Sensible of the disadvantages of spirit of wine, he tried another liquor which was homogenous enough, capable of a considerable rarefaction about 15 times greater than spirit of wine. This was linseed oil. It has not been observed to freeze even in very great colds, and it bears a heat about four times that of water before it boils. With these advantages it was made use of by Sir Isaac Newton, who discovered by it the comparative degree of heat for boiling water, melting wax, boiling spirit of wine, and melting tin; beyond which it does not appear that this thermometer was applied. The method he used for adjusting the scale of this oil thermometer was as follows: Supposing the bulb, when immersed in thawing snow, to contain 10,000 parts, he found the oil expand by the heat of the human body so as to take up 175 square parts; or, 10,256 such parts; and by the heat of water boiling strongly 10,725; and by the heat of melting tin 11,175. So that reckoning the freezing point as a common limit between heat and cold, he began his scale there, marking it 0; and the heat of the human body he made 1°; and consequently, the degree of heat being proportional to the degrees of rarefaction, or 256: 725: 12: 34, this number 34 will express the heat of boiling water; and by the same rule, 72 that of melting tin. This thermometer was constructed in 1701.

To the application of oil as a measure of heat and cold, there are insuperable objections. It is so viscous, that it adheres too strongly to the sides of the tube. On this account it ascends and descends too slowly in case of a sudden heat or cold. In a sudden cold, a great portion remains adhering to the sides of the tube after the rest has subsided, that the surface appears lower than the corresponding temperature of the air requires. An oil thermometer is therefore not a proper measure of heat and cold.

9 Reaumur's spirit of wine thermometer.

All the thermometers hitherto proposed were liable to many inconveniences, and could not be considered as exact standards for pointing out the various degrees of temperature. This led Reaumur to attempt a new one, an account of which was published in the year 1730 in the Memoirs of the Academy of Sciences. This thermometer was made with spirit of wine. He took a large ball and tube, the dimensions and capacities of which were known; he then graduated the tube, so that the space from one division to another might con-

ments already made can determine, it is of all the fluids hitherto employed in the construction of thermometers, that which measures most exactly equal differences of heat by equal differences of its bulk: its dilatations are in fact very nearly proportional to the augmentations of heat applied to it (A). 2. Of all liquids it is the most easily freed from air. 3. It is fitted to measure high degrees of heat and cold. It sustains a heat of 60° of Fahrenheit’s scale, and does not congeal till it fall 39 or 40 degrees below 0. 4. It is the most sensible of any fluid to heat and cold, even air not excepted. Count Rumford found that mercury was heated from the freezing to the boiling point in 38 seconds, while water took two minutes 13 seconds, and common air 10 minutes and 27 seconds. 5. Mercury is a homogeneous fluid, and every portion of it is equally dilated or contracted by equal variations of heat. Any one thermometer made of pure mercury is, ceteris paribus, possessed of the same properties with every other thermometer made of pure mercury. Its power of expansion is indeed about six times less than that of spirit of wine, but it is great enough to answer most of the purposes for which a thermometer is wanted.

The fixed points which are now universally chosen for adjusting thermometers to a scale, and to one another, are the boiling and freezing points of water. The boiling water point, it is well known, is not an invariable point, but varies some degrees according to the weight and temperature of the atmosphere. In an exhausted receiver, water will boil with a heat of 98° or 100°, whereas in Papan’s digestor it will require a heat of 412. Hence it appears that water will boil at a lower point, according to its height in the atmosphere, or to the weight of the column of air which presses upon it. In order to ensure uniformity therefore in the construction of thermometers, it is now agreed that the bulb of the tube be plunged in the water when it boils violently, the barometer standing at 30 English inches (which is its mean height round London, and the temperature of the atmosphere 55°). A thermometer made in this way, with its boiling point at 212°, is called by Dr Horsley Bird’s Fahrenheit, because Mr Bird was the first person who attended to the state of the barometer in constructing thermometers.

As artists may be often obliged to adjust thermometers to under very different pressures of the atmosphere, philosopher-theorists have been at pains to discover a general rule which might be applied on all occasions. M. de Luc, in the 14th of his Recherches sur les Mod. de l’Atmosphere, from a series of experiments, has given an equation for the allowance on account of this difference, in Paris measure, which has been verified by Sir George Shuckburgh; also Dr Horsley, Dr Maskelyne, and Sir George Shuckburgh, have adapted the equation and rules to English measures, and have reduced the allowances into tables for the use of the artist. Dr Horsley’s rule deduced from de Luc’s, is this:

\[ \log \frac{A}{800000} = -928.284 = h^{10} \]

where \( A \) denotes the height of a thermometer plunged in boiling water, above the point of melting ice, in degrees of Bird’s Fahrenheit, and \( h \) the height of the barometer in 10ths of an inch. From this rule he has computed the following table, for finding the heights, to which a good Bird’s Fahrenheit will rise when plunged in boiling water, in all states of the barometer, from 27 to 31 English inches; which will serve, among other uses, to direct instrument-makers in making a true allowance for the effect of the variation of the barometer, if they should be obliged to finish a thermometer at a time when the barometer is above or below 30 inches; though it is best to fix the boiling point when the barometer is at that height.

\[ \frac{A}{800000} = -928.284 = h^{10} \]

(A) We have affirmed that the expansions of the bulk of quicksilver by heat are nearly (for they are not strictly so) in a regular arithmetical progression, according to the quantity of heat it is exposed to; and such seems to be the case according to the Table published by M. de Luc, at page 309 of his first volume on the Modifications of the Atmosphere. The following extract of this table shows these variations: and the first and second differences arecraped, in order to render these irregularities more sensible. They are such as can hardly be conceived from the nature of any substance, without the influence of extraneous and accidental causes, which may have escaped the attention of the observer; neither have they been found exactly true by Dr Crawford. M. de Luc supposes the whole heat from melting ice to that of boiling water to be divided into 80 parts; by the fractional subdivisions of which he expresses the absolute quantities of heat, answering to each 5 or 10 degrees of Reaumur’s thermometer (\( = 22.5 \) of Fahrenheit’s scale); so that the whole sum of these fractions amounts exactly to the assumed number 80. They are as follow:

The numbers in the first column of this table express heights of the quicksilver in the barometer in English inches and decimal parts: the second column shows the equation to be applied, according to the sign prefixed, to 212° of Bird's Fahrenheit, to find the true boiling point for every such state of the barometer. The boiling point for all intermediate states of the barometer may be had with sufficient accuracy, by taking proportional parts, by means of the third column of differences of the equations. See Philosophical Transactions, vol. lixiv. art. 30; also Dr. Maskelyne's Paper, vol. lixiv. art. 20.

The Royal Society, fully apprized of the importance of adjusting the fixed points of thermometers, appointed a committee of seven gentlemen to consider of the best method for this purpose; and their report is published in the Phil. Trans. vol. lxvii. part ii. art. 37. They observed, that though the boiling point be placed so much higher on some of the thermometers now in use than on others, yet this does not produce any considerable error in the observations of the weather, at least in this climate; for an error of 1° in the position of the boiling point, will make an error only of half a degree in the position of 92°, and of not more than a quarter of a degree in the point of 62°. It is only in nice experiments, or in trying the heat of hot liquors, that this error in the boiling point can be of much importance.

In adjusting the freezing as well as the boiling point, the quicksilver in the tube ought to be kept of the same heat as that in the ball. When the freezing point is placed at a considerable distance from the ball, the pounded ice should be piled to such a height above the ball, that the error which can arise from the quicksilver in the remaining part of the tube not being heated equally with that in the ball, shall be very small, or the observed point must be corrected on that account according to the following table:

Table for correcting the freezing point.

The correction in this table is expressed in 1000ths parts of the distance between the freezing point and the surface of the ice: e.g. if the freezing point stands seven inches above the surface of the ice, and the heat of the room is 62°, the point of 32° should be placed 7 x .00261, or .018 of an inch lower than the observed point. A diagonal scale will facilitate this correction.
THE

The committee observe, that in trying the heat of
liquors, care should be taken that the quicksilver in the
tube of the thermometer be heated to the same degree
as that in the buns: or if this cannot be done con-
mumly, the observed heat should be corrected on that
account; for the manner of doing which, and a table cal-
culated for this purpose, we must refer to their excellent
report in the Phil. Trans. vol. lvii. part ii. art. 37.

With regard to the choice of tubes, they ought to be
easily cylindrical. But though the diameter should
vary a little, it is easy to manage that matter in the
manner proposed by the Abbé Nollet *, by making a
small portion of the quicksilver, e. g. as much as fills
up an inch or half an inch, slide backward and forward
in the tube; and thus to find the proportions of all its
inequalities, and from thence to adjust the divisions to a
scale of the most perfect equality. The capillary tubes
are preferable to others, because they require smaller
bulbs, and they are also more sensible, and less brittle.
The most convenient size for common experiments has
the internal diameter about 42th or 52th of an
inch, about nine inches long, and made of thin glass,
that the rise and fall of the mercury may be better
seen.

The next thing to be considered, is of what number of
degrees or divisions the scale ought to consist, and
from what point it ought to commence. As the number
of the divisions of the scale is an arbitrary matter, the
scales which have been employed differ much from one
another in this circumstance. Fahrenheit has made 180
degrees between the freezing and boiling water point.
Amontons made 73, and Sir Isaac Newton only 34.
There is, however, one general maxim, which ought to
be observed: That such an arithmetical number should
be chosen as can easily be divided and subdivided,
and that the number of divisions should be so great that
there shall seldom be occasion for fractions. The num-
er 80 chosen by Reaumur answers extremely well in
this respect, because it can be divided by several figures
without leaving a remainder; but it is too small a num-
er: the consequence of which is, that the degrees are
placed at too great a distance from one another, and
fractions must therefore be often employed. We think,
therefore, that 180 would have been a more convenient
number. Fahrenheit's number 180 is large enough,
but when divided its quotient soon becomes an odd
number.

As to the point at which the scale ought to com-
ence, various opinions have been entertained. If we
knew the beginning or lowest degree of heat, all
philosophers would agree, that the lowest point of the
thermometer ought to be fix'd there; but we know neither
the lowest nor the highest degrees of heat; we observe
only the intermediate parts. All that we can do, then,
is to begin it at some invariable point, to which thermo-
meters made in different places may easily be adjusted.
If possible too, it ought to be a point at which a na-
tural well-known body receives some remarkable change
from the effects of heat or cold. Fahrenheit began his
scale at the point at which snow and salt congeal. Kir-
wan proposes the freezing point of mercury. Sir Isaac
Newton, Hales, and Reaumur adopted the freezing
point of water. The objection to Fahrenheit's lowest
point, is that it commences at an artificial cold never
known in nature, and to which we cannot refer our

12

The number of degrees into which the scale ought to be divi-
ded.

22

At what point the scale ought to com-
mence.
In this thermometer it is evident that the mercury must be affected by the weight and elasticity of the spirit of wine, and therefore it will not correspond to any of the common mercurial thermometers.

The thermometer for showing the greatest degree of cold is represented in fig. 4. by the crooked tube ABCD. This instrument is filled with spirit of wine, with the addition of as much mercury as is sufficient to fill both legs of the syphon, and about a fourth or fifth part of the hollow ball C. We are not told what the proportion of mercury was to that of spirit of wine. The degrees of heat are shown by the rise or fall of the mercury in the leg AB. The thermometer marks the greatest fall by means of the hollow ball C. When the mercury in the longer leg sinks by cold, that in the shorter will rise and run over into the ball C, from which it cannot return when the mercury subsides in the shorter and rises in the longer leg. The upper part of the shorter leg will therefore be filled with a column of spirits of a length proportional to the increase of heat; the bottom or lower surface of which, by means of a proper scale, will show how much the mercury has been lower than it is; which being subtracted from the present height will give the lowest point to which the mercury has fallen. That the thermometer may be fitted for a new observation, the mercury must be made to run back from the ball into the shorter leg, by inclining the tube and heating the ball.

In 1782 Mr. Six proposed another self-registering thermometer. It is properly a spirit of wine thermometer, though mercury is also employed for supporting an index. A b, fig. 5. is a thin tube of glass 16 inches long, and $\frac{3}{4}$th of an inch calibcr: c d e and f g h are smaller tubes about $\frac{1}{10}$th of an inch caliber. These three tubes are filled with highly rectified spirit of wine, except the space between d and g, which is filled with mercury. As the spirit of wine contracts or expands in the middle tube, the mercury falls or rises in the outside tubes. An index, such as that represented in fig. 6, is placed on the surface, within each of these tubes, so light as to float upon it. k is a small glass tube $\frac{3}{4}$th of an inch long, hermetically sealed at each end, and inclining a piece of steel wire nearly of its own length. At each end l, m, of this small tube, a short tube of black glass is fixed of such a diameter as to pass freely up and down within either of the outside tubes of the thermometer e c or f h. From the upper end of the index is drawn a spring of glass to the fineness of a hair, and about $\frac{1}{8}$th of an inch long; which being placed a little oblique, presses lightly against the inner surface of the tube, and prevents the index from descending when the mercury descends. These indexes being inserted one into each of the outside tubes, it is easy to understand how they point out the greatest heat or cold that has happened in the observer’s abode. When the spirit of wine in the middle tube expands, it presses down the mercury in the tube h f, and consequently raises it in the tube e c; consequently the index on the left hand tube is left behind and marks the greatest cold, and the index in the right hand tube rises and marks the greatest heat.

In 1790 a paper was given in to the Royal Society of Edinburgh, describing two thermometers, newly invented, by Dr. John Rutherford of Middle Bailleih; the one for registering the highest and the other for registering the lowest degree of heat to which the thermometer has risen or fallen during the absence of the observer. An account of them may be found in the third volume of the Transactions of the Society.

A new self-registering thermometer has been invented by Mr. Keith of Havelstone, which we consider thermometers as the most ingenious, simple, and perfect, of any which hitherto appeared. Its simplicity is so great, that it requires only a very short description to make it intelligible.

AB, fig. 7. is a thin glass tube about 14 inches long Fig. 7. and $\frac{3}{4}$th of an inch caliber, close or hermetically sealed at top. To the lower end, which is open, there is joined the crooked glass tube B E, seven inches long, and $\frac{3}{4}$th of an inch caliber, and open at top. The tube AB is filled with the strongest spirit of wine, and the tube B E with mercury. This is properly a spirit of wine thermometer, and the mercury is used merely to support a piece of ivory or glass, to which is affixed a wire for raising one index or depressing another, according as the mercury rises or falls.

E is a small conical piece of ivory or glass, of such a weight as to float on the surface of the mercury. To the float is joined a wire called the float wire, which reaches upwards to H, where it terminates in a knee bent at right angles. The float wire, by means of an eye at o, moves easily along the small hemp chord wire G K. L L are two indexes made of thin black oiled silk, which slide upwards or downwards with a force not more than two grains. The one placed above the knee points out the greatest rise, and the one placed below it points out the greatest fall, of the thermometer.

When the instrument is to be prepared for an observation, both indexes are to be brought close to the knee II. It is evident, that when the mercury rises, the float and float wire, which can be moved with the smallest force, will be pushed upwards till the mercury become stationary. As the knee of the float wire moves upwards, it will carry along with it the upper index L. When the mercury again subsides, it leaves the index at the highest point at which it was raised, for it will not descend by its own weight: As the mercury falls the float wire does the same; it therefore brings along with it the lower index L, and continues to depress it till it again becomes stationary or ascend in the tube; in which case it leaves the lower index behind it as it had formerly left the upper. The scale to which the indexes point is placed parallel to the slender hemp chord wire. It may be seen more distinctly in fig. 8. Fig. 8.

That the scale and indexes may not be injured by the wind and rain, a cylindrical glass cover, close at top, and made so as exactly to fit the part G F, is placed over it.

The ingenious inventor has another improvement in contemplation, which, if, upon trial it be found to answer, will make this thermometer as perfect as can be desired, provided there do not arise some errors from the variable pressure of the atmosphere. He proposes to adapt clock-work to this thermometer, in such a way as to register with the utmost precision the degrees of heat and cold for every month, day, and minute in the year. The principles on which this clock work is to be formed we shall forbear to describe, hoping that the author himself, after his experiment has met with the success which
THERMO-METER.

which we ardently wish, will favour the world with his own account of it.

The same ingenious gentleman has invented a self-registering barometer, upon the same principles with the self registering thermometer. We have had the pleasure of seeing both; and are convinced that they will fully gratify the wishes of all who are engaged in meteorological studies. He is also in expectation of being soon able to produce an air-thermometer free from the defects of those which were formerly made, as he has found out a way of preventing it from being affected by the pressure of the atmosphere.

M. de Luc has described the best method of constructing a thermometer, fit for determining the temperature of the air, in the mensuration of heights by the barometer. He has also shown how to divide the scale of a thermometer, so as to adapt it for astronomical purposes in the observation of conjunctions.

Mr Cavallio, in 1781, proposed the construction of a temperamental barometer, which, by means of boiling water, might indicate the various gravity of the atmosphere, or the height of the barometer. But as he does not say that the instrument has been tried with the desired success, we forbear to describe it. Those who wish to know his ideas respecting it may consult the Philosophical Transactions, vol. xxi. p. 524.

15 Thermometers hitherto described are very limited in their extent; they indeed point out to us the lowest degrees of heat which are commonly observed even in cold climates; but they by no means reach to those degrees of heat which are very familiar to us. The mercury thermometer extends no farther than to 600 of Fahrenheit's scale, the heat of boiling mercury; but we are sure that the heat of solid bodies, when heated to ignition, or till they emit light, far exceeds the heat of boiling mercury.

In order to remedy this defect, Sir Isaac Newton, whose genius overcame those obstacles which ordinary minds could not approach, attempted by ingenious experiment to extend the scale to any degree required.

Having heated a mass of iron red hot, and exposed it to the cold air, he observed the time which elapsed till it became cold, or of the same temperature with the air; and when the heat so far decreased that he could apply some known measure (as a thermometer) to it, he observed the degrees of heat lost in given times; and thence drew the general conclusion, that the quantities of heat lost in given small spaces are always proportional to the heat remaining in the body, reckoning the heat to be the excess by which it is warmer than the ambient air. So that taking the number of minutes which it took to cool after it came to a determined point in an arithmetical progression, the decrements of the heat of the iron would be continually proportional. Having by this proportion found out the decrements of heat in a given time after it came to a known point, it was easy, by carrying upwards the same proportion to the beginning of its cooling, to determine the greatest heat which the body had acquired. This proportion of Sir Isaac's was found by Dr Martine to be somewhat inaccurate. The heat of a cooling body does not decrease exactly in proportion to that which the body retains. As the result of many observations, he found that two kinds of proportion took place, an arithmetical as well as the geometrical proportion which Sir Isaac Newton had adopted; namely, that the decrements of heat were partly proportional to the times (that is, that quantities of heat are lost in equal times), as well as partly in proportion to the remaining heat; and that if these two are added together the rule will be sufficiently accurate.

By the geometrical proportion which Sir Isaac Newton adopted, he discovered the heat of metals red hot or in fusion, in expectation of being one which he was sufficient to form a scale of high degrees of heat, but which was not convenient for practical purposes. Accordingly the late Mr Wedgwood invented a very small simple thermometer which marks with much precision the different degrees of ignition, from a dull red heat to the heat of an air-furnace. It consists of two rulers fixed upon a smooth flat plate, a little farther asunder at the one end than at the other, leaving an open longitudinal space between them. Small pieces of alum and clay mixed together are made of such a size as just to enter at the wide end; and are heated along with the body whose heat we wish to determine. The body contracts according to the degree of heat, so that when it is applied to the end of the gage, it will slide on towards the narrow end, less or more according to the degree of heat to which it has been exposed.

ABCD, fig. 9, is a smooth flat plate; and EF and FGH two rulers or flat pieces, a quarter of an inch thick, fixed flat upon the plate, with the sides that are towards one another made perfectly true, a little farther asunder at one end EG than at the other end FH: thus they include between them a long converging canal, which is divided on one side into a number of small equal parts, and which may be considered as performing the offices both of the tube and scale of the common thermometer. It is obvious, that if a body, so adjusted as to fit exactly at the wider end of this canal, be afterwards diminished in its bulk by fire, as the thermometer pieces are, it will then pass further in the canal, and more and more so according as the diminution is greater; and conversely, that if a body, so adjusted as to pass on to the narrow end, be afterwards expanded by fire, as is the case with metals, and applied in that expanded state to the scale, it will not pass so far; and that the divisions on the side will be the measures of the expansions of the one, as of the contractions of the other, reckoning in both cases from that point to which the body was adjusted at first.

And when the body whose alteration of bulk is thus to be measured. This is to be gently pushed or slid along towards the end FH, till it is stopped by the converging sides of the canal. See CHEMISTRY, No. 1412.

A very ingenious application of Fahrenheit's thermometer has been made by Mrs Lovi, glass-blower in Edinburgh, for ascertaining the temperature of compost dung-hills, for regulating the temperature of hot-beds, and observing the changes of temperature in corn and hay-stacks when they are put up damp. This may be called an agricultural thermometer, and has been found of great use for the above purposes.

THERMOPYLÆ, in Ancient Geography, a narrow pass or defile, between the Siphnian Malianus on the east, and a steep branch of Mount Oeta, covered with impassable woods, on the west; leading from Thessaly to Locris and Boeotia. These mountains:
THEMOPYLAE. When the Greeks and Persians met in battle at the Pass of Thermopylae, Xerxes, king of Persia, led a large army into Greece, but the Greeks were outnumbered and had little chance of success. However, they were determined to defend their land and fought heroically against the Persians. At the end of the battle, the Greek king, Leonidas, and his 300 Spartans were killed. The Persians finally managed to capture Athens, but the battle at Thermopylae is remembered as a symbol of Greek resistance against the Persians.

THESSALIA, a district of Greece, had its capital at Larissa. It was the site of the battle of Thermopylae, which was fought in 480 BC. The battle was a turning point in the Persian Wars and is remembered as a symbol of Greek resistance against the Persians. The city of Larissa, which is located in this region, is known for its archaeological sites, including the Temple of Poseidon, which dates back to the 5th century BC.

THESSALON, a town in Thessaly, was the birthplace of the great scientist Galen. The city is known for its ancient ruins, including the Temple of Poseidon, which dates back to the 5th century BC. The town was an important center of commerce and culture during the Roman period.

THESSALIC CHAIR, a type of chair that was used in ancient Greece. The chair is known for its distinctive design, which includes a high backrest and a footrest. The chair was often used in ancient Greek theaters and was a symbol of power and authority. The chair is named after Thessaly, the region in Greece where it was invented.

THESSALY, a region of ancient Greece, was known for its fertile soil and its important role in the development of Greek civilization. The region was home to many important ancient Greek cities, including Athens, Thessaloniki, and Larissa. The region was also the site of many important battles, including the battle of Thermopylae, which was fought in 480 BC.
About the time of the Reformation, this order was dropped, till James II. of Great Britain resumed it, by creating eight knights. The Revolution unsettled it again; and it lay neglected, till Queen Anne, in 1703, restored it to the primitive design, of twelve knights of St. Andrew.

THALPSI, BASTARD-CRESS, or Mithridate Mustard; a genus of plants belonging to the class of tetradynamia. See BOTANY INDEX.

THOMEANS, THOMISTS. See CHRISTIANS of St. Thomas.

THOMAS AQUINAS. See AQUINAS.

ST. THOMAS’s Day, a festival of the Christian church, observed on Dec. 21. in commemoration of St Thomas the apostle.

St. Thomas of Canterbury’s Day, a festival of the English church, observed on Dec. 29. in memory of Thomas Becket archbishop of Canterbury, who was murdered, or as the Romanists say, martyred, in the reign of King Henry II.

THOMAS the Reymour, called also Thomas Lermont and Thomas of Erceldoun, was born at Erceldoun, or Earlston, a village near Melrose in Tweeddale, in what year is uncertain; but he was an old man when Edward I. was carrying on war in Scotland.

The character of Lermont as a prophet, and which was common to him with Linus, Orpheus, and other early poets in many countries, arose, if we may believe Mackenzie in his Lives of Scottish Writers, from his having conferences with Eliza, a nun and prophetess at Haddington. Lermont put her predictions into verse, and thus came in for his share of the prophetic spirit. None of these ancient prophecies now remain; but the following, which pretends to be one of them, is given from a manuscript of the time of Edward I. or II. The countess of Dunbar is the lady famous for the defence of her castle against the English. Her property was Countess of March; but it was common in those times to style a nobleman from his chief residence, Thir-Gilbert Strongbow, earl of Pembroke, is called Earl of Striguil, from his residence at Striguel castle, near Chepstow, Monmouthshire, &c.

La Contesse de Donbar demeure a Thos de Erceldoun, quant la guer d’Escoye prendroit fyn. Eul la repoussy, et eul:

When man as mad a kyng of a capped mon.
When mon is leve other mons myght than is oewn.
When londe thowys forest, and forest ys feide.
When bares kendles othe hersten.
When Wyt and Wille werres togethere.
When mon makes stables of kyrykes; and steles castles wyt styes.
When Rokesborogh nys no burgh; ant market is at Forwyryse.
When the aile is gan, and the newe is come that doue nolt.
When Bamhorne ys dongoed with dede men.
When men ledes men in ropes to buyen ant to selen.
When a quarter of whate whetye is chaunged for a collt of ten markes.
When prude prikes, ant pees is leyd in prison.
When a Scot ne may hym hude awe hare in forme, that the English ne shall hym synde.
THO

When rhytst ant wrong astente the togedere.
When lades weddeth lovedies.
When Scottes flee so faste, that for faute of ship, by
drouneth hemselves.
When shal this be?
Noutther in thynse tyme, ne in myne.
Ab women, ant gone.
Withinke twenty wunter anton.

In fact, the prophecies of Lermont appear to have been merely traditional; nay, it seems doubtful if he ever pretended to such folly, notwithstanding Mackenzie's story of Eliza. The reverence of the people for a learned and respectable character seems to have been the sole foundation of Thomson's claim to prophecy. But, in the 17th century, prophecies were made, and ascribed to him, as well as others given to Bede, Merlin, &c. (A). They were printed at Edinburgh, 1615; reprinted 1670, and 1742.

THOMSON. See AQUINAS.

THOMSON, JAMES, an excellent British poet, the
son of a Scotch divine, was born in the shire of Rox-
burgh in 1703, and was educated in the university of
Edinburgh with a view to the ministry. But his gen-
ius inclining him to the study of poetry, which he
soon found would be incompatible with that of theology,
or at least might prevent his being provided for in
that way in his own country, he relinquished his views
of engaging in the sacred function, and repaired to
London in consequence of some encouragement which
he had received from a lady of quality there, a friend
of his mother.

The reception he met with wherever he was intro-
duced, emboldened him to risk the publication of his
excellent poem on Winter.—This piece was published
in 1725; and from the universal applause it met with,
Mr Thomson's acquaintance was courted by people of
the first taste and fashion. But the chief advantage
which it procured him was the acquaintance of Dr
Rundle, afterward bishop of Derry, who introduced
him to the late lord chancellor Talbot; and some years
after, when the eldest son of that nobleman was to make
his tour on the continent, Mr Thomson was chosen
as a proper companion for him. The expectations which
his Winter had raised, were fully satisfied by the suc-
sessive publications of the other seasons; of Summer,
in the year 1727; of Spring, in the following year; and
of Autumn, in a quarto edition of his works, in 1730.

Besides the Seasons, and his tragedy of Sophonisba,
written and acted with applause in the year 1729, he
had, in 1727, published his poem to the memory of
Sir Isaac Newton, with an account of his chief dis-
coversies; in which he was assisted by his friend Mr
Gray, a gentleman well versed in the Newtonian phil-
osophy. That same year the resentment of our mer-
chants, for the interruption of their trade by the Spa-
niards in America, running very high, Mr Thomson
zealously took part in it, and wrote his Britannia, to
rouse the nation to revenge.

(A) Sibilla and Banister Anglicus are mentioned in the time of Edward IV. (MSS. Cot. Dom. A. IX.). A long Latin prophecy of Bridlington is there given. Waldnave and Eltraine seem also English prophets. In the whole collection, therefore, Thomas is the only Scottish one.

With the honourable Charles Talbot, our author vi-
sited most of the courts in Europe, and returned with
his views greatly enlarged; not only of exterior nature
and the works of art, but of human life and manners,
and of the constitution and policy of the several states,
their connections, and their religious institutions. How
particular and judicious his observations were, we see in
his poem of Liberty, begun soon after his return to
England. We see at the same time to what a high
pitch his care of his country was raised, by the com-
parisons he had all along been making of our happy go-
vernment with those of other nations. To inspire his
fellow-subjects with the like sentiments, and show them
by what means the precious freedom we enjoy may be
preserved, and how it may be abused or lost, he employ-
ed two years in composing that noble work, upon which
he valued himself more than upon all his other writings.
On his return to England with Mr Talbot (who soon
after died), the chancellor made him his secretary of
briefs; a place of little attendance, suiting his retired
indolent way of life, and equal to all his wants. From
this office he was removed, when death, not long after,
deprived him of his noble patron. He then found him-
self reduced to a state of precarious dependence. In
this situation, having created some few debts, and his
creditors finding that he had no longer any certain support,
became inexorable; and imagined by confinement to
force that from his friends, which his modesty would
not permit him to ask. One of these occasions furnish-
ished Quin, the celebrated actor, with an opportunity
of displaying the natural goodness of his heart, and the dis-
interestedness of his friendship. Hearing that Thom-
son was confined in a spunging house for a debt of
about 70l. he repaired to the place; and, having inquir-
ed for him, was introduced to the bard. Thomson was
a good deal disconcerted at seeing Quin, as he had al-
tways taken pains to conceal his wants; and the more
so, as Quin told him he was come to sup with him.
His anxiety upon this head was however removed, upon
Quin's informing him, that, as he supposed it would
have been inconvenient to have had the supper dressed
in the place they were in, he had ordered it from an
adjacent tavern; and, as a prelude, half a dozen of
claret was introduced. Supper being over, and the
bottle circulating pretty briskly, Quin said, "It is time
now we should balance accounts." This astonished
Thomson, who imagined he had some demand upon him;
but Quin perceiving it, continued, "Mr Thomson, the
pleasure I have had in perusing your works I cannot
estimate at less than a hundred pounds, and I insist up-
on now acquitting the debt." On saying this, he put
down a note of that value, and took his leave, without
waiting for a reply.

The profits arising from his works were not inconside-
rable; his tragedy of Agenemone, acted in 1738, yield-
ed a good sum. But his chief dependence was upon
the prince of Wales, who settled on him a handsome
allowance, and honoured him with many marks of par-
ticular favour. Notwithstanding this, however, he

Thomson was refused a licence for his tragedy of Edward and Elennora, which he had prepared for the stage in the year 1736, for some political reasons. Mr Thomson's next performance was the Masque of Alfred, written in the year 1740 jointly with Mr Malet, by the command of the prince of Wales, for the entertainment of his royal highness's court at Clifton, his summer residence.

Mr Thomson's poem, entitled The Castle of Indolence, was his last work published by himself; his tragedy of Coriolanus being only prepared for the theatre, when a fatal accident robbed the world of one of the best of men and best of poets. He would commonly walk the distance between London and Richmond (where he lived) with any acquaintance that offered, with whom he might chat and rest himself, or perhaps dine by the way. One summer evening being alone in his walk from town to Hammersmith, he had over-heated himself, and in that condition imprudently took a boat to carry him to Kew; apprehending no bad consequence from the chill air on the river, which his walk to his house, towards the upper end of Kew-lane, had always hitherto prevented. But now the cold had so seized him, that the next day he was in a high fever. This, however, by the use of proper medicines, was removed, so that he was thought out of danger; till the fine weather having tempted him to expose himself once more to the evening Java, his fever returned with violence, and with such symptoms as left no hopes of a cure. His death happened on the 27th of August 1748.

Mr Thomson had improved his taste upon the finest originals, ancient and modern. The autumn was his favourite season for poetical composition, and the deep silence of the night he commonly chose for his studies. The amusement of his leisure hours were civil and natural history, voyages, and the best relations of travellers. Though he performed on no instrument, he was passionately fond of music, and would sometimes listen a full hour at his window to the nightingales in Richmond gardens; nor was his taste less exquisite in the arts of painting, sculpture, and architecture. As for the more distinguishing qualities of his mind and heart, they best appear in his writings. There his devotion to the Supreme Being, his love of mankind, of his country, and friends, shine out in every page; his tenderness of heart was so unbounded, that it took in even the brute creation. It is not known, that through his whole life he ever gave any person a moment's pain, either by his writings or otherwise. He took no part in the political squabbles of his time, and was therefore respected and left undisturbed by both sides. These amiable virtues did not fail of their due reward; the applause of the public attended all his productions, and his friends loved him with an enthusiastic ardour.

As a writer (says Dr Johnson), he is entitled to one praise of the highest kind; his mode of thinking, and of expressing his thoughts, is original. His blank verse is as men the blank verse of Milton, or of any other poet, than the rhymes of Prior are the rhymes of Cowley. His numbers, his pauses, his diction, are of his own growth, without transcription, without imitation. He thinks in a peculiar train, and thinks always as a man of genius; he looks round on Nature and on life with the eye which Nature bestows only on a poet; the eye that distinguishes, in every thing represented to its view, whatever there is on which imagination can delight to be detained, and with a mind that at once comprehends the vast, and attends to the minute. The reader of the Seasons wonders that he never saw before what Thomson shows him, and that he never yet has felt what Thomson impresses.

His testamentary executors were the Lord Lyttleton, whose care of our poet's fortune and fame ceased not with his life; and Mr Mitchell, a gentleman equally noted for the truth and constancy of his private friendship, and for his address and spirit as a public minister. By their united interests, the orphan play of Coriolanus was brought on the stage to the best advantage; from the profits of which, and the sale of manuscripts and other effects, a handsome sum was remitted to his sisters. His remains were deposited in the church of Richmond, under a plain stone, without any inscription. A handsome monument was erected to him in Westminster abbey in the year 1763, the charge of which was defrayed by the profits arising from a splendid edition of all his works in 4to; Mr Millar the bookseller, who had purchased all Mr Thomson's copies, giving up his property on this grateful occasion. A monument has also been erected to him at the place of his birth.

THOR. The eldest and bravest of the sons of Odin and Frea, was, after his parents, the greatest god of the Saxons and Danes while they continued heathens. They believed, that Thor reigned over all the aerial regions, which composed his immense palace, consisting of 540 halls; that he launched the thunder, pointed the lightning, and directed the meteors, winds, and storms. To him they addressed their prayers for favourable winds, refreshing rains, and fruitful seasons; and to him the fifth day of the week, which still bears his name, was consecrated.

THORAX. See Anatomy.

WHITE or HAW THORN. See CRATAEGUS, Botany Index.

THORN, a town of Poland, in Regal Prussia, and is the palatinate of Culm. It was formerly a Hanseatic town, but is now subject to Prussia; it is large and well fortified. Copernicus, the celebrated discoverer of the true system of the universe, was born here in 1472. It is seated on the Vistula, and contains 10,000 inhabitants. E. Long. 18. 30. N. Lat. 52. 55.

THORNBACK. See RAIL, Ichthyology Index.

THORNHILL, Sir James, an eminent English painter, was born in Dorsetshire in 1676, of an ancient family; but was constrained to apply to some profession by the distresses of his father, who had been reduced to the necessity of selling his family estate. His inclination directed him to the art of painting; and on his arrival at London he applied to his uncle, the famous Dr Sydenham, who enabled him to proceed in the study of the art under the direction of a painter who was not very eminent. However, the genius of Thornhill made ample amends for the insufficiency of his instructor, and by a happy application of his talents he made so great a progress, that he gradually rose to the highest reputation.

His genius was well adapted to historical and allegorical compositions; he possessed a fertile and fine invention; and he sketched his thoughts with great ease, freedom, and spirit. He excelled also equally in portrait,
and melody, and persuaded them to exchange their Thracian, Tereus, a Thracian, governed at Daulis in Phocis, where the tragical story of Philomela and Progne was acted. From thence a body of Thracians passed over to Eubea, and possessed themselves of that island. Of the same nation were the Aones, Tembices, and Hyanthians, who made themselves masters of Bceotia; and great part of Attica itself was inhabited by Thracians, under the command of the celebrated Eumolpus. It is not, therefore, without the utmost ingratitude and injustice that the Greeks style them Barbarians, since to them chiefly they were indebted both for the peopling and polishing of their country.

Thrace was anciently divided into a number of petty states, which were first subdued by Philip of Macedon. On the decline of the Macedonian empire, the country fell under the power of the Romans. It continued under subject to them till the irruption of the Turks, in whose hands it still remains.

THRESHING, in Agriculture, the operation by which corn is separated from the straw. This operation is performed in a variety of ways, sometimes by the feet of animals, sometimes by a flail, and sometimes by a machine.

The most ancient method of separating the corn from the straw was by the hoofs of cattle or horses. This was practised by the Israelites, as we find from the books of Moses; it was also common among the Greeks and Romans*. Flails and threshing machines were all.* Pliny, xliii. 35; which was used by the Romans, called baculus, fustis, or pertica, was probably nothing more than a cudgel of wood. The threshing machine, which was called tribula, tribua, or tribulum, and sometimes trado, was a kind of sledges made of boards joined together, and loaded with stone or iron. Horses were yoked to this machine, and a man was seated upon it to drive them over the sheaves of corn.

Different methods are employed in different countries for separating the corn from the stalk. In the greatest part of France the flail is used; but in the southern districts it is generally performed by the feet of animals. Animals are also used for the same purpose in Spain, in Italy, in the Morea, in the Canaries, in China, and in the vicinity of Canton, where the flail is also sometimes used. It appears that in hot climates the grains do not adhere so firmly to the stalk as in cold countries, and therefore may be more easily separated. This will explain the reason why animals are so frequently employed in hot countries for treading out the corn; whereas in cold climates we know they are seldom tried, and have no reason to suppose that they would answer the purpose.

In the Isle of France in Africa, rice and wheat are threshed with poles, and maize with sticks; for it has not been possible to teach the negroes the use of the flail.

The animals used for treading out corn are, oxen, cows, horses, mules, and even asses when the quantity is not great. The operation is performed in this manner: The sheaves, after being opened, are spread in such a manner that the ears of the corn are laid as much uppermost as possible, and a man, standing in the centre, holds the halters of the cattle, which are made to trot round as in a manger; whilst other men with forks...
Thrashing forks shake the straw up from time to time, and the cattle are trodden over it again and again till they have beaten out all the grain. This method is expeditious enough; but besides bruising a considerable quantity of corn, it requires a great many cattle, and injures the legs of the horses and mules, which are preferred before cows and oxen for this work.

The flail is undoubtedly a much better instrument for thrashing corn than the feet of animals, for it separates the grain from the straw and husks both more effectually and more expeditiously; yet it is liable to many objections. It is a very laborious employment, too severe indeed even for a strong man; and as it is usually the interest of the thrasher rather to thrash much than to thrash clean, a good deal of corn will generally be left upon the straw. It is therefore an object of great importance in husbandry to procure a proper machine for separating the corn from the straw.

The first thrashing machine attempted in modern times, of which we have received any account, was invented in Edinburgh by Mr. Michael Menzies about the year 1773. It consisted of a number of instruments like flails, fixed in a moveable beam, and inclined to it at an angle of ten degrees. On each side of the beam in which the flails were fixed, floors or benches were placed for spreading the sheaves on. The flails were moved backwards and forwards upon the benches by means of a crank fixed on the end of an axle, which made about 30 revolutions in a minute.

The second thrashing machine was invented by Mr. Michael Stirling, a farmer in the parish of Dunblane, Perthshire. Of this discovery we have received a very accurate and authentic account from his son, the reverend Mr. Robert Stirling minister of Crieff. It is an old proverb, that necessity is the mother of invention. This was verified on the present occasion. Besides his ordinary domestic servants, Mr. M. Stirling had occasion sometimes to hire an additional number to thrash out his grain, and frequently found it difficult to procure so many as he needed. This naturally led him to reflect whether the operation of thrashing could not easily be performed by machinery. Accordingly, as early as the year 1753, under the pretense of joining in the amusements of his children, he formed in miniature a water mill, in which two iron springs made to rise and fall alternately, represented the motion of two flails, by which a few stalks of corn put under them might be speedily thrashed. This plan he executed on a scale sufficiently large within two years after, making the springs about ten feet long, each of which had one end firmly screwed into a solid plank, and the other terminated in a round baton of solid iron, two feet long and above an inch in diameter. Under these sheaves were conveyed gradually forward in a narrow channel or trough, by passing between two indented horizontal cylinders, similar to those now used in the most of the thrashing mills in that part of the country, and called feeders. In this manner the thrashing was executed completely, and with considerable rapidity; but as the operation was performed on a low floor, and no method contrived for carrying off the straw, the accumulation of it produced such confusion, and the removal of it was attended with such danger that this scheme was very soon entirely abandoned. The mortification arising from disappointment, and especially the scolds of his neighbors, for what was universally accounted an absurd and ridiculous attempt, served only to stimulate the exertions of the inventor to accomplish his designs on another plan.

Laying aside therefore the iron springs with the feeders, and all the apparatus adapted to them, he retained only an outer or water wheel, with an inner or cog-wheel moving on the same axle: to this inner wheel, which had 48 teeth or cogs, he applied a vertical trundle or pinion, with seven notches, the axle of which passed through a floor above the wheel, and having its upper pivot secured in a beam six feet above that floor. At the distance of three feet three inches above the floor two straight pieces of squared wood, each four feet long, passed through the axle of the trundle at right angles, forming four arms, to be moved round horizontally. To the extremities of these arms were fixed four iron plates, each 20 inches long, and eight broad at the end next the arms, but tapering towards a point at the other end. This large horizontal fly constituting four threshers, was enclosed within a wooden cylindrical box three feet and a half high and eight in diameter. On the top of the box was an opening or port (two or three ports were made at first, but one was found sufficient) eight inches wide, and extending from the circumference a foot and a half towards its centre, through which the corn sheaves descended, being first opened and laid one by one on a board with two ledges gently declining towards the port; upon which board they were moderately pressed down with a boy's hand, to prevent them from being too hastily drawn in by the repeated strokes of the threshers. Within the box was an inclined plane, along which the straw and grain fell down into a wide wire riddle two feet square, placed immediately under a hole of nearly the same size. The riddle received a jerk at every revolution of the spindle from a knob placed on the side of it, and was instantly thrust backward by a small spring pressing it in the opposite direction. The short straw, with the grain and chaff which passed through the wide riddle, fell immediately into an oblong straight riddle, which hung with one end raised and the other depressed, and was moved by a contrivance equally by the hand and having no ledge at the lower end, the long chaff which could not pass through the riddle dropped from thence to the ground; while the grain and most of the chaff falling through the riddle into a pair of common barn-fanners that stood under it on the ground floor, the strong grain, the weak, and the chaff, were all separated with great exactness. The fansers were moved by a rope or band running circuitously in a shallow niche cut on the circumference of the cog-wheel. The straw collected gradually in the bottom of the box over the wide riddle, and through an opening two and a half feet wide, and as much in height, left in that side of the box nearest the brink of the lower floor, was drawn down to the ground with a rake by the person or persons employed to form it into sheaves or rolls.

Such was the thrashing mill invented by Mr. Michael Stirling, which, after various alterations and improvements he completed in the form now described, A.D. 1758. By experiment it was found that four bolls of oats, Linlithgow measure, could be thrashed by it in 25 minutes. From that period he never used a common flail in thrashing, except for humbling or barley.
In every other kind of grain he performed the whole operation of thrashing with the mill; and continued always to use it till 1772, when he retired from business, and his thrashing mill became the property of his second son, who continued to use it with equal advantage and satisfaction. Several machines were constructed on the same plan, particularly one near Stirling, under Mr. Stirling's direction, for Mr. Moir of Leckie; in 1765, which, we understand, has been used ever since, and gives complete satisfaction to the proprietor. There was another erected in 1798 by Mr. Thomas Keir (in the parish of Muthill and county of Perth), who has contrived a method of bearding barley with it: and by the addition of a small spindle with short arms contiguous to the front of the box, and moved by a band common to it and the great spindle to which it is parallel, the straw is shaken and whirled out of the box to the ground. That this machine did not come immediately into general use, was owing partly to the smallness of the farms in that part of the country, whose crops could easily be thrashed by the few bands necessarily retained on them for other purposes; and chiefly to an apprehension that the machine could only be moved by water; an apprehension which experience proves to be entirely groundless. The machine, however, was ingenious, and did great credit to the worthy inventor, and certainly deserved a better fate than it was destined to undergo.

A third thrashing mill was invented in 1772, by two persons nearly about the same time, and upon the same principles. The inventors were, Mr. Alderton who lived near Alnwick, and Mr. Smart at Wark in Northumberland. The operation was performed by rubbing. The sheaves were carried round between an indented drum of about six feet diameter, and a number of indented rollers arranged round the circumference of the drum, and attached to it by means of springs; so that while the drum revolved, the fluted rollers rubbed the corn off from the straw by rubbing against the flutings of the drum. But as a considerable quantity of the grain was bruised in passing between the rollers, the machine was soon laid aside.

In 1776 an attempt was made by Mr. Andrew Meikle, an ingenious millwright in the parish of Twynham, East Lothian, to construct a new machine upon the principles which had been adopted by Mr. Menzies already mentioned. This consisted in making joints in the flutes, which Mr. Menzies had formed without any. But this machine, after much labour and expense, was soon laid aside, on account of the difficulty of keeping it in repair, and the small quantity of work performed, which did not exceed one boll or six Winchester bushels of barley per hour.

Some time after this, Mr. Francis Kinloch, then junior of Gilmerton, having visited the machine invented in Northumberland, attempted an improvement upon it. He inclosed the drum in a fluted cover; and instead of making the drum itself fluted, he fixed upon the outside of it four fluted pieces of wood, which by means of springs could be raised a little above the circumference of the drum, so as to press against the fluted covering, and thus rub off the ears of corn as the sheaves passed round between the drum and the fluted covering. But not finding this machine to answer his expectation (for it bruised the grain in the same manner as the Northumberland machine did), he sent it to Mr. Meikle, that he might, if possible, rectify its errors.

Mr. Meikle, who had long directed his thoughts to this subject, applied himself with much ardour and perseverance to the improvement and correction of this machine; and after spending a good deal of time upon it, found it was constructed upon principles so erroneous, that to improve it was impracticable.

At length, however, Mr. Meikle's own genius invented a model, different in principle from the machines which had already been constructed. This model was made in the year 1783; and in the following year the first thrashing machine on the same principles was erected in the neighbourhood of Aiton, in the county of Stirling, by Mr. George Meikle the son of the inventor. This machine answered completely the wishes of Mr. Stein, the gentleman for whom it was erected, who gave the most ample testimony of his satisfaction both to the inventor and to the public. The fame of this discovery soon spread over the whole country, and a great many farmers immediately applied to Mr. Meikle, desiring to have thrashing-mills erected on their farms. By the discovery, it appeared, would be profitable, and it was reasonable that the inventor should enjoy the profits of his invention. He accordingly applied for a patent; which, after considerable expense, arising from the opposition of some persons, who claimed a share in the discovery, was granted. These machines are now becoming very common in many parts of Scotland, and are increasing very considerably in number every year over all the united kingdom.

We will now endeavour to describe this machine in its most improved state; which is so simple, that with the assistance of a plate, exhibiting the plan of elevation, fig. 1. the ground plan, fig. 2. and the 3d showing its essential parts in a distinct manner, we hope it will be easily understood by all our readers who have not had an opportunity of seeing it. The power employed for turning that part of the machine which separates the corn from the straw is produced by four wheels (when moved by horses), the teeth of which move in another and turn the drum, on which four scutchers are fixed. The sheaves are introduced between two fluted rollers, which hold them firm, and draw them in gradually, while the scutchers strike off the grain from the straw as it passes through. This will suffice for a general idea of this machine. We will now be more particular.

The large spur-wheel A, fig. 1. and 2. which has fig. 1. and 276 cogs, is horizontal, and moves the pinion B, which has 14 teeth. The pinion B moves the crown-wheel C, which has 84 teeth; the wheel C moves a second pinion D, which has 16 teeth; and the pinion D moves the drum HIKL. The drum is a hollow cylinder three feet and a half diameter, and placed horizontally; on the outside of which the scutchers are fixed by strong screw bolts. The scutchers consist of four pieces of wood, faced on one side with a thin plate of iron, placed at an equal distance from each other, and at right angles to the axis of the drum.

The sheaves are spread on an inclined board F, fig. 3. from which they are introduced between two fluted rollers GG made of cast iron, about three inches and a half in diameter, and making about 35 revolutions in a minute. As these rollers are only about three quarters of
Thrashing, of an inch distant from the scutchers or leaves of the drum HIKL, they serve to hold the sheaves fast, while the scutchers a, b, c, d, moving with prodigious velocity, separate the grain completely from the straw, and at the same time throw out both grain and straw upon the concave rack M, lying horizontally with slender parallel ribs, so that the corn passes through them into a hopper N placed below. From the hopper it passes through a harp or riddle O into a pair of fanners P, from which, in the most improved machines, it comes out clean and fit for the market. The straw, after being thrown by the scutchers a, b, c, d, into the rack, is removed from it by a rake QQRST into a place contiguous V. The rake consists of four thin pieces of wood or leaves; on the end of each of these leaves is ranged a row of teeth e, f, g, h, five inches long. The rake moves in a circular manner in the conveyance rack, while the teeth catch hold of the straw, and throw it out of the rack. These are the essential parts of the machine; the rest may be easily understood by the references to the plate. W is the horse-course, No. 1, which is 27 feet diameter. X is the pillar for supporting the beams on which the axle of the spur-wheel is fixed. YYY are three spindles for moving the two fluted rollers, the rake, and fanners. To the description now given we have only to add, that the drum has a covering of wood Z at a small distance above it, for the purpose of keeping the sheaves close to the scutchers.

The advantages of this machine are many. As the drum makes 300 revolutions in a minute, the four scutchers together make 1200 strokes in the same space of time. From such power and velocity, it is evident that much work must be performed. When the horses go at the rate of two and one-third miles per hour, from three to six bolls will be thrashed; but as the quantity threshed will be less when the straw is long than when it is short, we shall take the average at four bolls. One gentleman, whose veracity and accuracy we can depend on, assures us, that his mill threshed 63 bolls in a day; by which, we suppose, he meant 10 hours. To prove the superior advantage of this machine to the common method of thrashing with flails, a gentleman ordered two equal quantities of oats to be threshed by the mill and by flails. When the corn was cleaned and measured, he obtained one-sixteenth more from the sheaves threshed by the mill than from those threshed by the flail. We are also informed by another gentleman who has studied this machine with much attention, and calculated its advantages with care, that, independently of having the corn much cleaner separated from the straw than is usually done by flails, there is a saving of 30 or 40 per cent, in the expense of threshing.

The number of persons requisite for attending the mill when working is six: One person drives the horses; a second guides the sheaves to a third, who unites them, while a fourth spreads them on the inclined boards and presses them gently between the rollers; a fifth person is necessary to riddle the corn as it falls from the fanners, and a sixth to remove the straw (A).

This machine can be moved equally well by water, wind, or horses. Mr. Melville has made such improvements on the wind-mill as to render it much more manageable and convenient than formerly; and we are informed many windmills can be erected in different parts of the country. As to the comparative expense of these different machines, the erection of the horse machine is least; but then the expense of employing horses must be taken into consideration. One of this kind may be erected for 70l. A water-mill will cost 10l. more on account of the expense of the water-wheel. A wind-mill will cost from 200l. to 300l. sterling.

THRAVE of Corn, an expression denoting 24 sheaves or four shocks of six sheaves to the shock; though in some countries they only reckon 12 sheaves to the thrave.

THIRASBYBULUS, a renowned Athenian general and patriot, the deliverer of his country from the yoke of the 70 tyrants, lived about 294 B.C. See Al.

THIRASYMENUS LACUS, in Anciient Geography, is a lake of Etruria, near Perusia, and not far from the Tiber, fatal to the Romans in the Punic war. Now Il Lago de Perugia in the Ecclesiastical State.

THREAD, a small line made up of a number of fine fibres of any vegetable or animal substance, such as flax, cotton, or silk; from which it takes its name of linen, cotton, or silk thread.

THREATENING LETTERS. Knowingly to send any letter without a name, or with a fictitious name, demanding money, or any other valuable thing, or threatening (without any demand) to kill or fire the house of any person, is made felony without benefit of clergy. And sending letters, threatening to accuse any person of a crime punishable with death, transportation, pillory, or other infamous punishment, with a view to extort from him any money or other valuable chattels, is punishable by statute 30 Geo. II. cap. 24. at the discretion of the court, with fine, imprisonment, pillory, whipping, or transportation for seven years.

THRESHING. See Thrashing.

THRIERT. See Static, Botany Index.

THRINAX, SMALL JAMAICA PAN-PALM, a genus of plants belonging to the class of palm. See Botany Index.

THRIPS, a genus of insects belonging to the order of hemiptera. See Entomology Index.

THROAT, the anterior part of an animal, between the head and the shoulders.

THROAT-WORT. See Campanula, Botany Index.

THRONIE, a royal seat or chair of state, enriched with ornaments of architecture and sculpture, raised on one or more steps, and covered with a kind of canopy. Such are the thrones in the rooms of audience of kings and other sovereigns.

THROSTE.
The historian of Halicarnassus has often been compared with the son of Olorus, but each has his peculiar excellence. Sweetness of style, grace and elegance of expression, may be called the characteristics of the former; while Thucydides stands unequalled for the fire of his descriptions, the conciseness, and at the same time the strong and energetic manner of his narratives. His relations are authentic, as he himself was interested in the events he mentions; his impartiality is indubitable, as he nowhere betrays the least resentment against his countrymen, and the factious partizans of Cleon, who had banished him from Athens. The history of Thucydides was so admired by Demosthenes, that he transcribed it eight different times, and read it with such attention, that he could almost repeat it by heart. Thucydides died at Athens, where he had been recalled from his exile about 411 years B.C.

The best edition of Thucydides is that of Oxford, published in 1695, folio, and that of Duker, published at Amsterdam in 1731, folio.

THULE, or Thyle, in Ancient Geography, an island in the most northern parts of the German ocean. Its situation was never accurately ascertained by the ancients, hence its present name is unknown by modern historians. Some suppose that it is the island now called Iceland, or part of Greenland, and others that it was Fossa. See FOULA.

THUMB, in Anatomy, one of the extremities of the hand.

THUMB-CAP, an uninhabited island in the South sea, lies about seven leagues north-west of Lagoon island; it is low, woody, of a circular form, and not much above a mile in compass.

THUMMIM. See URIM.

THUNBERGIA, a genus of plants belonging to the class of didymaism. See BOTANY INDEX.

THUNDER, the noise of lightning, produced by the explosion of a flash of lightning echoing back from the inequalities on the surface of the earth, in like manner as the noise of a cannon is echoed, and in particular circumstances forms a rolling-lengthened sound. See ELECTRICITY.

THUNDERBOLT. When lightning acts with extraordinary violence, and breaks or shatters anything, it is called a thunderbolt; which the vulgar, to fit it for such effects, suppose to be a hard body, and even a stone. But that we need not have recourse to a hard solid body to account for the effects commonly attributed to the thunderbolt, will be evident to any one who considers those of the pulvis fulminans and of gunpowder; and more especially the astonishing powers of electricity. It has been supposed that meteoric stones may have given rise to the notion of a thunderbolt.

THUNDER-HOUSE. See ELECTRICITY.

THURINGIA, a division of the circle of Upper Saxony in Germany. It is a fruitful tract, abounding in corn, especially wheat; in black cattle, sheep, and horses. It is about 24 miles in length, and as much in breadth. It contains 47 towns, 14 boroughs, between 700 and 800 villages, 300 noble estates, 7 superintendencies, and 5 under consistories. Thuringia, the country of the ancient Thuringi, or Catti, a branch of the Vandals.
Vandals, mentioned by Tacitus, was formerly a kingdom, afterwards a county, then a landgrave, and was governed by its own princes for many ages, till 1124, when it devolved to the marquis of Misnia, and, with that country, afterwards to the dukes of Saxony. But the modern Thuringia is only a part of the ancient, nay, but a part of the ancient South Thuringia, which comprehends besides, a large share of modern Franconia, Hesse, &c. On the extinction of the male line of the ancient landgraves in 1247, it came to the margraves of Meissen, ancestors to the present electoral family. The elector has no voice in the diet, on account of his share in the landgrave or circle of Thuringia. Erfurt is the capital.

THURSDAY, the fifth day of the Christian week, but the sixth of that of the Jews.

THUS, FRANKINCENSE, a solid brittle resin, brought to us in little globes or masses, of a brownish or yellowish colour on the outside, internally whish or variegated with whitish specks. It is supposed to be the produce of the pine that yields the common turpentine, and to concrete upon the surface of the terebinthinate juice soon after it has issued from the tree. See Incense.

THUYA. See Thuja.

THYMUS, Thyme; a genus of plants belonging to the class of diynamia, and in the natural system ranging under the 42d order, Fertilelatae. See Botany Index.

THYMUS. See Anatomy Index.

THYRSUS, in antiquity, the sceptre which the poets put into the hand of Bacchus, and wherewith they furnished the menades in their Bacchanaelia.

THYRSUS, a mode of flowering resembling the cone of a pine. It is, says Linnaeus, a panicle contracted into an oval or egg-shaped form. The lower footstalks, which are longer, extend horizontally, whilst the upper ones are shorter and mount vertically. Lilac and butter-burr furnish examples.

TIARA, an ornament or habit wherewith the ancient Persians covered their head; and with which the Armenians and kings of Pontus are represented on medals; these last, because they were descended from the Persians. Latin authors call it indifferently tiara and cedaris. Strabo says the tiara was in form of a tower; and the scholiast on Aristophanes's comedy, Acharn., act i. scene 2. affirms that it was adorned with peacocks feathers.

The tiara is also the name of the pope's triple crown. The tiara and keys are the badge of the papal dignity; the tiara of his civil rank, and the keys of his jurisdiction: for as soon as the pope is dead, his arms are represented with the tiara alone, without the keys. The ancient tiara was a round high cap. John XXIII. first encompassed it with a crown. Boniface VIII. added a second crown; and Benedict XII. a third.

TIARELLA, a genus of plants, belonging to the class of decandria; and in the natural system ranging under the 12d order, Secesslentes. See Botany Index.

TIBER, a great river of Italy, which runs through the pope's territories; passing by Perugia and Orvietto; and having visited Rome, falls into the Tuscan sea at Ostia, 15 miles below that city.

TIBET, called by the Tartars Baranata, Bostan, or Tangot, and by the Chinese Tsang, is situated between 27° and 33° north latitude; and is reckoned to be 1350 miles from east to west, and 480 from north to south. It is bounded on the north by the country of the Mongols and the desert of Kobi; on the east by China; on the west by Hindostan, and on the south by the same country and the kingdom of Ava. In the valleys lying between the lower mountains are many tribes of Indian people; and a dispute happening between the heirs of one of the rajahs or petty princes, one party called to their assistance the Bontaners, and the other the British. The latter prevailed; and the fame of British valour being carried to the court of Tibet, the Teessho Lams, who ruled the state under the Delai-Lama, at that time in his minority, sent a deputation to Bengal, desiring peace for the prince who had been engaged in war with the British. This was readily granted by the governor; and Mr Bogle was sent ambassador to the court of Tibet, where he resided several months; and after an absence of a year and a quarter, returned to Calcutta. The account of this gentleman's expedition hath not been published by himself; but from Mr Stewart's letter to Sir John Pringle, published in the Philosophical Transactions, vol. lviii., we learn the following particulars, collected from his papers.

"Mr Bogle divides the territories of the Delai-Lama into two different parts. That which lies immediately contiguous to Bengal, and which is called by the inhabitants Doopo, he distinguishes by the name of Bostan; and the other, which extends to the northward as far as the frontiers of Tartary, called by the natives Pas, he styles Tibet. Bostan is ruled by the Dah Terrish, or Deb Rajah. It is a country of steep and inaccessible mountains, whose summits are crowned with eternal snow; they are intersected with deep valleys, through which pour numberless torrents that increase in their course, and at last, gaining the plains, lose themselves in the great rivers of Bengal. These mountains are covered down their sides with forests of stately trees of various sorts; some (such as pines, &c.) which are known in Europe; others, such as are peculiar to the country and climate. The valleys and sides of the hills which admit of cultivation are not unfruitful, but produce crops of wheat, barley, and rice. The inhabitants are stout and warlike people, of a copper complexion, in size rather above the middle European, cleanly and quarrelsom in their temper, and addicted to the use of spirituous liquors; but honest in their dealings, robbery by violence being almost unknown among them. The chief city is Tassey Seddea, situated on the Patchoo. Tibet begins properly from the top of the great ridge of the Caucasus, and extends from thence in breadth to the confines of Great Tartary, and perhaps to some of the dominions of the Russian empire. The woods, which everywhere cover the mountains in Bostan, are here totally unknown; and, except a few struggling trees near the villages, nothing of the sort is to be seen. The climate is extremely severe and rude. At Chammaning, where he wintered, although it be in latitude 31° 59', only 8° to the northward of Calcutta, he often found the thermometer in his room at 29° by Fahrenheit's scale; and in the middle of April the standing waters were all frozen, and heavy showers of snow perpetually fell. This, no doubt, must be owing to the great elevation of the country, and to the vast

...
TIB

TIB

vast frozen space over which the north wind blows uninterrupted from the pole, through the vast deserts of Siberia and Tartary, till it is stopped by this formidable wall.

The Tibetans are of a smaller size than their southern neighbours, and of a less robust make. Their complexion is also fairer, and many of them have a redness in their countenances unknown to the other climates of the east. Those whom Mr Bogle saw at Calcutta appeared to have quite the Tartar face. They are of a mild and cheerful temper; the higher ranks are polite and entertaining in conversation, in which they never mix either strained compliments or flattery. The common people, both in Bootan and Tibet are clothed in coarse woollen stuffs of their own manufacture, lined with such skins as they can procure: but the better orders of men are dressed in European cloth, or China silk, lined with the finest Siberian furs. The use of linen is totally unknown among them. The chief food of the inhabitants is the milk of their cattle, prepared into cheese, butter, or mixed with the flour of a coarse barley or of peas, the only grain which their soil produces; and even these articles are in a scanty proportion: but they are furnished with rice and wheat from Bengal and other countries in their neighbourhood. They also are supplied with fish from the rivers in their own and the neighbouring provinces, salted and sent into the interior parts. They have no want of animal food from the cattle, sheep, and hogs, which are raised on their hills; and are not destitute of game. They have a singular method of preparing their mutton, by exposing the carcasse entire, after the bowels are taken out, to the sun and bleak northern winds which blow in the months of August and September, without frost, and so dry up the juices and parch the skin, that the meat will keep uncorrupted for the year round. This they generally eat raw, without any other preparation.

The religion and political constitution of this country, which are intimately blended together, would make a considerable chapter in its history. It suffices to say, that at present, and ever since the expulsion of the Eluth Tartars, the kingdom of Tibet is regarded as depending on the empire of China, which they call Cathay; and there actually reside two mandarins, with a garrison of a thousand Chinese, at Labassa the capital, to support the government; but their power does not extend far: and in fact the Lama, whose empire is founded on the surest grounds, personal affection and religious reverence, governs every thing internally with unbounded authority. Every body knows that the Dri Lama is the great object of adoration for the various tribes of heathen Tartars, who roam through the vast tract of continent which stretches from the banks of the Volga to Corea on the sea of Japan, the most extensive religious dominion, perhaps, on the face of the globe. See LAMA.

It is an old notion, that the religion of Tibet is a corrupted Christianity; and even Father Disdierat, a Jesuit (but not of the Chinese mission) who visited the country about the beginning of this century, thinks he can resolve all their mysteries into ours; and asserts, with a truly mystical penetration, that they have certainly a good notion of the Trinity, since in their ad-

dress to the Deity, they say as often konvok oik in the plural as konvok in the singular, and with their rosaries pronounce these words om, ha, hum. The truth is, that the religion of Tibet, from whatever source it sprung, is pure and simple in its source, conveying very exalted notions of the Deity, with no contemptible system of morality; but in its progress it has been greatly altered and corrupted by the inventions of worldly men: a fate we can hardly regret in a system of error, since we know that that of truth has been subject to the same. Polygamy, at least in the sense we commonly receive the word, is not in practice among them; but it exists in a manner still more repugnant to European ideas; for there is a plurality of husbands, which is firmly established and highly respected there. In a country where the means of subsisting a family are not easily found, it seems not impolitic to allow a set of brothers to agree in raising one, which is to be maintained by their joint efforts. In short, it is usual in Tibet for the brothers in the family to have a wife in common, and they generally live in great harmony and comfort with her; but not sometimes little dissensions will arise (as may happen in families constituted upon different principles), an instance of which Mr Bogle mentions in the case of a modest and virtuous lady, the wife of half a dozen of the Teesboo Lama's nephews, who complained to the uncle that the two youngest of her husbands did not furnish her with that share of love and benevolence to the common stock which duty and religion required of them. In short, however strange this custom may appear to us, it is an undoubted fact that it prevails in Tibet.

The dead are exposed on the pinnacle of some neighbouring mountain, to be devoured by wild beasts and birds of prey, or wasted away by time and the vicissitudes of the weather in which they lie. The mangled carcasses and bleached bones lie scattered about; and amidst this scene of horror, some miserable wretch, man or woman, lost in all feelings but those of superstition, generally sets up an abode, to perform the dismal office of receiving the bodies, assigning each a place, and gathering up the remains when too widely dispersed.

To the account of Tibet which we have given from the communications of Mr Bogle, we may add the information which we have obtained from a later traveller, Mr Saunders, surgeon at Boglepoor in Bengal, who made a journey into Tibet in the year 1793. His observations chiefly respect the natural productions and diseases of the country.

The plants which Mr Saunders found were almost all European plants, a great number of them being natives of Britain. From the appearance of the hills he concludes that they must contain many ores of metal and pyrites. There are inexhaustible quantities of tical or borax, and rock-salt is plentiful; gold-dust is found in great quantities in the beds of rivers, and sometimes in large masses, lumps and irregular veins: lead, cinabar containing a large proportion of quicksilver, copper, and iron, he thinks might easily be procured. But the inhabitants of Tibet have no better fuel than the dung of animals. A coal mine would be a valuable discovery. We are told that, in some parts of China bordering on Tibet coal is found and used as fuel.

It is remarkable that the same disease prevails at the foot.
TIC [ 416 ] TID

TIBET. foot of the mountains of Tibet as in Switzerland at the foot of the Alps, a glandular swelling in the throat commonly called goitre.

The language spoken in Tibet is different from that of the Tartars. The astronomers are acquainted with the motion of the heavenly bodies, and able to calculate eclipses; but the lamas are generally ignorant; few of them can read, much less understand their ancient books. See Asia, Supplement.

TIBULLUS, Aulus Albius, a Roman knight, and a celebrated Latin poet, was born at Rome 43 B.C. He was the friend of Horace, Ovid, Macer, and other great men in the reign of Augustus. He accompanied Messala Corvinus in his expedition against the island of Corcyra: but falling sick, and being unable to support the fatigue of war on account of the weakness of his constitution, he quitting the profession of arms, returned to Rome, where he died before the year 17; when Ovid showed his grief for his death by writing a fine elegy upon him. Tibullus wrote four books of elegies, which are still extant: they are written in a tender and agreeable style, and in very elegant Latin. Muroet and Joseph Scaliger have written learned and curious commentaries on the works of this poet. The best edition of Tibullus is that of Janus Brocchusius, published at Amsterdam in 1708, in one volume quarto.

We have an English poetical version by Mr. Grainger.

TIBUR, in Ancient Geography, a town of Latium, pleasantly situated on the Anio. Here Horace had his villa and house; and here he wished to end his days. Here Adrian built an extraordinary villa called Tiburina, inscribed with the names of the provinces and of the most considerable places (Spartan); near which Zenobia had a house called Zenobia, (Trebillius, Follio). Hither Augustus often retired on account of its salubrity, (Suetonius); for which it is greatly recommended (Martialis). Anecdotally, when the Romans had far extended their territory, it was the utmost place of punishment, (Ovid). It had a temple of Hercules; and therefore called Herculeum. In the temple was a library, (A. Galliius). Now Tiboli in the Campagna di Roma, on the Teverone.

TICINUS, in Ancient Geography, a river in Insurbia, rising in Mount Audas, traversing the Lacus Verbanus southwards, and falling into the Po near Ticinum. Between this river and the Po Hannibal gained his first victory over the Romans under P. Scipio. The general himself escaped with the utmost difficulty, and that by the bravery of his son the first Scipio Africanus. Now the Tesino, rising in Mount Godard, running south through the Lago Maggiore and Milan, by Pavia, into the Po.

TICK. See ACARUS, ENTOMOLOGY Index.

TICKELL, Thomas, an excellent English poet, was the son of the Reverend Richard Tickell, and was born in 1686, at Bridgwater in Cumberland. He was educated at Queen's college, Oxford, of which he was made fellow; and while he continued at that university, he addressed to Mr. Addison a complimentary copy of verses on his Opera of Rosamond, which introduced him to an acquaintance with that gentleman, who discovering his merit, became his sincere friend. On Mr. Addison being made secretary of state, he appointed Mr. Tickell his under-secretary; and on his being obliged to resign that office on account of his ill-health, he recommended him so effectually to Mr. Craggs his successor, that he was continued in his post till that gentleman's death. In 1724, Mr. Tickell was appointed secretary to the lords justices in Ireland, and enjoyed that place as long as he lived. He wrote some poems, which, when separately published, met with a favourable reception, and passed through several editions: they are now printed in the second volume of the Minor Poems, after Mr. Addison's death, and a poem on his death. Mr. Tickell died in the year 1740.

TICKERBAY, a considerable article of merchandise in Fezzan in Africa; it is valued by travellers as a portable and highly salubrious food. It is a preparation of pounded dates, and the meal of Indian corn, formed into a paste, and highly dried in an oven.

TICKSEED, Sun-flower. See Coreopsis, Botany Index.

TICUNAS. See Poison.

TIDE, is a word which expresses that rising and falling of the waters which are observed on all maritime coasts.

There is a certain depth of the waters of the ocean which would obtain if all were at rest: but observation shows that they are continually varying from this level, and that some of these variations are regular and periodical.

1st, It is observed, that on the shores of the ocean, and in bays, creeks, and harbours, which communicate freely with the ocean, the waters rise up above this mean height twice a day, and as often sink below it, forming what is called a FLOOD and an EBB, a high and low water. The whole interval between high and low water is called a TIDE; the water is said to FLOW and to EBB; and the rising is called the FLOOD TIDE, and the falling is called the EBB TIDE.

2d, It is observed, that this rise and fall of the waters is variable in quantity. At Plymouth, for instance, it is sometimes 21 feet between the greatest and least depth of the water in one day, and sometimes only 13 feet.

These different heights of tide are observed to succeed each other in a regular series, diminishing from the greatest to the least, and then increasing from the least to the greatest. The greatest is called a SPRING TIDE, and the least is called a NEAP TIDE.

3d, This series is completed in about 15 days. More careful observation shows that two series are completed in the exact time of a lunation. For the spring tide in any place is observed to happen precisely at a certain interval of time (generally between two and three days) after new or full moon: and the neap tide at a certain interval after half moon; or, more accurately speaking, it is observed that the spring tide always happens when the moon has got a certain number of degrees eastward of the line of conjunction and opposition, and the neap tide happens when she is a certain number of degrees from her first or last quadrature. Thus the whole series of tides appears to be regulated by the moon.

4th, It is observed that high water happens at new and full moon, when the moon has a certain determined position with respect to the meridian of the place of observation, preceding or following the moon's southing
ly, and annual. He observes, that the sea rises as the moon gets near the meridian, whether above or below the horizon, and falls again as she rises or falls; also, that the tides increase at the time of new and full moon, and are greatest at the summer solstice. Pliny explains the phenomena at some length; and says, that both the sun and moon are their cause, dragging the waters along with them (B. H. c. 97). Seneca (Nat. Quest. III. 28) speaks of the tide with correctness; and Macrobius (Somn. Scip. I. 6) gives a very accurate description of their motions.

It is impossible that such phenomena should not exercise human curiosity as to their cause. Plutarch (Plut. Phil. III. 17), Galileo (Syst. Mund. Dial. 4), Riccioli in his Almagest, ii. p. 374, and Cassendi, ii. p. 27, have collected most of the notions of their predecessors on the subject; but they are of so little importance, that they do not deserve our notice. Kepler speaks more like a philosopher (De Stella Martis, and Epit. Astron. p. 555). He says that all bodies attract each other, and that the waters of the ocean would all go to the moon were they not retained by the attraction of the earth; and then goes on to explain their elevation under the moon and on the opposite side, because the earth is less attracted by the moon than by the nearer waters, but more than the waters which are more remote.

The honour of a complete explanation of the tides was reserved for Sir Isaac Newton. He laid hold of this class of phenomena as the most incontestable proof of universal gravitation, and has given a most beautiful and synoptical view of the whole subject; contesting himself, however, with merely exhibiting the chief consequences of the general principle, and applying it to the phenomena with singular address. But the wide steps taken by this great philosopher in his investigation leave ordinary readers frequently at fault: many of his assumptions require the greatest mathematical knowledge to satisfy us of their truth. The academy of Paris therefore proposed to illustrate this among other parts of the principles of natural philosophy, and published the theory of the tides as a prize problem. This produced three excellent dissertations by Mr. Laurin, Daniel Bernoulli, and Euler. Aided by these, and chiefly by the second, we shall here give a physical theory, and accommodate it to the purposes of navigation by giving the rules of calculation. We have demonstrated in our dissertations on the physical principles of the celestial motions, that it is an unexpected fact, that every particle of matter in the solar system is actually deflected toward every other particle; and that the deflection of a particle of matter toward any distant sphere is proportional to the quantity of matter in that sphere directly, and to the square of the distance of the particle from the centre of that sphere inversely: and having found that the heaviness of a piece of terrestrial matter is nothing but the supposed opposition to the force which we exert in carrying this piece of matter, we conceive it as possessing a property, that is, distinguishing quality, manifested by its being gravitas or heavy. This is heaviness, gravitas, gravity; and the manifestation of this quality, or the event in which it is seen, whether it be directly falling, or deflected in a parabolic curve, or stretching a coiled spring, or breaking a rope, or simply pressing on its subject, is gravitatio, gravitation; and the body is said to gravitate. When all obstacles are removed from the
body, as when we cut the string by which a stone is hung, it moves directly downwards, *tendit ad terram*. Si discindatur funis tenderet laps ad terram. Dum vero funis integer perseat, laps terram versus nitit eces teen.

By some metaphysical process, which it is needless at present to trace, this *nitus ad motum* has been called a *tendency* in our language. Indeed the word now comes to signify the energy of any active quality in those cases where its simplest and most immediate manifestation is prevented by some obstacle. The stone is now said to tend towards the earth, though it does not actually approach it, being withheld by the string. The stretching the string in a direction perpendicular to the horizon is conceived as a full manifestation of this tendency. This tendency, this energy of its heaviness, is therefore named by the word which distinguishes the quality; and it is called *gravitation*, and it is said to *gravitate*.

But Sir Isaac Newton discovered that this deflection of a heavy body differs in no respect from that general deflection observed in all the bodies of the solar system. For 16 feet, which is the deflection of a stone in one second, has the very same proportion to \( \pi \) of an inch, which is the simultaneous deflection of the moon, that the square of the moon’s distance from the centre of the earth has to the square of the stone’s distance from it, namely, that of 3600 to 1.

Thus we are enabled to compare all the effects of the mutual tendencies of the heavenly bodies with the tendency of gravity, whose effects and measures are familiar to us.

If the earth were a sphere covered to a great depth with water, the water would form a concentric spherical shell; for the gravitation of every particle of its surface would then be directed to the centre, and would be equal. The curvature of its surface therefore would be everywhere the same, that is, it would be the uniform curvature of a sphere.

It has been demonstrated in former articles, after Sir Isaac Newton, that the gravitation of a particle \( C \) (fig. 1.) to the centre \( O \) is to that of a particle \( E \) at the surface as \( CO \) to \( EO \). In like manner the gravitation of \( a \) is to that of \( p o \) to \( p o \). If therefore \( EO \) and \( op \) are two communicating canals, of equal lengths, the water in both would be in equilibrio, because each column would exert the same total pressure at \( O \). But if the gravitation of each particle in \( p o \) is diminished by a certain proportion, such as \( \pi / \pi \), it is plain that the total pressure of the column \( p o \) will be greater part less than that of the column \( EO \). Therefore they will now longer be in equilibrio.

The weight of the column \( EO \) will prevail; and if a hollow tower \( PP \) be built at the mouth of the pit \( po \), the water will sink in \( EO \) and rise in \( op \), till both be again in equilibrio, exerting equal total pressures at \( O \). Or we may prevent the sinking at \( E \) by pouring in more water into the tower \( PP \). The same thing must happen in the canal \( FC \) perpendicular to \( EO \), if the gravitation of every particle be diminished by a force acting in the direction \( CE \), and proportional to the distance of the particle from \( C \), such that when \( C \) is equal to \( O \), the force acting on \( C \) is equal to the force acting on \( O \). In order that the former equilibrium may be restored after this diminution of the gravitation of the column \( FC \), it is plain that more water must be poured in to the oblique tower \( FF \). All this is evident when we consider the matter hydrostatically. The gravitation of the particle \( c \) may be represented by \( o \); but the diminution of the pressure occasioned by this at \( O \) is represented by \( GC \).

Hence we can collect this, that the whole diminution of pressure at \( C \) is to the whole diminution of pressure at \( O \) as the sum of all the lines \( C \) to the sum of all the lines \( O \), that is, as \( FC \) to \( PO \). But the weight of the small quantity of water added in each tower is diminished in the same proportion; therefore the quantity added at \( FF \) must be to the quantity added at \( FP \) as \( FC \) to \( PO \). Therefore we must have \( FP \) : \( FC \) : \( PO \)

Thus it happens that the waters of the ocean have their equilibrium disturbed by the unequal gravitation of their different particles to the sun or to the moon; and this equilibrium cannot be restored till the waters come in from all hands, and rise up around the line joining the centres of the earth and of the moon. The spherical ocean must acquire the form of a prolate spheroid generated by the revolution of an ellipse round its transverse axis. The waters will be highest in that place which has the lunary in its zenith, and in the antipodes to that place; and they will be most depressed in all those places which have the lunary in their horizon. \( P \) and \( P' \) will be the poles, and \( E O Q \) will be the equator of this prolate spheroid.

Mr Ferguson, in his Astronomy, assigns another cause of this arrangement, viz. the difference of the centrifugal forces of the different particles of water, while the earth is turning round the common centre of gravity of the earth and moon. This, however, is a mistake. It would be just if the earth and moon were attached to the ends of a rod, and the earth kept always the same face toward the moon.

It is evident that the accumulation at \( P \) and \( P' \), and the depression at the equator, must augment and diminish in the same proportion with the disturbing force. It is also evident that its absolute quantity may be discovered by our knowledge of the proportion of the disturbing force to the force of gravity. Now this proportion is known; for the proportion of the gravitation of the earth’s centre to the sun or moon; to the force of gravity at the earth’s surface, is known; and the proportion of the gravitation of the earth’s centre to the lunary, to the difference of the gravitations of the centre and of the surface, is also known, being very nearly the proportion of the distance of the lunary to twice the radius of the earth.

Although this reasoning, by which we have ascertained the elliptical form of the watery spheroid, be sufficiently
TID 419

TID

sciently convincing, it is very imperfect, being accommodated to one condition only of equilibrium, viz. the equilibrium of the canals $c$ and $o$. There are several other conditions equally necessary to which this law reasoning will not apply, such as the direction of the whole remaining gravitation in any point $F$. This must be perpendicular to the surface, &c. &c. Nor will this mode of investigation ascertain the eccentricity of the spheroid without a most intricate process. We must therefore take the subject more generally, and show the proportion and directions of gravity in every point of the spheroid. We need not, however, again demonstrate that the gravitation of a particle placed anywhere without a perfect spherical shell, or a sphere consisting of concentric spherical shells, either of uniform density, or of densities varying according to some function of the radius, is the same as if the whole matter of the shell or sphere were collected in the centre. This has been demonstrated in the article Astronomy. We need only remind the reader of some consequences of this theorem which are of continual use in the present investigation.

1. The gravitation to a sphere is proportional to its quantity of matter directly, and to the square of the distance of its centre from the gravitating particle inversely.

2. If the spheres be homogeneous and of the same density, the gravitations of particles placed on their surfaces, or at distances which are proportional to their diameters, are as the radii; for the quantities of matter are as the cubes of the radii, and the attractions are inversely as the squares of the radii; and therefore the whole gravitations are as $\frac{r^3}{r^2}$, or as $r$.

3. A particle placed within a sphere has no tendency to the matter of the shell which lies without it, because its tendency to any part is balanced by an opposite tendency to the opposite part. Therefore,

4. A particle placed anywhere within a homogeneous sphere gravitates to its centre with a force proportional to its distance from it.

It is a much more difficult problem to determine the gravitation of particles to a spheroid. To do this in general terms, and for every situation of the particle, would require a train of propositions which our limits will by no means admit; we must content ourselves with as much as is necessary for merely ascertaining the ratio of the axes. This will be ascertained by knowing the ratio of the gravitation at the pole to that at the equator. Therefore,

\[ \frac{AG^2}{PA^2} \times GH, \] for $GH$ measures the number of parallel plates of which the solid ring is composed. This being decomposed in the direction $PG$ is $\frac{c^2}{r^2} \times \frac{AG^2}{PA^2} \times GH$. But $\frac{AG^2}{PA^2} = \frac{OG^2}{PE^2}$ and $\frac{PG}{PA} = \frac{FO}{PO}$.

Therefore the attraction of the ring, in the direction $PO$, is $\frac{c^2}{r^2} \times \frac{AG^2}{PA^2} \times \frac{OE^2}{PE^2} \times GH$.

Further, by the nature of the circle, we have $HG = AG : AO$; also $AB = BL : AO : OE$. But $PA : PO = OE, and OE = \frac{AG \times PO}{PA}$. Therefore

\[ AB = BL = AO : \frac{AG}{PA} : \frac{PO}{PA} = \frac{OE}{PE} \times \frac{EO}{PA}. \]

Also $BL : LA = EO : EA$, and $LA : F = PA : PE; F$ is ultimately $PA : PE$. Therefore, by equality, $HG = F = \frac{AG}{AO} : PA : PO = AO : PE : EA : PE$. Or $HG : F = EO : PA = PO : PE : EA \times F$, or $\frac{c^2}{r^2} \times \frac{OE^2}{PE^2} \times \frac{PO}{PA} \times \frac{EO}{PE} \times F$, or $\frac{c^2}{r^2} \times \frac{OE^2}{PA} \times \frac{PO}{EO} \times \frac{EO}{PE} \times F$. In like manner, the attraction of the

3 G 2 the
the ring generated by the revolution of CD c f is \( \frac{e^2}{r} \times \frac{OE}{OF} \times Ff \), therefore the attraction of both is \( \frac{e^2}{r} \times \frac{OE}{OF} \times \frac{PA^2 + PC^2}{PA^2 + PC^2} = \frac{e^2}{r} \times Ff \times \frac{PA^2 + PC^2}{PA^2 + PC^2} \). But PA^2 + PC^2 = 2 PE^2 + 2 EA^2 = 2 PE^2 + 2 a^2. Therefore the attraction is \( \frac{e^2}{r} \times \frac{PE^2 + a^2}{PA^2 + PC^2} \). But Ff = \( \frac{y}{x} \times \frac{x}{y} \), therefore \( \frac{e^2}{r} \times \frac{PE^2 + a^2}{PA^2 + PC^2} \). Therefore \( \frac{e^2}{r} \times \frac{PE^2 + a^2}{PA^2 + PC^2} \). Therefore \( \frac{e^2}{r} \times \frac{PE^2 + a^2}{PA^2 + PC^2} \). Therefore the attraction of the two rings is \( \frac{e^2}{r^2} \times \frac{PE^2 + a^2}{PA^2 + PC^2} \). But PE^2 = PO^2 - OE^2 = d^2 - (r^2 - x^2) = d^2 - r^2 + x^2. Therefore the attraction of the two rings is \( \frac{e^2}{r^2} \times \frac{d^2 - r^2 + x^2}{PA^2 + PC^2} \). The attraction of the whole shell of redundant matter will be had by taking the fluent of this formula, which is \( \frac{2e}{r d^2} \times \left( r^2 d^2 x + \frac{3}{3} r^2 x - r^2 d^2 - r^2 x - \frac{2}{2} x^2 \right) \), and then make \( x = r \). This gives \( \frac{2e}{r d^2} \times (d^2 r^2 + \frac{1}{2} r^2 - r^2) \), which is \( \frac{2}{3} \frac{e}{r d^2} \times (\frac{3}{3} d^2 r^2 - r^4) \), thus \( \frac{4e r}{3 d^2} \times \frac{r^4}{5 d^4} \). To this add the attraction of the inscribed sphere, which is \( \frac{r^3}{d^3} \), we have the attraction of the whole sphere \( \frac{e}{d^2} \times \frac{r^4}{d^2} \). and we have the attraction of the whole sphere \( \frac{e}{d^2} \times \frac{r^4}{d^2} \). 

Cor. 1. If the particle P is situated precisely in N, the pole of the spheroid, the attraction of the spheroid is \( \frac{e}{3} r + \frac{2}{d} c e \).

If the spheroid is not oblate, but oblong, and if the greater semimajor axis be \( r \), and the depression at the equator we \( e \), the analysis is the same, taking \( e \) negatively. Therefore the attraction for a particle in the pole, or the gravitation of a particle in the pole, is \( \frac{e}{3} r + \frac{2}{d} c e \).

But if the polar semimajor axis be \( r + c \), and the equatorial radius be \( r \), so that this oblong spheroid has the same axis with the former oblate one, the gravitation of a particle in the pole is \( \frac{e}{3} r + \frac{2}{d} c e \).

Cor. 2. If a number of parallel planes are drawn perpendicular to the equator of an oblong spheroid, whose longer semimajor axis is \( r + c \), and equatorial radius \( r \), they will divide the spheroid into a number of similar ellipses; and since the ellipse through the axis has \( r + c \) and \( r \) for its two semimajor axes, and the radius of a circle of equal area with this ellipse is a mean proportional between \( r \) and \( r + c \), and therefore very nearly \( r + \frac{1}{2} c \), when \( e \) is very small in comparison of \( r \), a particle on the equator of the oblong spheroid will be as much attracted by these circles of equal areas, with their corresponding ellipses, as by the ellipses. Now the attraction at the pole of an oblate spheroid was \( \frac{1}{2} c r + \frac{1}{2} c e \). Therefore putting \( \frac{1}{2} c \) in place of \( e \), the attraction on the equator of the oblong spheroid will be equal to \( \frac{1}{2} c r + \frac{1}{2} c e \).

Thus we have ascertained thegravitations of a particle situated in the pole, and of one situated in the equator, of a homogeneous oblong spheroid. This will enable us to solve the following problem:

If the particles of a homogeneous oblong fluid spheroid attract each other with a force inversely as the squares of their distances, and if they are attracted by a very distant body by the same law, and if the ratio of the equatorial gravity to this external force be given; to find what must be the proportion of the semimajor, so that all may be in equilibrio, and the spheroid preserve its form.

Let \( r \) be the equatorial radius, and \( r + c \) be the polar semimajor axis. Then the gravitation at the pole \( m \) is \( \frac{e}{3} r + \frac{2}{d} c e \), and the gravitation at the equator is \( \frac{e}{3} r + \frac{2}{d} c e \). Now by the gravitation towards the distant body placed in the direction of the polar axis, the polar gravitation is diminished, and the equatorial gravitation is increased; and the increase of the equatorial gravitation is to the diminution of the polar gravitation as \( NO \) to \( 2 m o \). Therefore if the whole attraction of the oblong spheroid for a particle on its equator be to the force with which the distant body exerts there, as \( G \) to \( P \), and if the spheroid is very nearly spherical, the absolute weight at the equator will be \( \frac{3}{2} c r + \frac{1}{2} c e \) and the absolute weight at the pole will be \( \frac{3}{2} c r + \frac{1}{2} c e \) and the absolute weight at the pole will be \( \frac{3}{2} c r + \frac{1}{2} c e \). Their difference is \( \frac{1}{2} c r + \frac{1}{2} c e \).

Now if we suppose this spheroid to be composed of similar concentric shells, all the forces will decrease in the same ratio. Therefore the weight of a particle in a column reaching from the equator to the centre will be to the weight of a similarly situated particle of a column reaching from the pole to the centre, as the weight of a particle at the equator to the weight of a particle at the pole. But the whole weights of the two columns must be equal, that they may balance each other at the centre. Their lengths must therefore be reciprocally as the weights of similarly situated particles; that is, the polar semimajor axis must be to the equatorial radius, as the weight of a particle at the equator to the weight of a particle at the pole. Therefore we must have \( \frac{1}{2} c r + \frac{1}{2} c e \).

Hence we derive \( r \) \( P \) \( G \) as \( \frac{1}{2} c r + \frac{1}{2} c e \), or \( 4 G : 15 P = r : e \).

This determines the form of the fluid spheroid when the ratio of \( G \) to \( P \) is given.

It is well known that the gravitation of the moon to the earth is to the disturbing force of the sun as 175,735 to 1 very nearly. The lunar gravitation is increased as she approaches the earth in the reciprocal duplicate ratio of the distances. The disturbing force of the sun diminishes in the simple ratio of the distances; therefore the weight of a body on the surface of the earth is to the disturbing
disturbing force of the sun on the same body in a ratio compounded of the ratio of 178,715 to 1, the ratio of 3,600 to 1, and the ratio of 60 to 1; that is, in the ratio of 386,0460 to 1. If the mean radius of the earth be 209,3450 feet, the difference of the axis, or the elevation of the pole of the watery spheroid produced by the gravitation to the sun, will be \( \frac{1}{2} \times 78,0450 \times \frac{2}{3} \), or very nearly 24 feet. This is the tide produced by the sun on a homogeneous fluid sphere.

It is plain, that if the earth consists of a solid nucleus of the same density with the water, the form of the solar tide will be the same. But if the density of the nucleus be different, the form of the tide will be different, and will depend both on the density and on the figure of the nucleus.

If the nucleus be of the same form as the surrounding fluid, the whole will still maintain its form with the same proportion of the axis. If the nucleus be spherical, its action on the surrounding fluid will be the same as if all the matter of the nucleus by which it exceeds an equal bulk of the fluid were collected at the centre. In this case, the ocean cannot maintain the same form: for the action of this central body being proportional to the square of the distance inversely, will augment the gravity of the equatorial fluid more than it augments that of the circumpolar fluid; and the ocean, which was in equilibrio (by supposition), must now become more protuberant at the poles. It may, however, be again balanced in an elliptical form, when it has acquired a just proportion of the axes. The process for determining this is tedious, but precisely similar to the preceding.

If the density of the nucleus exceed that of the fluid about \( \frac{1}{3} \), we shall have \( r = \frac{2}{3} \) of the form which has been determined for the earth, by the mensuration of degrees of the meridian, and by the vibration of pendulums. The curious reader will do well to consult the excellent dissertations by Clairaut and Boscovich on the Figure of the Earth, where this curious problem is treated in the most complete manner.

Mr. Bernoulli, in his dissertation on the Tides, has committed a great mistake in this particular. On the other hand, if the nucleus be less dense than the waters, or if there be a great central hollow, the elevation produced by the sun will exceed 24 inches.

It is needless to examine this any farther. We have collected enough for explaining the chief affections of the tides.

It is known that the earth is not a sphere, but swelled out at the equator by the diurnal rotation. But the change of form is so very small in proportion to the whole bulk, that it cannot sensibly affect the change of form afterwards induced by the sun on the waters of the ocean. For the disturbing force of the sun would produce a certain protuberance on a fluid sphere; and this protuberance depends on the ratio of the disturbing force to the force of gravity at the surface of this sphere. If the gravity be changed in any proportion, the protuberance will change in the same proportion. Therefore if the body be a spheroid, the protuberance produced at any point by the sun will increase or diminish in the same proportion that the gravity at this point has been changed by the change of form. Now the change of gravity, even at the pole of the terrestrial spheroid, is extremely small in comparison with the whole gravity. Therefore the change produced on the spheroid will not sensibly differ from that produced on the sphere; and the elevations of the waters above the surface, which they would have assumed independent of the sun’s action, will be the same on the spheroid as on the sphere. For the same reason, the moon will change the surface already changed by the sun, in the same manner as it would have changed the surface of the undisturbed ocean. Therefore the change produced by both these luminaries in any place will be the same when acting together as when acting separately; and it will be equal to the sum, or the difference of their separate changes, according as these would have been in the same or in opposite directions.

Let us now consider the most interesting circumstances of the form of an elliptical tide, which differs very little from a sphere.

Let \( T \) (fig. 1) be a point in the surface of the inscribed spheroid, and let \( Z \) express the angular distance \( T O Q \) from the longer axis of the surrounding spheroid \( S N Q \). Let \( T R \), \( T W \) be perpendicular to the equatorial diameter and to the axis, so that they are the cosine and the sine of \( T O Q \) to the radius \( T O \) or \( Q O \). Let \( S N \) be a section of the circumscribed sphere. Draw \( Q T \) cutting the spheroid in \( Z \) and the circumscribed sphere in \( t \). Also let \( a \) be a section of a sphere which has the same capacity with the spheroid, and let it cut the radius in \( r \). Then,

1. The elevation \( T Z \) of the point \( Z \) of the spheroid above the inscribed sphere is \( = q \times \cos^2 Z \), and the depression \( t Z \) below the circumscribed sphere is \( = q \times \sin^2 Z \). Produce \( RT \) till it meet the surface of the spheroid in \( V \). The minute triangle \( T V Z \) may be considered as rectilinear, right angled at \( Z \), and therefore similar to \( O T R \). Therefore \( T R = T V \), \( T Z = q \times \cos^2 Z \), \( O T \times = q \times \cos^2 Z \), \( O T = q \times \cos^2 Z \).

Let in the ellipse \( O Q \), or \( O T : T R = T V : T Z \). But in the ellipse \( O Q \), or \( O T : T R = T V : T Z \). Therefore \( T Z = q \times \cos^2 Z \), \( T Z = q \times \cos^2 Z \).

In the very same manner it may be shown, that \( T Z = q \times \sin^2 Z \).

2. The elevation of the point \( T \) above another point \( T' \), whose angular distance \( T O T' \) from the point \( T \) is \( q \), is \( = q \times \cos Z \times \sin Z \). Call the angle \( Q O T \) \( Z \). Then \( T' Z' = q \times \cos Z \times \sin Z \), and \( T Z = T' Z' = q \times \cos Z \times \sin Z \). But the arc \( T Q \) is the complement of \( T Q \), and therefore \( \cos Z = \sin Z \).

Therefore \( T Z = T' Z' = q \times \cos Z \times \sin Z \).

3. \( q = \frac{1}{2} \). For the inscribed sphere is to the spheroid as \( O Q \) to \( q \). But the inscribed sphere is to the sphere \( q \) as \( O Q \) to \( q \). Therefore because the sphere \( q \) is equal to the spheroid \( S Q N \), we have \( O Q = q \times \cos Z \), \( O Q = q \times \cos Z \), and \( O Q = q \) is the first of two mean proportionals between \( O Q \) and \( q \). But \( q \) is very small in comparison with \( O Q \). Therefore \( q \) is very nearly \( \frac{1}{2} \).

Since \( q \) is the sphere of equal capacity, it is the form of the undisturbed ocean. The best way therefore of conceiving the changes of form produced by the sun or moon, or by both together, is to consider the elevations or depressions which they produce above or below this surface. Therefore,
T I D  [ 422 ]

4. The elevation \( r Z \) of the point \( Z \) above the equi-
capacious sphere is evidently \( \frac{1}{2} Q y \times \sin^2 Z - \frac{1}{2} Q y \).
Also the depression \( r2'Z' \) of the point \( Z' \) is \( \frac{1}{2} Q y \times \sin^2 Z' - \frac{1}{2} Q y \).

N. B. Either of these formulas will answer for either
the elevation above, or the depression below, the natural
ocean: For if \( \cos^2 Z \) is less than \( \frac{1}{2} \), the elevation given
by the formula will be negative; that is, the point is
below the natural surface. In like manner, when
\( \sin^2 Z' \) is less than \( \frac{1}{2} \), the depression is negative,
and the point is above the surface. But if \( \cos^2 Z \) be \( \frac{1}{2} \),
or \( \sin^2 Z' \) be \( \frac{1}{2} \), the point is in the natural surface. This
marks the place where the spheroid and the equal sphere
intersect each other, viz. in \( 1^\circ \), the arch \( 1^\circ \) of being
\( 54^\circ 44' \) very nearly, and \( PS = 53^\circ 16' \).

Let \( S \) represent the whole elevation of the pole of the
solar tide above its equator, or the difference between
high and low water produced by the sun; and let \( M \)
represent the whole elevation produced by the moon.
Let \( x \) and \( y \) represent the zenith distances of the sun
and moon with respect to any point whatever on
the ocean. Then \( x \) and \( y \) will be the arches intercepted
between that point and the summits of the solar
and lunar tides. Then the elevation produced by each
luminaries in that plane is \( S \times \cos^2 x - \frac{1}{2} S + M \times \cos^2 y \)
\( - \frac{1}{2} M \); or, more concisely, \( S \times \cos^2 x + M \times \cos^2 y \)
\( - \frac{1}{2} S + M \); and the depression is \( S \times \sin^2 x + M \times \sin^2 y \)
\( - \frac{1}{2} S + M \).

Let the sun and moon be in the same point of the
heavens. The solar and lunar tides have the same
axis; the cosines of \( x \) and \( y \) each will be \( 1 \),
and the elevation at the compound pole will be
\( S + M - \frac{1}{2} S + M = \frac{1}{2} S + M \). The depression at any point \( 90^\circ \)
from this pole will be \( \frac{1}{2} S + M \), and the whole tide is
\( S + M \).

Let the moon be in quadrature, as in \( a \) (fig. 2). The
appearance at \( a \) will be known, by considering in this
place the cosine of \( x \) is \( 1 \), and the cosine of \( y \) is \( 0 \).
Therefore the elevation at \( a = S - \frac{1}{2} S + M = \frac{1}{2} S - \frac{1}{2} M \).
The depression at \( a = S - \frac{1}{2} S + M = \frac{1}{2} S - \frac{1}{2} M \).
The difference or whole tide \( = S - M \).

In like manner, when the whole elevation at \( a \) above the in-
scribed sphere is \( M - S \).
Hence we see that the whole tide, when the moon is
in quadrature is the difference of \( S \) and \( M \). We also
see, that if \( M \) exceeds \( S \), the water will be higher at \( a \)
than at \( a \). Now it is a matter of observation, that in
the quadratures it is high water under the moon, and
low water under the sun. It is also a matter of obser-
vation, that in the free ocean, the ebb tide, or the water
at \( a \), immediately under the sun, is below the natural
surface of the ocean. Hence we must conclude, that
\( \frac{1}{2} S \) is less than \( M \), or that \( M \) is more than double of
\( S \). This agrees with the phenomena of nutation and
precession, which seem to make \( S = \frac{1}{2} M \).

In all other positions of the sun and moon, the place
of high water will be different. It is high water where
the sum of the elevations produced by both luminaries
above the natural ocean is greatest; and the place of
low water is where the depression above the natural
ocean is greatest. Therefore, in order that it may be
high water, we must have \( S \times \cos^2 x + M \times \cos^2 y = \frac{1}{2} S + M \) a maximum; or, neglecting the constant quanti-

T I D

\[ T = \frac{S + M}{3} \]

\[ \text{maximum.} \]

In like manner, to have low water in a place where
the zenith distance of the sun and moon are \( x \) and \( y \),
we must have \( S \times \sin^2 x + M \times \sin^2 y = \text{minimum.} \)

Lemma 1. If we consider the sines of angles as numerals fractions of the radius \( 1 \), then we have
\( \cos^2 Z = \frac{1}{2} + \cos^2 Z \), and \( \sin^2 Z = \frac{1}{2} - \frac{1}{2} \cos^2 Z \).

Let \( a b c \) (fig. 3) be a quadrant of a circle of which \( O \)
is the centre, and \( O x \) is the radius. On \( O x \) describe
the semicircle \( O M N \), cutting \( O n \) in \( M \). Draw \( s M \),
and produce it till it cut the quadrant in \( n \). Also draw
towards the centre of the semicircle, and \( n d \) and \( n e \perpendicular \) to \( O x \).

It is plain that \( n M \) is perpendicular to \( O M \); and if \( O x \)
be radius, \( s M \) is the sine of the angle \( O M \), which
we may call \( Z \); \( O M \) is its cosine; and because \( Ox = OM \cdot OD \),
and \( O D = \cos x \), and \( OM = \cos \theta \), and \( OD = \cos \phi \),
and \( 
\text{Cos} = \cos^2 Z \).

Let \( a = \frac{1}{2} \), then \( OC = \frac{1}{2} \). \( CD = \cos \cdot \cos MCD = CM \cdot \cos 2 \theta = \frac{1}{2} \cos 2\theta \).

Therefore, \( \cos^2 Z = \frac{1}{2} \cos 2\theta \).

In like manner, because \( O s = s M = s D \), \( d D = \frac{1}{2} \cos 2\theta \).

This is evidently \( \frac{1}{2} - \frac{1}{2} \cos 2\theta \).

Lemma 2. \( \sin^2 Z = \sin^2 Z \). For, because \( n M \) is perpendicular to \( O M \), the arc \( s m \) is double of
the arc \( s m \), and because \( MD \) is parallel to \( n d \), \( d D = \frac{1}{2} \cos 2\theta \).

Therefore \( \sin^2 Z = \sin^2 Z \).

But \( d D \) is the cosine of \( n d \), \( \cos 2\theta = \cos 2\theta \).

By the first lemma we see, that in order that there
may be high water at any place, when the zenith dis-
tances of the sun and moon are \( x \) and \( y \), we must have
\( S \times \cos^2 x + M \times \cos^2 y = \text{maximum.} \)

That this may be the case, the fluxion of this for-
mula must be \( = 0 \). Now we know that the fluxions of
the cosines of two arches are as the sines of those
arches. Therefore we must have \( S \times \sin^2 x + M \times \sin^2 y = 0 \),
or \( S \times \sin^2 x - M \times \sin^2 y = 0 \), which gives us \( S \times \sin^2 x + M \times \sin^2 y = M = S \).

In like manner, the place of low water requires \( \sin^2 x = \sin 2\theta \times \cos 2\theta = M = S \).

From this last circumstance we learn, that the place
of low water is \( 0 \), removed \( 90^\circ \) from the place of high
water, whereas we might have expected, that the spher-
roid would have been most protuberant on that side on
which the moon is: For the sines of \( 2\theta \) and of \( 2\theta \) have
the same proportion with the sines of \( 2\theta x \) and \( 2\theta y \).
Now we know that the sine of the double of any arch is
the same with the sine of the double of its complement.
Therefore if low water be really distant \( 90^\circ \) from high
water, we shall have sin \( 2\theta x = \sin 2\theta y = \sin 2\theta \).

But if it is at any other place, the sines cannot have this
proportion.

Now let \( e \) be the point of the earth’s surface which
has the sun in the zenith, and \( m \) the point which has
the moon in the zenith. Let \( A \) be any other point.
Draw \( O A \) cutting the semicircle \( OM \) at \( s \). Make
OM to CS as the disturbing force of the moon to that
of the sun; and draw \( S \) parallel, and \( S \times M \) per-
pendicular to HH’. Join MH and MH’. The angle
\( HC \) is double of the angle \( HO \), and \( MCH \) is double
of \( MHH’ \), or of its equal \( MOH \). Because \( HMH \) is
a semicircle, HH’ is perpendicular to MO. There-

TIDE

For if $HH'$ be considered as radius, $HM$ is the sine and $HM'$ is the cosine of $MH'H$. And $Ct = MC \cdot \cos y = M \cdot \cos y$. And $Ct$ is $SC \cdot \cos z$. Therefore $t'r$ or $S'u = S \cdot \cos x + M \cdot \cos 2y$. Therefore $t'r$ or $S'u$ will express the whole difference of elevation between $h$ and the points that are go degrees from it on either side (by Lemma 2); and if $h$ be the place of high water, it will express the whole tide, because the high and low waters were shown to be $90^\circ$ avorder. But when $h$ is the place of high water, $S'u$ is a maximum. Because the place of the moon, and therefore the point $M$, is given, $S'u$ will be a maximum when it coincides with $SM$, and $CH$ is parallel to $SM$.

This suggested to us the following new, and not inessential, solution of the problem for determining the place of high water.

Let $SQU$ be a section of the terrestrial globe, by a plane passing through the sun and moon, and let $O$ be its centre. Let $s$ be the point which is immediately under the sun, and $m$ the place immediately under the moon. Bisect $Ox$ in $O$, and describe round $C$ the circle $OM = LO$, cutting $O$ in $M$. Take $Ct$ to represent the disturbing force of the moon, and make $Ct = C\overrightarrow{S}$ as the force of the moon to that of the sun (supposing this ratio to be known). Join $MS$, and draw $CH$ parallel to it. Draw $OH$, and $\lambda O\overrightarrow{L}p$ perpendicular to it. And lastly, draw $CI$ perpendicular to $SM$. Then we say that $s$ and its opposite $s'$ are the places of high water, $t$ and $t'$ are the places of low water, $MS$ is the height of the tide, and $MI$, $SI$ are the portions of this tide produced by the moon and sun.

For it is plain, that in this case the line $Su$ of the last proposition coincides with $MS$, and is a maximum. We may also observe, that $MC = SC = \sin m.$ $SC = \sin MSC = \sin HCS = \sin MCH = \sin 2hOx = \sin 2hOM = \sin 2x = \sin 2y$, or $M = S = \sin 2x = \sin 2y$, which are required to what was required for the maximum.

It is also evident, that $MC = MC \cdot \cos y = M \cdot \cos y$, and $SI = SC \cdot \cos ISC = S \cdot \cos 2x$; and therefore $MS$ is the difference of elevation between $h$ and the points $t$ and $t'$, which are $90^\circ$ from it, and is therefore the place of low water; that is, $MS$ is the whole tide.

The elevation of every other point may be determined in the same way, and thus may the form of the spheroid be completely determined.

If we suppose the figure to represent a section through the earth's equator (which is the case when the sun and moon are in the equator), and farther suppose the two luminaries to be in conjunction, the ocean is an oblong spheroid, whose axis is in the line of the syzygies, and whose equator coincides with the sun circle. But if the moon be in any other point of the equator, the figure of the ocean will be very complicated. It will not be any figure of revolution; because neither its equator (or most depressed part) nor its meridians are circles. The most depressed part of its equator will be in that section through the axis which is perpendicular to the plane in which the luminaries are situated. And this greatest depression, and its shortest equatorial diameter will be constant, while its other dimensions vary with the moon's place. We need not inquire more minutely into its form; and it is sufficient to know that all the sections perpendicular to the plane passing through the sun and moon are ellipses.

This construction will afford us a very simple, and, we hope, a very perspicuous explanation of the chief phenomena of the tides. The well informed reader will be pleased with observing its coincidence with the algebraic solution of the problem given by Daniel Bernoulli, in his excellent dissertation on the Tides, which shared with M. Lagrange and Euler the prize given by the Academy of Sciences at Paris, and with the case of pernicity with which the phenomena are deducible from it, being in some sort exhibited to the eye.

In our application, we shall begin with the simplest cases, and gradually introduce the complicating circumstances which accommodate the theory to the true state of things.

We begin, therefore, by supposing the earth covered, to a proper depth, with water, forming an ocean concentric with its solid nucleus.

In the next place, we suppose that this ocean adopts in an instant the form which is consistent with the equilibrium of gravity and the disturbing forces.

Thirdly, We suppose the sun stationary, and the moon to move eastward from him above $12^\circ$ every day.

Fourthly, We suppose that the solid nucleus turns round its proper axis to the eastward, making a rotation in 24 solar hours. Thus any place of observation will successively experience all the different depths of water.

Thus we shall obtain a certain succession of phenomena, precisely similar to the succession observed in nature, with this sole difference, that they do not correspond to the contemporaneous situations of the sun and moon. When we shall have accounted for this difference, we shall presume to think that we have given a just theory of the tides.

We begin with the simplest case, supposing the sun and moon to be always in the equator. Let the series begin with the sun and moon in conjunction in the line $Ox$. In this case the points $s$, $m$, and $h$ coincide, and we have high water at $12^\circ$ o'clock noon and midnight.

While the moon moves from $x$ to $Q$, $OM$ cuts the upper semicircle in $M$, and therefore $CH$, which is always parallel to $SM$, lies between $MC$ and $Ct$. Therefore $h$ is between $m$ and $s$, and we have high water after $12^\circ$ o'clock, but before the moon's southing. The same thing happens while the moon moves from $o$ to $g$, during her third quarter.

But while the moon moves from her first quadrature in $Q$ to opposition in $o$ (as in fig. 5), the line $mO$ drawn from the moon's place, cuts the lower semicircle in $M$ and $CH$, parallel to $SM$, again lies between $M$ and $s$, and therefore $h$ lies between $m$ and $o$. The place of high water is to the eastward of the moon, and we have high water after the moon's southing. The same thing happens while the moon is moving from her last quadrature in $g$ to the next syzygy. In short, the point $H$ is always between $M$ and $s$, and the place of high water is always between the moon and the nearest syzygy. The place of high water overtakes the moon in each quadrature, and is overtaken by the moon in each syzygy. Therefore during the first and third quarters, the place of high water gradually falls behind the moon for some time, and then gains upon her again, so as
TID [ 424 ] TID

Tide. as to overtake her in the next quadrature. But during
the second and fourth quarters, the place of high wa-
ter advances before the moon to a certain distance, and
then the moon gains upon it, and overtakes it in the next
quadrature.

If therefore we suppose the moon to advance uniform-
ly along the equator, the place of high water moves un-
equally, slowest in the time of new and full moon, and
swiftest in the time of the quadratures. There must be
some intermediate situations where the place of high
water neither gains nor loses upon high water, but
moves with the same velocity.

The rate of motion of the point A may be determined
as follows: Draw C, S n, making very small and equal
angles with C, H and M S. Draw n c, and about S, with
the distance S s, describe the arch n v, which may be
considered as a straight line perpendicular to s, or
to M S.

Then, because S M and S are parallel to C, H and
C, the points n and i are contemporaneous situations
of M and H, and the arches n M, s H, are in the ratio
of the angular motions of m and A. Also, because n v
and n M are perpendicular to n s and n c, the angle
v n M is equal to the angle s n c, or s M. Also, be-
cause the angles v M and M I C are right angles, and
the angles v n M, CM I, are also equal, the triangles
v n M, C M I, are similar. Therefore

\[ n M : n v = M C : M I. \]

And

\[ n v : s H = n s : s C, \text{ or } M S : M C; \text{ therefore } n M : s H = M S : M I. \]

Therefore the angular motion of the moon is to the angular motion of the place
of high water as M S to M I.

Therefore, when M S is perpendicular to C, and
the point I coincides with S, the motion of high water
is equal to that of the moon. But when M S is perpen-
dicular to C, H C is also perpendicular to C, s, and
the angle H O s is 45°, and the high water is in the octant.

While the moon moves from s to m', or the high water
from s to H, the point I falls between M and S, and
the motion of high water is slower than that of the
moon. The contrary obtains while the moon moves
from m' to Q, or the high water from the octant to the
quadrature.

It is evident, that the motion of A in the third quar-
ter of the lunation, that is, in passing from s to q, is
similar to its motion from s to Q. Also, that its mo-
tion from Q to o must retain by the same degrees as it
accelerated in passing from s to Q, and that its motion
in the last quarter from q to s is similar to its motion
from Q to o.

At new and full moon the point I coincides with C,
and the point M coincides with s. Therefore the motion
of the high water at full and change is to the motion
of the moon as s C to s S. But when the moon is
in quadrature, I coincides with C, and M with o.
Therefore the motion of the moon is to that of high
water as OS to OC or s C. Therefore the motion of
high water at full and change is to its motion in the
quadratures as OS to s C, or the difference of the
disturbing forces to their sum. The motion of the tide
is therefore slowest in the syzygies and swiftest in
the quadratures; yet even in the syzygies it passes the sun
along with the moon, but more slowly.

Let the interval between the morning tide of one
day and that of the next day be called a tide-day.

This is always greater than a solar day, or 2h 46,\textsuperscript{m} 0, \textsuperscript{m} 0,\textsuperscript{m} 0,\textsuperscript{m} 0,
because the place of high water is moving faster to the
eastward than the sun. It is less than a lunar day, or
24h. \textsuperscript{m} 50'\textsuperscript{m}, while the high water passes from the second
to the third octant, or from the fourth to the first. It is
equal to a lunar day when high water is in the octant, and
exceeds a lunar day while high water passes from the
first to the second octant, or from the third to the fourth.

The difference between a solar day and a tide day is
called the PRIMING or the RETARDATION of the tides.
This is evidently equal to the time of the earth's de-
scribing in its rotation an angle equal to the motion
of the high water in a day from the sun. The smallest
of these retardations is to the greatest as the difference
of the disturbing forces to their sum. Of all the pheno-
mena of the tides, this seems to be the fewest and
most inconsiderable derivations from local and acci-
dental circumstances. It therefore affords the best
means for determining the proportion of the disturbing
forces. By a comparison of a great number of observa-
tions made by Dr. Maskelyne at St. Helena, and at Bar-
badoes (places situated in the open sea), it appears that
the shortest tide-day is 24h. 37', and the longest is 24h.
27'. This gives M = S : M + S = 37 : 87, and S : M
= 2 : 4.96; which differs only 1 part in 124 from the
proportion of 2 to 5, which Daniel Bernoulli collected
from a variety of different observations. We shall there-
fore adopt the proportion of 2 to 5 as abundantly exact.
It also agrees exactly with the phenomena of the na-
tion of the earth's axis and the precession of the equi-
noxes; and the astronomers affect to have deduced this
proportion from these phenomena. But an intelligent
reader of their writings will perceive more fineness than
justice in this assertion. The nations and preces-
sion do not afford phenomena of which we can assign
the share to each luminary with sufficient precision for
determining the proportion of their disturbing forces;
and it is by means of many arbitrary combinations,
and without necessity, that D'Alembert has made out this
ratio. We cannot help being of opinion, that D'Ale-
bert has accommodated his distribution of the pheno-
mena to this ratio of 2 to 5, which Daniel Bernoull
(best philosopher and the most candid man of that
illustrious family of mathematicians) had, with so much
sagacity and justness of inference, deduced from the
phenomena of the tides. D'Alembert could not but see
the value of this inference; but he wanted to show his
own address in deducing it proprius mepe fonnis from
the nutation and precession. His procedure in this re-
sembles that of his no less vain countryman De la Place,
who affects to be highly pleased with finding that Mr
Bode's discovery that Meyer had seen the Georgium
Sidus in 1756, perfectly agree with the theory of its
motions which he (De la Place) had deduced from his
own doctrines. Any well informed mathematician will
see, that De la Place's data afforded no such precision;
and the Book on the Elliptical Motions of the Planets,
to which he alludes, contains no grounds for his infe-
rence. This observation we owe to the author of a pa-
per on that subject in the Transactions of the Royal So-
ciety of Edinburgh. We hope that our readers will ex-
cuse this occasional observation, by which we wish to
do justice to the merit of a modest man, and one of
the greatest philosophers of his time. Our only claim in
the present dissertation is the making his excellent per-
formance
The swelling tides obey the moon.

The height of high water above the low water constitutes what is usually called the tide. This is the interesting circumstance in practice. Many circumstances render it almost impossible to say what is the elevation of high water above the natural surface of the ocean. In many places the surface at low water is above the natural surface of the ocean. This is the case in rivers at a great distance from their mouths. This may appear absurd, and is certainly very paradoxical; but it is a fact established on the most unquestionable authority. One instance fell under our own observation. The low-water-mark at spring tide in the harbour of Alloa was found by accurate levelling to be three feet higher than the top of the stone pier at Leith, which is several feet above the high water mark of this harbour. A little attention to the motion of running waters will explain this completely. Whatever checks the motion of water in a canal must raise its surface. Water in a canal runs only in consequence of the declivity of this surface: (See River). Therefore a flood tide coming to the mouth of a river checks the current of its waters, and they accumulate at the mouth. This checks the current farther up, and therefore the waters accumulate there also; and this checking of the stream, and consequent rising of the waters, is gradually communicated up the river to a great distance. The water rises everywhere, though its surface still has a slope. In the mean time, the flood tide at the mouth passes by, and an ebb succeeds. This must accelerate even the ordinary course of the river. It will more remarkably accelerate the river now raised above its ordinary level, because the declivity at the mouth will be so much greater. Therefore the waters near the mouth, by accelerating, will sink in their channel, and increase the declivity of the canal beyond them. This will accelerate the waters beyond them; and thus a stream more rapid than ordinary will be produced along the whole

</table>
T I D [ 426 ]

1. \( \sin y = \sqrt{1 - \sqrt{1 - d^2}} \). For we shall have \( \cos \).
2. \( y = \sqrt{1 - \frac{1}{d^2}} \). But \( \sin y = \frac{1}{2} \cos 2y = \frac{1}{2} \sqrt{1 - \frac{1}{d^2}} \), and \( \sin y = \sqrt{1 - \frac{1}{d^2}} \).

2. \( \tan y = \frac{p}{1 + \sqrt{1 + p^2}} \). For because \( p = \tan \).
2. \( y = \sqrt{1 + p^2} \) is the secant of \( 2y \), and \( 1 + \sqrt{1 + p^2} = p : \tan y \).

These processes for obtaining \( y \) directly are abundantly simple. But it will be much more expeditious and easy to content ourselves with obtaining \( 2y \) by means of the value of its tangent, viz. \( \frac{M + S}{2} \cos 2a \). Or, we may find \( a \) by means of the similar value of its tangent \( \frac{M}{d} \) of fig. 4.

There is still an easier method of finding both \( 2a \) and \( 2y \), as follows.

Make \( M + S = \tan \alpha : \tan \beta \). Then \( \beta \) is the difference of \( x \) and \( y \), as \( a \) is their sum. For this analogy evidently gives the tangent of half the difference of the angles \( CSM \) and \( CMS \) of fig. 4, or of \( 2a \) and \( 2y \). Therefore to \( \alpha \), which is half the sum of \( 2x \) and \( 2y \), add \( a + b \), and we have \( 2x = a + b \), or \( x = \frac{a + b}{2} \), and \( y = \frac{a - b}{2} \).

By either of these methods a table may be readily computed of the value of \( x \) or \( y \) for every value of \( a \).

We must recollect that the values of \( S \) and \( M \) are by no means constant, but vary in the inverse tri- plicate ratio of the earth's distance from the sun and moon; and the ratio of \( x \) to \( y \) obtains only when these luminaries are at their mean distances from the earth. The forces corresponding to the perigee, medium, and apogee distances are as follow.

</tbody>
</table>

Hence we see that the ratio of \( S \) to \( M \) may vary from 1.90 : 4.25 to 2.10 : 5.92, that is, nearly from 1:3 to 1:2, or from 2:6 to 2:4. The solar force does not vary much, and may be retained as constant without any great error. But the change of the moon's force has great effects on the tides both as to their time and their quantity.

I. In respect of their Time.

1. The tide day following a spring tide is 24 h. 27', when the moon is in perigee, but 24 h. 33' when she is in apogee.
2. The tide day following neap tide is 25 h. 15', and 25 h. 40' in these two situations of the moon.
3. The greatest interval of time between high water and the moon's southing is 39' and 61'; the angle
II. In respect of their Heights.

1. If the moon is in perigee when new or full, the spring tide will be 8 feet instead of 7, which corresponds to her mean distance. The very next spring tide happens when she is near her apogee, and will be 6 feet instead of 7. The neap tides happen when she is at her mean distance, and will therefore be 3 feet.

But if the moon be at her mean distance when new or full, the two succeeding spring tides will be regular or 7 feet, and one of the neap tides will be 4 feet and the other only 2 feet.

Mr. Bernoulli has given us the following table of the time of high water for these three chief situations of the moon, namely, her perigee, mean distance, and apogee. It may be had by interpolation for all intermediate positions with as great accuracy as can be hoped for in phenomena which are subject to such a complication of disturbances. The first column contains the moon's elongation from the sun. The columns P, M, A, contain the minutes of time which elapse between the moon's southing and high water, according as she is in perigee, at her mean distance, or in apogee. The sign + indicates the priority, and - the posteriority, of high water to the moon's southing.

</table>

These always happen two or three days later. By comparing the difference of high water and the moon's southing in different places, he will hardly find any connecting principle. This shows evidently that the cause of this irregularity is local, and that the justness of the theory is not affected by it. By considering the phenomena in a navigable river, he will learn the real cause of the deviation. A flood tide arrives at the mouth of a river. The true theoretical tide differs in no respect from a wave. Suppose a spring tide actually formed on a fluid sphere, and the sun and moon then annihilated. The elevation must sink, pressing the under waters aside, and causing them to rise where they were depressed. The motion will not stop when the surface comes to a level; for the waters arrived at that position with a motion continually accelerated. They will therefore pass this position as a pendulum passes the perpendicular, and will rise as far on the other side, forming a high water where it was low water, and a low water where it was high water; and this would go on for ever, oscillating in a time which mathematicians can determine, if it were not for the viscosity, or something like friction, of the waters. If the sphere is not fluid to the centre, the motion of this wave will be different. The elevated waters cannot sink without diffusing themselves sideways, and occasioning a great horizontal motion, in order to fill up the hollow at the place of low water. This motion will be greatest about half way between the places of high and low water. The shallower we suppose the ocean, the greater must this horizontal motion be. The resistance of the bottom (though perfectly smooth and even) will greatly retard it all the way to the surface. Still, however, it will move till all be level, and will even move a little farther, and produce a small flood and ebb where the ebb and flood had been. Then a contrary motion will obtain; and after a few oscillations, which can be calculated, it will be insensible. If the bottom of the ocean (which we still suppose to cover the whole earth) be uneven, with long extended valleys running in various directions, and with elevations reaching near the surface, it is evident that this must occasion great irregularities in the motion of the undermost waters, both in respect of velocity and direction, and even occasion small inequalities on the surface, as we see in a river, with a rugged bottom and rapid current. The deviations of the under currents will drag with them the contiguous incumbent waters, and thus occasion greater superficial irregularities.

Now a flood arriving at the mouth of a river, must act precisely as this great wave does. It must be propagated up the river (or along it, even though perfectly level) in a certain time, and we shall have high water at all the different places in succession. This is distinctly seen in all rivers. It is high water at the mouth of the Thames at three o'clock, and later as we go up the river, till at London bridge we have not high water till three o'clock in the morning, at which time it is again high water at the Nore. But, in the mean time, there has been low water at the Nore, and high water about half way to London; and while the high water is proceeding to London, it is ebbing at this intermediate place, and is low water there when it is high water at London and at the Nore. Did the tide extend as far beyond London as London is from the Nore, we should
TID [ 428 ] TID

Tide.

should have three high waters, with two low waters inter-
terposed. The most remarkable instance of this kind is in
the Maragnon or Amazon river in South America. It
appears by the observations of Condamine and others,
that between Para, at the mouth of the river, and the
confluent of the Madera and Maragnon, there are seven
existent high waters, with six low waters between
them. Nothing can more evidently show that the tides
in these places are nothing but the propagation of a
wave. The velocity of its superficial motion, and the
distance to which it will sensibly go, must depend on
many circumstances. A deep channel and gentle ac-
activity will allow it to proceed much farther up the ri-
ver, and the distance between the successive summits
will be greater than when the channel is shallow and
steep. If we apply the ingenious theory of Chevalier
Bust delivered in the article River, we may tell both
the velocity of the motion and the interval of the suc-
cessive high waters. It may be imitated in artificial
canals, and experiments of this kind would be very in-
teresting. We have said enough at present for our pur-
pose of explaining the irregularity of the times of high
water in different places, with respect to the moon's
nouthing. For we now see clearly that something of
the same kind must happen in all great arms of the sea
which are of an oblong shape, and communicate by one
end with the open ocean. The general tide in this
ocean must proceed along this channel, and the high
water will happen on its shores in succession. This
fact is distinctly seen. The tide in the Atlantic ocean pro-
duces high water at new and full moon at a later and
later hour along the south coast of Great Britain in pro-
portion as we proceed from Scilly islands to Dover. In
the same manner it is later and later as we come along
the east coast from Orkney to Dover. Yet even in this
progress there are considerable irregularities, owing to
the sinuosities of the shores, deep indented bays, promi-
nent capes, and extensive ridges and valleys in the chan-
nel. A similar progress is observed along the coasts of
Spain and France; the tide advancing gradually from
the south, turning round Cape Finisterre, ranging along
the north coast of Spain, and along the west and north
coasts of France.

The attentive consideration of these facts will not
only satisfy us with respect to this difficulty, but will
enable us to trace a principle of connection amidst all
the irregularities that we observe.

We now add, that if we note the difference between
the time of high water of spring tide, as given by the-
theory, for any place, and the observed time of high water,
we shall find this interval to be very nearly constant
through the whole series of tides during a lunation.
Suppose this interval to be 40 hours. We shall find
- every other phenomenon succeed after the same inter-
val. And if we suppose the moon to be in the place
where she was 40 hours before, the observation will
agree pretty well with the theory, as to the succession
of tides, the length of tide day, the retardations of the
tides, and their gradual diminution from spring to neap
tide. We may pretty well; for there still remain sev-
eral small irregularities, different in different places, and
not following any observable law. These are therefore
local, and owing to local causes. Some of these we
shall afterwards point out. There is also a general de-
viation of the theory from the real series of tides. The

neap tides, and those adjoining, happen a little earlier
than the corrected theory points out. Thus at Brest
(where more numerous and accurate observations have
been made than at any other place in Europe), when
the moon changes precisely at noon, it is high water at
3 g 28'. When the moon enters her second quarter at
noon, it is high water at 8 h. 40', instead of 9 h. 48',
which theory assigns.

Something similar, and within a very few minutes
equal, to this is observed in every place on the sea-coast.
This is therefore something general, and indicates a
real defect in the theory.

But this arises from the same cause with the other
general deviation, viz. that the greatest and least tides do
not happen on the days of full and half moon, but a
certain time after. We shall attempt to explain this.

We set out with the supposition, that the water ac-
quired in an instant the elevation competent to its equi-
librium. But this is not true. No motion is instanta-
eneous, however great the force; and every motion and
change of motion produced by a sensible or finite force
increases from nothing to a sensible quantity by infinitely
small degrees. Time elapses before the body can ac-
quire any sensible velocity; and in order to acquire the
same sensible velocity by the action of different forces
acting similarly, a time must elapse inversely propor-
tional to the force. An infinitely small force requires a
finite time for communicating even an infinitely small
velocity; and a finite force, in an infinitely small time,
communicates only as an infinitely small velocity; and if
there be any kind of motion which changes by insensi-
bles degrees, it requires a finite force to prevent this
change. Thus a bucket of water, hanging by a cord
lapped round a light and easily moveable cylinder, will
run down with a motion uniformly accelerated; but
this motion will be prevented by hanging an equal bucket
on the other side, so as to act with a finite
force. This force prevents only infinitely small accele-
ration.

Now let ALKF (Fig. 6.) be the solid nucleus of the Fig.
earth, surrounded by the spherical ocean B H D G. Let
it be raised to a spheric BHDG by the action of the
moon at M, or in the direction of the axis CM. It will
be at rest, this spheric may have the force precisely competent to its equilibrium. But let the nucleus, with
its sphericidal ocean, have a motion round C in the di-
rection AFKL from west to east. When the line of
water BA is carried into the situation Fig. near to
BA, it is no longer in equilibrium; for s is too eleva-
ted, and the part now come to B is too much depressed.
There is a force tending to depress the waters at s, and
to raise those near at B; but this force is infinitely
small. It cannot therefore restore the shape competent
to equilibrium till a sensible time has elapsed; therefore
the disturbing force of the moon cannot keep the sum-
mit of the ocean in the line MC. The force must be of
a certain determinate magnitude before it can in an
instant undo the instantaneous effect of the rotation of
the waters and keep the summit of the ocean in the
same place. But this effect is possible; for the depre-
sation at s necessary for this purpose is nearly as the dis-
tance from B, being a depression, not from a straight
line, but from a circle described with the radius CB.
It is therefore an infinitesimal of the first order, and may
be restored in an instant, or the continuation of the depre-
must be less when the accumulating force is greater, and therefore less in spring tides than in neap tides; but the difference may be insensible. All this depends on circumstances which we are little acquainted with; many of these circumstances are local; and the situation of the summit of the ocean, with respect to the moon, may be different in different places.

Nor have we been able to determine theoretically what will be the height of the summit. It will certainly be less than the height necessary for perfect equilibrium. Daniel Bernoulli says, that, after very attentive consideration, he is convinced that the height at new or full moon will be to the theoretical height as the cosine of the angle $BCy$ to radius, or that the height at $y$ will be $BC 	imes \frac{C_2}{C_1}$.

The result of all this reasoning is, that we must always suppose the summit of the tide is at a certain distance eastward from the place assigned by the theory. Mr. Bernoulli concludes, from a very copious comparison of observations at different places, that the place of high water is about 20 degrees to the eastward of the place assigned by the theory. Therefore the table formerly given will correspond with observation, if the leading column of the moon’s elongation from the sun be altered accordingly. We have inserted it again in this place, with this alteration, and added three columns for the times of high water. Thus changed it will be of great use.

We have now an explanation of the acceleration of the neap tides, which should happen 6 hours later than the spring tides. They are in fact tides corresponding to positions of the moon, which are 25° more, and not the real spring and neap tides. These do not happen till two days after; and if the really greatest and least tides be observed, the least will be found 6 hours later than the first.

</table>

This table is general, and exhibits the time of high water.
Tide, and their difference from those of the moon's southing, in the open sea, from all local obstructions. If therefore the time of high water in any place on the earth's equator (for we have hitherto considered no other) be different from this table (supposed correct), we must attribute the difference to the distinguishing circumstances of the situation. Thus every place on the equator should have high water on the day that the moon, situated at her mean distance, changes precisely at noon, at 22 minutes past noon; because the moon passes the meridian along with the sun by supposition. Therefore, to make use of this table, we must take the difference between the first number of the column, intitled time of high water, from the time of high water at full and change peculiar to any place, and add this to all the numbers of that column. This adapts the table to the given place. Thus, to know the time of high water at Leith, when the moon is $52^\circ$ east of the sun, at her mean distance from the earth, take $22^\circ$ from $4h. 30^\prime$; this remains $4h. 08^\prime$. Add this to $2h. 48^\prime$ and we have $6^h. 56^\prime$ for the hour of high water. The hour of high water at new and full moon for Edinburgh is marked $4h. 30^\prime$ in Maskelyne's tables, but we do not pretend to give it as the exact determination. This would require a series of accurate observations.

It is by no means an easy matter to ascertain the time of high water with precision. It changes so very slowly, that we may easily mistake the exact minute. The best method is to have a pipe with a small hole near its bottom, and a float with a long graduated rod. The water gets in by the small hole, and raises the float, and the smallness of the hole prevents the sudden and irregular starts which waves would occasion. Instead of observing the moment of high water, observe the height of the rod about half an hour before, and wait after high water till the rod comes again to that height. Take the middle between them. The water rises sensibly half an hour after the top of the tide, and quickly changes the height of the rod, so that we cannot make a great mistake in the time.

Mr Bernoulli has made a very careful comparison of the theory thus corrected, with the great collection of observations preserved in the Deposit de la Marine at Brest and Rochfort *, and finds the coincidence very great, and far exceeding any rule which we had ever seen. Indeed we have no rules but what are purely empirical, or which suppose a uniform progression of the tides.

The heights of the tides are much more affected by local circumstances than the regular series of their times. The regular spring tide should be to the neap tide in the same proportion in all places; but nothing is more different than this proportion. In some places the spring tide is not double of the neap tide, and in other places it is more than quadruple. This prevented Bernoulli from attempting to fix the proportion of M to S by means of the heights of the tides. Newton had, however, done it by the tides at Bristol, and made the lunar force almost five times greater than the solar force. But this was very ill-founded, for the reason now given.

Yet Bernoulli saw, that in all places the tides gradually decreased from the syzygies to the quadratures. He therefore presumed, that they decreased by a similar law with the theoretical tides, and has given a very ingenious method of accommodating the theory to any tides which may be observed. Let A be the

</table>

Observe that this table is corrected for the retardation arising from the inertia of the waters. Thus when the moon is $20^\circ$ degrees from the sun, the mean distance tide is $1.05A + 0.00B$, which is the theoretical tide corresponding to conjunction or opposition.

We have now given in sufficient detail the phenomena of the tides along the equator, when the sun and moon are both in the equator, shewing both their times and their magnitude. When we recollect that all the sections of an oblong spheroid by a plane passing through an equatorial diameter are ellipses, and that the compound tide is a combination of two such spheroids, we perceive that every section of it through the centre, and perpendicular to the plane in which the sun and moon are situated, is also an ellipse, whose shorter axis is the equatorial diameter of a spring tide. This is the greatest depression in all situations of the luminaries; and the points of greatest depression are the lower poles of every compound tide. When the luminaries are in the equator, these lower poles coincide with the poles of the earth. The equator, therefore, of every compound tide is also an ellipse: the whole circumference of which is lower than any other section of this tide, and gives the place of low water in every part of the earth. In like manner, the section through the four poles, upper and lower, gives the place of high water. These two sections are terrestrial meridians or hour circles, when the luminaries are in the equator.

Hence
TIDE

Hence it follows, that all we have already said as to the times of high and low water may be applied to every place on the surface of the earth, when the sun and moon are in the equator. But the heights of tide will diminish as we recede from the equator. The heights must be reduced in the proportion of radius to the cosine of the latitude of the place. But in every other situation of the sun and moon all the circumstances vary exceedingly. It is very true, that the determination of the elevation of the waters in any place whatever is equally easy. The difficulty is, to exhibit for that place a connected view of the whole tide, with the hours of flood and ebb, and the difference between high and low water. This is not indeed difficult; but the process by the ordinary rules of spherical trigonometry is tedious. When the sun and moon are not near conjunction or opposition, the shape of the ocean resembles a turnip, which is flat and not round in its broadest part. Before we can determine with precision the different phenomena in connection, we must ascertain the position or attitude of this turnip; marking on the surface of the earth both its elliptical equators. One of these is the plane passing through the sun and moon, and the other is perpendicular to it, and marks the place of low water. And we must mark in like manner its first meridian, which passes through all the four poles, and marks on the surface of the earth the place of high water. The position of the greatest section of this compound spheroid is frequently much inclined to the earth’s equator; nay sometimes it is at right angles to it, when the moon has the same right ascension with the sun, but a different declination. In these cases the ebb tide on the equator is the greatest possible; for the lower poles of the compound spheroid are in the equator. Such situations occasion a very complicated calculus. We must therefore content ourselves with a good approximation.

And first, with respect to the times of high water. It will be sufficient to conceive the sun and moon as always in one plane, viz. the ecliptic. The orbits of the sun and moon are never more inclined than 5^\circ degrees. This will make very little difference; for when the luminaries are so situated that the great circle through them is much inclined to the equator, they are then very near to each other, and the form of the spheroid is little different from what it would be if they were really in conjunction or opposition. It will therefore be sufficient to consider the moon in three different situations.

1. In the equator. The point of highest water is never farther from the moon than 1^\circ, when she is in apogee, and the sun in perigee. Therefore if a meridian be drawn through the point of highest water to the equator, the arch m h of fig. 4, will be represented on the equator by another arch about 5^\circ of this by reason of the inclination of the equator and ecliptic. Therefore to have the time of high water, multiply the numbers of the columns which express the difference of high water and the moon’s southing by 5^\circ, and the products give the real difference.

2. Let the moon be in her greatest declination. The arch of right ascension corresponding to m h will be had by multiplying m h by the time corresponding to it in the table, by 5^\circ.

3. When the moon is in a middle situation between these two extremes, the numbers of the table will give the right ascension corresponding to m h without any correction, the distance from the equator compensating for the obliquity of the ecliptic arch m h.

The time of low water is not so easily found; and we must either go through the whole trigonometrical process, or content ourselves with a less perfect approximation. The trigonometrical process is not indeed difficult: we must find the position of the plane through the sun and moon. A great circle through the moon perpendicular to this is the line of high water; and another perpendicular circle cutting this at right angles is the circle of low water.

But it will be abundantly exact to consider the tide as accompanying the moon only.

Let NQSE (fig. 7.) be a section of the terraqueous globe, of which N and S are the north and south poles and EQ the equator. Let the moon be in the direction OM, having the declination BQ. Let D be any place on the earth’s surface. Draw the parallel LD of latitude. Let B’F F be the ocean, formed into a spheroid, of which B b is the axis and f f the equator.

As the place D is carried along the parallel CDL by the rotation of the earth, it will pass in succession through different depths of the watery spheroid. It will have high water when at C and L, and low water when it crosses the circle OF. Draw the meridian N d G, and the great circle B d d. The arch GQ, when converted into lunar hours (each about 63 minutes), gives the duration of the flood d c and of the subsequent ebb e d. which happen while the moon is above the horizon: and the arch EG will give the durations of the flood and of the ebb which happen when the moon is below the horizon.

It is evident, that these two floods and two ebb’s have unequal durations. When D is at C it has high water, and the height of the tide is CC. For, the spheroid is supposed to touch the sphere on the equator OF, so that of CC is the difference between high and low water. At L the height of the tide is LL; and if we describe the circle LN g, g is the difference of these high waters, or of these tides.

Hence it appears, that the two tides of one lunar day may be considerably different, and it is proper to distinguish them by different names. We shall call that a superior tide which happens when the moon is above the horizon during high waters. The other may be called the inferior tide. The duration of the superior tide is measured by 2GQ, and that of the inferior tide by 2EG; and GQ measures the difference between the whole duration of a .perior and of an inferior tide.

From this construction we may learn in general, 1. When the moon has no declination, the durations and also the heights of the superior and inferior tides are equal in all parts of the world. For in this case the tide equator F F coincides with the meridian NOS, and the poles B’F of the watery spheroid are on the earth’s equator.

2. When the moon has declination, the duration and also the height of a superior tide in any place is greater than that of the inferior; or is less than it, according as the moon’s declination and the latitude of the place are of the same or opposite names.

This is an important circumstance. It frequently happens that the inferior tide is found the greatest when it should be the least; which is particularly the case at the Nore. This shows, without further reasoning, that the tide at the Nore is only a branch of the regular tide.
Tide. The regular tide comes in between Scotland and the continent; and after travelling along the coast reaches the Thames, while the regular tide is just coming in again between Scotland and the continent.

3. If the moon's declination is equal to the colatitude of the place, or exceeds it, there will be only one tide in a lunar day. It will be a superior or an inferior tide, according as the declination of the moon and the latitude of the place are of the same or opposite kinds.

For the equator of the tide cuts the meridian in \( j \) and \( f \). Therefore a place which moves in the parallel of

has high water when at \( c \), and 12 lunar hours afterwards has low water when at \( f \). And any place \( k \) which is still nearer to the pole \( N \) has high water when at \( k \), and 12 lunar hours afterwards has low water at \( m \). Therefore, as the moon's declination extends to \( 30^\circ \), all places farther north or south than the latitude \( 60^\circ \) will sometimes have only one tide in a lunar day.

4. The sine of the arch \( GO \), which measures \( \theta \), the difference between the duration of a superior and inferior tide, is \( = \tan. \text{lat.} \times \tan. \text{decl.} \). For in the spherical triangle \( dOG \)

Rad. \( \cotan. dOG = \tan. dG : \sin. GO \), and
Sin. \( GO = \tan. dOG \times \tan. dG, = \tan. \text{decl.} \times \tan. \text{lat.} \)

Hence we see, that the difference of the durations of the superior and inferior tides of the same day increase both with the moon's declination and with the latitude of the place.

The different situations of the moon and of the place of observation affect the heights of the tides no less remarkably. When the point \( D \) comes under the meridian \( NB \) in which the moon is situated, there is a superior high water; and the height of the tide above the low water of that day is \( CC \). When \( D \) is at \( L \), the height of the inferior tide is \( LL' \). The elevation above the inscribed sphere is \( M \times \cos. y \), \( y \) being the zenith distance of the moon at the place of observation. Therefore at high water, which by the theory is in the place directly under the moon, the height of the tide is as the square of the cosine of the moon's zenith or nadir distance.

Hence we derive a construction which solves all questions relating to the height of the tides with great facility, free from all the intricacy and ambiguities of the algebraic analysis employed by Bernoulli.

With the radius \( CQ = M \) (the elevation produced by the moon above the inscribed sphere) describe the circle \( \rho \) (fig. 8), to represent a meridian, of which \( P \) and \( \eta \) are the poles, and \( EQ \) the equator. Bisect \( C \) in \( O \), and round \( O \) describe the circle \( PBCD \).

Let \( M \) be the place over which the moon is vertical, and \( Z \) be the place of observation. \( MQ \) is the moon's declination, and \( ZQ \) is the latitude of the place. Draw \( MC \), \( ZC \), cutting the small circle in \( A \) and \( B \). Draw \( AG \) perpendicular to \( CF \), and draw \( CH \), which will cut off an arch \( E \), \( = \) \( QM \). \( MZ \) and \( CN \) are the moon's zenith and nadir distances. Draw the diameter \( BO \), the BD, and the perpendiculars \( IK \), \( GH \), and \( AF \). Also draw \( OA \), \( PA \), \( AB \), and \( ID \).

Then \( DF \) is the superior tide, \( DK \) is the inferior tide, and \( DH \) is the arithmetical mean tide.

For the angles \( BCA \), \( BDA \), standing on \( BA \), are equal. Also the angles \( JDB \), \( \mu \) \( CN \), are equal, being

supplements of the angle \( JCB \). Therefore, if \( BD \) is made radius, \( DA \) and \( DI \) are the sines of the zenith and nadir distances of the moon.

But \( BD : DA = DA : DF \). Therefore \( DF = M \times \cos. y \), \( = \) the height \( Z \) of the superior tide. Also \( DK = M \times \cos. \eta \), \( = \) the height \( n \) of the inferior tide.

Also, because \( IA \) is bisected in \( G \), \( KF \) is bisected in \( H \), and \( DH = \frac{DK + DF}{2} \), \( = \) the medium tide.

Let us trace the relation of the consequences of the various positions of \( Z \) and \( M \), as we formerly considered the results of the various situations of the sun and moon.

First, then, let \( Z \) retain its place, and let \( M \) gradually approach it from the equator. When \( M \) is in the equator, \( A \) and \( I \) coincide with \( C \), and the three points \( F \), \( K \), and \( H \), coincide in \( i \).

As \( M \) approaches to \( Z \), \( A \) and \( I \) approach to \( B \) and \( D \); \( DF \) increases, and \( DK \) diminishes. The superior or inferior tide is greatest when the moon is in \( M \) or in \( N \); and \( DF \) is then \( = M \). As the moon passes to the northward of the place, the superior and inferior tides both diminish till \( I \) comes to \( D \); at which time \( MQ \) is equal to \( ZP \), and there is no inferior tide. This however cannot happen if \( \mu \) \( P \) is greater than \( 30^\circ \), because the moon never goes farther from the equator. \( M \) still going north, we have again a perpendicular from \( I \) on \( BD \), but below \( I \), indicating that the inferior tide, now measured by \( DK \), belongs to the hemisphere next the moon. Also, as \( M \) advances from the equator northward, \( DH \) diminishes continually. First, while \( H \) lies between \( O \) and \( B \), because \( G \) approaches \( O \); and afterwards, when \( G \) is above \( O \) and \( H \) lies between \( O \) and \( D \). It is otherwise, however, if \( ZQ \) is greater than \( 43^\circ \); for then \( DB \) is inclined to \( EQ \) the other way, and \( DH \) increases as the point \( G \) rises.

In the next place, let \( M \) retain its position, and \( Z \) proceed along the meridian.

Let us begin at the equator, or suppose \( Q \) the place of observation. \( BD \) then coincides with \( CP \), and the three lines \( DF \), \( DK \), and \( DH \), all coincide with \( PC \), denoting the two equal tides \( QC \) and \( LE \) and their medium, equal to either. As \( Z \) goes northward from \( Q \), \( BOD \) and \( DZ \) coincide itself from \( COP \); the line \( DF \) increases, while \( DK \) and \( DH \) diminish. When \( Z \) has come to \( M \), \( F \) and \( B \) coincide with \( A \), and \( DK \) and \( DH \) are still more diminished. When \( Z \) comes to \( E \), \( Z \) is \( M \), \( D \) is parallel to \( IA \), and \( Q \) coincides with \( O \). This situation of \( Z \) has the peculiar property that \( DH \) (now \( DO \)) is the same, whatever be the declination of the moon. For \( IA \) being always parallel to \( DB \), \( OK \) and \( OF \) will be equal, and \( DO \) will be half of \( DK \) and \( DF \), however they may vary. When \( Z \) gets so far north that \( ZP \) is \( = M \), the diameter \( d \) falls on \( i \); so that \( d \) \( k \) vanishes, and we have only \( dF \). And when \( Z \) goes still farther north, \( dF \) appears on the other side of \( I \). When \( Z \) arrives at the pole, \( BD \) again coincides with \( PC \), \( D \) with \( C \), and \( DF \), \( DK \), and \( DH \), coincide with \( CG \).

These variations of the points \( F \), \( K \), and \( H \), indicate the following phenomena.
1. The greatest tides happen when the moon is in the zenith or nadir of the place of observation; for then the point B coincides with A, and DF becomes DB; that is, M, indicating the full tide BB.

2. When the moon is in the equator, the superior and inferior tides have equal heights, M cos 4 lat. For then A and I coincide with C, and the points F and K coincide in it, and D = DB cos 4 BDC = M cos 4 lat.

3. If the place of observation is in the equator, the inferior and superior tides are again equal, whatever is the moon’s declination: For then B coincides with C, and the points F, K, and H, coincide with G; and PG x PC cos 4 APG = M cos 4 decl. moon.

4. The superior tides are greater or less than the inferior tides according as the latitude and declination are of the same or of opposite names. For by making Q = QZ, and drawing C αt, cutting our circle, we see that the figure is reversed. The difference between the superior and inferior tides is KE, or IA x cosin. of the angle formed by IA and DB; that is, of the angle DBE, which is the complement of the twin ZQ; because BOC = 2 ZQ. Now IA is 2 GA, = 2 OA sin. 2 MQ = PC sin. 2 MQ = M sin. 2 decl. Therefore the difference of the superior and inferior tides is M sin. 2 decl. sin. 2 lat.

5. If the colatitude be equal to the declination, or no superior tide, or no inferior tide, according as the latitude of the place and declination of the moon are of the same or opposite names.

For when FZ = MQ, D coincides with I, and IK vanishes. When FZ is less than MQ, the point D is between C and I, and the point Z never passes through the equator of the watery spheroid; and the low water of its only tide is really the summit of the inferior tide.

6. At the pole there is no daily tide: but there are two monthly tides = M sin 4 and declin. and it is low water when the moon is in the equator.

7. The medium tide, represented by DH, is = M x 1 cos 4 2 lat. x cos 2 decl. For DH = DO + OH.

Now OH = equal to OG x cos GOH = OG x cos 2ZQ. And OG = OA x cos GOA = OA x cos 2MQ. Therefore OH = OA x cos 2ZQ = OA = 2MQ. Therefore DH = OA + OA x cos 2ZQ = 2MQ = M x 1 cos 2ZQ = 2MQ.

Let this be called m.

N. B. The moon’s declination never exceeds 30°. Therefore cos 2MQ is always a positive quantity, and never less than 4, which is the cosine of 60°. While the latitude is less than 45°, cos 2 lat. is also a positive quantity. When it is precisely 45°, the cosine of its double is 0; and when it is greater than 45°, the cosine of its double is negative. Hence we see,

1. That the medium tides are equally affected by the northern and southern declinations of the moon.

2. If the latitude of the place is 45°, the medium tide is always 1/4 M. This is the reason why the tides along the coasts of France and Spain are so little affected by the declination of the moon.

3. If the latitude is less than 45°, the mean tides increase as the moon’s declination diminishes. The contrary happens if ZQ is greater than 45°. For DH in

4. creases or diminishes while the point G separates from C according as the angle COD is greater or less than COB; that is, according as PCZ is greater or less than ZCQ.

4. When Z is in the equator, H coincides with G, and the effect of the moon’s declination on the height of the tides is the most sensible. The mean tide is then = M 1 x cos 2 MQ.

All that we have now said may be said of the solar tide, putting S in place of M. Also the same things hold true of spring tides, putting M+S in place of M.

But in order to ascertain the effects of declination and latitude on other tides, we must make a much more complicated construction, even though we suppose both luminaries in the ecliptic. For in this case the two depressed poles of the watery spheroid are not in the poles of the earth; and therefore the sections of the ocean, made by meridians, are by means ellipses.

In a neap tide, the moon is vertical at B (fig. 7. or S.), and the sun at some point of Φ, 90° from B. If OB be this point, the construction for the heights of the tides may be made by adding to both the superior and inferior tides for any point D, the quantity M+ S−DF or DK x sin. d O = M+S−lite x sin. 2MQ as is evident.

But if the sun be vertical at d, d will be the highest point of the circle of Φ, and no correction is necessary. But in this case the role of high water will be inclined to the meridian in an angle equal to d BO (fig. 7.), and neither the times nor elevations of high water will be properly ascertained, and the error in time may be considerable in high latitudes.

The inaccuracies are not so great in intermediate tides, and respect chiefly the time of high water and the height of low water.

The exact computation is very tedious and peculiar, so that it is hardly possible to give any account of a regular progress of phenomena; and all we can do is, to ascertain the precise heights of detached points. For which reasons, we must content ourselves with the construction already given. It is the exact geometrical expression of Bernoulli’s analysis, and its consequences now related contain all that he has investigated. We may accommodate it very nearly to the real state of things, by supposing PC equal, not to CO of fig. 4. but to MS, exhibiting the whole compound tide. And the point B, instead of representing the moon’s place, must represent the place of high water.

Thus have we obtained a general, though not very accurate, view of the phenomena which must take place in different latitudes and in different declinations of the sun and moon, provided that the physical theory which determines the form and position of the watery spheroid be just. We have only to compute, by a very simple process of spherical trigonometry, the place of the pole of this spheroid. The second construction, in fig. 8, shows us all the circumstances of the time and height of high water at any point. It will be recollected, that in computing this place of the pole, the anticipation of 20 degrees, arising from the inertia of the waters, must be attended to.
Were we to institute a comparison of this theory with observation, without farther consideration, we should still find it unfavourable, partly in respect of the heights of the tides, and more remarkably in respect of the time of low water. We must again consider the effects of the inertia of the waters, and recollect, that a regular theoretical tide differs very little in its progress from the motion of a wave. Even along the free ocean, its motion much resembles that of any other wave. All waves are propagated by an oscillatory motion of the waters, precisely similar to that of a pendulum. It is well known, that if a pendulum receive a small impulse in the time of every descent, its vibrations may be increased to infinity. Did the successive actions of the sun or moon just keep time with the natural propagation of the tides, or the natural oscillations of the waters, the tides would also augment to infinity: But there is an infinite odds against this exact adjustment. It is much more probable that the action of to-day interrupts or checks the oscillation produced by yesterday’s action, and that the motion which we perceive in this day’s tide is what remains, and is compounded with the action of to-day. This being the case, we should expect that the nature of any tide will depend much on the nature of the preceding tide. Therefore we should expect that the superior and inferior tides of the same day will be more nearly equal than the theory determines. The whole course of observation confirms this. In latitude 45°, the superior and inferior tides of one day may differ in the proportion of 25:1, and the tides corresponding to the greatest and least declinations of the moon may differ nearly as much. But the difference of the superior and inferior tides, as they occur in the list of Observations at Rochefort, is not the third part of this, and the changes made by the moon’s declination is not above one-half. Therefore we shall come much nearer the true measure of a spring tide, by taking the arithmetical mean, than by taking either the superior or inferior.

We should expect less deviation from the theory in the gradual diminution of the tides from spring tide to neap tide, and in the gradual changes of the medium tide by the declination of the moon; because the successive changes are very small; and when they change in kind, that is, diminish after having for some time augmented, the change is by insensible degrees. This is most accurately confirmed by observation. The vast collection made by Cassini of the observations at Brest being examined by Bernoulli, and the medium of the two tides in one day being taken for the tide of that day, he found such an agreement between the progression of these medium tides and the procession of the lines MS of fig. 4. that the one seemed to be calculated by the other. He found no less agreement in the changes of the medium tide by the moon’s declination.

In like manner, the changes produced by the different distances of the moon from the earth, were found abundantly conformable to the theory, although not so exact as the other. This difference of inferiority is easily accounted for: When the moon changes in her mean distance, one of the neap tides is uncommonly small, and therefore the successive diminutions are very great, and one tide sensibly affects another. The same circumstance operates when she changes in apogee, by reason of a very large spring tide. And the changes corresponding both to the sun’s distance from the earth and his declination agreed almost exactly.

All these things considered together, we have abundant reason to conclude, that not only the theory itself is just in principle (a thing which no intelligent naturalist can doubt), but also that the data which are assumed in the application are properly chosen; that is, that the proportion of two to five is very nearly the true proportion of the mean solar and lunar forces. If we now compute the medium tide for any place in succession, from spring tide to neap tide, and still more, if we compute the series of times of their occurrence, we shall find as great an agreement as can be desired. Not but that there are many irregularities; but these are evidently so anomalous, that we can ascribe them to nothing but circumstances which are purely local.

This general rule of computation must be formed in the following manner:

The spring tide, according to theory, being called $A$, and the neap tide $B$, recollect that the spring tide, according to the regular theory, is measured by $M + S$. Recollect also, that when the lunar tide only is considered the superior spring tide is $M \times \sin^2 \theta$, $ZM$ (fig. 8). But when we consider the action of two adjoining tides on each other, we find it safer to take the medium of the superior and inferior tides for the measure; and this is $M \times 1 + \cos^2 \theta \times 2ZQ \times \cos 2MQ$. Let this be called $m$. This being totally the effect of $M$ as modified by latitude and declination, may be taken as its proper measure, by which we are to calculate the other tides of the monthly series from spring tide to neap tide.

In like manner, we must compute a value for $S$, as modified by declination and latitude; call this $s$. Then say,

$$M + S : A = m + s : A \times m + s \over M + S$$

This fourth proportional will give the spring tide as modified for the given declination of the luminaries, and the latitude of the place.

Now recall, that the medium tide, when the luminaries are in the equator, is $A \times \cos^2 \text{lat}$. Therefore let $F$ be the spring tide observed at any place when the luminaries are in the equator; and let this be the medium of a great many observations made in these circumstances. This gives $A \times \cos^2 \text{lat}$. (as modified by the peculiar circumstances of the place) $= F$. Therefore the fourth proportional now given changes to $F \times m + s$.

$$M + S \times \cos^2 \text{lat}$$

And a similar substitute for $B$ is

$$G \times m + s \over M + S \times \cos^2 \text{lat}$$

Lastly, To accommodate our formulas to every distance of the earth from the sun and moon, let $D$ and $d$ be the mean distances of the sun and moon, and $\delta$ and $\delta'$ their distances at the given time; and then the two substitutions become

$$\Delta^2 + \delta^2 \times M + S \times \delta^2$$

$$\Delta^2 + \delta^2 \times (M + S) \times \cos^2 \text{lat}$$

$$\Delta^2 + \delta^2 \times (M - S) \times \cos^2 \text{lat}$$

The
The half sum of these two quantities will be the MC, and their half difference will be the SC, of fig. 4, with which we may now operate, in order to find the tide for any other day of the menstrual series, by means of the elongation $a$ of the moon from the sun; that is, we must say $\frac{MC + CS}{2} = \tan a + \tan b$; then $x = \frac{a + b}{2}$, and $y = \frac{a - b}{2}$. And MS, the height of the tide, is $MC \times \cos 2y + CS \times \cos 2x$.

Such is the general theory of the tides, deduced from the principle of universal gravitation, and adjusted to that proportion of the solar and lunar forces which is most consistent with other celestial phenomena. The comparison of the greatest and least daily retardations of the tides was with great judgment preferred to the proportion of spring and neap tides, selected by Sir Isaac Newton for this purpose. This proportion must depend on many local circumstances. When a wave or tide comes to the mouths of two rivers, and sends a tide up each, and another tide of half the magnitude comes from the sea, the proportion of the heights of these rivers may be extremely different.

Nay, the proportion of tides sent up to two distant places of the same river can hardly be the same; nor are they the same in any river that we know. It can be demonstrated, in the strictest manner, that the farther we go up the river, where the declivity is greater, the neap tide will be smaller in proportion to the spring tide. But it does not appear that the time of succession of the different tides will be much affected by local circumstances. The tide of the second day of the moon being very little less than that of the first, will be nearly as much retarded, and the intervals between their arrivals cannot be very different from the real intervals of the undisturbed tides; accordingly, the succession of the highest to the highest but one is found to be the same in all places, when not disturbed by different winds. In like manner the succession of the lowest and the lowest but one is found equally variable; and the highest and the lowest tides observed in any place must be accounted the spring and neap tides of that place, whether they happen on the day of full and half moon or not. Nay, we can see here the explanation of a general deviation of the theory which we formerly noticed. A low tide, being less able to overcome obstructions, will be sooner stopped, and the neap tides should happen a little earlier than by the undisturbed theory.

With all these corrections, the theory now delivered will be found to correspond with observation, with all the exactness that we can reasonably expect. We had an opportunity of comparing it with the phenomena in a place where they are very singular, viz. in the harbour of Bissesterd in Iceland. The equator of the watery spheroid frequently passes through the neighbourhood of this place, in a variety of positions with respect to its parallel of diurnal revolution, and the differences of superior and inferior tides are most remarkable and various. We found a wonderful conformity to the most diversified circumstances of the theory.

There is a period of 18 years, respecting the tides in Iceland, after the proportion of tides sent up to

1. Atlantic

2. Atlantic

2. Atlantic
Atlantic ocean into the Mediterranean sea, but it sometimes comes out when the ebb tide in the Atlantic is considerable.

Suppose the moon over the middle of the Mediterranean. The surface of the sea will be level, and it will be half tide at both ends, and therefore within the Straits of Gibraltar. But without the Straits it is within half an hour of high water. Therefore there will be a current setting in from the Atlantic. About three and a half hours after, it is high water within and half ebb without. The current now sets out from the Mediterranean. Three hours later, it is low water without the Straits and half ebb within; therefore the current has been setting out all this while. Three hours later, it is half flood without the Straits and low water within, and the current is again setting in, &c.

Were the earth fluid to the centre, the only sensible motion of the waters would be up and down, like the waves on the open ocean, which are not brushed along by strong gales. But the shallowness of the channel makes a horizontal motion necessary, that water may be supplied to form the accumulation of the tide. When this is formed on a flat shelving coast, the water must flow in and out, on the flats and sands, while it rises and falls. These horizontal motions must be greatly modified by the channel or bed along which they move. When the channel contracts along the line of flowing water, the wave, as it moves up the channel, and is checked by the narrowing shores, must be reflected back, and keep a-top of the waters still flowing in underneath. Thus it may rise higher in these narrow seas than in the open ocean. This may serve to explain a little the great tides which happen on some coasts, such as the coast of Normandy. At St. Malo the tide frequently rises 50 feet. But we cannot give any thing like a full or satisfactory account of these singularities.

In the bay of Fundy, and particularly at Annapolis Royal, the water sometimes rises above 100 feet. This seems quite inexplicable by any force of the sun and moon, which cannot raise the waters of the free ocean more than eight feet. These great floods are unquestionably owing to the proper timing of certain oscillations or currents adjoining, by which they unite, and form one of great force. Such violent motions of water are frequently seen on a small scale in the motions of brooks and rivers; but we are too little acquainted with hydraulics to explain them with any precision.

We have seen that there is an oscillation of waters formed under the sun and moon; and that in consequence of the rotation of the earth, the inertia and the want of perfect fluidity of the waters, and obstructions in the channel, this accumulation never reaches the place where it would finally settle if the earth did not turn round its axis. The consequence of this must be a general current of the waters from east to west. This may be seen in another way. The moon in her orbit round the earth has her gravity to the earth diminished by the sun's disturbing force, and therefore moves in an orbit less incurvated than she would describe independent of the sun's action. She therefore employs a longer time. If the moon were so near the earth as almost to touch it, the same thing would happen. Therefore suppose the moon turning round the earth, almost in contact with the equator, with her natural undisturbed periodic time, and that the earth is revolving round its axis in the same time, the moon would remain continuously above the same spot of the earth's surface (suppose the city of Quito), and a spectator in another planet would see the moon always covering the same spot. Now let the sun act. This will not affect the rotation of the earth, because the action on one part is exactly balanced by the action on another. But it will affect the moon. It will move more slowly round the earth's centre, and at a greater distance. It will be left behind by the city of Quito, which it formerly covered. And as the earth moves round from west to east, the moon, moving more slowly, will have a motion to the west with respect to Quito. In like manner, every particle of water has its gravity diminished, and its diurnal motion retarded; and hence arises a general motion or current from east to west. This is very distinctly perceived in the Atlantic and Pacific oceans. It comes round the Cape of Good Hope, ranges along the coast of Africa, and then sets directly over America, where it meets a similar stream which comes in by the north of Europe. Meeting the shores of America, it is deflected both to the south along the coast of Brazil, and northward along the North American shores, where it forms what is called the Gulf Stream, because it comes from the Gulf of Mexico. This motion is indeed very slow, this being sufficient for the accumulation of seven or eight feet on the deep ocean; but it is not altogether insensible.

We may expect differences in the appearances on the western shores of Europe and Africa, and on the western shore of America, from the appearances on the eastern coasts of America and of Asia, for the general current obstructs the waters from the western shores, and sends them to the eastern shores. Also when we compare the wide opening of the northern extremity of the Atlantic ocean with the narrow opening between Kambtchka and America, we should expect differences between the appearances on the west coasts of Europe and of America. The observations made during the circumnavigation of Captain Cook and others show a remarkable difference. All along the west coast of North America the inferior tide is very trifling, and frequently is not perceived.

In the very same manner, the disturbing forces of the sun and moon form a tide in the fluid air which surrounds this globe, consisting of an elevation and depression, which moves gradually from east to west. Neither does this tide ever attain that position with respect to the disturbing planets which it would do were the earth at rest on its axis. Hence arises a motion of the whole air from east to west; and this is the principal cause of the trade-winds. They are a little accelerated by being heated, and therefore expanding. They expand more to the westward than in the opposite direction, because the air expands on that side into air which is now cooling and contracting. These winds very evidently follow the sun's motion, tending more to the south or north as he goes south or north. Were this motion considerably affected by the expansion of heated air, we should find the air rather coming northward and southward from the torrid zone, in consequence of its expansion in that climate. We repeat it, it is almost solely produced by the aerial tide, and is necessary for the very formation of this tide. We cannot perceive the accumulation. It cannot affect the barometer, as many
TIDE

many think, because, though the air becomes deeper, it becomes deeper only when it is made lighter by the gravitation to the sun. Instead of pressing more on the cistern of the barometer, we imagine that it presses less; because, like the ocean, it never attains the height to which it tends. It remains always too low for equilibrium, and therefore it should press with less force on the cistern of a barometer.

There is an appearance precisely similar to this in the planet Jupiter. He is surrounded by an atmosphere which is arranged in zones or belts, probably owing to climate differences of the different latitudes, by which each seems to be in a different kind of sky. Something like this will appear to a spectator in the moon looking at this earth. The general weather and appearance of the sky is considerably different in the torrid and temperate zones. Jupiter's belts are not of a constant shape and colour; but there often appear large spots or tracts of cloud, which retain their shape during several revolutions of Jupiter round his axis. To judge of his rotation by one of these, we should say that he turns round in 9.55. There is also a brighter spot which is frequently seen, occupying one certain situation on the body of Jupiter. This is surely adherent to his body, and is either a bright-coloured country, or perhaps a tract of clouds hovering over some volcano. This spot turns round in 9.51. And thus there is a general current in his atmosphere from east to west.

Both the motion of the air and of the water tend to diminish the rotation of the earth round its axis; for they move slower than the earth, because they are retarded by the luminaries. They must communicate this retardation to the earth, and must take from it a quantity resulting of the wisdom and goodness of God. For this he is entitled to the greater praise, that it required no small degree of fortitude to resist the influence of national example, and to retain his piety in the midst of a people who have drunk the very dregs of the atheism of ancient Greece. This is a species of merit rarely to be met with in a Frenchman of the present day; but as a philosopher, M. de St Pierre can lay claim to no other merit except that of having collected many important facts. The argument which he employs to prove that the earth is a prolate spheroid, is a direct demonstration of the truth of the contrary opinion; and the melting of the ice and snows at the poles cannot produce the smallest motion in the waters. Were there even ten times more ice and snow floating on the northern sea than there is, and were it all to melt in one minute, there would be no flux from it; for it would only fill up the space which it formerly occupied in the water. Of this any person will be convinced, who shall put a handful of snow squeezed hard into a jar of water, and note the exact height of the water. Let the snow melt, and he will find the water of the same height as before.

Tide-Waters, or Tidesmen, are inferior officers belonging to the customhouse, whose employment is to watch or attend upon ships until the customs be paid: they get his name from their going on board ships on their arrival in the mouth of the Thames or other ports, and so come up with the tide.

TIEND in Scots Law. See TEIND.

TIERCE, or Teirce, a measure of liquid things, as wine, oil, &c. containing the third part of a pipe, or 42 gallons.

TIERCED, in Heraldry, denotes the shield to be divided by any part of the partition lines, as party, couped, tranchy, or tailly, into three equal parts of different colours or metals.

TIGER. See FELIS, Mammalia Index.

Tiger-Wolf, the name of the hyena at the Cape of Good Hope. See CANIS, Mammalia Index.

TIGRIS, a river of Asia, which has its source near that of the Euphrates in the mountain Tchildir in Turcomania: afterwards it separates Diarbeck from Erzerum, and Khissistan from Irac-Arabia; and uniting with the Euphrates at Gorno, it falls into the gulf of Bassyrah, under the name of Schat el-Arab. This river passes by Diarbeckir, Gezira, Mousul, Bagdad, Gorno, and Bassyrah.

TILLA, Lime or Linden Tree, a genus of plants belonging to the class of polyandria; and in the natural system ranging under the Columniferae. See BOTANY INDEX.

TILLEMONT, SEBASTIAN LE NAIN DE. See NAIN.

TILLER of a Ship, a strong piece of wood fastened in the head of the rudder, and in small ships and boats called the helm.

TILLOEA, a genus of plants belonging to the class of tetrandria; and in the natural system ranging under the 13th order, Succulenta. See Botany Index.

TILLOTSON, JOHN, a celebrated archbishop of Canterbury, was the son of Robert Tilloston of Sowerby, in the parish of Halifax in Yorkshire, clothier; and was born there in the year 1630. He studied in Clare-hall, Cambridge; and in 1656 left this college, in order to become tutor to the son of Edmund Pri- deaux, Esq. of Ford abbey in Devonshire. He was afterwards curate to Dr Hacket, vicar of Cheshunt, in Hertfordshire. In 1663 he was presented by Sir Thomas Barnardiston to the rectory of Ketton or Keddington in the county of Suffolk; but was the next year chosen preacher to Lincoln's Inn, when he procured Ketton to be bestowed on his curate. He was greatly admired in London for his sermons; and in the same year was chosen Tuesday-lecturer at St Lawrence's church, London, where his lectures were frequented by all
TIMOTIOTON

Tillotson

all the divines of the city, and by many persons of quality and distinction. In 1666, he took the degree of Doctor of Divinity at Cambridge; in 1669, was made prebendary of Canterbury; in 1672, was admitted dean of that cathedral; and three years after, was made a prebendary of St Paul's cathedral, London. In 1679, he became acquainted with Charles earl of Shrewsbury, whom he converted from Popery; and the next year refused to sign the clergy of London's address of thanks to King Charles II. for not agreeing to the bill of exclusion of the duke of York. In 1683, he visited the unfortunate Lord Russell when under condemnation; and attended him in his last moments on the scaffold. In 1689, he was installed dean of St Paul's; made clerk of the close to King William and Queen Mary; and appointed one of the commissioners to prepare matters to be laid before the convocation, in order to a comprehension of all Protestants, as well dissenters as churchmen; but this attempt was frustrated by the zeal of those members of that body, who refused to admit of any alteration in things confessedly indifferent. In 1691, Dr Tillotson was, notwithstanding the warmest remonstrances and intreaties on his part, consecrated archbishop of Canterbury, and four days after was sworn one of the privy council; their majesties always reposing an entire confidence in his prudence, moderation, and integrity. In 1694, he was seized with a palsy, of which he died in the 63rd year of his age. He was interred in the church of St Lawrence Jewry, London, where a handsome monument is erected to his memory. This learned and pious divine, while living, was greatly inveighed against by the enemies of the revolution. After his death there was found a bundle of bitter libels which had been published against him, on which he had written with his own hand; "I forgive the authors of these books, and pray God that he may also forgive them." It is remarkable, that while this truly great man was in a private station, he always laid aside twenty-tenths of his income for charitable uses. One volume in folio of Dr Tillotson's sermons was published in his life-time, and corrected by his own hand; they were translated into French by Barbeyrac. Those which came abroad after his death, from his chaplain Dr Barker, made two volumes in folio, the copy of which was sold for 250l. This was the only legacy he left to his family, his extensive charity having consumed his yearly revenues as constantly as they came to his hands. King William, however, gave two grants to his widow; the first of which was an annuity of 40l. during the term of her natural life, and the second of 20l. as an addition to the former annuity. Dr Tillotson wrote some other works besides his Sermons; and also published Dr Barrow's works, and Dr Wilkin's Treatise of the Principles and Duties of Natural Religion, and a volume of that divine's Sermons.

TIMBER, wood fit for building, &c. See TREE, and STRENGTH OF MATERIALS.

TIMBERS, the ribs of a ship, or the incurvated pieces of wood, branching outward from the keel in a vertical direction, so as to give strength, figure, and solidity, to the whole fabric. See SHIP-BUILDING, book i. chap. ii.

TIME, a succession of phenomena in the universe, or a mode of duration marked by certain periods or measures, chiefly by the motion and revolution of the sun.

The general idea which time gives in every thing to which it is applied, is that of limited duration. Thus we cannot say of the Deity, that he exists in time; because eternity, which he inhabits, is absolutely uniform, neither admitting limitation nor succession. See METAPHYSICS, No. 209.

TIME, in Music, is an affection of sound, by which it is said to be long or short, with regard to its continuance in the same tone or degree of tune.

Musical time is distinguished into common or dupl time, and triple time.

Double, duple, or common time, is when the notes are in a dupl duration of each other, viz. a semibreve equal to two minims, a minim to two crotchets, a crotchet to two quavers, &c.

Common or double time is of two kinds. The first when every bar or measure is equal to a semibreve, or its value in any composition of notes of a less quantity. The second is where every bar is equal to a minim, or its value in less notes. The movements of this kind of measure are various, but there are three common distinctions; the first slow, denoted at the beginning of the line by the mark C; the second brisk, marked thus E; and the third very brisk, thus marked H.

Triple time is when the durations of the notes are triple of each other, that is, when the semibreve is equal to three minims, the minim to three crotchets, &c. and it is marked T.

TIME-KEEPERS, or Instruments for measuring Time. See CLOCK, DIAL, WATCH, &c.

Harrison's Time-Keeper. See Harrison and Longitude.

TIMOLEON, a celebrated Corinthian general, who restored the Syracusans to their liberty, and drove the Carthaginians out of Sicily. See SYRACUSE, No. 50—54.

TIMON the Sceptic, who is not to be confounded with Timon the Misanthropos, was a Phasisian, a disciple of Pyrrho, and lived in the time of Ptolemy Philadephus. He took so little pains to invite disciples to his school, that it has been said of him, that as the Sycthians shot flying, Timon gained pupils by running from them. He was fond of rural retirement; and was so much addicted to wine, that he had a successful contest with several celebrated champions in drinking. Like Lucian, he wrote with sarcastic humour against the whole body of philosophers. The fragments of his satirical poem Sill, often quoted by the ancients, have been carefully collected by Henry Stephens in his Poetae Philosophi. Timon lived to the age of 90 years.

TIMON, surnamed Misanthropos, or the Man-hater, a famous Athenian, who lived about 420 B.C. He was one day asked, why he loved the young Alcibiades while he detested all the rest of the human race? on which he replied, "It is because I foresee that he will be the ruin of the Athenians." He carefully avoided all sorts of company; yet went one day to an assembly of the people, and cried with a loud voice, "That he had a fig-tree on which several persons had hanged themselves;
TIMOEUS, one of the most celebrated poet-musicians of antiquity, was born at Mileteus, an Ionian city of Caria, 446 years B.C. He was contemporary with Philip of Macedon and Euripides; and not only excelled in lyric and dithyrambic poetry, but in his performance upon the cithara. According to Pausanias, he perfected that instrument by the addition of four new strings to the seven on which it had been before; though Suidas says it had nine before, and that Timotheus only added two, the 10th and 11th, to that number. See LYRE.

With respect to the number of strings upon the lyre of Timotheus: The account of Pausanias and Suidas is confirmed in the famous senatus-consultum against him, still extant, preserved at full length in Boethus. Mr Stillingfleet has given an extract from it, in proof of the simplicity of the ancient Spartan music. The fact is mentioned in Athenaeus; and Cassaebion, in his notes upon that author, has inserted the whole original text from Boethus, with corrections. The following is a faithful translation of this extraordinary Spartan act of parliament. “Whereas Timotheus the Milesian, coming to our city, has dishonoured our ancient music, and, despising the lyre of seven strings, has, by the introduction of a greater variety of notes, corrupted the ears of our youth; and by the number of his strings, and the novelty of his melody, has given to our music an effeminate and artificial dress, instead of the plain and orderly one in which it hitherto appeared; rendering melody infamous, by composing in the chromatic instead of the enharmonic:—The kings and the ephors have therefore resolved to pass censure upon Timotheus for these things; and, farther, to oblige him to cut all the superfluous strings of his eleven, leaving only the seven tones; and to banish him from our city; that men may be warned for the future not to introduce into Sparta any unbecoming custom.”

The same story, as related in Athenaeus, has this additional circumstance. That when the public executioner was on the point of fulfilling the sentence, by cutting off the new strings, Timotheus, perceiving a little statue in the same place, with a lyre in his hand of as many strings as that which had given the offence, and showing it to the judges, was acquitted.

It appears from Suidas, that the poetical and musical compositions of Timotheus were very numerous, and of various kinds. He attributes to him 19 nemes, or canticles, in hexameters; 36 proems, or preludes; 18 dithyrambs; 21 hymns; the poem in praise of Diana; one paean; the Persians, Phinidas, and Laertes; to which must be added the fourth, mentioned by several ancient authors, called Nidos, without forgetting the poem on the birth of Bacchus. Stephen of Byzantium makes him author of 18 books of nomes, or airs, for the cithara, to 8000 verses; and of 1000 συρυμα, or preludia, for the nomes of the flutes.

Timotheus died in Macedonia, according to Suidas, at the age of 97; though the Marbles, much better authority, say at 90; and Stephen of Byzantium fixes his death in the fourth year of the 105th Olympiad, two years before the birth of Alexander the Great; whence it appears, that this Timotheus was not the famous player on the flute so much beloved by the prince, who was animated to such a degree by his performance as to seize his arms; and who employed him, as Athenaeus informs us, together with the other great musicians of his time, at his nuptials. However, by an inattention to dates, and by forgetting that of these two musicians of the same name the one was a Milesian and the other a Theban, they have been hitherto often confounded.

TIMUR-Beck. See TAMERLANE.

TIN, a metallic substance. See CHEMISTRY and MINERALOGY Index for an account of its qualities and ores; and for the method of reducing its ores, see ORES, Reduction of.

TINCAL, the name by which crude or impure borax is sometimes known. See BORAX, CHEMISTRY Index.

TINCTURE, in Pharmacy. See MATERIA MEDICA Index.

TINDAL, Dr Matthew, a famous English writer, was the son of the reverend Mr John Tindal of Beer-Ferres in Devonshire, and was born about the year 1597. He studied at Lincoln college, and afterwards removed to Exeter, and was afterwards elected fellow of All Souls. In 1685 he took the degree of doctor of law, and in the reign of James II. declared himself a Roman Catholic; but soon renounced that religion. After the revolution he published several pamphlets in favour of government, the liberty of the press, &c. His “Rights of the Christian Church asserted,” occasioned his having a violent contest with the high-church clergy; and his treatise “Christianity as old as the Creation,” published in 1673, made much noise, and was answered by several writers, particularly by Dr Conybeare, Mr Foster, and Dr Leland. Dr Tindal died at London in August 1733. He left in manuscript a second volume of his “Christianity as old as the Creation;” the preface to which has been published. Mr Pope has satirized Dr Tindal in his Dunciad.

TINDALE, William. See TYNDALE.

TINNING, the covering or lining any thing with melted tin, or tin reduced to a very fine leaf. Looking-glasses are foliated or tinnited with plates of beaten tin, the whole thickness of the glass, and applied or fastened thereto by means of quicksilver. See FOLLATION OF LOOKING GLASSES.

TINNITUS AURUM, a noise in the ears like the continued sound of bells, very common in many disorders, particularly in nervous fevers.

TIPPERARY, a county of the province of Munster in Ireland, bounded on the west by those of Limerick and Clare, on the east by the county of Kilkenny and Queen’s county, on the south by the county of Waterford,
ford, and on the north and north-east by King's county and the territory of the ancient O'Cathlans. It extends about 32 miles in length, and 27 in breadth, containing 599,500 acres, divided into 12 baronies, containing 8000 inhabitants. It sends three members to parliament, viz: two for the county, and one for Clonmel. The north part of the county is mountainous and cold; but in the south the air is milder, and the soil much more fertile, producing plenty of corn, and good pasture for the numerous herds of cattle and flocks of sheep with which it abounds. The north part is called Ormond, and for a long time gave the title of earl, and afterwards of marquis and duke, to the noble family of Butler, descended from a sister of Thomas a Becket, archbishop of Canterbury, till, at the accession of George I., the last duke was attainted of high treason, and died abroad. In that part of the county, the family had great prerogatives and privileges granted them by Edward III. Another district in this county was anciently called the County of the Holy Cross of Tipperary, from a famous abbey in it styled Holy Cross, on account of a piece of Christ's cross that was said to be preserved there. The remains of the abbey, or rather the spot where it stood, are still held in great veneration. See TIPPERARY, SUPPLEMENT.

TIPSTAFF, an officer who attends the judges with a kind of staff tipped with silver, and takes into his charge all prisoners who are committed or turned over at a judge's chambers.

TIPULA, the CRANE-FLY; a genus of insects belonging to the order of Diptera. See ENTOMOLOGY, Index.

TIRE, in the sea language, is a row of cannon placed along a ship's side, either above upon deck, or below, distinguished by the epithets of upper and lower tirs.

TIREE, or TIREY, one of the Western islands of Scotland, 10 miles long and from one to two in breadth, contains above 2000 inhabitants, and produces sheep and black cattle, with some grain and kelp. W. Long. 6° 48', N. Lat. 56° 32'.

TIROL, or TYROL, a county of Germany in the circle of Austria, under which may be included the territories belonging to the bishops of Brixen, Trent, and Chur, the Teutonic Order, and the prince of Detrichstein, the Austrian seignories before the Arlberg, and the Austrian districts in Swabia. It is 150 miles in length, and 120 in breadth, and contains 28 large towns.

The face of the country is very mountainous. Of these mountains some have their tops always buried in snow; others are covered with woods abounding with game. Of the lower, some yield plenty of corn, others wine, and woods of chestnut trees. The valleys are exceedingly fertile also, and pleasant. In some places considerable quantities of flax are raised, in others there is a good breed of horses and horned cattle; and, among the mountains, abundance of chamois and wild goats. In this country are also found garnets, rubies, amethysts, agates, carnelians, calcadelons, malachites, &c.; nor is it without hot baths, acid waters, salt pits, mines of silver, copper, and lead. The principal river of Tirol is the Inn, which, after traversing the country, and receiving a number of lesser streams into it, enters Bavaria, in which, at Passau, it falls into the Danube. The men here are very tall, robust, and vigorous; the women also are stout, and generally fair; and both sexes have a mixture of the Italian and German in their temper and characters. As there is little trade or manufacture in the country, except what is occasioned by the mines and salt works, many of the common people are obliged to seek a subsistence elsewhere. A particular kind of salutation is used all over Tirol. When a person comes into a house, he says, "Hail! Jesus Christ:" the answer is, "May Christ be raised, and the Holy Virgin his mother:" Then the master of the house takes the visitor by the hand. This salutation is fixed up in print at all the doors, with an advertisement tacked to it, importing that Pope Clement XI. granted 100 days indulgence, and a plenary absolution, to those who should pronounce the salutation and answer, as often as they did it. The emperor has forts and citadels so advantageously situated on rocks and mountains all over the country, that they command all the valleys, avenues, and passes that lead unto it. The inhabitants, however, to keep them in good humour, are more gently treated, and not so highly taxed as those of the other hereditary countries. As to the states, they are much the same in this country as in the other Austrian territories, except that the peasants here send deputies to the diets. Tirol came to the house of Austria in the year 1363, when Margaret, countess thereof, bequeathed it to her uncles the dukes of Austria. Besides the governor, here are three sovereign colleges, subordinate to the court at Vienna, which sit at Inspurach, and have their different departments. Towards the expenses of the military establishment of this country, the proportion is 100,000 florins yearly; but no more than one regiment of foot is generally quartered in it.

Tirol is divided into six quarters, as they are called; namely, those of the Lower and Upper Innthal, Vintschow, Etch, Eisack, and Pusterthal. At the peace of Presburg in 1805, Austria was compelled to cede the Tirol. The brave inhabitants however took arms, and under Andrew Hofer an innkeeper, made an obstinate resistance. Deputies came to London to seek pecuniary supplies, and considerable sums were raised. But the French at last succeeded in subduing the country. The greater part of the Tirol was annexed to Bavaria, in whose possession it continued till 1815, when it was restored to Austria. Its population in 1815 amounted to 802,000 including Trent and Brixen.

TITAN, in fabulous history, the son of Caelus and Terra, and the elder brother of Saturn, suffered the latter to enjoy the crown, on condition that he should bring up none of his male issue, by which means the crown should at length revert to him; but Jupiter being spared by the address of Rhea, Saturn's wife, Titan and his children were so enraged at seeing their hopes frustrated, that they took up arms to revenge the injury; and not only defeated Saturn, but kept him and his wife prisoners till he was delivered by Jupiter, who defeated the Titans; when from the blood of these Titans slain in the battle, proceeded serpents, scorpions, and all venomous reptiles. See SATURN.

Such is the account given by the poets of this family of Grecian and Roman gods. From the fragments of Sanchoniatho, however, and other ancient writers, many learned men have inferred that the Titans were an early race of ambitious heroes, who laid the foundation of that idolatry which quickly overspread the world, and
that by assuming the names of the luminaries of heaven, they contrived to get themselves everywhere adored as the Dei maiorum genitivum. That the word Titans signifies the sun, there can indeed be very little doubt. Every one knows that such was its signification in the Ionic dialect; and as it is evidently compounded of Ty, which, in some oriental tongues, signifies bright or clear, and Tn, which signifies a country or the earth, it may be safely concluded that Titan was the name of the sun before the word was imported into Greece. But the great question among antiquarians is, of what country was that race, which, assuming to themselves the names of the heavenly bodies, introduced into the world the species of idolatry which is known by the appellation of Hero-worship?

M. Pezron, in a work published many years ago, and entitled The Antiquities of Nations, maintains that the Titans were a family of Bceus or Scythians, who made their first appearance beyond Media and Mount Imaus, in the upper regions of Asia; that they were the descendants of Comer the son of Japheth and grandson of Noah; and that after conquering a great part of the world, upon entering Upper Phrygia, they quitted their ancient name of Comerians or Cimmerians, and assumed that of Titans. All this, he says, happened before the birth of Abraham and the foundation of the Assyrian monarchy; and he makes Uranus, their second prince in the order of succession, to have conquered Thrace, Greece, the island of Crete, and a great part of Europe. Uranus was succeeded by Saturn, and Saturn by Jupiter, who flourished, he says, 500 years before Moses, and divided his vast empire between himself, his brother Pluto, and his cousin-german Atlas, who was called Telemos. For the truth of this genealogy of the Titans M. Pezron appeals to the most approved Greek historians; but unluckily for his hypothesis, these writers have not a single sentence by which it can be fairly supported. It supposes not only the great antiquity of the Scythians, but likewise their early progress in arts and sciences, contrary to what we have proved in other articles of this work. See Scripture, Note 4 and 5: and Scythia.

Others, taking the fragment of Sanchoniatho's Pharmcic history for their guide, have supposed the Titans to have been the descendants of Ham. Of this opinion was Bishop Cumberland; and our learned friend Dr Boig, to whom we have been indebted for greater favours, indulged us with the perusal of a manuscript, in which, with erudition and ingenuity struggling for the pre-eminence, he traces that impious family from the profane son of Noah, and shows by what means they spread the idolatrous worship of themselves over the greater part of the ancient world. Creous, of whose exploits some account has been given elsewhere (see Sanchoniatho), he holds to be Ham; and tracing the progress of the family from Pharamon to Cyprus, from Cyprus to Rhodes, thence to Crete, and from Crete to Samothrace, he finds reason to conclude that the branch called Titans or Titanides flourished about the era of Abraham, with whom, or with his sons Isaac, he thinks the Creton Jupiter must have been contemporaneous. As they proceeded from countries which were the original seat of civilization to others in which mankind had sunk into the grossest barbarism, it was easy for them to persuade the ignorant inhabitants that they derived the arts of civil life from their parent the sun, and in consequence of their relation to him to assume to themselves divine honours. To ask how they came to think of such gross impiety, is a question as foolish as it would be to ask how Ham their ancestor became so wicked as to entail the curse of God upon himself and his posterity. The origin of evil is involved in difficulties; but leaving all inquiries into it to be prosecuted by the metaphysician and moralist, it is surely more probable that the worship of dead men originated among the descendants of Ham than among those of Shem and Japheth; and that the fragment of Sanchoniatho, when giving an account of the origin of the Titans, the undoubted authors of that worship, is more deserving of credit than the fabulous and comparatively late writers of Greece and Rome.

TITHES, in ecclesiastical law, are defined to be the tenth part of the increase, yearly arising and renewing from the profits of lands, the stock upon lands, and the personal industry of the inhabitants: the first species being usually called predial, as of corn, hay and wood; the second mixed, as of wool, milk, pigs, &c., consisting of natural products, but nurtured and preserved in part by the care of man; and of these the tenth must be paid in gross; the third personal, as of manual occupations, trades, fisheries, and the like; and of these only the tenth part of the clear gains and profits is due.

We shall, in this article, consider, 1. The original of the right of tithes. 2. In whom that right at present resides. 3. Who may be discharged, either totally or in part, from paying them.

1. As to their original, we will not put the title of the clergy to tithes upon any divine right; though such a right certainly commenced, and we believe as certainly ceased, with the Jewish theocracy. Yet an honorable and competent maintenance for the ministers of the gospel is undoubtedly due divino, whatever the particular mode of that maintenance may be. For, besides the positive precepts of the New Testament, natural reason will tell us, that an order of men who are separated from the world, and excluded from other lucrative professions for the sake of the rest of mankind, have a right to be furnished with the necessaries, conveniences, and moderate enjoyments of life, at their expense; for whose benefit they forego the usual means of providing them. Accordingly all municipal laws have provided a liberal and decent maintenance for their national priests or clergy: ours, in particular, have established this of tithes, probably in imitation of the Jewish law: and perhaps, considering the degenerate state of the world in general, it may be more beneficial to the English clergy to found their title on the law of the land, than upon any divine right whatsoever, unacknowledged and unsupported by temporal sanctions.

We cannot precisely ascertain the time when tithes were first introduced into this country. Possibly they were contemporaneous with the planting of Christianity among the Saxons by Augustine the monk, about the end of the sixth century. But the first mention of them which we have met with in any written English law, is a constitutional decree, made in a synod held A.D. 786, wherein the payment of tithes in general is strongly enjoined. This canon or decree, which at first bound not the laity, was effectually confirmed by two
T I T

kingdoms of the heptarchy, in their parliamentary conventions of estates, respectively consisting of the kings of Mercia and Northumberland, the bishops, dukes, senators, and people. Which was a few years later than the time that Charlemagne established the payment of tithes in France, and made that famous division of them into four parts; one to maintain the edifice of the church, the second to support the poor, the third the bishop, and the fourth the parochial clergy.

The next authentic mention of them is in the *fideus Edwardi et Guthruni*; or the laws agreed upon between King Guthrun the Dane, and Alfred and his son Edward the Elder, successive kings of England, about the year 900. This was a kind of treaty between those monarchs, which may be found at large in the Anglo-Saxon laws: wherein it was necessary, as Guthrun was a Pagan, to provide for the subsistence of the Christian clergy under his dominion; and accordingly, we find the payment of tithes not only enjoined, but a penalty made for non-observance: which law is seconded by the laws of Athelstan, about the year 930. And this is as much as can certainly be traced out with regard to their legal original.

2. We are next to consider the persons to whom tithes are due. Upon their first introduction, though every man was obliged to pay tithes in general, yet he might give them to what priests he pleased; which were called *arbitrary consecrations of tithes*; or he might pay them into the hands of the bishop, who distributed among his diocesan clergy the revenues of the church, which were then in common. But when dioceses were divided into parishes, the tithes of each parish were allotted to its own particular minister; first by common consent or the appointments of lords of manors, and afterwards by the written law of the land.

Arbitrary consecrations of tithes took place again afterwards, and were in general use till the time of King John. This was probably owing to the intrigues of the regular clergy, or monks of the Benedictine and other orders, under Archbishop Dunstan and his successors; who endeavoured to wean the people from paying their dues to the secular or parochial clergy (a much more valuable set of men than themselves), and were then in hope to have drawn, by sanctimonious pretences to extraordinary purity of life, all ecclesiastical profits to the coffers of their own societies. And this will naturally enough account for the number and riches of the monasteries and religious houses which were founded in those days, and which were frequently endowed with tithes. For a layman, who was obliged to pay his tithes somewhere, might think it good policy to erect an abbey, and there pay them to his own monks, or grant them to some abbey already erected; since for this donation, which really cost the patron little or nothing, he might, according to the superstition of the times, have masses for ever sung for his soul. But in process of years, the income of the poor laborious parish-priests being scandalously reduced by these arbitrary consecrations of tithes, it was remedied by Pope Innocent III. about the year 1203, in a decretal epistle sent to the archbishop of Canterbury, and dated from the palace of Lateran: which has occasioned Sir Henry Hall and others to mistake it for a decree of the council of Lateran, held A. D. 1779, which only prohibited what was called the *infusion of tithes*, or their being granted to mere laymen; whereas this letter of Pope Innocent to the archbishop enjoined the payment of tithes to the parsons of the respective parishes where every man inhabited, agreeable to what was afterwards directed by the same pope in other countries. This epistle, says Sir Edward Coke, bound not the law subjects of this realm; but being reasonable and just, it was allowed of, and so became *lex terrae*. This put an effectual stop to all the arbitrary consecrations of tithes; except some footsteps which still continue in those portions of tithes which the parson of one parish hath, though rarely, a right to claim in another: for it is now universally held, that tithes are due, of common right, to the parson of the parish, unless there be a special exemption. This parson of the parish, may be either the actual incumbent, or else the appropriator of the benefice; appropriations being a method of endowing monasteries, which seems to have been devised by the regular clergy, by way of substitution to arbitrary consecrations of tithes.

3. We observed that tithes are due of common right to the parson, unless by special exemption; let us therefore see, thirdly, who may be exempted from the payment of tithes, and how lands and their occupiers may be exempted or discharged from the payment of tithes, either in a part or totally; first, by a real composition; or, secondly, by custom or prescription.

First, a real composition is when an agreement is made between the owner of the land and the parson or vicar, with the consent of the ordinary and the patron, that such lands shall for the future be discharged from the payment of tithes, by reason of some land or other real recompense given to the parson in lieu and satisfaction thereof. This was permitted by law, because it was supposed that the clergy would be no losers by such composition; since the consent of the ordinary, whose duty it is to take care of the church in general, and of the patron, whose interest it is to protect that particular church, were both made necessary to render the composition effectual: and hence have arisen all such compositions as exist at this day by force of the common law. But experience showing that even this caution was ineffectual, as the possessions of the church being by this and other means every day diminished, the disallowing statute 13 Eliz. c. 10. was made; which prevents among other spiritual persons, all parsons and vicars from making any conveyances of the estates of their churches, other than for three lives of 21 years. So that now, by virtue of this statute, no real composition made since the 13 Eliz. is good for any longer term than three lives or 21 years, though made by consent of the patron and ordinary: which has indeed effectually demolished this kind of traffic; such compositions being now rarely heard of, unless by authority of parliament.

Secondly, a discharge by custom or prescription, is where time out of mind such persons or such lands have been either partially or totally discharged from the payment of tithes. And this immemorial usage is binding upon all parties; as it is in its nature an evidence of universal consent and acquiescence, and with reason supposes a real composition to have been formerly made. This custom or prescription is either *de modo decimandi*, or *de non decimando*.

A *modus decimandii*, commonly called by the simple name of a *modus* only, is where there is by custom a particular
A prescription de non decimando is a claim to be entirely discharged of tithes, and to pay no compensation in lieu of them. Thir daily the king by his prerogative is discharged from all tithes. So a vicar shall pay no tithes to the rector, nor the rector to the vicar, for ecclésia de rectius non servit ecclesie. But these personal privileges (not arising from or being annexed to the land) are personally confined to both the king and the clergy; for their tenant or lessee shall pay tithes, though in their own occupation their lands are not generally titheable. And, generally speaking, it is an established rule, that in lay hands, modus de non decimando non volet. But spiritual persons or corporations, as monasteries, abbots, bishops, and the like, were always capable of having their lands totally discharged of tithes by various ways: as, 1. By real composition. 2. By the pope's bull of exemption. 3. By unity of possession; as when the rector of a parish, and lands in the same parish, both belonged to a religious house, those lands were discharged of tithes by this unity of possession. 4. By prescription; having never been liable to tithes, by being always in spiritual hands. 5. By virtue of their order; as the Knights Templars, Cistercians, and others, whose lands were privileged by the pope with a discharge of tithes. Though, upon the dissolution of abbeys by Henry VIII. most of these exemptions from tithes would have fallen with them, and the lands become titheable again, had they not been supported and upheld by the statute 31 Henry VIII. c. 13. which enacts, that all persons who should come to the possession of the lands of any abbey then dissolved, should hold them free and discharged of tithes, in as large and ample a manner as the abbeys themselves formerly held them. And from this original have sprung all the lands which being in lay hands, do at present claim to be tithe free: for if a man can show his lands to have been such abbey-lands, and also immemorially discharged of tithes by any of the means before mentioned, this is now a good prescription de non decimando. But he must show both these requisites: for abbey-lands, without a special ground of discharge, are not discharged of course; neither will any prescription de non decimando avail in total discharge of tithes, unless it relates to such abbey-lands.

It is universally acknowledged that the payment of tithes in kind is a great discouragement to agriculture. They are inconvenient and vexatious to the husbandman, and operate as an impolitic tax upon industry. The clergyman, too, frequently finds them troublesome and precarious; his expenses in collecting are a considerable drawback from their value, and his just rights are with difficulty secured: he is too often obliged to submit to imposition, or is embroiled with his parishioners in disputes and litigations, no less irksome to his feelings than prejudicial to his interest, and tending to prevent those good effects which his precepts should produce. It is therefore of the utmost importance to parochial tranquillity, and even to religion, that some just and reasonable standard of composition could be fixed. Land has been proposed, but in the present state of the division of property this is impossible: and as money is continually changing in its value, it would also be a very improper standard, unless some plan could be formed by which the composition could be increased as the value of money diminishes. A plan of this kind has been published in the Transactions of the Society instituted at Bath, vol. iv. which those who are interested in this subject may consult for farther information.

TITIANO VECCELLI, or TITIAN, the most universal genius for painting of all the Lombard-school, the best colourist of all the moderns, and the most eminent painting for histories, portraits, and landscapes, was born at Ca-toe's Diccore, in the province of Friuli, in the state of Venice, in 1477, or in 1478 according to Vasari and Sandrart. His parents sent him at ten years of age to one of his uncles at Venice, who finding that he had an inclination to painting, put him to the school of Giovanni Bellino.

But as soon as Titian had seen the works of Giorgione, whose manner appeared to him abundantly more elegant, and less constrained than that of Bellino, he determined to quit the style to which he had so long been accustomed, and to pursue the other that recommended itself to him, by having more force, more relief, more nature, and more truth. Some authors affirm, that he placed himself as a disciple with Giorgione; yet others only say, that he cultivated an intimacy with him; but it is undoubtedly certain that he studied with that great master; that he learned his method of blending and uniting the colours; and practised his manner so effectually, that several of the paintings of Titian were taken for the performances of Giorgione; and then his success inspired that artist with an invincible jealousy of Titian, which broke off their connection for ever after.

The reputation of Titian rose continually; every new work contributed to extend his fame through all Europe; and he was considered as the principal ornament of the age in which he flourished. And yet, Sandrart observes that amidst all his applause and constant employment at Venice, his income and fortune were inconsiderable;
Titian and he was more remarkable for the extensiveness of his talents, than for the affluence of his circumstances. But when his merit was made known to the emperor Chas. V. that monarch knew how to set a just value on his superior abilities; he enriched him by repeated bounties, allowed him a considerable pension, conferred on him the honour of knighthood, and, what was still more, honoured him with his friendship. He painted the portrait of that benefactor several times; and it is record
d by Sandrart, that one day, while the emperor was sitting for his picture, a pencil happening to drop from the painter, he stooped, took it up, and returned it; obligingly answering to the modest apology of the artist (who blushed at the condescension of so great a monarch), that the merit of a Titian was worthy of the attendance of an emperor.

The excellence of Titian was not so remarkably ap

Wealth, and happiness, more than all the world could

in the historical compositions which he painted as

in his portraits and landscapes, which seem to be superior
to all competition; and even to this day, many of them preserve their original beauty, being as much the admiration of the present age as they have deservedly been of the ages past. It is observed of Titian by many writers, that in the different periods of his life he had four different manners; one resembling his first instructor Bellino, which was somewhat stiff; another, in imitation of Giorgione, more bold, and full of force; his third manner was the result of experience, knowledge, and judgment, beautifully natural, and finished with exquisite care, which manner was peculiarly his own; and in those pictures which he painted between the years of approaching old age and his death may be noticed his fourth manner. His portraits were very differently

finished in his early, and in his latter time, according to the testimony of Sandrart. At first he laboured his pictures highly, and gave them a polished beauty and lustre, so as to produce their effect full as well when they were examined closely as when viewed at a distance; but afterwards, he so managed his pencilling, that their greatest force and beauty appeared at a more remote view, and they pleased less when they were beheld more closely. So that many of those artists who studied to imitate him, being misled by appearances which they did not sufficiently consider, have imagined that Titian executed his work with readiness and a masterly rapidity; and concluded that they should imitate his manner most effectually by a freedom of hand and a bold pencil: Whereas in reality, Titian took abundance of pains to work up his pictures to so high a degree of perfection; and the freedom that appears in the handling was entirely effected by a skilful combination of labour and judgment.

It cannot be truly affirmed, that Titian equalled the great masters of the Roman school in design; but he al

ways took care to dispose his figures in such attitudes as shewed the most beautiful parts of the body. His taste in designing men was not generally so correct or elegant as it appeared in his boys and female figures; but his colouring had all the look of real flesh, his figures breathe. He was not so bold as Giorgione, but in tenderness and delicacy he proved himself much superior to him and all other artists. The expression of the pass

ions was not his excellence, though even in that respect many of his figures merited the justest commendation; but he always gave his figures an air of ease and digni

ty. His landscapes are universally allowed to be unequalled, whether we consider the forms of his trees, the grand ideas of nature which appear in his scenery, or his distances which agreeably delude and delight the eye of every observer; and they are executed with a light, tender, and mellow pencil. He learned from nature the harmony of colours, and his tints seem astonishing, not only for their force, but their sweetness; and in that respect his colouring is accounted the standard of excellence to all professors of the art. It would prove almost an endless task to enumerate the variety of works executed by this illustrious artist, at Rome, Venice, Bologna, and Florence, as well as those which are to be seen in other cities of Italy, in England, Spain, Germany, and France; but there are two, which are mentioned as being truly admirable. One is, a Last Supper, preserved in the refectory at the Escurial in Spain, which is inimitably fine; the other is at Milan, representing Christ crowned with thorns. The principal figure in the latter has an attitude full of grace and dignity more than mortal, and the countenance shows a benevolence and humility, combined with dignity and pain, which no pencil but that of T

This text is extracted from the work "A Natural History of Animals" by Natural History of Animals. The text discusses the life and works of Titian, a famous Italian painter, and his influence on art and society. The passage highlights Titian's versatility and the different styles he developed throughout his career, from his early works to his mature compositions. Titian's landscapes, especially his distant views and harmonious use of colour, are praised, as are his portraits, which convey a sense of the subjects' personalities. The text concludes with a description of two of Titian's most famous works, the Last Supper at the Escurial and one at Milan depicting Christ, which are noted for their artistic excellence and emotional depth.
The emperor is given the title of Imperial Majesty, to kings, that of Majesty; to the princes of Great Britain, Royal Highness; to those of Spain, Infants; to electors, Electoral Highness; to the grand duke of Tuscany, Most Serene Highness; to the other princes of Italy and Germany, Highness; to the dog of Venice, Most Serene Prince; to the grand-master of Malta, Eminence; to nuncios and ambassadors of crowned heads, Excellency; to dukes, Grace; to marquises, ears, and barons, Lordship.

The emperor of China, among his titles, takes that of Tien Su, "Son of Heaven." The Orientals, it is observed, are exceedingly fond of titles; the simple governor of Schiraz, for instance, after a pompous enumeration of qualities, lordships, &c. adds the titles of Flower of Courtesy, Nutmeg of Consulat, and Rose of Delight.

Title, in Law, denotes any right which a person has to the possession of a thing, or an authentic instrument whereby he can prove his right. See the articles Right, Property, &c.

Titmouse. See Parus, Ornithology Index.

Titular, denotes a person invested with a title, in virtue of which he holds an office or benefice, whether he performs the functions thereof or not.

Titus Vespasianus, the Roman emperor, the son of Vespasian; of whom it is related, that not being able to recollect any remarkable good action he had done on a certain day, he exclaimed, "I have lost a day!" He might truly be called the father of his people; and though Rome laboured under various public calamities during his reign, such was his equitable and mild administration, that he constantly preserved his popularity. He was a great lover of learning, and composed several poems. He reigned two years; and it is thought Domitian his brother poisoned him, A. D. 81, aged 41.

Tobacco-Pipes, Manufacture of. The art of making tobacco-pipes, or, as it is commonly called, pipe-making, though one of the simplest species of pottery, is sufficiently curious to merit description in a dictionary of arts and sciences.

The process of pipe-making may be divided into six stages: viz. 1. Beating or preparing the clay; 2. Rolling; 3. Moulding; 4. Trimming; 5. Drying; and, 6. Burning.

Preparation of the Clay. The fine white clay employed by the pipe-makers, is dug from the quarries in masses of about a cubic foot each. Before it can be used in the manufacture of tobacco-pipes, it must be reduced to the consistence of a tough paste. To effect this, after its outer surface has been cleared from dirt or dust, it is broken into small pieces about as large as a goose's egg, and thrown into a tub with such a quantity of soft water as experience has shown to be sufficient to bring it to the proper consistence. After lying till it has soaked up all the water, which usually requires from 12 to 24 hours, it is taken from the tub and laid on a thick strong wooden bench. Here it is beaten by a heavy four-square iron instrument, in such a manner as to cut it from one end to the other into very thin slices. It requires considerable address to perform this operation, and it is surprising how thin the workmen will sometimes cut the slices, and how equally they will thus divide the clay. This beating is continued, alternately folding up the clay and slicing it, till the whole is perfectly smooth. It is then ready for rolling.

Rolling. The operation of rolling reduces the clay into pieces of a proper size and length for making pipes, and almost to the proper form. The roller sits at a bench with a smooth board before him, and holds in his hand another smooth board about 18 inches long, four broad, and about half an inch thick, having one end rounded off on one side, so as to produce a corresponding hollow in the clay. He now takes a piece of the beaten clay, and rolls it out, first with his hands, and then with the board, till it acquire the form of a long slender cylinder, with one end larger than the rest. This large end is to form the hole, and the cylinder the shank of the future pipe. The pieces of clay thus formed are laid beside each other on a flat board, and are now ready for moulding.

Moulding. This is the most complex operation, and requires the greatest number of instruments. The principal of these is the mould, which is composed of two long pieces of iron, formed so as to join together, and having their corresponding sides cut into the shape of half a tobacco-pipe, each piece being hollowed so as to form half a slender cylinder, with a larger cavity at the upper end, and at such an angle as it is intended the hole of the pipe shall make with the shank. Just above that part of each side of the mould which stands beyond what is intended to form the hole, there is a notch for admitting a knife to cut off the superfluous clay. To receive the united mould there is a vice, having at one end two upright posts, between which moves a long lever, and to this lever, near the posts, there is loosely attached a piece of iron ending below in a smooth conical head, capable of entering the large opening of the mould, but rather smaller than the opening, so that when forced down into it, a sufficient thickness of clay may be left between the cone and the sides of the mould, to form the hole of the pipe. One side of this vice is fixed, and the other moveable, towards the former. The moveable side has attached to it an iron screw with a very long lever as its handle, so that by turning the screw one way or the other, the moveable side of the vice may be forced nearer the fixed side, or suffered to return to its original position.

Besides these principal instruments, the moulder requires a slender steel wire, fixed in a handle at one end, and having its other extremity formed into a very small head; a vessel containing well impregnated with oil, and a small woollen or cotton brush.

When about to mould his pipes, he lays hold of the shank of one of the rolled pieces, and with great dexterity, which practice alone can teach, he passes up the oil.
Tobacco, oiled wire through its whole length, till he finds it arrived at the commencement of the larger extremity of the clay. This extremity he then bends to the proper angle, and having oiled the inside of each part of his mould, he lays the piece of clay with the wire in it, into one part of the mould, and covers it with the other. He now puts the mould containing the clay into the vice, and with the left hand turning round the handle of the screw, so as to fix the mould firmly within the vice, he, with the right hand, presses down the lever with its conical head, and thus forms the cavity of the bole. He now withdraws the mould, cuts off with his knife the superfluous clay from the bole, opens the mould, takes out the pipe, and now only withdraws the wire. He then lays the moulded pipe on a flat board, in the same manner as the rolled pieces before described. The pipes thus moulded require to be trimmed, that is, to have the prominences arising from the joining of the mould, and other superfluous pieces of clay taken off, so as to render the surface smooth and round.

Trimming.—The operation of trimming is generally performed by boys and girls, as it requires very little skill. The trimmer has before him a smooth block of wood, about the length of the pipe, and of considerable thickness, elevated a little at the remote end. He has also a thick piece of smooth iron, one edge of which has across it two or more semicylindrical grooves, capable of receiving half the shank of a pipe. Taking one of the rough moulded pipes, the trimmer carefully passes up the hollow of the shank, a wire similar to that employed in moulding, and holding the pipe by the bole, while the shank lies before him on the wooden block, he pares off with a blunt knife all the excrences of clay, both from the shank and bole, and rubs the former, while lying on the block, with the grooved part of his iron, so as to render it as smooth as possible. He now cuts off the ragged pieces at the extremity of the shank, withdraws the wire, and lays the pipe on the drying frame. One great object of the trimmer is, to see that the pipe is completely perforated, which he discovers by blowing through it; and if he finds the hole choked up, he must open it by pushing the wire as far as possible. If this does not succeed, he breaks the pipe as useless.

Drying.—The pipe has now received all the work that can be bestowed on it by the maker, previous to its being burned; but as the exposing of it to heat, while soft and pliable, would make it crack, it is necessary that it be properly dried. For this purpose, a frame is prepared, composed of three or four long pieces of wood, fastened to two end pieces in such a manner, as that the middle of the frame shall be the lowest, to give the shanks of the pipes that curve which they generally possess. After being trimmed, the pipes are laid beside each other in this concave frame, with their boles hanging down over the edges of the frame, and their shanks bending within its hollow. In this position they are exposed to the air till they are dry and firm. They are then ready for burning or baking.

Baking.—For burning or baking the pipes, there is to be prepared a kiln of a simple but peculiar construction. It is built in the form of a cylinder, close at the bottom and on the sides, and open at the top. Below the bottom is a grate for receiving the fuel, and round the sides are constructed vertical or spiral flues, opening at the top, and communicating below with the grate.

The sides of the furnace on its interior are pretty thin, and are formed of a cement composed of clay mixed with fresh cow dung. In the middle of the cavity is placed a pedestal composed of the same materials, for the pipes to lean against. When the pipes are sufficiently dried, they are arranged round this pedestal, resting against it, and against each other, with their boles next the bottom of the furnace. They are thus placed in successive layers, till the furnace be sufficiently full, when the open space at top is filled up with bricks placed over each other, so as to leave interstices for the free circulation of the air, and of the smoke and flame which issue through the flues. In these interstices are laid several pieces of broken dried pipes, to serve as pyrometers for ascertaining the state of the included pipes during the burning. The fire is now lighted, and kept up, till, on examining the pieces of clay laid in the interstices of the bricks, it is concluded that the pipes within the furnace are sufficiently baked. The fire is then suffered to go out, and the whole to cool till the next day, when the bricks are taken down, the pipes removed, and packed in barrels.

After being burnt, the pipes are sometimes glazed, which is done by rubbing them, while warm, with flannel and a little white flux. In some places the extremities of the shanks are rendered smooth by dipping them before burning in the ordinary potters' glazing, which prevents that adhesion to the lips so unpleasant in unglazed pipes.

TOBAGO, one of the Caribbean islands, ceded to Great Britain by the treaty of Paris in 1763, taken by the French in 1781, and retaken by the British in 1793. It lies in the latitude of 11 degrees 10 minutes north, and 39 degrees 40 minutes longitude west from London, about 45 leagues south-west by west from Barbados, 35 south-east from St. Vincent, 20 south-east from Grenada, 12 north-east from the Spanish island of Trinidad, and between 30 and 40 north-east from the Spanish main. According to the latest accounts, it is somewhat more than 30 miles in length from north-east to south-west, between 8 and 9 in breadth, and from 23 to 25 leagues in circumference. The English visited this island very early, Sir Robert Dudley being there in the reign of Queen Elizabeth. In that of Charles I., William earl of Pembroke procured a grant of this, with two other small islands; but died before he was able to carry into execution his design of settling them. In A.D. 1632 some merchants of Zealand sent over a small colony thither, and gave it the name of New Vateren; but before they were able thoroughly to establish themselves, they were destroyed by the Indians assisted by the Spaniards. Ten years after, James duke of Courland sent a colony thither, who settled themselves upon Great Courland bay, and made a considerable progress in planting. A.D. 1654, Messieurs Adrien and Cornelius Lampsins, two opulent merchants of Flushing, sent a considerable number of people thither, who settled on the other side of the island, and lived in amity with the Courlanders, until they learned that the king of Sweden had seized the person of their duke and dispossessed him of his dominions, when they attacked and forced his subjects to submit. The duke being afterwards restored, he obtained from Charles II. a grant of this island, dated the 17th of November 1664.
Tobolsk, the capital of a province of the same name in Asiatic Russia, comprehending the greater part of the country known by the name of Siberia, is situated at the confluence of the rivers Tobol and Irtysh, in N. Lat. 58° 12', E. Long. 65° 32'. The city stands on the ascent of a high hill, the lower part of which is inhabited by Mahometan Tatars, who carry on a considerable traffic upon the river Irtysh, and convey their merchandise quite across Great Tartary, as far as China. The river Irtysh joins the Tobol, and both fall into the Oby. By means of these two rivers, there is a constant flow of merchandise into the city during the summer season. Tobolsk is therefore a great mart for the commodities of Muscovy, Tartary, and other countries; and here is a great concourse of merchants. All sorts of provisions are plentiful and cheap. An hundred weight of rice is sold for 16 copecks, equal to about eightpence sterling; a stove weighing 40 pounds; for half that money; an ox for two rix-dollars, and every other article in proportion. The adjacent country abounds with game in great variety. The supreme court of judicature for all Siberia is held in this city, which is also the seat of a metropolitan, sent hither from Moscow to exercise spiritual jurisdiction over the whole kingdom. Tobolsk is well fortified, and defended by a strong garrison, under the command of the governor, who resides in the place, and takes charge of the fur tribute, which is here deposited in proper magazines. This governor enjoys a very extensive command, and can occasionally bring into the field 9000 men besides a strong body of Tartars on horseback, to make head against the Calmucks and Cossacks, in their repeated incursions. A sufficient number of Russians, called Jemskoiks, are kept in continual pay by the government, on the banks of the Irtysh, to supply travellers on the czar's account with men, boats, or carriages, to convey them as far as Surgut on the Oby, a voyage of 200 leagues by water. This is the common method of travelling in the summer; but in winter the journey by land is not half so long, being performed in sleds over the ice and snow, with which the country is covered. These sleds are moved by a pair of dogs, which will draw a load of 300 pounds with surprising expedition. They are hired at easy rates, and during one half of the year may be seen flying over the snow in great numbers. The city is supposed to contain 15,000 inhabitants. It is 500 miles east from Moscow, and 1200 from Petersburg.

TODDA PAVIA. See Cyclops, Botany Index.

TODDY, a name given to the juice of the cocoa-nut tree. See ARAK.—Tody is also a name given to a mixture of spirits, water, and sugar.

TODDY-Bird. See Loxia, Ornithology Index.

TODUS, the Tody; a genus of birds belonging to the order of pice. See Ornithology Index.

TOGA, in Roman antiquity, a wide woollen gown or mantle, which seems to have been of a semicircular form, without sleeves; differing both in richness and largeness, according to the circumstances of the wearer, and used only upon occasion of appearing in public.

Every body knows that the toga was the distinguished mark of a Roman: hence the jus toge, or privilege of a Roman citizen; i.e. the right of wearing a Roman habit, and of taking as they explain it, fire and water through the Roman empire.

TOKAY WINE, derives its name from a town of Hungary, where it is produced. There are four sorts of wine made from the same grapes, distinguished at Tokay by the names of essener, auspruch, maslach, and the common wine. The essence is made by picking out the half-dried and shrivelled grapes, and putting them into a perforated vessel, where they remain as long as any juice runs off by the mere pressure of their own weight. This is put into small casks. The auspruch is made by pouring the expressed juice of the grapes from which the former had been picked on those that yielded the essence, and treasuring them with the feet. The liquor thus obtained stands for a day or two to ferment, and then is poured into small casks, which are kept in the air for about a month, and afterwards put into casks. The same process is again repeated by the addition of more juice to the grapes which have already undergone the two former pressures, and they are now wrung with the hands; and thus is had the maslach. The fourth kind is made by taking all the kinds together at first, and submitting them to the greatest pressure: this is chiefly prepared by the peasants. The essence is thick, and very sweet and lucious: it is chiefly used to mix with the other kinds. The auspruch is the wine commonly exported, and which is known in foreign countries by the name of Tokay.

The goodness of it is determined by the following rules. The colour should neither be reddish nor very pale, but a light silver: in trying it, the palate and tip
of the tongue should be wetted without swallowing it; if it manifest any acrimony to the tongue it is not good; but the taste ought to be soft and mild; when powdered out, it should form globules in the glass, and have an oily appearance; when genuine, the strongest is always of the best quality: when swallowed, it should have an earthy astringent taste in the mouth, which is called the taste of the root. All toky wine has an aromatic taste, which distinguishes it from every other species of wine. It keeps to any age, and improves by time: but is never good till about three years old. It is the best way to transport it in casks; for when it is on the seas, it ferments three times every season, and thus refines itself. When in bottles, there must be an empty space left between the wine and the cork, otherwise it would burst the bottle. A little oil is put upon the surface, and a piece of bladder tied over the cork. The bottles are always laid on their sides in sand. Phil. Trans. vol. liii. part ii. p. 292, &c.

TOKENS. See TRADESMEN'S TOKENS.

TOISE, or FATHOM, a French measure containing six of their feet, equal to 6,394 English feet.

TOLAND, John, a famous writer, was born near Londonderry in Ireland in 1670, and educated in the Popish religion; but at 16 years of age embraced the principles of the Protestants. He studied three years at the university of Glasgow; was created master of arts in the university of Edinburgh; and afterwards completed his studies at Leyden, where he resided two years. He then went to Oxford, where, having the advantage of the public library, he collected materials upon various subjects, and composed some pieces; among which was a Dissertation to prove the received history of the tragi-comical death of Attilius Regulus, the Roman consul, to be a fable. He began likewise a work of greater consequence, in which he undertook to shew that there are no mysteries in the Christian religion. He published it in 1696 at London, under the title of Christianity not mysterious. This book gave great offence, and was attacked by several writers. He afterward wrote in favour of the Hanoverian succession, and many other pieces. In 1707 he went into Germany, where he visited several courts; and in 1710 he was introduced to Prince Eugene, who gave him several marks of his generosity. Upon his return to England he was for some time supported by the liberality of the earl of Oxford lord-treasurer, and kept a country house at Epsom; but soon losing his lordship's favour, he published several pamphlets against that minister's measures. In the last four years of his life he lived at Putney, but used to spend most part of the winter in London. Mr Toland died at London in 1722. He was a man of uncommon abilities, published a number of curious tracts, and was perhaps the most learned of all the infidel writers; but his private character was far from being an amiable one: for he was extremely vain, and wanted those social virtues which are the chief ornaments as well as duties of life. His posthumous works, two volumes octavo, were published in 1726, with an account of his life and writings, by Mr Den Manxieu.

TOLEDO, an ancient and trading city of Spain in the province of Castile, about two centuries ago it is said to have contained more than 200,000 inhabitants; but they are now diminished to 20,000, or at most to 50,000. It is a

vantageously seated on the river Tajo, which surrounds it on two sides; and on the land side, it has an ancient Toledo wall built by a Gothic king, and flanked with 100 towers. It is seated on a mountain, which renders the streets uneven, and which are narrow; but the houses are fine, and there are a great number of superb structures, besides 17 public squares, where the markets are kept. The finest buildings are the royal castle and the cathedral church; which last is the richest and most considerable in Spain. It is seated in the middle of the city, joining to a handsome street, with a fine square before it. Several of the gates are very large, and of bronze. There is also a superb steeple, extremely high, from whence there is a very distant prospect. The iglesia mayor, or principal chapel, is a real treasury, in which are 35 large cabinets let into the wall, full of prodigious quantities of gold and silver vessels, and other works. There are two mitres of silver gilt, set all over with pearls and precious stones, with three collars of many gold, enriched in like manner. There are two bracelets and an imperial crown of the Virgin Mary, consisting of large diamonds and other jewels. The weight of the gold in the crown is 15 pounds. The vessel which contains the consecrated wafer is of silver gilt, as high as a man, and so heavy, that it requires 30 men to carry it; within it is another of pure gold enriched with jewels. Here are 39 religious houses, most of which are worthy a traveller's notice, with many other sacred buildings, besides severall churches belonging to 27 parishes, and fifteen hospitals. Without the town are the remains of an amphitheatre, and other antiquities.

Toledo is an archbishop's see, who is primate of Spain, and perhaps the richest prelate in Europe. His revenue of lands and revenues is said to amount to 125,000 sterling; but there are large deductions to be made from it. He pays 15,000 ducats to the monks of the Escorial, besides several other perquisites. Toledo has also a university. It was formerly celebrated for the exquisite temper of the sword blades made there. It is situated in E. Long. 3° 15 N. Lat. 39° 59', and is 37 miles south from Madrid.

TOLERATION, in its widest sense, is either civil or ecclesiastical. Civil toleration is an impunity and safety granted by the state to every sect that does not maintain doctrines inconsistent with the public peace; and ecclesiastical toleration is the allowance which the church grants to its members to differ in certain opinions, not reputed fundamental.

As the gods of Paganism were almost all local and tutelary, and it was a maxim universally received that it was the duty of every man to worship, together with his own deities, the tutelary gods of the country in which he might chance to reside, there was no room for persecution in the Heathen world. On account of different sentiments in religion, or of the different rites with which the various deities were worshipped. Had the primitive Christians joined their fellow-citizens in the worship of Jupiter, Juno, and the rest of the gods; of Roman divinities, they would have been suffered to worship, without molestation, the Creator of the world and the Redeemer of mankind; for in that case the God of the Christians would have been looked upon as a Being of the same kind with the gods of the empire; and the great principle of intercommunity would have remained unviolated. But the true God did expressly prohibit
Toleration, prohibited both Jews and Christians from worshipping any other god besides Himself; and it was their refusal to break that precept of their religion which made their Heathen masters look upon them as Atheists, and persecute them as a people inimical to the state. Utility, and not truth, was the object for which the different sects of the clergy, of the rewards of Elysium, and of the punishments of Tartarus, were a collection of senseless fables; but they had nothing better to propose to the vulgar, and they were not such strangers to the human heart, as to suppose that mankind could live together in society without being influenced in their conduct by some religion.

Widely different from the spirit of Paganism was the spirit of the Jewish dispensation, which is in fact always coincident with general utility, was the great object of the Mosaic law. The children of Israel were separated from the rest of the world, to preserve the knowledge and worship of the true God, at a time when all the other nations on earth, forgetting the Lord that made them, were falling prostrate to stocks and stones, and worshipping devils and impure spirits. Such was the contagion of idolatry, and so strong the propensity of the Israelites to the customs and manners of the Egyptians, and other polytheistic nations around them, that the purpose of their separation could not have been served, had not Jehovah condescended to become not only their tutelary God, but even their supreme civil magistrate (see Theology, No. 151); so that under the Mosaic economy, idolatry was the crime of high treason, and as such justly punished by the laws of the state. Among the Jews, the church and state were not indeed different societies. They were so thoroughly incorporated, that what was a sin in the one was a crime in the other; and the forfeiture of ecclesiastical privileges was the forfeiture of the rights of citizens.

In many respects the Christian religion is directly opposite to the ritual law of Moses. It is calculated for all nations, and intended to be propagated among all. Instead of separating one people from another, one of its principal objects is to disseminate universal benevolence, and to inculcate upon the whole human race, that mutual love which naturally springs from the knowledge that all men are brethren. Its ultimate end being to train its votaries for heaven, it concerns itself no farther with the affairs of earth than to enforce by eternal sanctions the laws of morality; and the kingdom of its Founder not being of this world, it leaves every nation at liberty to fabricate its own municipal laws, so as best to serve its own interest in the various circumstances in which it may be placed; and denounces a curse upon all who pay not to those laws the fullest obedience, when they are not obviously inconsistent with the laws of piety and virtue, which are of prior obligation. The Christian church therefore must always remain a distinct society from the state; and though, till the present age of hazardous innovations, it has been deemed expedient in every country, where the truth of the gospel is admitted, to give to the religion of Christ a legal establishment, and to confer immunities on its ministers, this measure has been adopted, not to secure the purity of the faith, which appeals to the private judgment of each individual, but merely to preserve the peace of society, and to put a restraint upon those actions of which human laws cannot take cognizance.

With religion, Christian governments have no farther concern than as it tends to promote the practice of virtue. The early Christians, however, not understanding the principle upon which penal laws were employed to preserve the purity of the Jewish religion; and, as our blessed Lord observed to two of his apostles, not knowing what spirit they were of—blistly concluded that they had a right to enforce the doctrines and worship of the New Testament, by the same means which had been used to preserve the Israelites steady to the doctrines and worship of the Old. Hence, though they had suffered the cruelest persecutions themselves (see Persecution), they no sooner got the power of the state in their hands, than they persecuted the Pagans for their idolatry; and afterwards, when heresies arose in the church, persecuted one another for expressing in different phrases metaphysical propositions, of such a nature as no human mind can fully comprehend. The apostle had forewarned them that there must be heresies in the church, that they who are approved may be made manifest; but it did not occur to them that persecution for opinion is the worst of all heresies, as it violates at once truth and charity.

Hitherto these unhallowed means of bringing Christians to uniformity of faith and practice, had been only occasionally employed, from their not accurately distinguishing between the spirit of the gospel and that of the law; but as soon as the bishops of Rome had brought the inhabitants of Europe to recognize their infallibility in explaining articles of faith and deciding points of controversy, persecution became a popular and permanent instrument of ecclesiastical discipline. To doubt or to deny any doctrine to which these unrering instructors had given the sanction of their approbation, was held to be not only a resisting of the truth, but an act of rebellion against their sacred authority; and the secular power, of which, by various acts, they had acquired the absolute direction, was instantly employed to avenge both.

Thus Europe had been accustomed, during many centuries, to see speculative opinions propagated or defended by force; the charity and mutual forbearance which Christianity recommends with so much warmth, were forgotten; the sacred rights of conscience and of private judgment were unheard of; and not only the idea of toleration, but even the word itself, in the sense now affixed to it, was unknown. A right to extirpate error by force, was universally allowed to be the prerogative of those who possessed the knowledge of truth; and though the first reformers did not arrogate to themselves in direct terms that infallibility which they had refused to the church of Rome, they were not less confident of the truth of their own doctrines, and required with equal ardour the princes of their party to check such as presumed to impugn or to oppose them. To this request too many of these princes lent a willing ear. It flattered at once their piety and their pride, to be considered as possessing all the rights of Jewish princes; and Henry the VIII. of England, after laboring to make his divines declare that all authority ecclesiastical as well as civil flows from the crown, persecuted alternately the Papists and Protestants. Many of his successors, whose characters were much better than his, thought themselves duly authorized
TOLEMAISM, as authorized, in virtue of their acknowledged supremacy over all states and conditions of men, to enforce by means of penal laws a uniformity of faith and worship among their subjects: and it was not till the revolution that any sect in England seems to have fully understood, that all men have an unalienable right to worship God in the manner which to them may seem most suitable to his nature, and the relation in which they stand to him; or that it is impossible to produce uniformity of opinion by any other means than candid disquisition and sound reasoning. That the civil magistrate has a right to check the propagation of opinions which tend only to sap the foundations of virtue, and to disturb the peace of society, cannot, we think, be questioned; but that he has no right to restrain mankind from publicly professing any system of faith, which comprehends the being and providence of God, the great laws of morality, and a future state of rewards and punishments, is as evident as that it is the object of religion to fit mankind for heaven, and the whole duty of the magistrates to maintain peace, liberty, and property, upon earth.

We have elsewhere observed (see TEST), that among a number of different sects of Christians, it is not the superior purity of the system of faith professed by one of them, that gives it a right to the immunities of an establishment in preference to all its rivals; but though the legislature is authorized, in certain circumstances, to make a distinction between the religion of the state, it would be the height of absurdity to suppose that any man, or body of men, can have authority to prevent a purer system from being acknowledged as the religion of individuals. For propagating opinions and pursuing practices which necessarily create civil disturbance, every man is answerable to the laws of his country; but for the soundness of his faith, and the purity of his worship, he is answerable to no tribunal but that which can search the heart.

When churches are established, and creeds drawn up as guides to the preaching of the national clergy, it is obvious that every clergyman who teaches any thing directly contrary to the doctrine of such creeds, violates the condition on which he holds his living, and may be justly deprived of that living, whether his obnoxious opinion be in itself true or false, important or unimportant; but his punishment should be extended no farther. To expel a Christian from private communion for teaching any doctrine which is neither injurious to the state nor contrary to the few simple articles which comprise the sum of the Christian faith, is the grossest tyranny; and the governors of that church which is guilty of it, usurp the prerogative of the blessed Lord, who commanded the apostles themselves not to be called masters in this sense; for one (says he) is your master (Jesus Christ), even Christ. It is indeed a hardship to deprive a man of his living for conscientiously illustrating what he believes to be a truth of the gospel, only because his illustration may be different from that which had formerly been given by men fallible like himself; but if the establishment of human compilations of faith be necessary, this hardship cannot be removed, but by making such compilations as simple as possible, and writing them up in scripture language. Such a reformation, could it be effected peaceably, would serve other good purposes; for while it would sufficiently guard the purity of the faith, it would withdraw that temptation which too many establishments throw in the way of men, to subscribe to the truth of what they do not really believe; and it would effectually banish from the Christian church everything which can be called by the name of persecution. See NONCONFORMISTS.

TOLL, a tax or custom paid for liberty to vend goods in a market or fair, or for keeping roads in proper repair. The first appointment of a toll on highways of which we read, took place in 1346. See ROAD.

TOULOUSE. See TOULOUSE.

TOLU, a town of South America in Terra Firma, and in the government of Carthagenas; famous for the fine balsam of Tolu, brought into Europe from thence, and produced from a tree like a pine. It is seated on a bay of the Carribbean sea, 60 miles south of Carthagenas. W. Long. 75. 25. N. Lat. 9. 45.

TOLUIFERA, the BALSAM-OF-TOLU TREE; a genus of plants belonging to the class of decandria. See BOTANY, p. 182. and CHEMISTRY, N° 2483.

TOMATOES. See SOLANUM, BOTANY Index.

TOMB, includes both the grave or sepulchre wherein a defunct is interred, and the monument erected to preserve his memory. The word is formed from the Greek τάφος, ταφέω, “sepulchre” or “to bury.” See BURIAL.

In many nations it has been customary to bury the bodies of the dead, and to collect the ashes with pious care into an urn, which was deposited in a tomb or sepulchre. See CEMETERY. Among many nations it has also been the practice to lay the dead body in a tomb, without consuming it, after having wrapped it up decently, and sometimes placing it in a coffin. See Coffin.

The tombs of the Jews were generally hollow places hewn out of a rock. Abraham buried Sarah in a cave. Such was the place too in which the kings of Judah and Israel were interred: and such was the place in which the body of our Saviour was deposited by Joseph of Arimathea. But it is probable that the common people buried their dead in graves; for our Saviour compares the Pharisees to “graves which cannot be opened, and the dead which walk over them are not aware of them.” Over the tombs, perhaps only of people of distinction, a stone or monument was erected, to intimate to passengers that they were burying places, that they might not pollute themselves by touching them. With the same intention, as Lightfoot informs us, they whitened them every year on the 15th of February.

The Egyptians also buried their dead in caves, called catacombs. See Catacomb. The pyramids, as some think, were also employed for the same purpose. Sometimes also, after embalming their dead, they placed them in niches in some magnificent apartment in their houses.

The Greeks and Romans burned their dead, and deposited their ashes in a tomb. The Greeks interred the ashes without the cities, by the sides of their highways. Sometimes indeed, by way of particular honour, they were buried in an elevated part of the town; and the Lacadaemonians were allowed by Lycurgus to bury in the city and round their temples: But this was forbidden among the Romans by the law of the twelve tables, In urbe ne sepelito, neve writo; yet Valerius Publicola, Posthumus Tubertius, and the family of the Catulli, were buried in the Capitol. To bury by the sides of public

Digitized by Google
public roads was common among the Romans also; hence their epitaphs frequently began with Siste vivat. Highways were made choice of probably for two reasons: 1. That the dead might not be offensive or injure the health of the living, which they certainly would if buried in towns or populous places; and, 2dly, that they might hold out to travellers a lesson of mortality, and teach the rustic moralist to die.

As it would swell this article to too great a size, to describe all the different kinds of tombs which have been used by different nations and ages, we must content ourselves with shortly describing the tombs of a few nations, and adding a few concomitant circumstances.

The tombs of the Parsees are singular. The deceased, after lying a proper time in his own house, for the purposes of mourning, is carried, followed by his relations and friends, the females chanting a requiem, and deposited in a tomb of the following construction: It is a circular building, open at top, about 55 feet diameter, and 25 feet in height, filled to within 7 feet of the top, excepting a well of 15 feet diameter in the centre. The port is filled with terra-cotta, with a slight declivity toward the well. Two circular grooves three inches deep are raised round the well; the first at the distance of four, the second at ten, feet from the well. Grooves of the like depth or height, and four feet distance from each other at the outer part of the outer circle, are carried straight from the wall to the well, communicating with the circular ones, for the purpose of conveying off the water, &c. The tomb, by this means, is divided into three circles of partitions: the outer, about seven feet by four: the middle six by three: the inner, four by two; the outer for the men, the middle for the women, the inner for the children; in which the bodies are respectively placed, wrapped loosely in a piece of cloth, and left to be devoured by the vultures; which is very soon done, as numbers of these animals are always seen hovering and watching about these charnel houses, in expectation of their prey. The friends of the deceased, or the persons who have charge of the tomb, come, at the proper time, and throw the bones into the receptacle, the well in the centre; for which purpose, iron rakes and tongs are deposited in the tomb. The entrance is closed by an iron door, four feet square, on the eastern side, as high up as the terrace, to which a road is raised. Upon the wall, above the door, an additional wall is raised, to prevent people from looking into the tomb, which the Parsees are particularly careful to prevent. A Persian inscription is on a stone inserted over the door, which we once copied, but have forgotten its tenor. From the bottom of the wall subterraneous passages lead to receive the bones, &c. and prevent the well from filling.

Of the ancient sepulchres found in Russia and Siberia, some are perfect tumuli, raised to an enormous height, while others are almost level with the ground. Some of them are encompassed with a square wall of large quarry stones placed in an erect position; others are covered only with a small heap of stones, or they are tumuli adorned with stones at top. Some are walled with brick within, and vaulted over; others are no more than pits or common graves. In some the earth is excavated several fathoms deep; others, and especially those which are topped by a lofty tumulus, are only dug of a sufficient depth for covering the carcasse. In many of these sepulchres the bones of men, and frequently of horses, are found, and in a condition that renders it probable the bodies were not burnt before they were inhumed. Other bones show clearly that they have been previously burnt; because a part of them is unconsommé, and because they lie in a disordered manner, and some of them are wanting. Urns, in which other nations of antiquity have deposited the ashes of their dead, are never met with here. But sometimes what remained of their bodies after the combustion, and even whole carcasses, are found wrapped up in thin plates of gold.

Many dead bodies are frequently seen deposited together in one tomb; a certain indication that either a battle had been fought in the neighbourhood of the place, or that some families buried their relations in a hereditary tomb.

The Moors, like all other Mahometans, hold it contrary to the spirit of religion to bury their dead in mosques, and to profane the temple of the Most High by the putrefaction of dead bodies. In the infancy of the church the Christians had the like respect for their temples. The burial grounds of the Mahometans are Chéméré's, without the city; the emperors have their sepulchres Moroccos, distant and distant from the mosque, in sanctuaries, built by themselves: their tombs are exceedingly simple.

All Mahometans inter the dead at the hour set apart for prayer. The defunct is not kept in the house, except he expires after sunset; but the body is transported to the mosque, whither it is carried by those who are going to prayer. Each, from a spirit of devotion, is desirous to carry it in his turn. The Moors sing at their burial service; which usage perhaps they have imitated after the Christians of Spain. They have no particular colour appropriated to mourning. Women regularly go on the Friday to weep over and pray at the sepulchres of the dead, whose memory they hold dear.

Among the northern nations it was customary to bury their dead under heaps of stones called Cairns, or under barrows: (See the articles Cairns and Barrow.) The inhabitants of Tibet, it is said, neither bury nor burn their dead, but expose them on the tops of mountains. See Tibet.

TOMBUCTOO, a city of Africa, and capital of a rich and populous country, situated near the Niger, in E. Long. 15° 30' and N. Lat. 16° 30'. Some manufactures, particularly of that of cotton cloth, are carried on in Tombuctoo; and it has a considerable trade with the caravans. Many fruitless attempts have recently been made by European travellers to reach this city, which is supposed to be one of the most considerable in the interior of Africa. See Africa, Supplement.

TOMPION, a sort of hung or cork used to stop the mouth of a cannon. At sea this is carefully encircled with tallow or putty, to prevent the penetration of the water into the bore, whereby the powder contained in the chamber might be damaged or rendered incapable of service.

TON, a measure or weight. See Tun.

TONE, or TUNE, in Music, a property of sound, whereby it comes under the relation of grave and acute;
or the degree of elevation any sound has, from the degree of swiftness of the vibrations of the parts of the sonorous body.

The variety of tones in human voices arises partly from the dimensions of the windpipe, which, like a flute, the longer and narrower it is, the sharper the tone it gives; but principally from the head of the larynx or knot of the throat; the tone of the voice being more or less grave as the rima or cleft thereof is more or less open.

The word tone is taken in four different senses among the ancients: 1. For any sound; 2. For a certain interval, as when it is said the difference between the diapente and diatessaron is a tone; 3. For a certain locus or compass of the voice, in which sense they used the Dorian, Phrygian, Lydian tones; 4. For tension, as when they speak of an acute, grave, or a middle tone.

Tone is more particularly used, in music, for a certain degree or interval of tune, whereby a sound may be either raised or lowered from one extreme of a concord to the other, so as still to produce true melody.

TONGUE. See ANATOMY, No 102.

Tonic, in Music, signifies a certain degree of tension, or the sound produced by a vocal string in a given degree of tension, or by any sonorous body when put in vibration.

Tonic says Rousseau, is likewise the name given by Aristoxen to one of the three kinds of chromatic music, whose divisions he explains, and which was the ordinary chromatic of the Greeks, proceeding by two semitones in succession, and afterwards a third minor.

Tonic Dominant. See DOMINANT.

TONNAGE and POUNDAGE, an ancient duty on wine and other goods, the origin of which seems to have been this: About the 21st of Edward III. complaint was made that merchants were robbed and murdered on the sea. The king thereupon, with the consent of the peers, levied a duty of 2s. on every ton of wine, and 12d. in the pound on all goods imported; which was treated as illegal by the commons. About 25 years after, the king, when the knights of shires were returned home, obtained a like grant from the citizens and burgesses, and the year after it was regularly granted in parliament. These duties were diminished sometimes, and sometimes increased; at length they seem to have been fixed at 3d. tonnage and 1s. poundage. They were at first usually granted only for a stated term of years, as, for two years in 5 Ric. II. but in Henry VI.'s time they were granted him for life by a statute in the 31st year of his reign; and again to Edward IV. for the term of his life also; since which time they were regularly granted to all his successors for life, sometimes at the first, sometimes at other subsequent parliaments, till the reign of Charles I.; when, as the noble historian expresses it, his ministers were not sufficiently solicitous for a renewal of his legal grant. And yet these imposts were imprudently and unconstitutionally levied and taken, without consent of parliament, for 15 years together; which was one of the causes of those unhappy discontent, justifiable at first in too many instances, but which degenerated at last into causeless rebellion and murder. For, as in every other, so in this particular case, the King (previous to the commencement of hostilities) gave the nation ample satisfaction for the errors of his former conduct, by passing an act, whereby he renounced all power in the crown of Tonnage, levying the duty of tonnage and poundage, without the Tonquin, express consent of parliament; and also all power of imposition upon any merchandises whatever. Upon the restoration, this duty was granted to King Charles II. for life, and so it went to his two immediate successors, but now, by three several statutes, 9 Am. c. 6. 1 Geo. I. c. 12 and 3 Geo. I. c. 7, it is made perpetual, and mortgaged for the debt of the public.

TONQUIN, a kingdom of Asia, in the East Indies, beyond the Ganges; bounded on the north by the province of Yunnan in China, on the east by the province of Canton and the bay of Tonquin, on the south by Cochin China, and on the west by the kingdom of Laos. It is about 1300 miles in length and 500 in breadth; and is one of the finest and most considerable kingdoms of the East, as well on account of the number of inhabitants as the riches it contains and the trade it carries on. The country is thick set with villages; and the natives in general are of a middle stature and clean limbed, with a tawney complexion. Their faces are oval and flattish, and their noses and lips well proportioned. Their hair is black, long, lank, and coarse; and they let it hang down their shoulders. They are generally dexterous, nimble, active, and ingenious in mechanical arts. They weave a multitude of fine silks, and make curious lacquer works, which are transported to other countries. There is such a number of people, that many want employment; for they seldom go to work but when foreign ships arrive. The money and goods brought hither by the English and Dutch put them in action; for they have not money of their own sufficient to employ themselves; and therefore one-third at least must be advanced beforehand by the merchants, and the ships must stay here till the goods are finished, which is generally five or six months. They are so addicted to gaming, that when every thing else is lost, they will stake their wives and children. The garments of the Tonquines are made either of silk or cotton; but the poor people and soldiers wear only a sort of a dark tawney colour. Their houses are small and low, and the walls either of mud, or hurdles daubed over with clay. They have only a ground floor, with two or three partitions; and each room has a square hole to let in the light. The villages consist of 30 or 40 houses, surrounded with trees; and in some places there are banks to keep the water from overflowing their gardens, where they have oranges, betels, melons, and salad-herbs. In the rainy season they cannot pass from one house to another without wading through the water; they sometimes have boats. In the capital city called Caloo there are about 20,000 houses with mud walls, and covered with thatch; a few are built with brick, and roofed with pantiles. In each yard is a small arched building like an oven, about six feet high, made of brick, which serves to secure their goods in case of fire. The principal streets are very wide, and paved with small stones. The king of Tonquin has three palaces in it, such as they are; and near them are stables for his horses and elephants. The house of the English factory is seated at the north end of the city, fronting the river, and is the best in the city. The people in general are courteous, and civil to strangers; but the great men are proud, haughty, and ambitious; the soldiers insolent, and the poor thievish. They buy all their
their wives, of which the great men have several; but the poor are stinted for want of money. In hard times the men will sell both their wives and children to buy rice to maintain themselves. The women offer themselves to strangers as wives while they stay, and agree with them for a certain price. Even the great men will offer their daughters to the merchants and officers who are likely to stay six months in the country. They are not afraid of being with child; for if they are girls they can sell them well when they are young, because they are fairs than the other inhabitants. These women are said to be very faithful; and are trusted with money and goods by the Europeans during their absence, and will make great advantage with them. The first new moon in the year which happens after the middle of January, is a great festival; when they rejoice for 10 or 12 days together, and spend their time in all manner of sports. Their common drink is tea, but they make themselves merry with arrack. The language is spoken very much in the throat; and some of the words are pronounced through the teeth, and has a great resemblance to the Chinese. They have several mechanic arts or trades; such as smiths, carpenters, joiners, turners, weavers, tailors, potters, painters, money-changers, paper-makers, workers in lacquer, and bell-founders.—Their commodities are gold, musk, silks, calicoes, drugs of many sorts, woods for dyeing, lacquered wares, earthen wares, salt, aniseeds, and worm-seeds. The lacquered ware is not inferior to that of Japan, which is accounted the best in the world: The chief trade is carried on by the Chinese, English, and Dutch. Tonquin is considered as forming part of the Chinese empire, but established its independence about 1553. From that period it was governed by its own princes till the year 1805, when a long struggle it was finally conquered by the sovereign of Cochín China.

TONSILS. See Anatomy, No 192.

TONTINE, in Ecclesiastical History, a particular manner of shaving or clipping the hair of ecclesiastics or monks. The ancient tonsure of the clergy was nothing more than polling the head, and cutting the hair to a moderate degree, for the sake of decency and gravity: and the same observation is true with respect to the tonsure of the ancient monks. But the Romans have carried the affair of tonsure much farther; the candidate for it kneeling before the bishop, who cuts the hair in five different parts of the head, viz. before, behind, on each side, and on the crown.

TONTINE, a loan given for life annuities with benefit of survivorship; so called from the inventor Lawrence Tonti, a Neapolitan. He proposed his scheme in 1633 to reconcile the people to Cardinal Magazine’s government, by amusing them with the hope of becoming suddenly rich. He obtained the consent of the court, but the parliament would not register the edict. He made attempts afterwards, but without success.

It was not till Louis XIV. was distressed by the league of Augsburg, and by his own immense expenses, that he had recourse to the plans of Tonti, which, though long laid aside, were not forgotten. By an edict in 1685 he created a Tontine royale of 14,000,000 livres annual rent, divided into 14 classes. The actions were 300 livres a piece, and the proprietors were to receive 10 per cent. with benefit of survivorship in every class. This scheme was executed but very imperfectly; for none of the classes rose to above 25,000 livres, instead of 100,000, according to the original institution; though the annuities were very regularly paid. A few years after, the people seeming in better humour for projects of this kind, another tontine was erected upon nearly the same terms, but this was never above half full. They both subsisted in the year 1726, when the French king united the 13th class of the first tontine with the 14th of the second; all the actions of which were possessed by Charlotte Bonneymay, widow of Louis Barbier, a surgeon of Paris, who died at the age of 96. This gentlewoman had ventured 300 livres in each tontine, and in the last year of her life she had for her annuity 75,300 livres, or about 3500l. a year, for about 30 years.

The nature of the tontine is this; there is an annuity, after a certain rate of interest, granted to a number of people; divided into classes, according to their respective ages; so that annually the whole fund of each class is divided among the survivors of that class; till at last it falls to one, and upon the extinction of that life, reverts to the power by which the tontine was erected, and which becomes thereby security for the due payment of the annuities.

TOOLS, among mechanics, denotes in general any instrument used for making other complex instruments and machines, or in other operations of the mechanic arts.

TOOTH, for a description of, see Anatomy, No 27.

TOOTHACH. See Medicine, No 210, and Surgery Index.

TOOTHACH-Tree. See Zanthoxyllum, Botany Index.

TOOTHWORT. See Plumbago, Index.

TOP, a sort of platform, surrounding the lower masthead, from which it projects on all sides like a scaffold.

The principal intention of the top is to extend the topmast shrouds, so as to form a greater angle with the mast, and thereby give additional support to the latter. It is sustained by certain timbers fixed across the hounds or shoulders of the masts, and called the trestle-trees and cross-trees.

Besides the use above mentioned, the top is otherwise extremely convenient to contain the materials necessary for extending the small sails, and for fixing or repairing the rigging and machinery with more facility and expedition. In ships of war it is used as a kind of redoubt, and is accordingly fortified for attack or defence; being furnished with swivels, musketry, and other fire-arms, and guarded by a thick fence of corded hammocks. Finally, it is employed as a place for looking out, either in the day or night.

Top-Mast, the second division of a mast, or that part which stands between the upper and lower pieces. See the article Mast.

Top-Sails, certain large sails extended across the top-masts by the top-sail yard above, and by the yard attached to the lower mast beneath; being fastened to the former by robands, and to the latter by means of two great blocks fixed on its extremities, through which the top-sail-sheets are inserted, passing from thence to two other blocks fixed on the inner part of the yard close.
close by the mast; and from these latter the sheets lead downwards to the deck, where they may be slackened or extended at pleasure. See the article Sails.

TOPAZ, a gem or precious stone. See Mineralogy Index.

TOPE, a species of Squalus. See Ichthyology Index.

Tophet. See Hinnom and Moloch.

Tophus, in Medicina, denotes a chalky or stony concretion in any part of the body; as the bladder, kidney, &c., but especially in the joints.

Topic, a general head or subject of discourse.

Topics, in Oratory. See Oratory, No. 10—13.

Topics, or Topical Medicines, are the same with external remedies, or those applied outwardly to some diseased and painful part: such are plasters, cataplasms, unguents, &c.

Topography, a description or draught of some particular place, or small tract of land, as of a city or town, manor, or township, field, garden, house, castle, or the like; such as surveyors set out in their plots, or make draughts of, for the information and satisfaction of the proprietors.

Topsham, a town in Devonshire, in England, seated on the river Exe, which is navigable; but in time of war was choked up designedly, so that ships are now obliged to load and unload at Topsham. W. Long. 33° 36'. N. Lat. 50° 20'.

Topsey, a fine bay of the English channel, on the coast of Devonshire, a little to the east of Dartmouth, formed by two capes, called Burry Points, and Bob's Nose.

Torda, or Razor-bill. See Alca, Ornithology Index.

Tordylium, Hary-wort, a genus of plants belonging to the class of pentandria, and in the natural system arranged under the 45th order, Umbellata. See Botany Index.

Tories, a political faction in Britain, opposed to the Whigs.

The name of Tories was given to a sort of banditti in Ireland, and was thence transferred to the adherents of Charles II. by his enemies, under the pretense that he favoured the rebels in Ireland. His partisans, to be even with the republicans, gave them the name of Whigs, from a word which signifies whey, in decision of their poor fare. The Tories, or cavaliers, as they were also called, had then principally in view the political interest of the king, the crown, and the church of England; and the round-heads, or Whigs, proposed chinify the maintaining of the rights and interests of the people, and of Protestantism. This is the most popular account; and yet it is certain the names Whig and Tory were but little known till about the middle of the reign of King Charles II. M. de Cire relates, that it was in the year 1678 that the whole nation was first observed to be divided into Whigs and Tories; and that on occasion of the famous deposition of Titus Oates, who accused the Catholics of having conspired against the king and the state, the appellation of Whig was given to such as believ'd the plot real; and Tory to those who held it fictitious.

These parties may be considered either with regard to the state or to religion. The state Tories are either violent or moderate: the first would have the king to be absolute, and therefore plead for passive obedience, non-resistance, and the hereditary right of the house of Stuart. The moderate Tories would not suffer the king to lose any of his prerogative; but then they would not sacrifice those of the people. The state Whigs are either strong republicans or moderate ones. The first (says Rapin) are the remains of the party of the long parliament, who attempted to change monarchy to a commonwealth: but these make so slender a figure, that they only served to strengthen the party of other Whigs. The Tories would persuade the world, that all the Whigs are of this kind; as the Whigs would make us believe that all the Tories are violent. The moderate state Whigs are much in the same sentiments with the moderate Tories, and desire that the government may be maintained on the ancient foundation: all the difference is, that the first bear a little more to the parliament and people, and the latter to that of the king. In short, the old Whigs were always jealous of the encroachments of the royal prerogative, and watchful over the preservation of the liberties and properties of the people.

Tormentilla, Tormentilla, a genus of plants belonging to the class of icossandria, and in the natural system ranging under the 35th order, Scrophulariaceae. See Botany Index.

Tornado, a sudden and vehement gust of wind from one of the points of the compass, frequent on the coast of Guinea.

Torpedo, the Cram-fish. See Catarrh, Ichthyology Index.

Torpor, a numbness, or defect of feeling and motion. Galen says it is a sort of intermediate disorder between palsy and apoplexy.

Torrefaction, in Chemistry, is the roasting or scorching of a body by the fire, in order to discharge a part either unnecessary or hurtful in another operation. Sulphur is thus discharged from an ore before it can be wrought to advantage.

Torrence, denotes a temporary stream of water falling suddenly from mountains, whereon there have been great rains or an extraordinary thaw of snow.

Torricelli, Evangelista, an illustrious Italian mathematician and philosopher, born at Faenza in 1608. He was trained in Latin literature by his uncle a monk; and after cultivating mathematical knowledge for some time without a master, he studied it under Father Benedict Castelli, professor of mathematics at Rome. Having read Galileo's dialogues, he composed a treatise on motion, on his principles, which brought him acquainted with Galileo, who took him home as an assistant; but Galileo died in three months after. He became professor of mathematics at Florence, and greatly improved the art of making telescopes and microscopes: but he is best known for finding out a method of ascertaining the weight of the atmosphere by quicksilver; the barometer being called, from him, the Torricellian tube. He published Opera Geometrica, 1644; and died in 1647.

Torricellian experiment, a famous experiment made by Torricelli, by which he demonstrated the pressure of the atmosphere in opposition to the doctrines of suction, &c. finding that pressure able to support only
TORTOISE. See Testudo, Erpetology Index.

TORTOISE, tortoise-shell, the shell, or rather scales, of the testaceous animal called a tortoise; used in inlaying, and in various other works, as for snuff-boxes, combs, &c. Mr. Catesby observes, that the hard strong covering which incloses all sorts of tortoises, is very improperly called a shell; being of a perfect bony constitution; but covering on the outside with scales, or rather plates, of a horny substance; which are what the workmen call tortoise-shell.

There are two distinct kinds of tortoises, viz. the land and sea tortoise, testudo terrestris and marina. The sea-tortoise, again, is of several kinds; but it is the caretor testudo inicara of Linneus, alone which furnishes that beautiful shell so much admired in Europe.

The shell of the caretta, or hawksbill tortoise, is thick; and consists of two parts, the upper, which covers the back, and the lower the belly: the two are joined together at the sides by strong ligaments, which yet allow of a little motion. In the fore-part is an aperture for the head and fore-legs, and behind for the hind-legs and tail. It is the under shell alone that is used: to separate it, they make a little fire beneath it, and as soon as ever it is warm, the under shell becomes easily separable with a point of a knife, and is taken off in lamina or leaves.

The whole spoils of the caret consist in 13 leaves or scales, eight of them flat, and five a little bent. Of the flat ones, there are four large ones, sometimes a foot long, and seven inches broad. The best tortoise-shell is thick, clear, transparent, of the colour of antimony, sprinkled with brown and white. When used in marquetry, &c. the workmen give it what colour they please by means of coloured leaves, which they put underneath it.

Working and joining of Tortoise-shell.—Tortoise-shell and horn become soft in a moderate heat, as that of boiling water, so as to be pressed, in a mould, into any form, the shell or horn being previously cut into plates of a proper size. Plutarch informs us, in his Art de Turnier, that two plates are likewise united into one by heating and pressing them; the edges being thoroughly cleaned, and made to sit close to one another. The tortoise-shell is conveniently heated for this purpose by applying a hot iron above and beneath the juncture, with the interposition of a wet cloth to prevent the shell from being scorched by the iron: these should be pretty thick, that they may not lose their heat before the union is effected. Both tortoise-shell and horns may be stained of a variety of colours, by means of the colouring drugs commonly used in dyeing, and by certain metallic solutions.

TORTURE, a violent pain inflicted on persons to force them to confess the crimes laid to their charge, or as a punishment for crimes committed.

Torture was never permitted among the Romans except in the examination of slaves: it would therefore appear, that it was a general opinion among them, that a slave had such a tendency to falsehood, that the truth could only be extorted from him. To the disgrace of the professors of Christianity, torture was long practised by those who called themselves Catholics, against those whom they termed heretics; that is, those who differed in opinion from themselves. Finding that they could not bring over others to adopt their sentiments by the force of argument, they judged it proper to compel them by the force of punishment. This practice was very general among orthodox Christians, but especially among Roman Catholics. See Inquisition.

By the law of England, torture was at one period employed to compel those criminals who stood obstinately mute when brought to trial, and refused either to plead guilty or not guilty; but it is now abolished (see Arraignment, and Rack). A history of the machines which have been invented to torture men, and an account of the instances in which they have been employed, would exhibit a dismal picture of the human character.

TORSUS, in Architecture, a large round moulding used in the bases of columns. See Architecture.

TOUCAN. See Rhinastas, Ornithology.

TOUCHE, TOUCHE, among assayers, refiners, &c. little bars of gold, silver, and copper, combined together, in all the different proportions and degrees of mixture; the use of which is to discover the degree of purity of any piece of gold or silver, by comparing the mark it leaves on the touchstone with those of the bars.

The metals usually tried by the touchstone are gold, silver, and copper, either pure, or mixed with one another in different degrees and proportions, by fusion. In order to find out the purity or quantity of base metal in these various admixtures, they are to be examined they are compared with these needles, which are mixed in a known proportion, and prepared for this purpose. The metals of these needles, both pure and mixed, are all made into lamina or plates, one-twelfth of an inch broad, and of a fourth part of their breadth in thickness, and an inch and half long; these being thus prepared, you are to engrave on each a mark indicating its purity, or the nature and quantity of the admixture in it. The black rough marbles, the basaltites, or the softer kinds of black pebbles, are the most proper for touchstones.

The method of using the needles and stone is thus:

The piece of metal to be tried ought first to be wiped well with a clean towel or piece of soft leather, that you may the better see its true colour; for from this alone an experienced person will in some degree, judge beforehand what the principal metal is, and how and with what debased.

Then choose a convenient, not too large, part of the surface of the metal, and rub it several times very hardly and strongly against the touchstone, that in case a deceitful coat or crust should have been laid upon it, it may be worn off by that friction: this, however, is more readily done by a grindsone or small file. Then wipe a flat and very clear part of the touchstone, and rub against it, over and over, the just-mentioned part of the surface of the piece of metal, till you have, on the flat surface of the stone, a thin metallic crust, an inch long, and about an eighth of an inch broad: this done, look out the needle that seems most like to the metal under trial, wipe the lower part of this nee
very clean, and then rub it against the touchstone, as you did the metal, by the side of the other line, and in a direction parallel to it.

When this is done, if you find no difference between the colours of the two marks made by your needle and the metal under trial, you may with great probability pronounce that metal and your needle to be of the same alloy, which is immediately known by the mark engraved on your needle. But if you find a difference between the colour of the mark given by the metal, and that by the needle you have tried, choose another needle, either of a darker or lighter colour than the former, as the difference of the tinge on the touchstone directs; and by one or more trials of this kind you will be able to determine which of your needles the metal answers, and thence what alloy it is of, by the mark of the needle; or else you will find that the alloy is extraordinary, and not to be determined by the comparison of your needles.

TOUCHSTONE. A black, smooth, glossy stone, used to examine the purity of metals. The ancients called it lapis Lydus, the Lydian stone, from the name of the country whence it was originally brought.

Any piece of pebbly or black flint will answer the purposes of the best lapis Lydus of Asia. Even a piece of glass made rough with emery is used with success, to distinguish true gold from such as is counterfeit; both by the metallic colour and the test of aquafortis. The true touchstone is of a black colour, and is not uncommon in many parts of the world.

TOUCHWOOD. See BOLETUS, BOTANY INDEX.

TOULON, a celebrated city and seaport of France, in that part of the late province of Provence which is now denominated the department of the Var. It is a very ancient place, having been founded, according to the common opinion, by a Roman general. It is the chief town of the department, and before the great revolution in 1789 was an episcopal see. The inhabitants were computed at 29,000 in 1817. It is divided into the Old Town and the New Quarter. The first, which is very ill built, has nothing remarkable in it but the Rue aux Ardres, the Tree-Street, which is a kind of course or mall, and the town-house; the gate of this is surrounded by a balcony, which is supported by two termini, the masterpieces of the famous Pouyet. The New Quarter, which forms as it were a second city, contains the magnificent works constructed in the reign of Louis XIV. many fine houses (among which that of the late seminary merits beyond comparison the preference) and a grand oblong square, lined with trees, and serving as a parade.

The Merchants Haven, along which extends a noble quay, on which stands the town-house, is protected by two moleys, begun by Henry IV. The New Haven was constructed by Louis XIV. as were the fortifications of the city. In the front of this haven is an arsenal, containing all the places necessary for the construction and fitting out of vessels: the first object that appears is a rope-walk, entirely arched, extending as far as the eye can reach, and built after the designs of Vauban: here cables are made, and above is a place for the preparation of hemp. Here likewise is the armoury for muskets, pistols, halberds, &c. In the park of artillery are cannon placed in piles, bombs, grenades, mortars, and balls of various kinds, ranged in wonder-

ful order. The long-sail-room, the foundery for cannon, the dockyards, the basons, &c. are all worthy of observation.

Both the Old and New Port have an outlet into the spacious outer road or harbour, which is surrounded by hills, and formed by nature almost circular. Its circuit is of very great extent, and the entrance is defended on both sides by a fort with strong batteries. In a word, the basons, docks, and arsenal, at Toulon, warranted the remark of a foreigner that visited them in the late reign, that "the king of France was greater there than at Versailles." Toulon is the only mart in the Mediterranean for the re-exportation of the products of the East Indies.

This place was destroyed toward the end of the tenth century, and pillaged by the African pirates almost as soon as rebuilt. The constable of Bourbon, at the head of the Imperial troops, obtained possession of it in 1524, as did Charles V. in 1536; but in the next century Charles Emanuel duke of Savoy could not enter it, and Prince Eugene in 1707 ineffectually laid siege to it. This city was surrendered by the inhabitants in September 1793 to the British admiral Lord Hood, as a condition and means of enabling them to effect the re-establishment of monarchy in France, according to the constitution of 1789. Lord Hood accordingly, in conjunction with the Spanish land and naval forces, took possession of the harbour and forts in trust for Louis XVII.

It was garrisoned for some time by the British troops, and their allies the Spaniards, Neapolitans, and Sardinians; but the French having laid seige to it, the garrison was obliged to evacuate the place in the month of December following, after having destroyed the grand arsenal, two ships of 84 guns, eight of 74, and two frigates; and carried off the Commerce de Marseilles, a ship of 120 guns, with an 80 and 74 gun ship. This exploit was most gallantly performed, after it was found impossible to defend the town, or to carry off the ships. Lord Hood entrusted the management of the affair to Sir Sydney Smith, so distinguished for his intrepidity. Captain Hare commanded the fire-ship which was towed into the grand arsenal; and so eager was he to execute his orders, that instead of setting fire to the train in the usual cautious manner, he fired a pistol loaded with powder into the bowl of the train, composed of 35 pounds of powder and other combustibles. The consequence was, he was blown into the water with such violence, as to knock a lieutenant of the Victory's boat overboard, and narrowly escaped with his life. A Spanish captain was appointed to set fire to the small arsenal, but cowardice prevented him from executing his orders; and this is the reason why the whole French ships were not destroyed. We have been favoured with this account by an officer of the British fleet.

Toulon is seated on a bay of the Mediterranean, 17 leagues south-east of Aix, 15 south-east of Marseilles, and 217 south-east of Paris. E. Long. 5° 36'. Lat. 43° 7'.

TOULOUSE, a very ancient city of France, in the department of Upper Garonne, and late province of Languedoc, with an archbishop's see. It is one of the most considerable cities in the south of France, although its population bears no proportion to its extent. In 1817 it was estimated to contain 48,000 inhabitants. The streets are very hand-
TOULOUSE, Tour., some, and the walls of the city, as well as the houses, are built with bricks. The town-house, a modern structure, forms a perfect square, 324 feet long and 266 feet wide. The principal front occupies an entire side of the grand square, lately called the Place Royale. In the great hall, called the Hall of Illustrious Men, is the statue of the Chevalier Isoure, and the busts of all the great men to whom Toulouse has given birth. Communicating with the ocean on one side by the river Garonne, and with the Mediterranean on the other by the canal of Languedoc, Toulouse might have been a great commercial city; but the taste of the inhabitants has been directed to the sciences and belles-lettres. Of course, there are two colleges, two public libraries, and three academies. The little commerce of Toulouse consists in leather, drapery, blankets, mignonets, oil, iron, mercury, hardware, and books. The bridge over the Garonne is at least equal to those of Tours and Orleans; it forms the communication between the suburb of St. Cyprian and the city. A bloody battle was fought at Toulouse on the 10th April 1814, between the British army under Lord Wellington, and the French army under Soulé, in which the latter was defeated with great loss. Toulouse is 37 miles east of Auch, 125 southeast of Bordeaux, and 350 south-west of Paris.

TOUR, Henry de la, Viscount Turenne, was the second son of Henry de la Tour duke of Bouillon, and was born at Sedan in 1611. He made his first campaigns in Holland, under Maurice and Frederic Henry princes of Orange; who were his uncles by the mother's side; and even then distinguished himself by his bravery. In 1634 he marched with his regiment into Lorraine; and having contributed to the taking of La Motte, was, though very young, made maréchal de camp. In 1636 he took Saverne, and the year following the castles of Hisson and Sole; on which occasion he performed an action like that of Scipio's, with respect to a very beautiful woman whom he sent back to her husband. The viscount Turenne continued to distinguish himself in several sieges and battles, and in 1644 was made marshal of France; but had the misfortune to be defeated at the battle of Marienfeld in 1645. However, he gained the battle of Nordlingen three months after; restored the elector of Treves to his dominions; and the following year made the famous junction of the French army with that of Sweden commanded by General Wrangel, which obliged the duke of Bavaria to demand a peace. Afterwards that duke breaking the treaty he had concluded with France, he was defeated by the viscount Turenne at the battle of Zumarhauseen, and in 1648 driven entirely out of his dominions. During the civil wars in France, he sided with the princes, and was defeated at the battle of Rhétel in 1650; but soon after was restored to the favour of the king, who in 1652 gave him the command of his army. He acquired great honour at the battles of Jersens, Gren, and the suburbs of St. Anthony, and by the retreat he made before the army commanded by the princes at Ville Voile St. George. In 1654 he made the Spaniards raise the siege of Arras: the next year he took Conde, St. Guilian, and several other places; gained the famous battle of Donez; and made himself master of Dunkirk, Oudenarde, and almost all Flanders: this obliged the Spaniards to con-

TOURNELENE, a province of France, bounded on the north by Maine, on the east by Orleans, on the south by Berris, and on the west by Ajon and Poitou. It is about 38 miles in length, and 55 in breadth where it is broadest. This country is watered by 17 rivers, besides many brooks, which not only render it delightful, but keep up a communication with the neighbouring provinces. The air is temperate, and the soil is so fruitful that it is called the garden of France. It now forms the department of Indre and Loire, of which Tours is the capital.

TOURMALINE, a species of mineral belonging to the siliceous genus. See MINERALOGY INDEX.

TOURNAMENT, a martial sport or exercise which the ancient cavaliers used to perform, to show their bravery and address. It is derived from the French word tourner, i.e. "to turn round," because to be expert in these exercises, much agility both of horse and man was requisite, they riding round a ring in imitation of the ancient Circus.

The first tournaments were only courses on horseback, wherein the cavaliers tilted at each other with cones in manner of lances; and were distinguished from jousts, which were courses or careers, accompanied with attacks and combats, with blunted lances and swords. See JUST.

The prince who published the tournament, used to send a king at arms, with a safe-conduct, and a sword, to all the princes, knights, &c. signifying that he intended a tournament and clashing of swords, in the presence of ladies and damsel's; which was the usual formula of invitation.

They first engaged man against man, and then troop against troop; and, after the combat, the judges allotted the prize to the best cavalier, and the best striker of swords; who was accordingly conducted in pomp to the lady of the tournament; where, after thanking her very reverently, he saluted her and likewise her two attendants.

These tournaments made the principal diversion of the 13th and 14th centuries. Munster says, it was Henry the Fowler, duke of Saxony, and afterwards emperor, who died in 976, that first introduced them, but it appears from the chronicle of Tours, that the true inventor of this famous sport, at least in France, was one Geoffrey, lord of Preuill, about the year 1066.
TOURNEFORT, Joseph Pitton de, a famous French botanist, was born at Aix in Provence in 1636. He had a passion for plants from his childhood, which overcame his father's views in putting him to study philosophy and divinity; therefore on his death he quitted theology, and gave himself up entirely to physics, natural history, and botany. He wandered over the mountains of Dauphiny, Savoy, Catalonia, the Pyrenees, and the Alps, in search of new species of plants, which he acquired with much fatigue and danger. His fame in 1683 procured him the employment of botanic professor, in the king's garden; and by the king's order, he travelled into Spain, Portugal, Holland, and England, where he made prodigious collections of plants. In 1750, Mr Tournefort, in obedience to another order, simplord over all the isles of the Archipelago, upon the coasts of the Black sea, in Bithynia, Pontus, Cappado-
cia, Armenia, and Georgia; making observations on natural history at large, and modern geography, religion, manners, and commerce. He spent three years in this learned voyage; and then resuming his profession, was made professor of physic in the college-
royal.
He died in consequence of an accidental crush
of his breast by a cart-wheel, which brought on a spitting of blood and hydrothorax, that carried him off in 1758. He wrote Elements of Botany, both in French and Latin; A relation of his Voyage into the Levant; with other pieces of less consideration.

TOURNIQUET, in Surgery, an instrument form-
ed with screws, for compressing any part with rollers, &c for the stopping of hemorhages. See SUCTOR

INDEX.

TOWER, a tall building consisting of several sto-
ries, usually of a round form, though some are square or polygonal. Towers are built for fortresses, &c. as the Tower of London. See LONDON, N° 46.

TOWN, a place inhabited by a considerable num-
er of people, being of a middle size between a city and a village.

TOXICODENDRON. See RHUS, BOTANY INDEX.

TRAAS. See TERRAS.

TRACHEA. See ANATOMY, N° 119.

TRACHINUS, the Weever, a genus of fishes be-
ongling to the order of jugulares. See ICHTHYOLOGY

INDEX.

TRACT, in Geography, an extent of ground, or a
portion of the earth's surface.

TRACT, in matters of literature, denotes a small trea-
tise or written discourse upon any subject.

TRADE, in general, denotes the same with com-
merce, consisting in buying, selling, and exchanging of
commodities, bills, money, &c. See COMMERCE, COIN,
MONEY, COMPANY, &c.

TRADE-WINDS, denote certain regular winds at sea,
blowing either constantly the same way, or alternately
this way and that; thus called from their use in naviga-
tion, and the Indian commerce. See METEOROLOGY.

TRADESMEN'S TOKENS, a term synonymous am-
ong medallists with provincial coins.

This is a subject curious enough to deserve attention, though we will not go so far as Mr Pinkerton does, who says that it is a subject in which the perpetual glory of the nation is interested. Since the year 1789 provincial halfpence have been made and circulated in considerable quantity. As ancient medals and coins have been frequently of use to historians, it is to be regretted that many of these provincial halfpence are rendered useless in this respect by unmeaning figures and puerile devices. Utility and elegance ought to be studied: for this view it has been proposed by a gentleman of taste on this subject, that all coins should be distinguished by one of the following five characteristics. 1. Fac similes of magnificent beautiful buildings. 2. Representations of great and useful undertakings. 3. Emblems of the
industry and commerce of the age. 4. The illustrious
men, &c. to whom the nation has given birth. 5. Impor-
tant historical events.

TRADITION, something handed down from one
generation to another without being written. Thus the
TRADITION. See Astragali, Materia Medica Index.

TRAGEDY, a dramatic poem, representing some signal action performed by illustrious persons, and which has frequently a fatal issue or end. See Poetry, Part II. sect. 1.

TRAGI-COMEDY; a dramatic piece, partaking both of the nature of tragedy and comedy; in which a mixture of merry and serious events is admitted.

TRAGOPOGON, Goat's-Beard; a genus of plants belonging to the class of syngecosia; and in the natural system ranging under the 49th order Compositae. See Botany Index.

TRAJAN, Marcus Ulpia, a celebrated Roman emperor, who gained many victories over the Parthians and Germans, pushing the empire to its utmost extent on the east and north sides. He died at Silinunte, a city of Sicilia, which from him was called Trajanopolis, in the year 117.

Trajan's Column, a famous historical column erected in Rome, in honour of the emperor Trajan. It is of the Tuscan order, though somewhat irregular: its height is eight diameters, and its pedestal Corinthian; it was built in a large square called Forum Romanum. Its base consists of 12 stones of enormous size, and is raised on a socle, or foot, of eight steps: within the side is a staircase illuminated with 44 windows. It is 140 feet high, which is 35 feet short of the Antonine column, but the workmanship of the former is more much valued. It is adorned from top to bottom with baso relieves, representing the great actions of the emperor against the Dacians.

TRAIN, a line of gunpowder laid to give fire to a magazine thereof, in order to do execution by blowing up earth, works, buildings, &c.

Train of Artillery, includes the great guns and other pieces of ordnance belonging to an army in the field.

Train-Oil, the oil procured from the blubber of a whale by boiling.

TRALLIAN, Alexander, a Greek writer on physics, a native of Trales in Lydia, who lived about the middle of the sixth century. His works are divided into 12 books; in which he treats of distempers as they occur from head to foot. He was the first who opened the jugular vein, and that used cannicides as a blister for the gout. Dr Freind, in his History of Physic, styles him one of the most valuable authors since the time of Hippocrates. Though he appears on the whole to have been a rational physician, yet there are things in his writings that savour of enthusiasm and superstition.

TRA-LOS-MONTES, a province of Portugal, called in Latin Transmontana, because situated on the east side of a chain of hills that separate it from Entre Duero et Minho. It is bounded on the north by Galicia; on the south by the provinces of Beira and León; by the last of which it is bounded also to the east. Its length from north to south is upwards of 120 miles, and its breadth about 80. It is full of mountains, and produces little corn, but plenty of wine, fruits of several sorts, and abundance of game.

TRANSACTIONS, a name generally given to a collection of the papers read before literary or philosophical societies. The name of Philosophical Transactions was first adopted by the Royal Society of London. The Philosophical Transactions to the end of the year 1700 were abridged in three volumes by Mr John Lowthorp: those from the year 1700 to 1720 were abridged in two volumes by Mr Henry Jones; those from 1719 to 1733 were abridged in two volumes by Mr John Eames and Mr John Martyn; Mr Martyn continued the abridgement of those from 1732 to 1744 in two volumes, and of those from 1743 to 1750 in two volumes.

They were for many years published in numbers, and the printing of them was always, from time to time, the single act of the respective secretaries, till the year 1752, when the society thought fit that a committee should be appointed to reconsider the papers read before them, and to select out of them such as they should judge most proper for publication in the future Transactions. They are published annually in two parts at the expense of the society, and each fellow is entitled to receive one copy gratis of every volume published after his admission into the society.

They were first set on foot in 1665, by Mr Oldenburg, secretary of the society, and were continued by him till the year 1677. Upon his death, they were discontinued till January 1678, when Dr Crew resumed the publication of them, and continued it for the months of December 1678, and January and February 1679, after which they were interrupted till January 1685. During this last interval they were supplied in some measure by Dr Hooke's Philosophical Collections. They were also interrupted for three years, from December 1687 to January 1691, beside other smaller interruptions, amounting to near one year and a half more, before October 1695, since which time the Transactions have been regularly carried on.

TRANSCENDENTAL, or Transcendent, something elevated, or raised above other things; which passes and transcends the nature of other inferior things.

TRANSCRIPT, a copy of any original writing, particularly that of an act or instrument inserted in the body of another.

TRANSFER, in commerce, an act whereby a person surrenders his right, interest, or property, in any thing moveable or immovable, to another.

TRANSFORMATION, in general, denotes a change of form, or the assuming a new form different from a former one.

TRANSFUSION, the act of pouring a liquor out of one vessel into another.

Transfusion of Blood, an operation by which it was some time ago imagined that the age of animals would be renewed, and immortality, or the next thing to it, conferred on those who had undergone it. The method of transfusing Dr Lowder gives us to the following effect: take up the carotid artery of the dog, or other animal, whose blood is to be transfused into another of the same, or a different kind: separate it from the nerver of the eighth pair, and lay it bare above
TRANSIT, from transit, "it passes over," signifies the passage of any planet over the sun, moon, or stars.

TRANSITION, the passage of any thing from one place to another.

TRANSITION, in Oratory. See Oratory, No. 39.

TRANSITIVE, in Grammar, an epithet applied to such verbs as signify an action which passes from the subject that does it, to or upon another subject which receives it. Under the head of verbs transitive come what we usually call verbs active and passive; other verbs, whose action does not pass out of themselves, are called neuters.

TRANSLATION, the act of transferring or removing a thing from one place to another; as we say, the translation of a bishop's see, a council, a seat of justice, &c.

TRANSLATION is also used for the version of a book or writing out of one language into another.

The principles of translation have been clearly and accurately laid down by Dr. Campbell of Aberdeen in his invaluable Preliminary Dissertations to his excellent translations of the gospels. The fundamental rules which he establishes are three: 1. That the translation should give a complete transcript of the ideas of the original. 2. That the style and manner of the original should be preserved in the translation. 3. That the translation should have all the ease of original composition. The rules deducible from these general laws are explained and illustrated with much judgment and taste, in an Essay on the Principles of Translation, by Mr. Tytler, judge-advocate of Scotland.

TRANSMARINE, something that comes from or belongs to the parts beyond sea.

TRANSMIGRATION, the removal or translation of a whole people into another country, by the power of a conqueror.

TRANSMIGRATION is particularly used for the passage of the soul out of one body into another. See Metempsychosis.

TRANSMUTATION, the act of changing one substance into another.

Nature, says Sir Isaac Newton, is delighted with transmutation: water, which is a fluid, volatile, tasteless salt, is, by heat, transmuted into vapour, which is a kind of air; and by cold into ice, which is a cold, transparent, brittle stone, easily dissolvable; and this stone is convertible again into water by heat, as vapour is by cold.—Earth, by heat, becomes fire, and, by cold, is turned into earth again: dense bodies, by fermentation, are rarefied into various kinds of air; and that air, by fermentation also, and sometimes without it, reverts into gross bodies. All bodies, beasts, fishes, plants, &c. with all the various parts, grow and increase out of water and aqueous and saline tinctures; and, by putrefaction, all of them revert into water, or an aqueous liquor again.

TRANSMUTATION, in alchemy, denotes the act of changing imperfect metals into gold or silver. This is also called the grand operation; and, they say, it is to be effected with the philosopher's stone.

The trick of transmuting cinnabar into silver is thus: the cinnabar, being bruised grossly, is stratified in a crucible with granulated silver, and the crucible placed in a great fire; and, after due time for calculation, taken off; then the matter, being poured out, is found to be cinnabar.
dergone various revolutions; but it now belongs to the
house of Austria. The inhabitants are of several sorts
of religions; as Papists, Lutherans, Calvinists, Socini-
anists, Photinians, Arians, Greeks, and Mahometans.
It is about 162 miles in length, and 150 in breadth.
The administration of affairs is conducted by twelve
persons; namely, three Roman Catholics, three Lutherans,
three Calvinists, and three Socinians. The militia is
commanded by the governor, whose commission is the more
important, as Transylvania is the bulwark of Christen-
dom. It is divided into several small districts, called
polonates and counties; and its inhabitants, who con-
sist of Saxons, Silesians, and Hungarians, amounted to
1,655,400 in 1805, Hermanstadt is the capital town.

TRAPEZIUM, in Geometry, a plane figure con-
tained under four unequal right lines.

TRAPEZIUS, a muscle. See Anatomy, Part II.

TRAPP, a compound rock. See Geology.

TRAVELLERS' JOY. See Clematis, Botany Index.

TRAVERSE, or Transverse, in general, denotes
something that goes athwart another; that is, across
and cuts it obliquely.

TRAVERSE, in Navigation, implies a compound
course, or an assemblage of various courses, lying at
different angles with the meridian. See Navigation.

TRAVERSE BOARD, a thin circular piece of board,
marked with all the points of the compass, and having
eight holes bored in each, and eight small pegs hang-
ing from the centre of the board. It is used to de-
termined the different courses run by a ship during
the period of the watch, and to ascertain the distance
of each course.

TRAVESTY, a name given to a humorous transla-
tion of any author. The word is derived from the
French travestier, "to disguise."

TREACLE, or MELASSES. See Sugar.

TREACLE BEER. See Spruce.

TREACLE MUSTARD. See CLYPEOLA, Botany Index.

TREASON, a general appellation, made use of
by the law, to denote not only offences against the king
and government, but also that accumulation of guilt
which arises whenever a superior repose a confidence
in a subject or inferior, between whom and himself
there subsists a natural, a civil, or even a spiritual rela-
tion; and the inferior so abuses that confidence, so
forgets the obligations of duty, subjection, and allegiance,
as to destroy the life of any such superior or lord. Hence
treason is of two kinds, high and petty.

High Treason, or Treason Paramount (which is equi-
valent to the crimen lese majestatis of the Romans, as
Gianvii denominates it also in our English law), is an
offence committed against the security of the king or
kingdom, whether by imagination, word, or deed. In
order to prevent the inconveniences which arose in En-
gland from a multitude of constructive treasons, the sta-
tute 25 Edw. III c. 2. was made; which defines what
offences only for the future should be held to be trea-
son; and this statute comprehends all kinds of high-
treason under seven distinct branches.

1. When a man doth compass or imagine the death
of our lord the king, of our lady his queen, or of
their eldest son and heir." Under this description it is held
that a queen-regnant (such as Queen Elizabeth and
Queen
TREASEN. \[ 462 \]  

Queen Anne) is within the words of the act, being invested with royal power, and intitled to the allegiance of her subjects: but the husband of such a queen is not comprised within these words; and therefore no treason can be committed against him.

Let us next see what is a compassing or imagining the death of the king, &c. These are synonymous terms: the word compass signifying the purpose or design of the mind or will; and not, as in common speech, the carrying such design to effect. And therefore an accidental stroke, which may mortally wound the sovereign, per infortunium, without any traitorous intent, is no treason: as was the case of Sir Walter Tytrel, who, by the command of King William Rufus, shooting at a hart, the arrow glanced against a tree, and killed the king upon the spot. But as this compassing or imagining is an act of the mind, it cannot possibly fall under any judicial cognizance, unless it be demonstrated by some open or overt act. The statute expressly requires, that the accused be thereof upon sufficient proof attainted of some open act by men of his own condition. Thus, to provide weapons or ammunition for the purpose of killing the king, is held to be a palpable overt act of treason in imagining his death. To conspire to imprison the king by force, and move towards it by assembling company, is an overt act of compassing the king’s death; for all force used to the poison of the king, in its consequence may tend to his death, and is a strong presumption of something worse intended than the present force, by such as have so far thrown off their bounden duty to their sovereign: it being an old observation, that there is generally but a short interval between the prisons and the graves of princes. It seems clearly to be agreed, that by the common law and the statute of Edw. III., words spoken amount only to a high misdemeanor, and no treason. For they may be spoken in heat, without any intention; or be mistaken, perverted, or misrepresented by the hearers; their meaning depends always on their connection with other words and things; they may signify differently even according to the tone of voice with which they are delivered; and sometimes silence itself is more expressive than any discourse. As therefore there can be nothing more equivocal and ambiguous than words, it would indeed be unreasonable to make them amount to high treason. And accordingly, in 4 Car. I. on a reference to all the judges, concerning some very atrocious words spoken by one Pyne, they testified to the king, “that though the words were as wicked as might be, yet they were no treason; for unless it be by some particular statute, no words will be treason.” If the words be set down in writing, it argues more deliberate intention; and it has been held, that writing is an overt act of treason; for scribere est cogere. But even in this case the bare words are not the treason, but the deliberate act of writing them.

2. The second species of treason is, “if a man do violate the king’s companion, or the king’s eldest daughter unmarried, or the wife of the king’s eldest son and heir.” By the king’s companion is meant his wife: and by violation is understood carnal knowledge, as well without force as with it: and this is high treason in both parties.

3. The third species of treason is, “if a man do levy war against our lord the king in his realm.” And this may be done by taking arms, not only to dethrone the king, but under pretense to reform religion, or the laws, or to remove evil counsellors, or other grievances whether real or pretended. For the law does not, neither can it permit any private man, or set of men, to interfere forcibly in matters of such high importance; especially as it has established a sufficient power for these purposes in the high court of parliament: neither does the constitution justify any private or particular resistance for private or particular grievances; though, in cases of national oppression, the nation has very justifiably risen as one man, to vindicate the original contract subsisting between the king and his people.

4. “If a man be adherent to the king’s enemies in his realm, giving them aid and comfort in the realm or elsewhere,” he is also declared guilty of high-treason. This must likewise be proved by some overt act; as by giving them intelligence, by sending them provisions, by telling them arms, by treacherously surrendering a fortress, or the like.

5. “If a man counterfeit the king’s great or privy seal,” this is also high-treason. But if a man takes wax bearing the impression of the great seal off from one patent, and fixes it to another, this is held to be only an abuse of the seal, and not a counterfeiting of it: as was the case of a certain chaplain, who in such a manner framed a dispensation for non-residence. But the knavish artifice of a lawyer much exceeded this of the divine. One of the clerks in chancery glued together two pieces of parchment; on the uppermost of which he wrote a patent, to which he regularly obtained the great seal, the label going through both the skins. He then dissolved the cement, and taking off the written patent, on the blank skin, wrote a fresh patent of a different import from the former, and published it as true. This was held no counterfeiting of the great seal, but only great misprision; and Sir Edward Coke mentions it with some indignation that the party was living at that day.

6. The sixth species of treason under this statute is, “if a man counterfeit the king’s money; and if a man bring false money into the realm counterfeit to the money of England, knowing the money to be false, to merchandise and make payment withal.” As to the first branch, counterfeiting the king’s money: this is treason, whether the false money be uttered in payment or not. Also if the king’s own minters alter the standard or alloy established by law, it is treason. But gold and silver money only are held to be within this statute.

With regard likewise to the second branch, importing foreign counterfeit money in order to utter it here; it is held that uttering it, without importing it, is not within the statute.

7. The last species of treason ascertained by this statute is, “if a man slay the chancellor, treasurer, or the king’s justices of the one bench or the other, justices in eyre, or justices of assize, and all other justices assigned to hear and determine, being in their places doing their offices.” These high magistrates, as they represent the king’s majesty during the execution of their offices, are therefore for the time equally regard the law. But this statute extends only to the actual killing of them: and not to wounding, or a bare attempt to kill them. It extends also only to the officers therein specified; and therefore the barons of the exchequer, as such, are not within
TREASON
within the protection of this act; but the lord keeper or
commissioner of the great seal now seem to be within
by virtue of the statutes 5 Eliz. c. 18. and 1 W. and
M. c. 21.

The new treasons, created since the statute 1 M. c. 11.
and not comprehended under the description of statute
25 Edw. III. may be comprised under three heads. The
first species relates to Papists; the second to falsifying
the coin or any royal signature, as falsely forging the
sign manual, privy signet, or privy seal, which shall be
deemed high treason (1 M. stat. ii. c. 6.). The third
new species of high treason is such as was created for
the security of the Protestant succession in the house of
Hanover. For this purpose, after the act of settlement
was made, it was enacted by statute 13 and 14 W. III.
c. 3. that the pretended prince of Wales, assuming the
title of King James III. should be attainted of high trea-
sion; and it was made high treason for any of the king's
subjects to hold correspondence with him or any person
employed by him, or to remit money for his use. And
by 17 Geo. II. c. 39. it is enacted, that if any of the
sons of the pretender shall land or attempt to land in
this kingdom, or be found in the kingdom or any of
its dominions, he shall be adjudged attainted of high-
treason, and corresponding with them or remitting money
to their use is made high treason. By 1 Ann. stat. 2.
c. 17. the offence of hindering the next in succession
from succeeding to the crown is high treason: and by
6 Ann. c. 7. if any person shall maliciously, advisedly,
and directly, by writing or printing, maintain, that any
other person hath any right to the crown of this realm,
otherwise than according to the act of settlement, or
that the kings of this realm with the authority of par-
liament are not able to make laws to bind the crown
and its descent; such person shall be guilty of high-
treason.

The punishment of high treason in general is very so-
lemn and terrible. 1. That the offender be drawn to
the gallows, and not be carried or walk; though usual-
ly (by cavillance, at length ripened by humanity into
law) a slide or hurdle is allowed, to preserve the of-
fender from the extreme torment of being dragged on
the ground or pavement. 2. That he be hanged by the
neck, and then cut down alive. 3. That his entrails be
taken out, and burned while he is yet alive. 4. That
his head be cut off. 5. That his body be divided into
four parts. 6. That his head and quarters be at the
king's disposal.

The king may, and often doth, discharge all the pun-
ishment except beheading, especially where any of noble
blood are attainted. For beheading being part of the
judgment, that may be executed, though all the rest be
omitted by the king's command. But where beheading
is no part of the judgment, as in murder or other fel-
ocies, it hath been said that the king cannot change the
judgment, although at the request of the party, from one
species of death to another.

In the case of coining, which is a treason of a diffe-
rent complexion from the rest, the punishment is milder
for male offenders; being only to be drawn and hanged
by the neck till dead. But in treasons of every kind,
the punishment of women is the same, and different from
that of men. For as the natural modesty of the sex for-
bits the exposing and publicly mangling their bodies;
their sentence (which is to the full as terrible to sense as
the other) is to be drawn to the gallows, and there to be
burned alive.

For the consequences of this judgment, see ATTAIN-
der, FORFEITURE, and CORRUPTION OF Blood.

Petty or Petit Treason, according to the statute 25
Edward III. c. 2. may happen three ways: by a serv-
ant killing his master, a wife her husband, or an eccle-
siastical person (either secular or regular) his superior,
to whom he owes faith and obedience. A servant who
kills his master whom he has left, upon a grudge con-
ceived against him during his service, is guilty of petty
treason: for the traitorous intention was hatched while
the relation subsisted between them, and this is only an
execution of that intention. So if a wife be divorced
a mensa et thoro, still the vinculum matrimonii subsists;
and if she kills such divorced husband, she is a traitress.

And a clergyman is understood to owe canonical obe-
dience to the bishop who ordained him, to him whom
in whose diocese he is benedicted, and also to the metropoli-
tan of such suffragan or diocesan bishop; and therefore to kill
any of these is petty treason. As to the rest, whatever
has been said with respect to wilful MURDER, is also
applicable to the crime of petit treason, which is no other
than murder in its most odious degree; except that
the trial shall be as in cases of high treason, before
the improvements therein made by the statutes of Wil-
liam III. But a person indicted of petit treason may be
acquitted thereof, and found guilty of manslaughter
or murder: and in such case it should seem that two
witnesses are not necessary, as in cases of petit treason
they are. Which crime is also distinguished from mur-
der in its punishment.

The punishment of petit treason in a man, is to be
drawn and hanged, and in a woman to be drawn and
burned: the idea of which latter punishment seems to
have been handed down to us from the laws of the an-
cient Druids, which condemned a woman to be burned
for murdering her husband; and it is now the usual
punishment for all sorts of treasons committed by those
of the female sex. Persons guilty of petit treason were
first debarr'd the benefit of clergy by statute 12 Henry
VII. c. 7. which has since been extended to their aiders,
abetors, and counsellors, by statutes 23 Henry VIII. c.
1, 4, and 5 P. and M. c. 4.

TREASURE, in general, denotes a store or stock of
money in reserve.

Treasure-Trove, in Law, derived from the French
word trover, "to find," called in Latin theaurus inven-
tus, is where any money or coin, gold, silver, plate, or
bullion, is found hidden in the earth or other private
place, the owner thereof being unknown; in which case
the treasure belongs to the king; but if he that had hid
it be known, or afterwards found out, the owner and not
the king is intitled to it.

Treasurer, an officer to whom the treasure of a
prince or corporation is committed to be kept and duly
disposed of, in payment of officers and other expences.
See Treasury.

Of these there is great variety. His majesty of Great
Britain, in quality of elector of Hanover, is arch-tre-
surer of the Roman empire. In England, the principal
officers under this denomination are, the lord high-tre-
surer, the treasurer of the household, treasurer of the
navy, of the king's chamber, &c.

The lord high-treasurer of Great Britain, or first com-
missioner

Trees sometimes attain a very great size: this must depend in a great measure on the richness of soil, but no less on the degree of soil. Indeed heat is so essential to the growth of trees, that as we go from the place within the polar circles where vegetation begins, and advance to the equator, we find the trees increase in size. Greenland, Iceland, and other places in the same latitude, yield no trees at all; and the shrubs which they produce are dwarfed; whereas, in warm climates, they often grow to an immense size. Mr. Marshall saw spruce and silver firs in the dock-yard in Venice above 40 yards long, and one of 39 yards was 18 inches diameter at the small end. He was informed that they came from Switzerland.

The largest tree in Europe, mentioned by travellers, is the chestnut tree on Mount Etna, already described under the article Etna, No. 18. It is a certain fact that trees acquire a very great size in volcanic countries. Besides the multitude of fine groves in the neighbourhood of Albano in Italy, there are many detached oaks 20 feet in circumference, and many elms of the same size, especially in the romantic way to Castello, called the Galleria. In travelling by the side of the lake of Bolsena, the road leads through an immense number of oaks, spread upon beautiful hills. Where the lava has been sufficiently softened, they are clean and straight, and of a considerable size; but where the lava has not been converted into a soil proper for strong vegetation, they are round-headed, and of less size; however, taken all together, they make a magnificent appearance; and the spot itself ought to be ranked among the fine parts of Italy. The same may be observed of the small lake of Vico, encompassed with gentle risings, that are all clothed with forest-trees.

Some yews have been found in Britain 60 feet round. Palms in Jamaica attain the height of 200 feet; and some of the pines in Norfolk island are 280 feet high.

Of all the different kinds known in Europe, oak is best for building; and even when it lies exposed to air and water, there is none equal to it. Fir timber is the next in degree of goodness for building, especially in Vol. XX. Part II.
Some advise the planks of timber to be laid for a few days in some pool or running stream, in order to extract the sap, and afterwards to dry them in the sun or air. By this means, it is said, they will be prevented from either chopping, casting, or cleaving; but against shrinking there is no remedy. Some again are for burying them in the earth, others in a boat; and some for scooping and seasoning them in fire, especially piles, posts, &c., which are to stand in water or earth. The Venetians first found out the method of seasoning by fire; which is done after this manner: They put the piece to be seasoned into a strong and violent flame; in this they continually turn it round by means of an engine, and take it out when it is everywhere covered with a black coaly crust; the internal part of the wood is thereby so hardened, that neither earth nor water can damage it for a long time afterwards.

Dr. Plot says, it is found by long experience, that the trunk or body of the trees, when barked in the spring, and left standing naked all the summer exposed to the sun and wind, are so dried and hardened, that the rainy part in a manner becomes as firm and durable as the heart itself. This is confirmed by M. Buffon, who, in 1738, presented to the Royal Academy of Sciences at Paris a memoir entitled, "An easy method of increasing the solidity, strength, and duration of timber," for which purpose he observes, "nothing more is necessary than to strip the tree entirely of its bark during the season of the rising of the sap, and to leave it to dry completely before it be cut down."

By many experiments, particularly described in that essay, it appears, that the tree should not be felled till the third year after it has been stripped of the bark; that it is then perfectly dry, and the sap become almost as strong as the rest of the timber, and stronger than the heart of any other oak tree which has not been so stripped; and the whole of the timber stronger, heavier, and harder; from which he thinks it fair to conclude, that it is also more durable. "It would no longer be adds be necessary, if this method were practiced, to cut off the sap; the whole of the tree might be used as timber; one of 40 years growth would serve all the purposes for which one of 60 years is now required; and this practice would have the double advantage of increasing the quantity, as well as the strength and solidity of the timber."

The navy board, in answer to the inquiries of the commissioners of the land revenue, in May 1789, informed them, that they had then standing some trees stripped of their bark two years before, in order to try the experiment of building one half of a ship of war with that timber, and the other half with timber felled and stripped in the common way. This very judicious mode of making the experiment, if it be properly executed, will undoubtedly go far to ascertain the effects of this practice. We are sorry that we are not able to inform our readers what was the result of the experiment.

After the planks of timber have been well seasoned and fixed in their places, care is to be taken to defend or preserve them; to which the smearing them with live oil, turpentine, or the like oelaginous matter, contributes much. The ancients, particularly Hesiod and Virgil, advise the smoke-drying of all instruments made of wood, by hanging them up in the chimneys where wood fires are used. The Dutch preserve their gates, portcullises, drawbridges, sluices, &c., by coating them over with a mixture of pitch and tar, wherein they strew small pieces of cockle and other shells, beaten almost to powder, and mixed with sea-sand, which incrusts and arms them wonderfully against all assaults of wind and weather. When timber is felled before the sap is perfectly at rest, it is very subjected to worms; but to prevent and cure this, Mr. Evelyn recommends the following remedy as the most approved: Put common sulphur into a cucurbit, with as much aquafortis as will cover it three fingers deep; distil it to dryness, which is performed by two or three rectifications. Lay the sulphur that remains at bottom, being of a blackish or sand-red colour, on a marble, or put it in a glass, and it will dissolve into an oil; with this oil anoint the timber which is infected with worms. This, he says, will not only prevent worms, but preserve all kinds of woods, and many other things, as ropes, nets, and masts, from putrefaction, either in water, air, or snow.

An experiment to determine the comparative durability of different kinds of timber, when exposed to the weather, was made by a nobleman in Norfolk; of which an account is given by Sir Thomas Bever. This nobleman, in the year 1774, ordered three posts, forming two sides of a quadrangle, to be fixed in the earth on a rising ground in his park. Into these posts were mortised planks, an inch and a half thick, cut out of trees from 30 to 45 years growth. These, after standing 10 years, were examined, and found in the following state and condition:

The cedar was perfectly sound; larch, the heart sound, but the sap quite decayed; spruce fir, sound; silver fir, in decay; Scotch fir, much decayed; pine, quite rotten; chestnut, perfectly sound; abel, sound; beech, sound; walnut, in decay; sycamore, much decayed; birch, quite rotten. Sir Thomas Bever justly remarks, that the trees ought to have been of the same age; and Mr. Arthur Young adds, they ought to have been cut out of the same plantation.

The immense quantity of timber consumed of late years in ship-building and other purposes has diminished in a very great degree the quantity produced in this country. On this account, many gentlemen who wish well to their country, alarmed with the fear of scarcity, have strongly recommended it to government to pay some attention to the cultivation and preservation of timber.

We find, on the best authority, that of Mr. Irving inspector general of imports and exports, that the shipping of England in 1760 amounted to 6170 number, the tonnage being 433,922; and the shipping in Scotland amounted to 976 in number, the tonnage being 52,818. In 1788 the whole shipping of Britain and Ireland and their colonies amounted to 13,680, being 1,359,752 tons burden, and employing 107,025 men. The tonnage of the royal navy in the same year was 413,667. We are informed also, on what we consider as the best authority (the report of the commissioners of the land revenue), that the quantity of oak timber, of English growth, delivered into the dockyards from 1760 to 1788 was no less than 768,576 loads, and that the quantity used in the merchant yards in the same time was 516,630 loads; in all 1,285,206 loads. The foreign oak used in the same period was only 137,766 loads.
loads. So that, after deducting the quantity remaining in the dock-yards in 1762 and 1788, and the foreign oak, there will remain about 1,054,284 loads of English oak, consumed in 28 years, which is at an average 37,533 loads per annum; besides from 5,000 to 10,000 loads expended annually by the East India Company within the same period (a).

The price of wood has risen in proportion to the demand and to its diminution. At the conquest, woods were valued, not by the quantity of timber which they contained, but the number of quire which the oaks could support. In 1608, oak in the forests was sold at 10s. per load, and fir-wood for 2s. per load. In 1665 or 1666, in navy contracts from 21. to 21. 15s. 6d. per load was given. In 1756 it rose to 41. 3s. per load, and 5s. in addition, because no tops are received. Plank four inch sold in 1769 for 71. a load, three inch 6l., which prices were the same in 1792.

So great an expenditure of valuable timber within so short a period, gives reason to fear that the forests of this country will soon be entirely dismantled, unless some thing is done to raise fresh supplies. The building of a 70 gun ship, it is said, would take 40 acres of timber. This calculation is indeed so excessive, that it is scarcely credible. This, however, is no exaggeration. According to the prevailing opinion of experienced surveyors, it will require a good soil and good management to produce 40 trees on an acre, which, in a hundred years, may, at an average, be computed at two loads each. Reckoning, therefore, two loads at 81. 16s. one acre will be worth 30l. and consequently 40 acres will only be worth 14,200l. Now a 70 gun ship is generally supposed to cost 70,000l.; and as ships do not last a great many years, the navy continually requires new ships, so that the forests must be stripped in a century or two, unless young trees are planted to supply their place.

Many plans have been proposed for recruiting the forests. Premiums have been held forth to individuals; and it has been proposed that the crown-lands should be set apart for the special purpose of raising timber. Without respect to individuals, as they must generally be disposed to sow or plant their lands with those vegetables which will best reward their labours, it is not to be expected that they will separate their fields for planting trees unless they have a greater return from them than other crops. But bad must that land be which will not yield much more than 35l. produce in 100 years. But though it be evident that good land will produce crops much more lucrative to the proprietor than timber, yet still there are lands or pieces of land which might be applied with very great advantage to the production of wood. Uneven ground, or the sides of fields where corn cannot be cultivated, might very properly be set apart for this purpose; barren lands, or such as cannot be cultivated without great labour and expense, might also be planted. Hedge-rows and clumps of trees, and little woods scattered up and down, would shelter and defend the fields from destructive winds, would beautify the face of the country, render the climate warmer, improve barren lands, and furnish wood for the arts and manufactures.

But to cultivate forest timber has also been thought of such national importance, that it has been deemed worthy of the attention of government. It has been proposed to appropriate such part of the crown lands as are fit for the purpose solely of producing timber for the navy. This appears a very proper scheme in speculation; but it has been objected, that for government to attempt the farming of forests would be really to establish groups of officers to pocket salaries for doing what, it is well known, will never be done at all. But to this objection we reply, that such an agreement might be made with the inspectors of forests, as to make it their own interest to cultivate trees with as much care as possible. Their salary might be fixed very low, and raised in proportion to the number of trees which they could furnish of such a size in a certain number of years. After all, we must acknowledge that we must depend greatly on Russia, Sweden, Norway, and America, for supplying us with timber; and while these countries take our manufactures in exchange, we have no reason to complain. Still, however, we ought surely not to neglect the cultivation of what is of so much importance to our existence as a nation, for it may often be impossible in time of war to obtain timber from foreign countries.

In the beginning of this article we mentioned the general division of trees into timber or forest-trees and fruit trees. We have already said that all our limits will permit respecting the former: we will now, therefore, say something of the latter. Our observations shall be confined to the methods of preserving fruit trees in blossom from the effects of frost, and from other diseases to which they are liable.

The Chevalier de Dienneberg of Prague, we are told, has discovered a method of effectually preserving trees in blossom from the fatal effects of those frosts which sometimes in the spring destroy the most promising hopes of a plentiful crop of fruit. His method is extremely simple. He surrounds the trunk of the tree in blossom with a wisp of straw or hemp. The end of this he sinks, by means of a stone tied to it, in a vessel of spring water, at a little distance from the tree. One vessel will conveniently serve two trees: or the cord may be lengthened so as to surround several, before its end is plunged into the water. It is necessary that the vessel be placed in an open situation, and by no means shaded by the branches of the neighbouring trees, that the frost may produce all its effect on the water, by means of the cord communicating with it. This precaution is particularly necessary for those trees the flowers of which appear nearly at the same time as the leaves; which trees are peculiarly exposed to the ravages of the frost. The proofs of its efficacy, which he had an opportunity of observing in the spring (a) A writer in the Bath Transactions says, that the aggregate of oaks felled in England and Wales for 30 years past has amounted to 320,000 loads a year; and affirms that he has documents in his possession founded on indisputable facts. The difference between this account, and that which we have given in the text from the report of the commissioners, we leave to be reconciled by those who have proper opportunities. We give the facts merely on the authority of others.
The year 1877, were remarkably striking. Seven apricot espaliers in his garden began to blossom in the month of March. Fearing that they would suffer from the late frosts, he surrounded them with cords as above directed. In effect, pretty sharp frosts took place six to eight nights: the apricot trees in the neighbouring gardens were all frozen, and none of them produced any fruit, whilst each of the chevalier's produced fruit in abundance, which came to the greatest perfection.

The following is the method proposed by Mr William Forsyth for curing injuries and defects in trees; for which a reward was given to him by his majesty, on condition that he should make it public. It is equally applicable to forest as to fruit trees (8).

Take one bushel of fresh cow-dung; half a bushel of lime rubbish of old buildings (that from the ceilings of rooms is preferable); half a bushel of wood ashes; and a sixteenth part of a bushel of pit or river sand. The three last articles are to be sifted fine before they are mixed; then work them well together with a spade, and afterwards with a wooden beater, until the stuff is very smooth, like fine plaster used for the ceilings of rooms. The composition being thus made, care must be taken to prepare the tree properly for its application, by cutting away all the dead, decayed, and injured parts, till you come to the fresh sound wood, leaving the surface of the wood very smooth, and rounding off the edges of the bark with a draw-knife, or other instrument, perfectly smooth, which must be particularly attended to. Then lay on the plaster about one-eighth of an inch thick all over the part where the wood or bark has been cut away, finishing off the edges as thin as possible. Then take a quantity of dry powder of wood ashes, mixed with a sixth part of the same quantity of the ashes of burnt bones; put it into a tin box, with holes in the top, and shake the powder on the surface of the plaster, till the whole is covered over with it, letting it remain for half an hour to absorb the moisture; then apply more powder, rubbing it on gently with the hand, and repeating the application of the powder, till the whole plaster becomes a dry smooth surface.

All trees cut down near the ground should have the surface made quite smooth, rounding it off in a small degree, as before mentioned; and the dry powder directed to be used afterwards should have an equal quantity of powder of alabaster mixed with it, in order the better to resist the dripping of trees and heavy rains. If any of the composition be left for a future occasion, it should be kept in a tub or other vessel, and urine of any kind poured on it, so as to cover the surface; otherwise the atmosphere will greatly hurt the efficacy of the application. Where lime rubbish of old buildings cannot be easily got, take powdered chalk, or common lime, after having been slaked a month at least. As the growth of the tree will gradually affect the plaster, by raising up its edges next the bark, care should be taken, where that happens, to rub it over with the finger when occasion may require (which is best done when moistened by rain), that the plaster may be kept whole, to prevent the air and wet from penetrating into the wound.

By this process, some old wound-out pear trees, that bore only a few small, hard fruit, of a kernelly texture, there were made to produce pears of the best quality and finest flavor, the second summer after the operation; and in four or five years they bore such a plentiful crop, as a young healthy tree would not have produced in four times that period.

By this process, too, some large ancient elms, in a most decayed state, having all their upper parts broken, and a small portion only of the bark remaining, shot out stems from their tops, above thirty feet in height, in six or seven years from the first application of the composition.

Thus may valuable trees be renovated; and forest trees, which are useful or ornamental from their particular situation, be preserved in a flourishing state. But what is far more interesting, a perfect cure has been made, and sound timber produced, in oak trees, which had received very considerable damage from blows, bruises, cutting of deep letters, the rubbing off the bark by the ends of rollers, or wheels of carts, or from the breaking of branches by storms.

TREFOIL. See TRIFOLIUM, BOTANY INDEX.
TREMELLA, a genus of plants belonging to the class of cryptogamia. See BOTANY INDEX.
TREMOR, an involuntary shaking, chiefly of the hands and head, sometimes of the feet, and sometimes of the tongue and heart. - Tremors arising from a too free use of spiritual liquors require the same treatment as palsy.
TRENCHES, in fortification, are ditches cut by the besiegers, that they may approach the more securely the place attacked, whence they are also called lines of approach.
TRENT, BISHOPRIC OF, a province of Germany, in the circle of Austria, near the frontiers of Italy; is bounded on the north by Tirol; on the east by the Feltrino and Bellunese; on the south, by Vincentino, the Veronese, Bresciano, and the lake de Garda; and on the west, by the Bresciano, and the lake de Garda. The soil is said to be very fruitful, and to abound in wine and oil. It is subject to Austria.
TRENT, a city of Germany, and capital of the bishopric of that name, is a very ancient place, and stands in a fertile and pleasant plain, in the midst of the high mountains of the Alps. The river Adige washes its walls, and creeping for some time among the hills, runs swiftly into Italy. Trent has three considerable churches, the principal of which is the cathedral: this is a very regular piece of architecture. The church of St Maria Major is all of red and white marble; and is remarkable for being the place where the famous council of Trent.

(8) A paste for covering the wounds of trees, and the place where grafts are inserted, was discovered long ago. It is recommended in a Treatise on Fruit Trees, published by Thomas Hitt in 1755; a third edition of which, with additions, was published in 1768. It consists of a mixture of clay and cow's dung diluted with water. This paste is directed to be laid on the wound with a brush; it adheres firmly, he says, without cracking, till the wound heals. We are informed by a gentleman, to whose opinion and experience we pay great respect, that this paste answers every purpose which Mr Forsyth's can serve.
TRENT

Trent was held, whose decisions are now the standing rule of the Romish church. E. Long. 11. 5. N. Lat. 46.

Trent, one of the largest rivers in England, which rises in the moorland of Staffordshire, and runs southwest by Newcastle-under-Lyme; and afterwards dividing the county into two parts, runs to Burton, then to Nottingham and Newark; and so continuing its course due north to Gainsborough on the confines of Lincolnshire, it joins several rivers, and falls into the Humber.

Trent, Council of, in Ecclesiastical History, denotes the council assembled by Paul III. in 1545, and continued by 25 sessions till the year 1563, under Julius III. and Pius IV. in order to correct, illustrate, and fix with perspicuity, the doctrine of the church, to restore the vigour of its discipline, and to reform the lives of its ministers. The decrees of this council, together with the creed of Pope Pius IV. contain a summary of the doctrines of the Roman Catholics. These decrees were subscribed by 255 clergy, consisting of four legates, 2 other cardinals, 3 patriarchs, 25 archbishops, 168 bishops, besides inferior clergy. Of these 150 came from Italy, of course the council was entirely under the influence of the pope. For a more particular account of the council of Trent, see Mosheim's Church History, the Modern Universal History, vol. xxiii. and Father Paul's History of the Council of Trent.

TRENTON. See New Jersey.

TREPPANNING. See Surgery Index.

TRES TABERNÆ, in Ancient Geography, a place in Latium, lying on the Via Appia, on the left or south side of the river Astura, to the north of the Paludes Pompeiae. Its ruins are now seen near Cisterna, a village in the Campagna di Roma, 21 miles from Rome, whence the Christians went out to meet St Paul.

TRESPASS, in Law, signifies any transgression of the law, its prescription, felony, or misprision of either: but it is commonly used for any wrong or damage that is done by one private person to another, or to the king in his forest.

TRESSE TREE, in Ship-Building, two strong bars of timber fixed horizontally on the opposite sides of the lower mast head, to support the frame of the top and the weight of the top-mast.

TREASURE, in Heraldry, a diminutive of an orle, usually held to be half the breadth thereof.

TREASURY, in Commerce, an allowance made for the waste or the dirt that may be mixed with any commodity; which is commonly four pounds in every 104 pounds weight.

TREVIRI, or TREVIRI, in Ancient Geography, an ancient and a powerful people, both in horse and foot, according to Caesar; extending far and wide between the Meuse and the Rhine. Their chief town was called Treveris. Now Trevirs or Treves.

TREVES, or TRIEUS (in Latin Treviri, Treveri, Treveres, or Augustea Treviroorum), the capital of the Germanic bishopric of the same name, stands 60 miles west of Mentz, 22 south of Cologne, and 82 north of Strasburg. This city vies with most in Europe for antiquity, having been a large and noted town before Augustus settled a colony in it. It was free and imperial till the year 1560, when it was surprised and subjected by its archbishop James III. It stands on the Moselle, over which it has a fair stone bridge. The cathedral is a large building; and near it stands the elector's palace. Here are three collegiate and five parish churches, an university founded in 1472, with some remains of the ancient Roman theatre. Roman coins and medals are often found in the ruins of the old city. The private houses here are mean; and the city is neither well fortified nor inhabited. Four-fifths of this archbishopric were seized by France in 1794 and united to her territories; and the remaining parts were secularized and distributed among certain princes in 1802. In 1814 the part which France held was given to Prussia. E. Long. 6. 41. N. Lat. 49. 45.

TRIAL, in Law, the examination of a cause according to the laws of the land before a proper judge; or it is the manner and order observed in the hearing and determining of causes.

Trials are either civil or criminal.

I. Civil Trials. The species of trials in civil cases are seven: By record; by inspection or examination; by certificate; by witnesses; by wager of battle; by wager of law; and by jury. The first six are only had in certain special or eccentrical cases, where the trial by jury would not be so proper or effectual: (See them explained under their respective titles.) The nature of the last, that principal criterion of truth in the law of England, shall be explained in this article.

As trial by jury is esteemed one of the most important privileges which members of society can enjoy, and the bulwark of the British constitution, every man of reflection must be stimulated by the desire of inquiring into its origin and history, as well as to be acquainted with the forms and advantages by which it is accompanied. We will therefore begin with tracing it to its origin. Its institution has been ascribed to our Saxon ancestors by Sir William Blackstone.

Some authors (says that illustrious lawyer) have endeavored to trace the original of jusris up as high as the Britons themselves, the first inhabitants of our island; but certain it is that they were in use among the earliest Saxons colonists, their institution being ascribed by Bishop Nicholson to Woden himself, their great legislator and captain. Hence it is, that we may find traces of juries in the laws of all those nations which adopted the feudal system, as in Germany, France, and Italy; who had all of them a tribunal composed of twelve good men and true, boni homines, usually the vassals or tenants of the lord, being the equals or peers of the parties litigant; and, as the lord's vassals judged each other in the lord's court, so the king's vassals, or the lords themselves, judged each other in the king's court. In England we find actual mention of them so early as the laws of King Ethelred, and that not as a new invention. Stiernhock ascribes the invention of the jury, which in the Teutonic language is denominated nembo, to Regner king of Sweden and Denmark, who was contemporary with our King Egbert. Just as we are apt to impute the invention of this, and some other pieces of juridical policy, to the superior genius of Alfred the Great; to whom, on account of his having done much, it is usual to attribute every thing; and as the tradition of ancient Greece placed to the account of their own Hercules whatever achievement was performed superior to the ordinary prowess of mankind. Whereas the truth seems to be, that this tribunal was universally established among all the northern nations, and so interwoven in their very constitution.

Trial.

constitutions, that the earliest accounts of the one give us also some traces of the other.

This opinion has been controverted with much learning and ingenuity by Dr Pettingill in his Inquiry into the Use and Practice of Juries among the Greeks and Romans, who deduces the origin of jury from these ancient nations.

He begins with determining the meaning of the word ἰκαστα in the Greek, and ἰκαστος in the Roman, writers.

"The common acceptation of these words (says he), and the idea generally annexed to them, is that of presidents of courts, or, as we call them, judges; as such they are understood by commentators, and rendered by critics. Dr Middleton, in his Life of Cicero, expressly calls the judges, judges of the bench; and Archbishop Potter, and in short all modern writers upon the Greek or Roman orators, or authors in general, express δικαστα and δικαστος by such terms as convey the idea of presidents in courts of justice. The propriety of this is doubted of, and hath given occasion for this inquiry; in which it is shown, from the best Greek and Roman authorities, that neither the δικαστα of the Greeks, or the judges of the Romans, ever signified presidents in courts of judicature, or judges of the bench; but, on the contrary, they were distinguished from each other, and the difference of their duty and function was carefully and clearly pointed out by the orators in their pleadings, who were the best authorities in those cases, where the question related to forms of law, and methods of proceeding in judicial affairs and criminal process.

The presidents of the courts in criminal trials at Athens were the nine archons, or chief magistrates, of which whoever presided was called ἀρχων δικαστας, or president of the court. These nine presided in different causes peculiar to each jurisdiction. The archon, properly so called, had belonging to his department all pupillary and inheritable cases; the δεατος or ἐξορκος, the chief priest, all cases where religion was concerned; the pole-marchus, or general, the affairs of the army and all military matters; and the six therapeutae, the other ordinary suits.

Wherever then the δικαστα or judicial men, are addressed by the Greek orators in their speeches, they are not to be understood to be the presiding magistrates, but another class of men, who were to inquire into the state of the cause before them, by witnesses and other methods of coming at truth; and after inquiry made and witnesses heard, to report their opinion and verdict to the president, who was to declare it.

The several steps and circumstances attending this judicial proceeding are so similar to the forms observed by our jury, that the learned reader, for such I must suppose him, cannot doubt but that the nature, intent, and proceedings of the δικαστα among the Greeks were the same with the English jury; namely, for the protection of the lower people from the power and oppression of the great, by administering equal law and justice to all ranks; and therefore when the Greek orators directed their speeches to the ἰκαστα or δικαστα, as we see in Demosthenes, Ἀ-chesines, and Lyssias, we are to understand it in the same sense as when our lawyers at the bar say, Gentlemen of the jury.

So likewise among the Romans, the ἰκαστος, in their pleadings at the bar, never signified judges of the bench, or presidents of the court, but a body or order of men, whose office in the courts of judicature was distinct from that of the praetor or judge questionis, which answered to our judge of the bench, and was the same with the archon, or ἀρχων δικαστας, of the Greeks: whereas the duty of the judges consisted in being impaneled, as we call it, challenged, and swore to try uprightly the case before them; and when they had agreed upon their opinion or verdict, to deliver it to the president who was to pronounce it. This kind of judicial process was first introduced into the Athenian polity by Solon, and thence copied into the Roman republic, as probable means of procuring just judgment, and protecting the lower people from the oppression or arbitrary decisions of their superiors.

When the Romans were settled in Britain as a province, they carried with them their jura and instituta, their laws and customs, which was a practice essential to all colonies; hence the Britons, and other countries of Germany and Gaul, learned from them the Roman laws and customs; and upon the irruption of the northern nations into the southern kingdoms of Europe, the laws and institutions of the Romans remained, when the power that introduced them was withdrawn: and Montesquieu tells us, that under the first race of kings in France, about the fifth century, the Romans that remained, and the Burgundians their new masters, lived together under the same Roman laws and police, and particularly the same forms of judicature. How reasonable then is it to conclude, that in the Roman courts of judicature continued among the Burgundians, the form of a jury remained in the same state it was used at Rome. It is certain, Montesquieu speaking of those times, mentions the paires or hommes de grief, homagers or peers, which in the same chapter he calls juge, judges or jurymen: so that we bence see how at that times the hommes de grief, or "men of the grief," were called peers, and those peers were juge, or jurymen. These were the same as are called in the laws of the Confessor per de la tenure, the "peers of the tenure," or homagers, out of whom the jury of peers were chosen, to try a matter in dispute between the lord and his tenant, or any other point of controversy in the manor. So likewise in all other parts of Europe, where the Roman colonies had been, the Goths succeeding them, continued to make use of the same laws and institutions, which they found to be established there by the first conquerors. This is a much more natural way of accounting for the origin of a jury in Europe, than having recourse to the fabulous story of Woden and his savage Scythian companions, as the first introducers of so humane and beneficent an institution.

Trials by jury in civil causes are of two kinds; extraordinary and ordinary.

1. The first species of extraordinary trial by jury is that of the grand assize, which was instituted by King Henry II. in parliament, by way of alternative offered to the choice of the tenant or defendant in a writ of right, instead of the barbarous and unchristian custom of duelling. For this purpose a writ de magna assisa eligenda is directed to the sheriff, to return four knights, who are to elect and choose 12 others to be joined with them; and these all together form the grand assize, or great jury, which is to try the matter of right, and must now consist of 16 jurors. Another species of extraordinary jury is the jury to try an attainder; which is a process commenced against a former jury for bringing a false verdict. See the article ATTAIN.
TRI

2. With regard to the ordinary trial by jury in civil cases, the most clear and perspicuous way of treating it will be by following the order and course of the proceedings themselves.

When therefore an issue is joined by these words, "And this the said A prays may be inquired of by the court?" or "And of this he puts himself upon the country, and the said B does the like;" the court awards a writ of venire facias upon the roll or record, commanding the sheriff "that he cause to come here, on such a day, twelve free and lawful men, liberes et legales homines, of the body of his country, by whom the truth of the matter may be better known, and who are neither of kin to the aforesaid A nor the aforesaid B, to recognize the truth of the issue between the said parties." And such writ is accordingly issued to the sheriff. It is made returnable on the last return of the same term wherein issue is joined, viz. bilary or Trinity terms; which, from the making up of the issues therein, are usually called issuable terms. And he returns the names of the jurors in a panel (a little pane or oblong piece of parchment) annexed to the writ. This jury is not summoned, and therefore not appearing at the day most unavoidably make default. For which reason a compulsive process is now awarded against the jurors, called in the common pleas a writ of habes corpus iustorum, and in the King's Bench distressing, commanding the sheriff to have their bodies, or to distrain them by their lands and goods, that they may appear upon the day appointed. The entry therefore on the roll of record is, "That the jury is respited, through defect of the jurors, till the first day of the next term, then to appear at Westminster; unless before that time, viz. on Wednesday the fourth of March, the justices of our lord the king appointed to take assizes in that county shall have come to Oxford, that is, to the place assigned for holding the assizes. Therefore the sheriff is commanded to have their bodies at Westminster on the said first day of next term, or before the said issue of assize, if before that time they come to Oxford, viz. on the fourth of March aforesaid." And as the judges are sure to come and open the circuit commissions on the day mentioned in the writ, the sheriff returns and summons this jury to appear at the assizes: and there the trial is had before the justices of assize and nisi prius: among whom (as hath been said *) are usually two of the judges of the courts at Westminster, the whole kingdom being divided into six circuits for this purpose. And thus we may observe, that the trial of common issues, at nisi prius, was in its original only a collateral incident to the original business of the justices of assize; though now, by the various revolutions of practice, it is become their principal civil employment; hardly any thing remaining in use of the real assizes but the name. If the sheriff be not an indifferent person, as if he be a party in the suit, or be related by either blood or affinity to either of the parties, he is not then trusted to return the jury; but the venire shall be directed to the coroners, who in this, as in many other instances, are the substitutes of the sheriff to execute process when he is deemed an improper person. If any exception lies to the coroners, the venire shall be directed to two clerks of the court, or two persons of the county named by the court, and sworn. And these two, who are called obors, or electors, shall indifferently name the jury, and

their return is final; no challenge being allowed to their array.

Let us now pause a while, and observe (with Sir Matthew Hale *), in these first preparatory stages of the trial, how admirably this constitution is adapted and framed for the investigation of truth beyond any other method of trial in the world. For, first, the person returning the jurors is a man of some fortune and consequence; so that he may be not only the less tempted to commit wilful errors, but likewise be responsible for the faults of either himself or his officers; and he is also bound by the obligation of an oath faithfully to execute his duty. Next, as to the time of their return: the panel is returned to the court upon the original venire, and the jurors are to be summoned and brought in many weeks afterwards to the trial, whereas the parties may have notice of the jurors, and of their sufficiency or insufficiency, characters, connections, and relations, so that they may be challenged upon just cause; while, at the same time, by means of the compulsory process (of distinguis, or habeas corpus) the cause is not likely to be retarded through defect of jurors. Thirdly, As to the place of their appearance: which in causes of weight and consequence is at the bar of the court; but in ordinary cases at the assizes, held in the county where the cause of action arises, and the witnesses and jurors live: a provision most excellently calculated for the saving of expense to the parties. For though the preparation of the causes in point of pleading is transacted at Westminster, whereby the order and uniformity of proceeding is preserved throughout the kingdom, and multiplicity of forms is prevented; yet this is no great charge or trouble, one attorney being able to transact the business of 40 clients. But the troublesome and most expensive attendance is that of jurors and witnesses at the trial; which therefore is brought home to them, in the county where most of them inhabit. Fourthly, The persons before whom they are to appear, and before whom the trial is to be held, are the judges of the superior court, if it be a trial at bar, or judges of assize, delegated from the courts at Westminster by the king, if the trial be held in the country: persons, whose learning and dignity secure their jurisdiction from contempt, and the novelty and very parade of whose appearance have no small influence upon the multitude. The very point of their being strangers in the county is of infinite service, in preventing those factions and parties which would intrude in every cause of moment, were it tried only before persons resident on the spot, as justices of the peace, and the like. And the better to remove all suspicion of partiality, it was wholly provided by the statutes 4 Edw. Ill. c. 2, 8 Ric. II. c. 2. and 33 Hen. VIII. c. 24, that no judge of assize should hold pleas in any county wherein he was born or inhabits. And as this institution prevents party and faction from intermingling in the trial of right, so it keeps both the rule and the administration of the laws uniform. These justices, though thus varied and shifted at every assizes, are all sworn to the same laws, have had the same education, have pursued the same studies, converse and consult together, communicate their decisions and resolutions, and preside in those courts which are mutually connected, and their judgments blended together, as if they are interchangeably courts of appeal or advice to each other. And hence their administration of justice, and conduct
conduct of trials, are consonant and uniform; whereby that confusion and contrariety are avoided, which would naturally arise from a variety of uncommunicating judges, or from any provincial establishment. Let us now return to the assizes.

When the general day of trial is fixed, the plaintiff or his attorney must bring down the record to the assizes, and enter it with the proper officer, in order to its being called on in course.

These steps being taken, and the cause called on in court, the record is then handed to the judge, to peruse and observe the pleadings, and what issues the parties are to maintain and prove, while the jury is called and sworn. To this end the sheriff returns his compulsory process, the writ of habeas corpus or distraings, with the panel of jurors annexed, to the judge’s officer in court.

The jurors contained in the panel are either special or common jurors. Special juries were originally introduced in trials at bar, when the causes were of too great nicety for the discussion of ordinary freeholders; or where the sheriff was suspected of partiality, though not upon such apparent cause as to warrant an exception to him. He is in such cases, upon motion in court, and a rule granted thereupon, to attend the prothonotary or other proper officer with his freeholder’s book; and the officer is to take indifferently 48 of the principal freeholders in the presence of the attorneys on both sides: who are each of them to strike off 12, and the remaining 24 are returned upon the panel. By the statute 3 Geo. II. c. 25, either party is entitled upon motion to have a special jury struck upon the trial of any issue, as well at the assizes as at bar, by paying the extraordinary expense, unless the judge will certify (in pursuance of the statute 24 Geo. II. c. 18.) that the cause required such special jury.

A common jury is one returned by the sheriff according to the directions of the statute 3 Geo. II. c 25, which appoints that the sheriff or officer shall not return a separate panel for every separate cause, as formerly; but one and the same panel for every cause to be tried at the same assizes, containing not less than 48, nor more than 72, jurors; and that their names being written on tickets, shall be put into a box of glass; and when each cause is called, 12 of these persons, whose names shall be first drawn out of the box, shall be sworn upon the jury, unless absent, challenged, or excused; or unless a previous view of the messages, lands, or place in question, shall have been thought necessary by the court; in which case, six or more of the jurors returned, to be agreed on by the parties, or named by a judge or other proper officer of the court, shall be appointed by special writ of habeas corpus or distraings, to have the matters in question shown to them by two persons named in the writ; and then such of the jury as have had the view, or so many of them as appear, shall be sworn on the inquest previous to any other jurors. These acts are well calculated to restrain any suspicion of partiality in the sheriff, or any tampering with the jurors when returned.

As the jurors appear when called, they shall be sworn unless challenged by either party. See the article CHALLENGE.

If by means of challenges or other cause, a sufficient number of unexceptionable jurors doth not appear at the trial, either party may pray a tales.

A tales is a supply of such men as are summoned upon the first panel, in order to make up the deficiency. For this purpose a writ of decem tales, octo tales, and the like, was wont to be issued to the sheriff at common law, and must be still so done at a trial at bar, if the jurors make default. But at the assizes, or nisi prius, by virtue of the statute 55 Hen. VIII. c. 6. and other subsequent statutes, the judge is empowered at the prayer of either party to award a tales de circumstantibus of persons present in court, to be joined to the other jurors to try the cause; who are liable, however, to the same challenges as the principal jurors. This is usually done still the legal number of 12 be completed; in which patriarchal and apostolical name Sir Edward Coke hath discovered abundance of mystery.

When a sufficient number of persons impannelled, or talesmen appear, they are then separately sworn, well and truly to try the issue between the parties, and a true verdict to give according to the evidence; and hence they are denominated “the jury,” jurato, and “jurors,” sc. juratores.

The jury are now ready to hear the merits; and to fix their attention the closer to the facts which they are impannelled and sworn to try, the pleadings are opened to them by counsel on that side which holds the affirmative of the question in issue. For the issue is said to lie, and proof is always first required upon that side which affirms the matter in question: in which our law agrees with the civil, eis incumbit probatio qui dicit, non qui negat; cum per rerum naturalium factum negavit proba(n) nulla sit. The opening counsel briefly informs them what has been transacted in the court above; the parties, the nature of the action, the declaration, the plea, replication, and other proceedings; and lastly, upon what point the issue is joined, which is there sent down to be determined. Instead of which, formerly the whole record and process of the pleadings were read to them in English by the court, and the matter of issue clearly explained to their capacities. The nature of the case, and the evidence intended to be produced, are next laid before them by counsel also on the same side; and when their evidence is gone through, the advocate on the other side opens the adverse case, and supports it by evidence; and then the party which began is heard by way of reply. See PLEADINGS.

Evidence in the trial by jury is of two kinds; either that which is given in proof, or that which the jury may receive by their own private knowledge. The former, or proofs, (to which in common speech the name of evidence is usually confined) are either written or oral; that is, by word of mouth. Written proofs, or evidence, are, 1. Records; and, 2. Ancient deeds of 30 years standing, which prove themselves: but, 3. Modern deeds; and, 4. Other writings, must be attested and verified by parol evidence of witnesses. With regard to parol evidence or witnesses; it must first be remembered that there is a process to bring them in by writ of subpoena ad testificandum; which commands them, laying aside all pretences and excuses, to appear at the trial on pain of 10l. to be forfeited to the king; to which the statute 5 Eliz. c. 9. has added a penalty of 10l. to the party aggrieved, and damages equivalent to the loss sustained by want of his evidence. But no witness, unless his reasonable expenses be tendered him is bound to appear at all; nor, if he appear, is he bound to
to give evidence till such charges are actually paid him; except he resides within the bills of mortality, and is summoned to give evidence within the same. This compulsory process, to bring in unwilling witnesses, and the additional terror of an attachment in case of disobedience, are of excellent use in the thorough investigation of truth: and, upon the same principle, in the Athenian courts, the witnesses who were summoned to attend the trial had their choice of three things: either to swear to the truth of the fact in question, to deny or abjure it, or else to pay a fine of 1000 drachmas.

All witnesses, of whatever religion or country, that have the use of their reason, are to be received and examined, except such as are infamous, or such as are interested in the event of the cause. All others are competent witnesses; though the jury from other circumstances will judge of their credibility. Infamous persons are such as may be challenged as jurors, proper dicturn: and therefore never shall be admitted to give evidence to inform that jury, with whom they were too scandalous to associate. Interested witnesses may be examined upon a voir dire, if suspected to be secretly concerned in the event; or their interest may be proved in court. Which last is the only method of supporting an objection to the former class; for no man is to be examined to prove his own infamy. And no counsel, attorney, or other person, intrusted with the secrets of the cause by the party himself, shall be compelled, or perhaps allowed, to give evidence of such conversation or matters of privacy as came to his knowledge by virtue of such trust and confidence: but he may be examined as to mere matters of fact, as the execution of a deed or the like, which might have come to his knowledge without being intrusted in the cause.

One witness (if credible) is sufficient evidence to a jury of any single fact: though undoubtedly the concurrence of two or more corroborates the proof. Yet our law considers that there are many transactions to which only one person is privy; and therefore does not always demand the testimony of two. Positive proof is always required, where, from the nature of the case, it appears it might possibly have been had. But, next to positive proof, circumstantial evidence, or the doctrine of presumptions, must take place: for when the fact itself cannot be demonstratively evinced, which comes nearest to the proof of the fact is the proof of such circumstances which either necessarily or usually attend such facts; and these are called presumptions, which are only to be relied upon till the contrary be actually proved.

The oath administered to the witness is not only that what he deposes shall be true, but that he shall also depose the whole truth: so that he is not to conceal any part of what he knows, whether interrogated particularly to that point or not. And all this evidence is to be given in open court, in the presence of the parties, their attorneys, the counsel, and all bystanders: and before the judge and jury: each party having liberty to except to its competency, which exceptions are publicly stated, and by the judge are openly and publicly allowed or disallowed, in the face of the country: which must curb any secret bias or partiality that might arise in his own breast.

When the evidence is gone through on both sides,
the defendant upon the same ground of complaint. But in case the plaintiff appears, the jury by their foreman deliver in their verdict.

A verdict, vere dictum, is either privy or public. A privy verdict is when the judge hath left or adjourned the court: and the jury, being agreed, in order to be delivered from their confinement, obtain leave to give their verdict privily to the judge out of court: which privy verdict is of no force, unless afterwards affirmed by a public verdict given openly in court; wherein the jury may, if they please, vary from their privy verdict. So that the privy verdict is indeed a mere nullity; and yet it is a dangerous practice, allowing time for the parties to tamper with the jury, and therefore very seldom indulged. But the only effectual and legal verdict is the public verdict: in which they openly declare to have found the issue for the plaintiff, or for the defendant; and if for the plaintiff, they assess the damages also sustained by the plaintiff, in consequence of the injury upon which the action is brought.

When the jury have delivered in their verdict, and it is recorded in court, they are then discharged: and so ends the trial by jury: a trial which ever has been, and it is hoped ever will be, looked upon as the glory of the English law. It is certainly the most transcendent privilege which any subject can enjoy or wish for, that he cannot be affected either in his property, his liberty, or his person, but by the unanimous consent of 12 of his neighbours and equals. A constitution that we may venture to affirm has, under providence, secured the just liberties of this nation for a long succession of ages.

And therefore a celebrated French writer, who concludes, that because Rome, Sparta, and Carthage, have lost their liberties, therefore those of England in time must perish, should have recollected that Rome, Sparta, and Carthage, at the time when their liberties were lost, were strangers to the trial by jury.

Great as this eulogium may seem, it is no more than this admirable constitution, when traced to its principles, will be found in sober reason to deserve.

The impartiality which secures both our persons and our properties, is the great end of civil society. But if that be entirely entrusted to the magistracy, a select body of men, and those generally selected by the prince or such as enjoy the highest offices in the state, their decisions, in spite of their own natural integrity, will have frequently an involuntary bias towards those of their own rank and dignity: it is not to be expected from human nature, that the few should be always attentive to the interests and good of the many. On the other hand, if the power of judicature were placed at random in the hands of the multitude, their decisions would be wild and capricious, and a new rule of action would be every day established in our courts. It is wisely therefore ordered, that the principles and axioms of law, which are general propositions flowing from abstracted reason, and not accommodated to times or to men, should be deposited in the breasts of the judges, to be occasionally applied to such facts as come properly ascertained before them. For here partiality can have little scope; the law is well known, and is the same for all ranks and degrees: it follows as a regular conclusion from the premises of fact pre-established. But in settling and adjusting a question of fact, when intrusted to any single magistrate, partiality and injustice have an ample field to range in, either by boldly asserting that to be proved which is not so, or more artfully by suppressing some circumstances, stretching and warping others, and distinguishing away the remainder. Here therefore a competent number of sensible and upright jurymen, chosen by lot from among those of the middle rank, will be found the best investigators of truth, and the surest guardians of public justice. For the most powerful individual in the state will be cautious of committing any flagrant invasion of another's right, when he knows that the fact of his oppression must be examined and decided by 12 indifferent men not appointed till the hour of trial; and that when once the fact is ascertained, the law must of course redress it. This therefore preserves in the hands of the people that share which they ought to have in the administration of public justice, and prevents the encroachments of the more powerful and wealthy citizens.

Criminal Trials. The regular and ordinary method of proceeding in the courts of criminal jurisdiction may be distributed under 12 general heads, following each other in a progressive order: viz. 1. Arrest; 2. Commitment and bail; 3. Procurement; 4. Arrestment, and its incidents; 5. Plead, and issue; 7. Trial, and conviction; 8. Clergy; 9. Judgment, and its consequences; 10. Reversal of judgment; 11. Reprieve, or pardon; 12. Execution. See Arrest, Commitment, Presentation, Indictment, Information, Appeal, Process upon an Indictment, Arraignment, and Plea; in which articles all the forms which precede the trial are described, and are here enumerated in the proper order.

The several methods of trial and conviction of offenders, established by the laws of England, were formerly more numerous than at present, through the superstition of our Saxon ancestors; who, like other northern nations, were extremely addicted to divination: a character which Tacitus observes of the ancient Germans. They therefore invented a considerable number of methods of purgation or trial, to preserve innocence from the danger of false witness, and in consequence of a notion that God would always interpose miraculously to vindicate the guileless; as, 1. By Odeal; 2. By Corse; 3. By Battell. See these articles.

4. A fourth method is that by the peers of Great Britain, in the Court of Parliament; or the Court of the Lord High Steward, when a peer is capitally indicted; for in case of an appeal, a peer shall be tried by jury. This differs little from the trial per patriam, or by jury; except that the peers need not all agree in their verdict; and except also, that no special verdict can be given in the trial of a peer; because the lords of parliament, or the lord high steward (if the trial be had in his court), are judges sufficiently competent of the law that may arise from the fact; but the greater number, consisting of 12 at the least, will conclude, and bind the minority.

The trial by jury, or the country, per patriam, is also that trial by the peers of every Briton, which, as the great bulwark of his liberties, is secured to him by the great charter: nultus liber homo capitetur, vel imprimis, tur ex ex, aut aliquo alio modo destruatur, nisi per legale judicium parium suorum, vel per legem terrae. When therefore a prisoner on his Arraignment has pleaded not guilty, and for his trial hath put himself upon
Trials upon the country, in which country the jury are, the sheriff of the county must return a panel of jurors, liberos et legatos homines, de viceneto; that is, freeholders without just exception, and of the vico or neighbourhood; which is interpreted to be of the county where the fact is committed. If the proceedings are before the court of king's bench, there is a time allowed between the arraignment and the trial, for a jury to be impannelled by writ of venire faciatis to the sheriff, as in civil causes; and the trial in case of a misdemeanor is had at nisi prius, unless it be of such consequence as to merit a trial at bar; which is always invariably had when the prisoner is tried for any capital offence. But, before commissioners of oyer and terminer and gaol-delivery, the sheriff, by virtue of a general precept directed to him beforehand, returns to the court a panel of 48 jurors, to try all felonies that may be called upon their trial at that session; and therefore it is there usual to try all felonies immediately or soon after their arraignment. But it is not customary, nor agreeable to the general course of proceedings, unless by consent of parties, to try persons indicted of smaller misdemeanours at the same court in which they have pleaded not guilty, or traversed the indictment. But they usually give security to the court to appear at the next assizes or session, and then there to try the traverse, giving notice to the prosecutor of the same.

In cases of high-treason, whereby corruption of blood may ensue (except treason in counterfeiting the king's coin or seals), or misprision of such treason, it is enacted by statute 7 W. III. c. 3, first, that no person shall be tried for any such treason, except an attempt to assassinate the king, unless the indictment be found within three years after the offence committed: next, that the prisoner shall have a copy of the indictment (which includes the caption), but not the names of the witnesses, five days at least before the trial, that is, upon the true construction of the act, before his arraignment; for then is his time to take any exceptions thereto, by way of plea or demurrer; thirdly, that he shall also have a copy of the panel of jurors two days before his trial: and, lastly, that he shall have the same compellative process the court in his witnesses for him, as was usual to compel their appearance against him. And by statute 7 Ann. c. 21 (which did not take place till after the decease of the late pretender) all persons indicted for high-treason, or misprisions thereof, shall have not only a copy of the indictment, but a list of all the witnesses to be produced, and of the jurors impannelled, with their professions and places of abode, delivered to him ten days before the trial, and in the presence of two witnesses, the better to prepare him to make his challenges and defence. And no person indicted for felony is, as (as the law stands) ever can, be entitled to such copies before the time of his trial.

When the trial is called on, the jurors are to be sworn as they appear, to the number of 12, unless they are challenged by the party.

Challenges may here be made, either on the part of the king, or on that of the prisoner; and either to the whole array, or to the separate polls, for the very same reasons that they may be made in civil causes. But in criminal causes, or at least in capital ones, there is, in favoribus vitis, allowed to the prisoner an arbitrary and capricious species of challenge, to a certain number of jurors, without showing any cause at all; which is called a peremptory challenge; a provision full of that tenderness and humanity to prisoners for which our English laws are justly famous. This is grounded on two reasons. 1. As every one must be sensible what sudden impressions and accountable prejudices we are apt to conceive upon the bare looks and gestures of another; and how necessary it is that a prisoner (when put to defend his life) should have a good opinion of his jury, the want of which might totally disconnect him; the law wills not that he should be tried by any one man against whom he has conceived a prejudice, even without being able to assign a reason for such his dislike. 2. Because, upon challenges for cause shown, if the reason assigned prove insufficient to set aside the juror, perhaps the bare questioning his indifference may sometimes provoke a resentment; to prevent all ill consequences from which, the prisoner is still at liberty, if he pleases, peremptorily to set him aside.

The peremptory challenges of the prisoner must, however, have some reasonable boundary; otherwise he might never be tried. This reasonable boundary is settled by the common law to be the number of 35; that is, one under the number of three full juries.

If by reason of challenges or the default of the jurors, a sufficient number cannot be had of the original panel, a takes may be awarded as in civil causes, till the number of 12 is sworn, "well and truly to try, and true deliverance make, between our sovereign lord the king and the prisoner whom they have in charge, and a true verdict to give, according to their evidence."

When the jury is sworn, if it be a cause of any consequence, the INDICTMENT is usually opened, and the evidence marshalled, examined, and enforced by the counsel for the crown or prosecution. But it is a settled rule at common law, that no counsel shall be allowed a prisoner upon his trial upon the general issue, in any capital crime, unless some point of law shall arise proper to be debated. A rule which (however it may be palliated under cover of that noble declaration of the law, when rightly understood, that the judge shall be counsel for the prisoner; that is, shall see that the proceedings against him are legal and strictly regular) seems to be not at all of a piece with the rest of the humane treatment of prisoners by the English law. For upon what face of reason can that assistance be denied to save the life of a man, which yet is allowed him in prosecutions for every petty trespass? Nor indeed is it, strictly speaking, a part of our ancient law; for the Mirror, having observed the necessity of counsel in civil suits, "who know how to forward and defend the cause by the rules of law, and customs of the realm," immediately afterwards subjoins, "and more necessary are they for defence upon indictments and appeals of felony, than upon other venal causes." And, to say the truth, the judges themselves are so sensible of this defect in our modern practice, that they seldom scruple to allow a prisoner counsel to stand by him at the bar, and to instruct him what questions to ask, or even to ask questions for him, with regard to matters of fact; for as to matters of law arising on the trial, they are entitled to the assistance of counsel. But still this is a matter of too much importance to be left to the good pleasure of any judge, and is worthy the interposition of the legislature; which has shown its inclination to indulge
TRIBAL prisoners with this reasonable assistance, by enacting, in statute 7 W. III. c. 3. that persons indicted for such high-treason as works a corruption of the blood or misprisonment thereof (except treason in counterfeiting the king's coins or seals), may make their full defence by counsel, not exceeding two, to be named by the prisoner, and assigned by the court or judge; and this indulgence, by statute 20 Geo. II. c. 35. is extended to parliamentary impeachments for high-treason, which were excepted in the former act.

When the evidence on both sides is closed, the jury cannot be discharged (unless in cases of evident necessity) till they have given in their VERDICT. If they find the prisoner not guilty, he is then for ever quit and discharged of the accusation, except he be appealed of felony within the time limited by law. And upon such his acquittal, or discharge for want of prosecution, he shall be immediately set at large without payment of any fine to the gaoler. But if the jury find him guilty, he is then said to be convicted of the crime whereas he stands indicted. See the article CONVICTION; and subsequent thereto, the article JUDGMENT, ATTAINDER, FORFEITURE, EXECUTION, also BENEFIT OF CLERGY, REPRIEVE, PARDON.

TRIAL, in Scotland. See Scots Law.

TRIANDRIA, (from τρις, "three," and ἄνθες, "a man or husband"), the name of the third class in Linnaeus's sexual system, consisting of plants with hermaphrodite flowers, which have three stamina or male organs.

TRIANGLE, in Geometry, a figure of three sides and three angles.

TRIBE, in antiquity, a certain quantity or number of persons, when a division was made of a city or people into quarters or districts.

TRIBRACHY, in Ancient Poetry, a foot consisting of three syllables, and all these short; as, melius.

TRIBUNAL, in general, denotes the seat of a judge, called in our courts bench.

TRIBUNAL, among the ancient Romans, a magistrate chosen out of the commons, to protect them against the oppressions of the great, and to defend the liberty of the people against the attempts of the senate and consuls.

The tribunes of the people were first established in the year of Rome 259. The first design of their creation was to shelter the people from the cruelty of usurers, and to engage them to quit the Aventine mount, whether they had retired in displeasure.

Their number at first was but two; but the next year, under the consulate of A. Posthumius Arrius and Cassius Visconti, there were three more added; and this number of five was afterwards increased by L. Trebonius to ten.

Military TRIBUNE, an officer in the Roman army, commander in chief over a body of forces, particularly the division of a legion; much the same with our colonel, or the French maire de camp.

TRIBUTARY, one who pays tribute to another in order to live in peace with or share in his protection.

TRIBUTE, a tax or impost which one prince or state is obliged to pay to another as a token of dependence, or in virtue of a treaty, and as a purchase of peace.

TRICERPS, in Anatomy. See there, Tables of the Muscles.

TRICHECUS, WALRUS; a genus of aquatic animals belonging to the class of mammalia, and order of bruta. See Mammalia Index.

TRICHOMANES, a genus of plants belonging to the class of cryptogamia, and order of cactaceae. See Botany Index.

TRICOCEAE, (τρις, "three," and κοκκής, "a grain"), the name of the 38th order in Linnaeus's Fragments of a Natural Method, consisting of plants with a single three-cornered capsule, having three cells, or internal divisions, each containing a single seed. See Botany Index.

TRICOSANTHES, a genus of plants belonging to the class of monocotyledonae, and in the natural system ranging under the 34th order, Cucurbitaceae. See Botany Index.

TRIDENT, an attribute of Neptune, being a kind of sceptre which the painters and poets put into the hands of that god, in form of a spear or fork with three teeth; whence the word.

TRIENNIAL, an epithet applied chiefly to offices or employments which last for three years.

TRIENS, in antiquity, a copper money of the value of one third of an as, which on one side bore a Jove's head, and on the other a water rat.

TRIENTALIS, CHICKWEED WINTER-GREEN, a genus of plants belonging to the class of heptandria, and in the natural system ranging under the 20th order, Rotaceae. See Botany Index.

TIERS, or TREVES. See Treves.

TRIFOLIUM, TREFOIL, or Clover, a genus of plants belonging to the class of dudetophyta, and in the natural system ranging under the 32d order, Papilionacae. See Botany Index.

TRIG, in antiquity, denotes a kind of car or chariot drawn by three horses; whence the name.

TRIGLAREA, a genus of fishes belonging to the order of thoracic. See Ichthyology Index.

TRIGLOCHIN, a genus of plants belonging to the class of hennandrea, and in the natural system ranging under the fifth order, Tripetaloides. See Botany Index.

TRIGLYPS, in Architecture, a sort of ornament repeated at equal intervals, in the Doric order.

Dialing TRIGON. See DIALING.

TRIGONALIS. See PILA.

TRIGONELLA, FENUGREEK, a genus of plants belonging to the class of dudetophyta, and in the natural system arranged under the 32 order, Papilionacae. See Botany Index.
TRIGONOMETRY.

Nature and Construction of Triangonometrical Tables.

Plane trigonometry treats of the application of numbers to determine the relations of the sides and angles of a plane triangle to one another.

Spherical trigonometry treats of the application of numbers in like manner to spherical triangles; the nature of these will be explained in the course of this article.

Both branches of the subject depend essentially upon certain numerical tables, the nature and construction of which we shall now proceed to explain.

SECTION I.

NATURE AND CONSTRUCTION OF TRIGONOMETRICAL TABLES.

It has been demonstrated in GEOMETRY (Theor. 31, Sect. IV.), that any angles at the centre of a circle have to one another the same proportion as the arcs intercepted between the lines which contain the angles. Hence it is easy to infer, that an angle at the centre of a circle has the same ratio to four right angles, that the arc intercepted between the lines which contain the angle has to the whole circumference. It also follows that we may employ arcs of a circle as measures of angles, and thus the comparison of angles is reduced to the comparison of arches of a circle. From this principle we infer the consistency of the first of the following series of definitions.

Definitions.

I. If two straight lines intersect one another in the centre of a circle, the arch of the circumference intercepted between them is called the Measure of the angle.

II. If the circumference of a circle be divided into $360$ equal parts, each of these is called a Degree; and if a degree be divided into $60$ equal parts, each of these is called a Minute; and if a minute be divided into $60$ equal parts, each of these is called a Second, and so on; and as many degrees, minutes, seconds, &c. as are in any arch, so many degrees, minutes, seconds, &c. are said to be in the angle measured by that arch.

Cor. 1. Any arch is to the whole circumference of which it is a part, as the number of degrees and parts of a degree in it is to the number $360$. And any angle is to four right angles as the number of degrees, &c. in the arch which is the measure of the angle to $360$.

Cor. 2. Hence also it appears that the arches which measure the same angle, whatever be the radii with which they are described, contain the same number of degrees and parts of a degree.

The degrees, minutes, seconds, &c. contained in an arc or angle are commonly written thus, $23^\circ 29' 32''$, which expression means $23$ degrees $29$ minutes $32$ seconds, and $\frac{1}{3}$ of a minute.

III. Two angles which make together two right angles, also two arches which make together a semi-circle, are called the Supplements of one another.

IV. A straight line BG drawn through B, one of the extremities of the arch AB, perpendicular to the diameter passing through the other extremity A, is called the Sine of the arch AC, or of the angle ABD, having the arch AB for its measure.

Cor. 1. The sine of a quadrant or of a right angle is equal to the radius.

Cor. 2. The sine of an arc is half the chord of twice the arc.

V. The segment AG of the diameter intercepted between its extremity and the sine BG is called the Versed Sine of the arch AB, or of the angle ABD.

VI. A straight line AH touching the circle at A, one extremity of the arch AB, and meeting the diameter CB which passes through B the other extremity, is called the Tangent of the arch AB, or of the angle ABD.

Cor. The tangent of half a right angle is equal to the radius.

VII. The straight line CH between the centre and the extremity of the tangent AH is called the Secant of the arc AB or of the angle ABD.

Cor. to Def. 4, 6, 7. The sine, tangent, and secant of any angle ABD, are also the sine, tangent, and secant of its supplement BCE. For by the definition, BG is the sine of the angle BCE; and if BC be produced to meet the circle in I, then AH is the tangent and CH the secant of the angle ACI or BCE.

Cor. to Def. 4, 5, 6, 7. The sine, versed sine, tangent, and secant of an arch which is the measure of the angle ABD is to the sine, versed sine, and secant of any other arch which is the measure of the same angle, as the radius of the first arch is to the radius of the second.

Let BG, fig. 2. be the sine, AG the versed sine, AH the tangent, and CH the secant of the arch AB to the radius CA; and $bg, ag, ah, ch$ the same things to the radius $ga$. From similar triangles $BG : bg :: BC : bc$; and because $CG : CG :: CB : cb$; therefore, by division $AG : ag :: CA : ca$. Also $AH : ah :: CH : CA :: CA : ca$.

Hence it appears that if tables be constructed exhibiting in numbers the sines, tangents, and versed sines of certain angles to a given radius, they will exhibit the ratios of the sines, tangents, and versed sines of the same angles to any radius whatever. In such tables, which are called trigonometrical tables, the radius is either supposed 1, or some number in the series 10, 100, 1000, &c.
The construction and use of these tables shall presently explain.

VIII. The difference between any angle and a right angle, or between any arch and a quadrant, is called the complement of that angle, or of that arch. Thus, if the angle ACD, fig. 1, be a right angle, and consequently the arch AD, which is its measure, a quadrant, the angle BCD is the complement of the angle BCA, and the arch BD is the complement of the arch AB. Also the complement of the obtuse angle BCD is BCD, its excess above a right angle; and the complement of the arch BDE is the arch BD.

IX. The sine, tangent, or secant of the complement of any angle is called the cosine, cotangent, or cosecant of that angle. Thus, supposing the angle ACD to be a right angle, then BF = CG, the sine of the angle BCD, is the cosine of the angle BCA; DK, the tangent of the angle BCD, is the cotangent of the angle BCA, and CK, the secant of the angle BCD, is the cosecant of the angle BCA.

The following properties of the lines which have been defined flow immediately from their position.

1. The sum of the squares of the sine and cosine of any angle is equal to the square of the radius. For, in the right-angled triangle BGC, BC² = BG² + GC². (Geometry, Sect. IV. theor. 13.) Now BG is the sine, and CG = BF is the cosine of the angle BCA.

2. The radius is a mean proportional between the tangent of any angle and its cotangent, or tan. ACD × cot. ACD = rad.². For since DK, CA are parallel, the angles DKC, HCA are equal; now CDK, CAH are right angles, therefore the triangles CDK, HCA are similar, and therefore AH: AC :: CD: AC :: DK: AC, and AC = AH × DK.

3. The radius is a mean proportional between the cosine and secant of any angle. Or cos. ACD × sec. ACD = rad.². For the triangles CGB, CAH are similar; therefore CG : CB :: CA :: CH.

4. The tangent of an arch is a fourth proportional to its cosine, its sign and the radius, or tan. ACD = sin. a × cot. ACD × rad. For, from similar triangles CG : GB :: CA : AH.

Trigonometrical tables usually exhibit the sines, tangents, and secants of all angles which can be expressed by an exact number of degrees and minutes from 1 minute to 90 degrees, or a right angle. These may be computed in various ways, the most elementary is to calculate by the help of principles deducible immediately from the elements of geometry.

It has been demonstrated in Geometry, (Sect. V, prob. 22.) that the chord of one-sixth of the circumference, or an arch of 6°, is equal to the radius; therefore, if BD be an arch of 30°, its sine BF will be half the radius (cor. 2, def. 4.). Let us suppose the radius to be expressed by unity, or 1, then sin. 30° = 1/2; now since 0 being put for any arch, cos. a = sin. a · rad. (where by cos. a is meant the square of the number expressing the cosine of the arch a, &c.) and as sin. 30° = 1/2, therefore cos. 30° = √3. 8660240, &c. Cos. 30° = \(\sqrt{3}\).

It has been demonstrated in the arithmetical sine (Algebra, § 356.) that 2 cos.² a = 1 - cos.² a; hence we have the following formula for finding the cosine of an arch, having given the cosine of its double; cos. a² = \(\frac{1 + \cos. 2a}{2}\).

We may find that of 15°, and again from cos. 15° we may find cos. 7° 30', and proceeding in this way we shall find the cosines of 3° 45', 1° 52' 30'', and so on. After bisecting the cosine of 52° 4' 3'' 45'' we may then find the sine of this arch by the formula \(\sin. a = \sqrt{\frac{1 - \cos. a}{2}}\). Now, as from the nature of a circle the ratio of an arc to its sine approaches continually to that of equality, when the arc is continually diminished, it follows that the sines of very small arcs will be very nearly to one another as the arcs themselves! Therefore, as 52° 44'' 31'' to 1° 52' 30'', so is the sine of the former arch to the sine of the latter.

By performing all the calculations which we have here indicated, it will be found that the sine of 1° is .000908882.

It has been shown in the arithmetic of sines (Algebra, § 355.) that a and b being put for any two sines, (a + b)/2 cos. a sin. a = sin. (a - b), hence putting a° for a, and 1°, 2°, 3°, &c. successively for a, we have,

\[\sin. 2° = 2 \cos. 1° \cdot \sin. 1°,\]
\[\sin. 3° = 2 \cos. 1° \cdot \sin. 2° - \sin. 1°,\]
\[\sin. 4° = 2 \cos. 1° \cdot \sin. 3° - \sin. 2°,\]

\&c.

In this way the sines for every minute of the quadrant may be computed, and as the multiplier cos. 1° remains always the same, the calculation is easy. If instead of 1°, the common difference of the series of sines are any other angle, the very same formula would apply.

The sines, and consequently the cosines of any number of arcs being supposed found, their tangents may be found by considering that \(\tan. a = \frac{\sin. a}{\cos. a}\); and their secants from the formula sec. \(a = \frac{1}{\cos. a}\).

We have here very briefly indicated the manner of constructing the trigonometrical canon, as it is sometimes called. There are, however, various properties of sines, tangents, &c., which greatly facilitate the actual calculation of the numbers; these the reader will find detailed in Algebra, Sect. XXV, which treats expressly of the Arithmetic of Sines.

The most expeditious mode of computing the sine or cosine of a single angle is by means of infinite series: The investigation of these is given in Fluxions, § 74, and it is there shown that if \(a\) denote any arch, then the radius is expressed by \(1 - 1\cdot2\cdot3\cdot4\cdot5 \cdot \cdots\)

\[\cos. a = 1 - \frac{a^2}{2!} + \frac{a^4}{4!} - \frac{a^6}{6!} + \frac{a^8}{8!} - \cdots &c.\]

To apply these we must have the arch expressed in parts of the radius, which requires that we know the proportion of the diameter of the circle to its circumference.

We have investigated this proportion in Geometry, Prop. 6, Sect. vi.; also in Fluxions, § 137; and subsequently in the article entitled Squaring the Circle.

From these series others may be found which shall express the tangent and secant. Thus because tan
TRIGONOMETRY.

Nature and Construction of Trigonometrical Tables.

\[ \tan a = a + \frac{a^3}{3} + \frac{2a^5}{15} + \frac{17a^7}{315} + \text{&c.} \]

And in like manner, dividing unity by the series for \( \cos a \), because \( \sec a = \frac{1}{\cos a} \), we get

\[ \sec a = 1 + \frac{a^2}{2} + \frac{5a^4}{24} + \frac{61a^6}{720} + \text{&c.} \]

We shall conclude what we proposed to say on the construction of the tables, by referring such of our readers as wish for more extensive information on this subject to Dr Hutton's Introduction to his excellent Mathematical Tables; also to the treatises which treat expressly of trigonometry, among which are those of Emerson, Simpson, Bonycastle, Cognolli, Mauduit, Lagrange, Legendre. In particular, we refer to an excellent treatise on this subject by Mr R. Woodhouse of Caius college, Cambridge.

Description of the Table of Logarithmic Sines, &c.

That trigonometrical tables may be extensively useful, they ought to contain not only the sine, tangent, and secant to every minute of the quadrant, but also the logarithms of these numbers; and these are given in Dr Hutton's Mathematical Tables, a work which we have already mentioned; as, however, the sines, &c., or the natural sines, &c., as they are called, are much less frequently wanted than their logarithms, we have only given a table of the latter. See LOGARITHMS.

This table contains the logarithms of the sines and tangents, or the logarithmic sines and tangents, to every minute of the quadrant, the degrees at top and minutes descending down the left-hand side, as far as 45°, and from thence returning with the degrees at the bottom and the minutes ascending by the right-hand side to 90°, in such a manner that any arch on the one side is in the same line with its complement on the other, the respective sines, cosines, tangents, and cotangents, being in the same lines with the minutes, and on the columns figured with their respective names at top when the degrees are at top, but at the bottom when the degrees are at the bottom. The differences of the sines and cosines are placed in columns to the right-hand, marked D; and the differences of the tangents and cotangents are placed in a column between them, each difference belonging equally to the columns on both sides of it. Also each differential number is set opposite the space between the numbers whose difference it is. All this will be evident by inspecting the table itself.

There are no logarithmic secants in the table, but these are easily had from the cosines; for since sec \( a \) = \frac{1}{\cos a} \), therefore, log. sec. = 2 log. rad. - log. cos. \( a \), now log. rad. = 10, therefore the log. secant of any arch is had by subtracting its log. cosine from 20.

The log. sine, log. tangent, or log. secant of any angle is expressed by the same numbers as the log. sine, log. tangent, or log. secant of its supplement; therefore, when an angle exceeds 90°, subtract it from 180° and take the log. sine, &c. of the remainder for that of the angle.

To find the log. sine of any angle expressed by degrees and minutes, if the angle be less than 45°, look for the number of degrees at the top, and opposite to the minutes on the left hand will be found the sine required; thus the log. sine of 8° 10' is 0.13245. But if the angle be 45° or more than 45°, look for the degrees at the bottom and the minutes on the right hand, and opposite will be found the log. sine required. Thus the log. sine of 58° 12' is 9.2936. The very same directions apply for the cosine, tangent, and cotangent; and from what has been said, the manner of finding the angle to degrees and minutes, having given its sine, &c., must be obvious.

If the angle consists of degrees, minutes, and seconds, find the sine or tangents to the degrees and minutes, and add to this a proportional part of the difference given in the column of differences for the seconds, observing that the whole difference corresponds to 1° or 60°. Thus to find the log. sine of 30° 23' 28"; first the sine of 30° 23' is 0.970396. The difference is 21. As 60" 28" :: 21 : \frac{28}{60} = 0.10 nearly, the part of the difference to be added, therefore the sine of 30° 23' 28" is 0.970506.

On the contrary, let it be required to find the angle corresponding to the tangent 10.14152.

The next less tangent in the table is 10.14140, which corresponds to 54° 10'; the difference between the proposed tangent and next less is 12; and the difference between the next less and next greater, as given in the table, is 26; therefore, 26 : 12 : 60 '" : \frac{12}{60} :: 28" 26 nearly, hence the angle corresponding to the proposed log. tangent is 34° 10' 28''.

SECTION II.

PLANE TRIGONOMETRY.

The following propositions express as many of the properties of plane triangles as are essentially necessary in plane trigonometry.

THEOR. I.

In a right-angled plane triangle, as the hypothenuse is to either of the sides, so is the radius to the sine of the angle opposite to that side; and as either of the sides to the other side, so is the radius to the tangent of the angle opposite to that side.

Let ABC be a right-angled plane triangle (fig. 3), fig. 3. of which AC is the hypothenuse. On A as a centre with any radius, describe the arch DE; draw EG at right angles to AB, and draw DF touching the circle at D, and meeting AC in E. Then EG is the sine of the angle A to the radius AD or AE, and DF is its tangent.

The triangles AFG, ADF are manifestly similar to the triangle ABC. Therefore AC : CB :: AE : EG, that is, AC : CB :: rad. : sin. A.
TRIGONOMETRY.

THEOR. II.

The sides of a plane triangle are to one another as the sines of the opposite angles.

From B any angle of the triangle ABC (fig. 4.) draw BD perpendicular to AC. Then, by last theorem,

\[ \frac{AB}{BD} = \tan \alpha, \quad \text{also} \quad \frac{BD}{BC} = \sin \alpha, \quad \frac{BC}{BA} = \sin \alpha. \]

Therefore \( \cot \alpha \) inversely (Geometry, Sect. III. Theor. 7.), \( \frac{AB}{BC} = \tan \alpha \).

THEOR. III.

The sum of any two sides of a triangle is to their difference as the tangent of half the sum of the angle opposite to these sides to the tangent of half their difference.

Let ABC, fig. 5. be a triangle; \( \frac{AB + BC}{AB - BC} = \tan \frac{1}{2} \angle BCA + \frac{1}{2} \angle BAC \) : \( \tan \frac{1}{2} \angle BCA - \frac{1}{2} \angle BAC \).

In AB produced take BE = BC, and on B as a centre with BC or BE as a radius, describe the semicircle ECF meeting AC in D; join BD, CF, and CE, and from F draw FG parallel to AC, meeting CE in G.

Because the angles CFE, CBE, stand on the same arch CE, and the former is at the circumference of the circle, and the latter at the centre; therefore, the angle CFE is half the angle CBE (Geometry, Sect. II. Theor. XVII.); but the angle CBE is the sum of the angles BAC, BCA (Geometry, Sect. I. Theor. XXIII.); therefore the angle CFE is half the sum of the angles BCA, BAC.

Because the angle BDC is the sum of the angles BAC, BDC, therefore the angle BDC is the difference between the angles BDC, BAC; but since BD = BC, the angle BDC is equal to BCD or BCA, therefore BDC = the difference of the angles BCA, BAC; but BCD, or BFD, being an angle at the centre of the circle, is double the angle FCD at the circumference, which last is equal to the alternate angle CFE; therefore the angle CFE is half the difference of the angles BCA, BAC.

Because CE is manifestly the tangent of the angle CFE to the radius CF, and CG the tangent of the angle CFE to the same radius; therefore \( \frac{CE}{FG} = \tan \alpha, \quad \text{that is} \quad \frac{CE}{CG} = \tan \frac{1}{2} \angle BCA + \frac{1}{2} \angle BAC \) : \( \tan \frac{1}{2} \angle BCA - \frac{1}{2} \angle BAC \); but because FG is parallel to AC, CE : CG :: AE : AF, that is, CE : CG :: \( \frac{AB + BC}{AB - BC} \), therefore \( \frac{AB + BC}{AB - BC} = \tan \frac{1}{2} \angle (BCA + BAC) \tan \frac{1}{2} \angle (BCA - BAC) \).
Plane Trigonometry.

Here the logarithms of the second and third terms are added, and the logarithm of the first term subtracted or rejected from the sum.

Case 2. A side $AB$, and an acute angle $A$ (and consequently the other angle $C$) being given, to find the hypotenuse $AC$, and remaining side $BC$.

Solution. \[ \frac{\cos A}{\text{rad}} :: \frac{AB}{AC}, \quad \frac{\text{Rad}}{\text{rad}} :: \frac{AB}{BC}. \]

Example. In the triangle $ABC$ are given $AB = 208$, and the angle $A = 38^\circ 16'$, to find $AC$ and $BC$.

To find $AC$.

\[
\begin{array}{l}
\text{Cos} \ A = 38^\circ 16' & 9.91194 \\
\text{Rad} & - \quad 10.00000 \\
AB = 208 & 2.31805 \\
\text{BC} = 147.1 & 2.16738 \\
\end{array}
\]

AC = 254.7

Case 3. The hypotenuse $AC$ and a side $AB$ being given, to find the angle $A$ (and consequently $C$) and the side $BC$.

Solution. \[ \begin{align*}
\frac{AC}{\text{rad}} & :: \frac{AB}{\cos A}, \\
\frac{\text{Rad}}{\text{rad}} & :: \frac{AB}{AC}.
\end{align*} \]

Example. Let the hypotenuse $AC$ be 272, and the side $AB$ 232. Required the angle $A$ and the side $BC$.

To find $A$.

\[
\begin{array}{l}
AC = 272 & 2.43457 \\
AB = 232 & 2.53549 \\
\text{Sin} \ A = 31^\circ 28' & 9.77179 \\
AC = 272 & 2.43457 \\
BC = 142 & 2.15224 \\
\text{Cos} \ A = 31^\circ 28' & 9.93092
\end{array}
\]

Case 4. The sides $AB$ and $BC$ about the right angle being given, to find the angle $A$ (and thence $C$) and the hypotenuse $AC$.

Solution. \[ \begin{align*}
\frac{AB}{\text{rad}} & :: \frac{BC}{\text{rad}} :: \tan A, \\
\frac{AC}{\text{rad}} & :: \frac{AB}{\text{rad}} :: \text{AC}.
\end{align*} \]

Example. Let the side $AB$ be 186, the side $BC$ 152. Required the angle $A$, and the hypotenuse $AC$.

To find $A$.

\[
\begin{array}{l}
AB = 186 & 2.26051 \\
BC = 152 & 2.18184 \\
\text{Rad} & - \quad 10.00000 \\
\text{Cos} \ A = 39^\circ 15' & 9.88969 \\
AB = 186 & 2.26051 \\
\text{BC} = 152 & 2.18184 \\
\text{Sin} \ A = 39^\circ 15' & 9.97133 \\
AC = 240.2 & 2.38055
\end{array}
\]

Solution of the Cases of Oblique-angled Triangles.

In oblique-angled triangles there are also four cases, which, with their solutions, are as follows.

Case 1. Two angles $A$ and $B$, and a side $AB$, being given, to find the other sides $AC$, $BC$.

Vol. XX. Part II.
TRIGONOMETRY.

Case 3. Two sides CA, CB and the included angle C being given, to find the remaining angles B, A, and side AB.

Solution. Find AC + CB, the sum of the sides, and AC - CB their difference; also find the sum of the angles A and B (that sum is the supplement of C), and half that sum; then half the difference of the angles will be got from this proportion. (See Theor. III.).

AC + CB : AC - CB :: tan \( \frac{1}{2} (B + A) \) : tan \( \frac{1}{2} (B - A) \).

Having now the sum and difference of the angles B and A, the angles will be found by the rule given in the problem following Theor. IV.

The remaining side may be found by either of these proportions.

Example. Let AC be 128, CB 93, and the angle C 49° 2'. Required the remaining parts of the triangle.

\[
\begin{align*}
AC + CB &= 218 & \Rightarrow & 2.33846 \\
AC - CB &= 38 & \Rightarrow & 1.15975 \\
\tan \frac{1}{2} (B + A) &= 65° 54' & \Rightarrow & 10.34938 \\
\Rightarrow & 11.92916 \\
\tan \frac{1}{2} (B - A) &= 21° 17' & \Rightarrow & 9.59079
\end{align*}
\]

Hence by the given rule in the above-mentioned problem, B = 87° 11', A = 43° 37'. As we now know all the angles and two sides, the remaining side may be found by Case 1.

Case 4. The three sides AB, BC and AC (fig. 10.) being given, to find the three angles A, B, C.

Solution. Let fall a perpendicular CD upon the greatest of the three sides from the opposite angle. Then find the difference between AD and DB by this proportion.

\[
AB : AC + CB :: AC - CB : AD - DB.
\]

The segments AD, DB may now be found severally by the rule given for finding each of the quantities whose sum and difference is given, and then the angles A and B may be found by the following proportions.

\[
CA : AD :: \text{rad.} : \cos. A, \\
CB : BD :: \text{rad.} : \cos. B.
\]

The angles A, B being found, C of course is known. The first part of this solution follows from Theor. IV., the latter part from Theor. I.

Example. Let AB be 125, AC 105, and BC 95. Required the angles.

In this case AC + BC = 200, AC - BC = 10, therefore we have

\[
125 : 200 :: \frac{10}{125} : AD - DB = \frac{200 \times 10}{125} = 16.
\]

Now AD + DB = 125, therefore AD = 70.5 DB = 54.5.

SPHERICAL TRIGONOMETRY.

Theor. I.

If a sphere be cut by a plane through the centre, the section is a circle.

The truth of this proposition is evident from the definition of a sphere. See Geometry, Sect. IX. Def. 3.

Definitions.

I. Any circle which is a section of a sphere by a plane passing through its centre, is called a great circle of the sphere.

II. The pole of a great circle of the sphere is a point in the superficies of the sphere from which all straight lines drawn to the circumference of the circle are equal.

III. A spherical angle is that which on the superficies of a sphere is contained by two arches of great circles, and is the same with the inclination of the planes of these great circles.

IV. A spherical triangle is a figure upon the superficies of a sphere comprehended by three arches of three great circles, each of which is less than a semicircle.

Theor. II.

The arch of a great circle between the pole and the circumference of another circle is a quadrant.

Let ABC be a great circle (fig. 11.), and D its pole; let the great circle ADC pass through D, and let AEC be the common section of the planes of the two circles, which will pass through E, the centre of the circle, join DA, DC. Because the chord DA is equal to the chord DC, (Def. 2.) the arc DA is equal to the arc DC; now ADC is a semicircle, therefore the arches AD and DC are quadrants.

Cor. 1. If DE be drawn, the angle AED is a right angle, and DE being therefore at right angles to every line it meets with in the plane of the circle ABC, is at right angles to that plane. Therefore the straight line drawn from the pole of any great circle to the centre of the sphere is at right angles to the plane of that circle.

Cor. 2. The circle has two poles D, D', one on each
TRIGONOMETRY.

Spherical each side of its plane, which are the extremities of 
A diameter of the sphere perpendicular to the plane ABC.

THEOR. III.

A spherical angle is measured by the arch of a 
great circle intercepted between the great circles 
containing the angle, and having the angular 
point for its pole.

Let AB, AC be two arches of great circles con-
taining the spherical angle BAC; let BC be an arch 
of a great circle intercepted between them, and having 
A for its pole, and let BD, CD, AD be drawn to D 
the centre of the sphere. The arches AB, AC are 
quadrate, (Theor. II.), and therefore the angles ADB, 
ACD right angles; therefore (Geometry, Sect. VII. 
Def. 4.) the angle BDC is equal to the angle DBC 
and is equal to the spherical angle BAC (Def. 3).

Cor. If AB, AC two arches of great circles meet in 
A, then shall be the pole of a great circle passing 
through B and C.

THEOR. IV.

Two great circles whose planes are 
perpendicular pass through each others poles.

Let ACBD, AEBF be two great circles, the 
planes of which are at right angles to one another; 
from G the centre of a sphere, draw GC in the plane 
ACBD perpendicular to AB, then GC is also perpen-
dicular to the plane AEBF, (Geometry, Sect. VII. 
Theor. 12.) therefore C is the pole of the circle AEB, 
and if CG be produced to D, D is the other pole of 
the circle AEBF.

In the same manner, by drawing GE in the plane 
AEBF perpendicular to AB, and producing it to F, 
it is seen that E and F are the poles of the circle 
ACBD.

Cor. 1. If two great circles pass through each others 
poles, their planes are perpendicular to one another.

Cor. 2. If of two great circles the first passes through 
the poles of the second, the second also passes through 
the poles of the first.

THEOR. V.

If the angular points of any spherical triangle be 
the poles of three great circles, another 
triangle will be formed by their intersections, 
such, that the sides of the one triangle will be 
respectively the supplements of the measures of 
the angles opposite to them in the other.

Let the angular points of the triangle ABC be the 
poles of three great circles; which by their inter-
sections form the three lunar surfaces DQ, FR, and EO; 
A being the pole of EF, B the pole of DF, and C the 
pole of ED. Then the triangle DEF, which is commo 
to three lunar surfaces, will be in every respect 
supplemental to the triangle ABC.

For let each side of ABC be produced to meet the 
Spherical 
ides that contain the angle opposite to it, in the tri-
gonometric angel DEF; then, because BC passes through the poles 
of ED, DF, ED, DF must also pass through the poles 
of BC. (Theor. II. Cor. 2.) Therefore the points 
D, Q are the poles of BC. In like manner R, F are 
the poles of AB, and E, O the poles of AC. Hence 
EL, FK are quadrants, (Theor. II.); and therefore EF 
is the supplement of KL, but since A is the pole of EF, 
KL is the measure of the angle at A; thus EF is the 
supplement of the measure of the angle at A. In like 
manner FD is the supplement of the measure of the 
angle at B, and DE the supplement of the measure of 
the angle at C.

Further, it will appear in the same manner that BC 
is the supplement of HM, the measure of the angle at D; 
that AB is the supplement of NK the measure of 
the angle at F; and that AC is the supplement of GL, 
the measure of the angle at E.

THEOR. VI.

If from any point E, which is not the pole of the 
great circle ABC, there be drawn arches of 
great circles EA, EK, EB, &c. the greatest of these 
is EGA, which passes through G the pole 
of ABC, and EC the remainder of the semicircle 
is the least, and of the other, EK, EB, &c. EK 
which is nearer to EA is greater than EB, which 
is more remote.

Let AC be the common section of the planes of the Fig. 15-great circles AEC, ABC; draw EH perpendicular to 
AC, which will be perpendicular to the plane of the 
circle ABC (Geometry, Sect. VII. Theor. XII.), and 
join AE, KE, BE, KH, BH. Then of all the straight 
lines drawn from H to the circumference, HA is the 
greatest, HC the least, and HK greater than HB; 
Therefore in the right-angled triangles EHA, EHK, 
EHB, EHC, which have the side EH common, EA 
is the greatest hypotenuse, EC the least, and EK 
greater than EB, consequently the arch EGA is the 
greatest, EC the least, and EK greater than EB.

THEOR. VII.

Any two sides of a spherical triangle are together 
greater than the third, and all the three sides 
are together less than a circle.

Let ABC be a spherical triangle, let D be the cen-
tre of the sphere, join DA, DB, DC. The solid angle 
at D is contained by three plane angles ADB, BDC, 
ADC, any two of which are greater than the third, 
(Geometry, Sect. VII. Theor. XV.) and therefore 
any two of the arches AB, BC, AC which measure 
these angles must be greater than the third arch.

To prove the second part of the proposition, sup-
pose the sides AB, AC until they meet again in E; 
then ECA and EBA are semicircles; now CB is less 
than CE+EB, therefore CB+CA+BA is less than 
CE+EB+CA+BA, but these four arches make up 
two semicircles; therefore CB+CA+BA is less than 
a circle.
TRIGONOMETRY.

Theor. VIII.

If two sides of a spherical triangle be equal, the angles opposite to them are equal, and conversely.

Fig. 17. In the triangle ABC, if the sides AB, AC be equal, the angles ABC, ACB are also equal. If AB, AC be quadrants, ABC, ACB are right angles. If not, let the tangent to the side AB at B meet EA the line of common section of the planes AB, AC in F, and let the tangents to the base BC at its extremities meet each other in G; also, let FC, FG, GC, and EB be joined. Then the triangles FEB, FEC have FE common, EB=EG, and the angle AEB=AEC, therefore FB = FC, and the angle FCE=FEA a right angle; hence FC is a tangent, and the triangles FCB, GCF are mutually equilateral, therefore the angle FBG = FGC, and consequently the spherical angle ABC=ACB.

Again, if the angles ABC, ACB be equal, the side AB=AC. For, if in fig. 14. the angle ABC be equal to ACB, the side DE of the supplemental triangle DEF will be equal to the side DE (Theor. V.); therefore the angle DEF=DFE, and consequently in the triangle ABC, the side BC=AB by Theorem V.

Cor. In any triangle the greater angle is subtended by the greater side; and conversely. For if the angle ABC be greater than ABC (fig. 18.) let BCD=ABC, then BD=DC, and AB=AD+DC, which is greater than AC (Theor. VII.). The converse is demonstrated in the same manner as the like property of plane triangles, (Geometry, Sect. I. Theor. XIII.).

Theor. IX.

All the angles of a spherical triangle are together greater than two, and less than six right angles.

Fig. 14. In the triangle ABC (fig. 14.) the three angles are altogether less than six right angles, because when added to the three exterior angles they only make six; and they are greater than two right angles, because their measures GH, KL, MN, added to DE, EF, FD, are equal to three semicircles; and DE, EF, FD being less than two semicircles (Theor. VII.) GH, KL, MN must be greater than one.

Theor. X.

Any two angles of a spherical triangle are together greater, equal, or less than two right angles, according as the sum of the opposite side is greater, equal, or less than a semicircle; and conversely.

Fig. 19. Let the sides AB, AG (fig. 19.) of the spherical triangle ABC be produced to meet in D; then it is evident, that according as the sum of AB, BC is greater, equal, or less than the semicircle ABD, the side BC will be greater, equal, or less than BD; the angle D or A will be greater, equal, or less than BCD, and the sum of the angle BAC, BCA greater, equal, or less than the sum of BCA, BCD, which is two right angles.

Cor. According as half the sum of any two sides of a spherical triangle is greater, equal, or less than a quadrant, half the sum of the opposite angles will be great, equal, or less than a right angle.

Theor. XI.

In a right-angled triangle, according as either of the sides about the right angles is greater, equal, or less than a quadrant, its opposite angle is greater, equal, or less than a right angle; and conversely.

Let ABC (fig. 20.) be a triangle right-angled at B, and let the sides AB, BC be produced to meet in D; then, because they pass through each other poles, the middle point of BAD will be the pole of BCD; let a great circle pass through the points CE. The arch EC is a quadrant, and the angle ECB a right angle. Now it is plain, that according as AB is greater, equal, or less than the quadrant EB, the opposite angle ACB will be greater, equal, or less than the right angle ECB, and conversely.

Cor. 1. If the two sides be both greater, or both less than quadrants, the hypotenuse will be less than a quadrant; but if the one be greater and the other less, the hypotenuse will be greater than a quadrant, and conversely.

For in the triangles ABC, ADC, right-angled at B, D, in which the sides AB, BC are less, and consequently AD, DC greater than quadrants, the hypotenuse AC is less than a quadrant, because it is nearer to CB than the quadrant CE. But in the triangle ABC, of which the side AB is greater, and BC less than a quadrant, the hypotenuse AC is greater than a quadrant, because it is further from CB than CE is.

Cor. 2. In every spherical triangle, of which the two sides are not both quadrants, if the perpendicular from the vertex fall within, the angles at the base will be both acute, or both obtuse; but if it fall without, the one will be obtuse, and the other acute, and conversely.

Theor. XII.

In any right-angled spherical triangle, as radius is to the sine of the hypotenuse, so is the sine of one of the oblique angles to the sine of its opposite side.

Let ABC (fig. 21.) be a spherical triangle, having a right angle at B; and let AD, BD, CD be drawn to the centre of the sphere. From C, in the plane DCA, let CE be drawn perpendicular to DA, and from E, in the plane DBA, draw EF perpendicular to the same line, and let CF be joined. Then because DA is perpendicular to the two lines CE, EF, it is perpendicular to the plane CEF, and consequently the plane CEF is perpendicular to the plane DBA; but the plane DBC is also perpendicular to DBC; therefore their line of common section CF is perpendicular to the same. Hence CFD, CFE are right angles.

Now in the right-angled triangle CFE, rad. CE:: sin. E:: CF; but the angle CEF, being the inclination of the planes DCA, DBA, is the same with the spherical angle CAB, CE is the sine of AC, and CF the sine of BC; therefore rad. sin. AC:: sin. A:: sin. BC.

Cor.
TRIGONOMETRY.

Spherical
Trigonometry; or the relations of the sides, angles, 
and areas of spherical triangles.

Fig. 12.

Cor. 1. As radius to the cosine of either of the sides, 
so is the cosine of the other to the cosine of the hypo-
thenuse.

For let the great circle of which A is the pole, meet 
the three sides in D, E, F; then F is the pole of AD; 
and applying this proposition to the complementary tri-
gle FCE, rad. : sin. FCE :: sin. F : sin. CE ; that is, 
rad. : cos. BC :: cos. AB : cos. AC.

Cor. 2. As radius to the cosine of one of the sides, 
so is the sine of its adjacent angle to the cosine of 
the other angle.

THEOREM XIII.

In any right-angled triangle, as radius to the sine 
of one of the sides, so is the tangent of the 
adjacent angle to the tangent of the other side.

Fig. 13.

From B let BE be drawn perpendicular to DA, and 
from E, EF also perpendicular to DA, in the plane 
DCA, to meet DC in F, and let BE be joined. It may 
be shown as in the preceding proposition, that FB is 
perpendicular to the plane DAB; hence FB is the 
tangent of BC, and FBE is a right-angled triangle; there-
fore rad. : EB :: tan. E : FB; that is, rad. : sin. AB :: 
tan. A : tan. BC.

Cor. 1. As radius to the cosine of the hypothenuse, 
so is the tangent of one of the angles to the cotangent 
of the other. For, in the complementary triangle FCE, 
(rad. 23.) rad. : sin. C :: tan. C : tan. FE; that is, 
rad. : cos. AC :: tan. C : cot. A, or rad. : cos. AC :: 
tan. A : cot. C.

Cor. 2. As radius is to the cosine of one of the 
angles, so is the tangent of the hypothenuse to the 
tangent of the side adjacent to that angle.

For rad. : sin. FE :: tan. F : tan. CE; that is, rad. : 
cos. A :: cot. AB : cot. AC or rad. : cos. A :: tan. 
AC : tan. AB.

Napier’s Rule for Circular Parts.

Let the hypothenuse, the two angles, and the comple-
mments of the two sides of any right-angled spherical 
triangle be called the five circular parts of the triangle.
Any one of these being considered as the middle part, 
let the two which are next to it be called the adjacent 
parts, and the remaining two the opposite parts. Then 
the two preceding theorems, with their corollaries, may 
be all expressed in one proposition adapted to practice, 
as follows.

In any right-angled spherical triangle, the rectangle 
under radius, and the cosine of the middle part, is equal 
to the rectangle under the cotangents of the adjacent 
parts, or to the rectangle under the sines of the opposite 
parts.

Fig. 14.

Case 1. Let the hypothenuse AC be the middle part.

Cor. 1.).

Therefore (rad. : tan. C :: cot. C : rad. : cos. AC :: 
cot. A.

And rad. : cos. AB :: cos. BC : cos. AC (Theor. 12. 
Cor. 1.).

Case 2. Let the angle A be the middle part.

Then (Theor. 13. Cor. 2.) rad. : cos. A :: tan. AC :: 
sec. AB.

Therefore, (rad. : tan. AC :: cot. AC : rad. : cos. A :: 
tan. AB.

And (Theor. 12. Cor. 2.) rad. : cos. BC :: sin. C :: 
sec. A.

Case 3. Let the complement of the side AB be the 
middle part.

Then (Theor. 13.) rad. : sin. AB :: tan. A : tan. BC.

Therefore (rad. : tan. A :: cot. A : rad. : sin. AB :: 
tan. BC.

And (Theor. 12.) rad. : sin. AC :: sin. C : sin. AB.

We are indebted for the foregoing rule to Napier, 
the celebrated inventor of logarithms. It comprehends 
all the propositions which are necessary for the resolu-
tion of right-angled triangles, and being easily remem-
bered, is perhaps one of the happiest instances of arti-
ficial memory that is known.

THEOREM XIV.

In any spherical triangle, the sines of the sides are 
proportional to the sines of the opposite angle.

This proposition has been demonstrated in the case Fig. 15. 
of right-angled triangles. Let ABC be any oblique-
angled triangle, divided into two right-angled triangles, 
ABD, CBD, by the perpendicular BD, falling from 
the vertex upon the base AC. In the former, the 
complement of BD being the middle part, rad. x sin. 
BD = sin. AB x sin. A, (Napier’s Rule). In the 
 latter, the complement of BD being the middle part, 
rad. x sin. BD = sin. BC x sin. C. Hence sin. AB 
x sin. A = sin. BC x sin. C, and sin. AB : sin. BC :: 
sin. C : sin. A.

Cor. 1. The cosines of the two sides are to one 
other directly as the cosines of the segments of the 
 base. This is proved by making AB, BC the middle 
part.

Cor. 2. The tangents of the two sides are to one 
other inversely as the cosines of the vertical angles. 
This will follow from making the angles ABD, CBD 
the middle parts.

Lemmas. 1. The sum of the tangents of two arches is 
to their difference, as the rectangle under the sine and 
 cosine of half their sum to the rectangle under the sine 
and cosine of half their difference.

For, putting a and b for any two arches, by the arith-
metic of sines (Algebra, § 353),

sin. a cos. b + cos. a sin. b = sin. (a + b).

Let each side of this equation be divided by cos. a 
cos. b, and we get

sin. a + sin. b = sin. (a + b)

that is, tan. a + tan. b = sin. (a + b)

sin. a cos. b.

In like manner, from the formula sin. (a—b) = 
sin. a cos. b—cos. a sin. b, we get

tan. a — tan. b = sin. (a—b)

sin. a cos. b.

therefore tan. a + tan. b : tan. a — tan. b : sin. (a + b) 
: sin. (a — b), and remarking that sin. (a + b) = 2 sin. 
\frac{1}{2}(a + b)
TRIGONOMETRY.

Spherical $\cos^2 \frac{1}{2} (a+b) \cos^2 \frac{1}{2} (a-b)$, and sin. $(a-b) = 2 \sin a \cos^2 \frac{1}{2} (a+b)$. (ALGEBRA, § 333.) It follows that tan. $a = \tan. b$; tan. $a = \tan. b = \sin. \frac{1}{2} (a+b)$.

2. LEMMA. The sum of the sines of two arches is to their difference, as the rectangle under the sine of half the sum and cosine of half the difference of these arches is to the rectangle under the sine of half the difference and cosine of half the sum.

For it has been shown in the arithmetic of sines (ALGEBRA, § 335), that

\[
\sin. (p+q) + \sin. (q-p) = 2 \sin. p \cos. q, \\
\sin. (p-q) = \sin. (q-p) = 2 \cos. p \sin. q.
\]

Let $p = \frac{1}{2} (a+b)$, and $q = \frac{1}{2} (a-b)$, so that $p+q = a$ and $p-q = b$, then these formulas become

\[
\sin. a = \sin. b = \sin. \frac{1}{2} (a+b) \cos. \frac{1}{2} (a-b), \\
\sin. a = \sin. b = \cos. \frac{1}{2} (a-b) \sin. \frac{1}{2} (a-b).
\]

Therefore, sin. $a + \sin. b = \sin. a - \sin. b = \sin. \frac{1}{2} (a+b) \cos. \frac{1}{2} (a-b)$.

LEMMA 3. The sum of the sines of two arches is to their difference, as the tangent of half the sum of these arches is to the tangent of half their difference.

For, dividing the latter antecedent and consequent of the proportion in the foregoing lemma by $\sin. \frac{1}{2} (a+b) \times \cos. \frac{1}{2} (a-b)$, we have $\sin. a + \sin. b: \sin. a - \sin. b = \sin. \frac{1}{2} (a+b): \sin. \frac{1}{2} (a-b)$, that is, because $\cos. \frac{1}{2} (a+b) = \cos. \frac{1}{2} (a-b)$, tan. $a + \sin. b: \sin. a - \sin. b = \tan. \frac{1}{2} (a+b): \tan. \frac{1}{2} (a-b)$.

LEMMA 4. The sum of the cosines of two arches is to their difference, as the cotangent of half the sum of these arches is to the tangent of half their difference.

By arithmetic of sines (ALGEBRA, § 335),

\[
\cos. (p+q) + \cos. (p+q) = 2 \cos. p \cos. q, \\
\cos. (p-q) = \cos. (p+q) = 2 \cos. p \sin. q.
\]

Let $p = \frac{1}{2} (b+a)$ and $q = \frac{1}{2} (b-a)$, then $p-q = a$ and $p+q = b$, and the two formulas become

\[
\cos. a + \cos. b = 2 \cos. \frac{1}{2} (b+a) \cos. \frac{1}{2} (b-a), \\
\cos. a - \cos. b = 2 \sin. \frac{1}{2} (b+a) \sin. \frac{1}{2} (b-a).
\]

Hence, cos. $a + \cos. b: \cos. a - \cos. b = \cos. \frac{1}{2} (b+a): \sin. \frac{1}{2} (b+a)$.

and dividing the latter antecedent and consequent by sin. $\frac{1}{2} (b-a)$,

\[
\frac{\cos. a + \cos. b}{\cos. a - \cos. b} = \frac{\cos. \frac{1}{2} (b+a)}{\sin. \frac{1}{2} (b+a)} = \cot. \frac{1}{2} (b-a) \quad \text{that is, because} \quad \frac{\cos. \frac{1}{2} (b-a)}{\sin. \frac{1}{2} (b-a)} = \cot. \frac{1}{2} (b-a).
\]

In the demonstration of the remaining theorems, we shall put $a$, $b$, for the angles $A$ and $B$ at the base of the spherical triangle $ABC$ (fig. 26.) $a$ and $b$ for the sides opposite to these angles, and $p$ and $q$ for the segments of the base $BD$, $AD$ made by the perpendicular arch $CD$, $P$ and $Q$ for the vertical angles $BCD$, $ACD$; we shall also put $s$ for $\frac{1}{2} (a+b)$, $s'$ for $\frac{1}{2} (a-b)$, $s''$ for $\frac{1}{2} (p+q)$, $S$ for $\frac{1}{2} (A+B)$, $D$ for $\frac{1}{2} (A-B)$, $S'$ for $\frac{1}{2} (P+Q)$, and $D'$ for $\frac{1}{2} (P-Q)$.

THEOR. XV.

In any spherical triangle, the tangent of half the sum of the segments of the base is to the tangent of half the sum of the two sides, as the tangent of half their difference to the tangent of half the difference of the segments of the base.

For by Theor. XIV. Cor. 1. cos. $a + \cos. b = \cos. p$; therefore, cos. $a + \cos. b : \cos. a - \cos. b = \cos. p + \cos. q : \cos. p - \cos. q$, hence (Lemma 4) cot. $s = \tan. a = \cot. \frac{1}{2} (s) = \tan. s = \cot. a = \tan. s = \cot. s = \tan. s$. This proposition expressed in words at length is the theorem to be demonstrated.

THEOR. XVI.

The cotangent of half the sum of the vertical angles and the tangent of half their difference, or the cotangent of half their difference and the tangent of half their sum, according as the perpendiculars fall within or without, are reciprocally proportional to the tangents of half the sum and half the difference of the angles at the base.

For, taking the case in which the perpendicular $CD$, (fig. 27.) falls within, let $EFG$ be the supplemental triangle, let the arches $GE$, $GF$ meet again in $L$, and produce $CA$, $CB$ to meet $EF$ in $H$ and $K$. Because $G$ and $L$ are the poles of $AB$, the perpendicular $CD$, if produced, will pass through $G$ and $L$; let it meet $EF$ in $I$; and then, because $C$ is the pole of $EF$, the arch $GCI$ is perpendicular to $EF$, and since $E$ is the pole of $BC$, $KE$ a quadrant $= FH$, and $EH$ a quadrant $= KE$, and $IF$ is $IK$. In the triangle $LEF$, by the preceding proposition, $\tan. \frac{1}{2} (FL+IE) = \tan. \frac{1}{2} (FL+IE) = \tan. \frac{1}{2} (K1+IH)$. Now $FL+IE$ or $EF$, being the supplement of $G$, (Theor. 5.), $\tan. \frac{1}{2} FE = \cot. \frac{1}{2} C$; and $FL, LE$ being the supplements of $FG$ and $GE$, $FL$ and $LE$ are the measures of the angles $A, B$; moreover, $IK, IH$ are the measures of the angles $ACD, ABC$, therefore, cot. $\frac{1}{2} C$ or cot. $\frac{1}{2} (P+Q) = \tan. \frac{1}{2} (A+B) = \tan. \frac{1}{2} (P-Q)$. In the very same way it may be proved, when the perpendicular falls without the triangle, that cot. $\frac{1}{2} (P-Q) = \tan. \frac{1}{2} (A+B)$, so that $\frac{1}{2} (P+Q)$.

THEOR. XVII.

In any spherical triangle, the sine of half the sum of the sides is to the sine of half their difference, as the cotangent of half the vertical angle is to the tangent of half the difference of the angles at the base.

For since $\tan. a = \tan. b = \cos. Q = \cos. P$, therefore,
TRIGONOMETRY.

Spherical tan. \( a + \tan. \) \( b \) \( : \) \( \tan. \) \( a - \tan. \) \( b \) \( :: \) \( \cos. \) \( Q + \cos. \) \( P \) \( :: \) \( \cos. \) \( Q - \cos. \) \( P \); hence, by Lemma 2. and 4.

\( \sin. s \cdot \cos. s \cdot \sin. d \cdot \cos. d \cdot \cot. s' \cdot \tan. D' \cdot \ldots \cdot (1) \).

Again, because (by Theor. XIV.) \( \sin. a \cdot \sin. b \cdot \sin. A \cdot \sin. B \); hence, by (Lemma 2. and 3.)

\( \sin. s \cdot \cos. d \cdot \sin. c \cdot \cos. s \cdot \tan. S \cdot \tan. D' \cdot \tan. D \cdot \cdot \cdot (2) \).

Taking now the product of the corresponding terms of the proportions (1) and (2), and rejecting the factor \( \cos. s \cdot \cos. d \), which is common to the first antecedent and consequent of the resulting proportion, we have,

\( \sin. s \cdot \sin. d \cdot \cot. s' \cdot \sin. S \cdot \tan. D \cdot \tan. D' \cdot \tan. D \cdot \tan. D' \cdot \tan. D \).\)

But since by Theor. XVI. \( \tan. S \cdot \tan. D' \cdot \cot. S' \cdot \tan. D' \cdot \tan. D \cdot \cot. S' \cdot \tan. D' \cdot \tan. D' \cdot \tan. D \); therefore, \( \cos. s \cdot \sin. d \cdot \cot. S' \cdot \tan. S \cdot \tan. D \cdot \tan. D' \cdot \tan. D \).

Therefore, dividing the terms of the first two proportions by the corresponding terms of the second, we get

\( \cos. s \cdot \cos. d \cdot \cot. S' \cdot \tan. D' \cdot \cos. s \cdot \cos. d \cdot \cot. S' \cdot \tan. D \).

Hence, multiplying the first and second terms by \( \cos. s \times \cos. d \) and the third and fourth by \( \tan. S \cdot \tan. D \), we have

\( \cos. s \cdot \cos. d \cdot \cot. S' \cdot \tan. D' \cdot \tan. S \cdot \tan. D \).

But since by Theor. XVI. \( \tan. S \cdot \tan. D' \cdot \cot. S' \cdot \tan. S \cdot \tan. D \cdot \cot. S' \cdot \tan. S \cdot \tan. D \); therefore, \( \cot. S' \cdot \cos. s \cdot \cos. d \cdot \cot. S' \cdot \tan. S \cdot \tan. S \cdot \tan. S \cdot \tan. S \).

In any spherical triangle, the sine of half the sum of the angles at the base is to the sine of half their differences as the tangent of half the base to the tangent of half the sum of the two sides.

For in the triangle ELF, \( \cos. \frac{1}{2} (LF + LE) \cdot \cos. \frac{1}{2} LE \cdot \cot. \frac{1}{2} LF \cdot \tan. \frac{1}{2} (E + F) \) (Theor. XVIII.) is, because of the relation of the triangle FLE to ABC, as expressed in last theorem, \( \cos. \frac{1}{2} (A + B) \cdot \cos. \frac{1}{2} (A - B) \cdot \tan. \frac{1}{2} AB \cdot \tan. \frac{1}{2} BC \cdot \tan. \frac{1}{2} AC \).

THEOR. XX.

In any spherical triangle, the cosine of half the sum of the angles at the base is to the cosine of half their differences as the tangent of half the base to the tangent of half the sum of the two sides.

SCHOLIUM.

Let one of the six parts of any spherical triangle be neglected; let the one opposite to it, or its supplement, if an angle, be called the middle part, the two next to it the adjacent parts, and the remaining two the opposite parts. Then the four preceding propositions, which are called Napier's Analogies, because first invented by him, may be included in one, as follows.

In any spherical triangle, the sine or cosine of half the sum of the adjacent parts is to the sine or cosine of half the sum of the middle part to the tangent of half the difference or half the sum of the opposite parts, that is:

\( \sin. \frac{1}{2} (A + a) \cdot \sin. \frac{1}{2} (A - a) \cdot \tan. \frac{1}{2} M \cdot \tan. \frac{1}{2} O \cdot \cot. (O + a) \).

When \( A, a \) and \( M \) are given, by the first proportion, \( \frac{1}{2} (O - a) \) is found, and by the second \( \frac{1}{2} (O + a) \); hence \( O \) and \( a \) may be had immediately by the problem following, Theo. IV. PLANE TRIGONOMETRY.

The Cases of Right-angled Spherical Triangles.

In a right-angled triangle, let \( c \) denote the side opposite the right angle, \( a, b \) the sides containing it, and \( A, B \) the opposite angles, \( A \) being opposite to \( a \), and \( B \) to \( b \). Then, combining these quantities two by two, there will be found to be six distinct combinations, or cases.

CASE 1. When \( c, A \), the hypotenuse and one of the angles are given; to find \( a, b, B \).

\( a \) is found by Theor. XII.; \( b \) by Theor. XIII. Cor. 2. and \( B \) by Theor. XIII. Cor. 1.

CASE 2. Given \( a, B \), a side and its adjacent angle. Sought, \( A, b, c \).

\( A \) is found by Theor. XII. Cor. 2.; \( b \) by Theor. XIII. Cor. 2.

CASE 3. Given \( a, A \), a side and its opposite angle; to find \( b, B, c \).

\( b \) is found by Theor. XIII.; \( B \) by Theor. XII. Cor. 2.; \( c \) by Theor. XII.

CASE 4. Given \( c, a \), the hypotenuse, and one of the sides; to find \( A, b, B \).

\( A \) is found by Theor. XII.; \( b \) by Theor. XII. Cor. 1.; \( B \) by Theor. XIII. Cor. 2.
TRIGONOMETRY.

Find \( \frac{1}{2} (A-B) \) by Theor. XVII. and \( \frac{1}{2} (A+B) \) by Spherical Theor. XVIII. and thence A and B by the rule Trigon. Sect. II. for finding each of two quantities whose sum and difference are given. All the angles being known, also two sides, c is found by Theor. XIV.

CASE 4. Given A, c, B, two angles and a side between them. Sought a, C, b.

Find \( \frac{1}{2} (a-b) \) by Theor. XIX. and \( \frac{1}{2} (a+b) \) by Theor. XX. and thence a, b. All the sides and two angles being now known, C is found by Theor. XIV.

CASE 5. Given a, b, c, the three sides. Sought A, B, C.

Draw a perpendicular from any one of the angles, dividing the opposite side into the segments p, q. Find \( \frac{1}{2} (p-q) \) by Theor. XV. and then, from \( \frac{1}{2} (p+q) \) and \( \frac{1}{2} (p-q) \), find p, q. The triangle being now resolved into two right-angled triangles, the angles may be found by Case 4 of right-angled triangles.

CASE 6. Given A, B, C, the three angles. Sought a, b, c.

Draw a perpendicular, dividing any one of the angles into the parts P, Q. Find \( \frac{1}{2} (P-Q) \) by Theor. XVI. and then P, Q. The triangle being now resolved into two right-angled triangles, the sides may be found by Case 6 of right-angled triangles.

By Theor. X. XI. and Cor. each of the unknown parts is limited to one value in all the cases, except in some of the subcases of the first and second.

As every oblique-angled triangle may be resolved into two right-angles, all these cases may be resolved by means of Napier's Rule, and the 15th proposition only. And the cases may be reduced to three, by using the supplemental triangle.

TRIANGLE

TRIANGULATIONS, from tres, "three," and hilum, "an external mark on the seed;" the name of the 23rd class in Linnaeus's Fragments of a Natural Method; consisting of plants with three seeds, which are marked with an external cicatrix or scar, where they are fastened within the fruit. See BOTANY.

TRIM, implies in general the state or disposition by which a ship is best calculated for the several purposes of navigation.

Thus the trim of the hold denotes the most convenient and proper arrangement of the various materials contained therein relatively to the ship's motion or stability at sea. The trim of the masts and sails is also their most appropriate situation with regard to the construction of the ship and the effect of the wind upon her sails. See SEAMANSHIP.

TRINGA, Sandpiper; a genus of birds belonging to the order of grallae. See ORNITHOLOGY.

TRINIDAD, an island in the gulf of Mexico, separated from New Andalusia, in Terra Firma, by a strait about three miles wide. The soil is fruitful, producing sugar, cotton, Indian corn, fine tobacco, and fruits. It was taken by Sir Walter Raleigh in 1595, and by the French in 1676, who plundered the island and then left it. It is about 62 miles in length, and 45 in breadth; and was discovered by Christopher Columbus in 1498. It is now in the possession of Britain. What was called a bituminous lake in this island, appears, from the experiments of Mr Hatcher, to be a porous stone from which the mineral pitch exudes.

TRINITARIANS, those who believe in the Trinity; those who do not believe therein being called Anthropitarians.

TRINITY,
TRIPLICATE, in Grammar, an assemblage or concourse of three vowels in one syllable; as qua.

TRIPETHONG, in Grammar, an assembly or concourse of three vowels in one syllable; as qua.

TRIPOD, in antiquity, a famed sacred seat or stool, supported by three feet, wherein the priest and sibyls were placed to render oracles. It was on the tripod that the gods were said to inspire the Pythias with that divine fury and enthusiasm wherein they were seized at the delivery of their predictions.

TRIPOLOI, a country of Africa, in Barbary; bounded on the north by the Mediterranean sea; on the south, by the country of the Berbers; on the west, by the kingdom of Tunis and Blededulgerid; and on the east, by Egypt. It is about 692 miles along the sea coast, but the breadth is variable. Some parts of it are more fertile than others; but that towards Egypt is a sandy desert. It had the title of a kingdom but is governed by a dey. Early in the last century Tripoli shook off its dependence on the grand Turk. In other respects the government is not essentially changed. It is still a military despotism of the most ferocious description. Its pirates are now confined to Naples, Sardinia, and other states which have no efficient navy. See Barbary States, Supplement.

TRIPOLI, a considerable town of Africa, and capital of a state of the same name in Barbary, with a castle and a fort. It is pretty large, and the inhabitants are noted pirates. It was taken by Charles V., who settled the knights of Malta there; but they were driven away by the Turks in 1551. It was formerly very flourishing; and has now some trade in stuffs, saffron, corn, oil, wool, dates, ostrich feathers, and skins: but they make more of the Christian slaves which they take at sea, for they either set free ransoms upon them, or make them perform all sorts of work. It is situated on the coast of the Mediterranean, in a sandy soil, and surrounded by a wall, strengthened by other fortifications.

TRIPOLIS, a city in Phrygia, in Phrygia, distinguished from its being an anciently formed of three cities at a small distance from each other, one of which belonged to the Aradians, or ancient kingdom of Arad, the second to the Sidonians, and the third to the Tyrians, perhaps as a common mart to those maritime powers. The present town of Tripoli is built at the distance of a mile and a half from the other, upon the declivity of a hill facing the sea, in 34° 20' north latitude, and in 35° 50' east longitude from Greenwich. It is surrounded with walls, fortified with seven high strong towers, and a castle, all of Go-
a branch of laurel, and in the other a truncheon. He was carried in a magnificent chariot, adorned with ivory and plates of gold, drawn usually by two white horses; though sometimes by other animals, as that of Pompey, when he triumphed over Africa, by elephants; that of Mark Antony by lions; that of Heliogabalus by tigers; that of Aurelian by deer, &c. His children were at his feet, and sometimes on the chariot-horses. The procession was led by the musicians, who played triumphal pieces in praise of the general; these were followed by young men, who led the victims to the sacrifice, with their horns gilded, and their heads adorned with ribbons and garlands; next came the carts and waggon, loaded with all the spoils taken from the enemy, with their horses, chariots, &c.; these were followed by the kings, princes, and generals, who had been taken captives, loaded with chains; after these appeared the triumphal chariot, before which, as it passed, they all along strewn flowers, and the people with loud acclamations called out Io triumphi! The chariot was followed by the senate, clad in white robes; and the senate by such citizens as had been set at liberty or ransomed; and the procession was closed by the priests and their officers and utensils, with a white ox led along for the chief victim. In this order they proceeded through the triumphal gate, along the Via Sacra, to the Capitol, where the victims were slain. In the mean time all the temples were open, and all the altars loaded with offerings and incense; games and combats were celebrated in the public places, and rejoicings appeared everywhere.

TRIUMVIR, one of three persons who govern absolutely, and with equal authority, in a state. It is chiefly applied to the Roman government: Caesar, Pompey, and Crassus, were the first triumvirs who divided the government among them. There were also other officers so called; as the triumviri or tresviri capitales, who were the keepers of the public gaol; they had the office of punishing malefactors; for which purpose they kept eight lictors under them.

TROAS, a country of Phrygia in Asia Minor, of which Troy was the capital. When Troyas is taken for the TROAS, in prosody, a foot consisting of a long and short syllable.

TROCHÆUS, in Anatomy. See there, No. 58.

TROCHE, in Pharmacy, a sort of medicine made of glutinous substances into little cakes, and afterwards exsiccated. See MATERIA MEDICA INDEX.

TROCHILUS, HUMMING BIRD, a genus of birds belonging to the order of nectar.

TROCHLOIDES, in the Ancient Geography, a people of Ethiopia, said to have lived in caves under ground. Pomponius Melius gives a strange account of the Trochloides: he says they did not so properly speak as shriek; and that they lived on serpents.

TROGUS POMPEIUS, a Latin universal historian to the time of Augustus Caesar, of whom we have only an abridgment by Justin, flourished about 41 B. C.

TROJA, the capital city of Troas, or, according to others, a country of which Ilum was the capital. It was built on a small eminence near Mount Ida, and the promontory of Scyoeum, at the distance of about four miles from the sea-shore. Dardanus the first king of the country built it, and called it Dardanum, and from Troj one of his successors it was called Trojum, and from Ilus Ilum. This city has been celebrated by Homer and Virgil.

A description of the plain of Troy has been published in French in the 3d volume of the Philosophical Transactions of The Royal Society of Edinburgh, by M. Chevalier. The city of Troy, according to him, stood on the present site of the modern village of Bonnarbach, which is situated four leagues from the sea, on the side of an eminence, at the termination of a spacious plain, the soil of which is rich and of a blackish colour. Close to the village is to be seen a marsh covered with tall reeds; and the situation is im- penable on all sides except at Erin (Homer's name), the hill of wild fig-trees, which extended between the Scæan gate and the sources of the Scamander. In the plain there are several conical mounds or barrows, some of them 100 feet in diameter at the base; and which the author maintains to be the identical tombs over the ashes of the heroes of the Trojan war.

Since Chevalier's dissertation appeared, this plain has been investigated by Mr. Morrisset, Mr. Gell, Dr. Clarke, Mr. Hobhouse, and several other travellers. Dr. Clarke traversed the ground in different directions seventeen times. He rejects the hypothesis of Chera- lier, and reasoning from the authority of Strabo, and from the act of New Ilium, which he ascertained by inscriptions found among ruins, he fixes the situation of Troy four or five miles to the northward of Boun- bachi, near a sluggish rivulet, called Calisat Osmak, which he considers to be the Simias. The name of the Scamander is still preserved in the Mender, the most considerable stream in the district, rising in Mount Ida, as described by Homer; and the Thymbros is still preserved in the Thymbrek. Dr. Clarke also finds objects corresponding to the Calicoline, the tomb of Ilus, and the Throsmos or mound of the plain. But very strong objections have been stated to Dr. Clarke's opinions by Mr. Hobhouse and others; and, upon the whole, the more the subject is investigated, the more insuperable difficulties seem to present themselves to any attempt to identify the places and objects alluded to by the poet. See Clarke's Travels, vol. 3d, 8vo. and Edinburgh Review, vol. 6th, p. 237.

TROLLIUS, GLOBE-FLOWER, or Lucken Gown, a genus of plants belonging to the class of polyanthra, and in the natural system ranging under the 26th order, Multiflorae. See BOTANY INDEX.

TROMP, MARTIN HAPPERTZ VAN, a celebrated Dutch admiral, was born at the Baille, in Holland. He raised himself by his merit, after having distinguished himself on many occasions, especially at the famous engagement near Gibraltar in 1607. He passed for one of the greatest seamen that had till that time appeared in the world; and was declared admiral of Holland, even by the advice of the prince of Orange. He in that character defeated a large Spanish fleet in 1639, and gained 32 other victories at sea; but was killed when under deck, in an engagement with the English in 1653. The states-general caused medals to be struck to his honour, and lamented him as one of the greatest heroes of their republic. Van Tromp, in the midst
TROVER, in Law, an action that a man hath against one that, having found any of his goods, refuseth to deliver them upon demand.

TROUT. See SALMO, Ichthyology Index.

TROY. See TROJA.

Troy-Weight, one of the most ancient of the different kinds used in Britain. The ounce of this weight was brought from Grand Cairo in Egypt, about the time of the crusades into Europe, and first adopted in Troyes, a city of Champagne; whence the name.

The pound English Troy contains 12 ounces, or 5760 grains. It was formerly used for every purpose; and is still retained for weighing gold, silver, and jewels; for compounding medicines; for experiments in natural philosophy; and for comparing different weights with each other.

Scots Troy-Weight was established by James VI. in the year 1618, who enacted that only one weight should be used in Scotland, viz. the French Troy stone of 16 pounds, and 16 ounces in the pound. The pound contains 7680 grains, and is equal to 17 oz. 6. dr. avoirdupois. The cwt. or 112 lb. avoirdupois, contains only 196 lb. 24 oz. of this weight, though generally reckoned equal to 196 lb. This weight is nearly, if not exactly, the same as that of Paris and Amsterdam; and is generally known by the name of Dutch weight. Though prohibited by the articles of union, it is still used in weighing iron, hemp, flax, most Dutch and Baltic goods, meal, butcher-meat, unwrought pewter and lead, and some other articles.

TRUE-LOVE. See PARIS, BOTANY.

TRUFFLES. See Lycoperdon, Botany Index.

TRUMPET, a musical instrument, the most noble of all portable ones of the wind kind; used chiefly in war, among the cavalry, to direct them in the service. Each troop of cavalry has one. The cords of the trumpets are of crimson, mixed with the colours of the facings of the regiments.

As to the invention of the trumpet, some Greek historians ascribe it to the Tyrrenians; but others, with greater probability, to the Egyptians; from whom it might have been transmitted to the Israelites. The trumpet was not in use among the Greeks at the time of the Trojan war; though it was in common use in the time of Homer. According to Potter (Arch. Græc. vol. ii. cap. 4.), before the invention of trumpets, the first signals of battles in primitive wars were lighted torches; to these succeeded shells of fishes, which were sounded like trumpets. And when the trumpet became common in military use, it may well be imagined to have served at first only as a rough and noisy signal of battle, like that at present in Abyssinia and New Zealand, and perhaps with only one sound. But even when more notes were produced from it, so noisy an instrument must have been an unfit accompaniment for the voice and poetry; so that it is probable the trumpet was the first solo instrument in use among the ancients.

TRUMPET, Articulate, comprehends both the speaking and the hearing trumpet, is by much the most valuable instrument, and has, in one of its forms, been used by people among whom we should hardly have expected to find such improvements.

That the speaking trumpet, of which the object is to increase the force of articulate sounds, should have been known to the ancient Greeks, can excite no wonder; and
and therefore we easily admit the accounts which we read of the horn or trumpet, with which Alexander addressed his army, as well as of the whispering caverns of the Byrtierian tyrant. But that the natives of Peru were acquainted with this instrument, will probably surprise many of our readers. The fact, however, seems incontrovertible.

In the History of the Order of Jesuits, published at Naples in 1662 by Berrettaria, it is said, that in the year 1595 a small convent of that order in Peru, situated in a remote corner, was in danger of immediate destruction by famine. One evening the superior Father Samanie had implored the help of the cacique; next morning, on opening the gate of the monastery, he found it surrounded by a number of women each of whom carried a small basket of provisions. He returned thanks to heaven for having miraculously interposed, by inspiring the good people with pity for the distress of his friars. But when he expressed to them his wonder how they came all to be moved as if by mutual agreement with these benevolent sentiments, they told him it was no such thing; that they looked upon him and his countrymen as a pack of infernal magicians, who by their sorceries had enslaved the country, and had bewitched their good cacique, who hitherto had treated them with kindness and attention, as became a true worshipper of the sun; but that the preceding evening at sunset he had ordered the inhabitants of such and such villages, about six miles off, to come that morning with provisions to this nest of wizards.

The superior asked them in what manner the governor had warned so many of them in so short a time, at such a distance from his own residence? They told him that it was by the trumpet; and that every person heard at their own door the distinct terms of the order. The father had heard nothing; but they told him that none heard the trumpet but the inhabitants of the villages to which it was directed. This is a piece of very curious information; but, after allowing a good deal to the exaggeration of the reverend Jesuits, it cannot, we think, be doubted but that the Peruvians actually possessed this stentoronic art. For we may observe that the effect described in this narration resembles what we now know to be the effect of speaking trumpets, while it is unlike what the inventor of such a tale would naturally and ignorantly say. Till speaking trumpets were really known, we should expect the sound to be equally diffused on all sides, which is not the case; for it is much stronger in the line of the trumpet than in any direction very oblique to it.

About the middle of the 17th century, Athanasius Kircher turned his attention to the philosophy of sound, and in different works threw out many useful and scientific hints on the construction of speaking trumpets (see Acoustics and Kircher); but his mathematical illustrations were so vague, and his own character of attention and credibility so notorious, that for some time these works did not attract the notice to which they were well entitled.

About the year 1670, Sir Samuel Morland, a gentleman of great ingenuity, science, and order, took up the subject, and proposed as a question to the Royal Society of London, What is the best form for a speaking trumpet? which he called a stentoronic horn. He accompanied his demand with an account of his own notions on the subject (which he acknowledged to be very vague and conjectural), and an exhibition of some instruments constructed according to his views. They were in general very large conical tubes, suddenly spreading at the very mouth to a greater width. Their effect was really wonderful. They were tried in St James's park; and his majesty K. Charles II. speaking in his ordinary colloquial pitch of voice through a trumpet only 3 feet long, was clearly and most distinctly heard at the distance of a thousand yards. Another person, selected we suppose for the loudness and distinctness of his voice, was perfectly understood at the distance of four miles and a half. The fame of this soon spread; Sir Samuel Morland's principles were refined, considering the novelty of the thing, and differ considerably from Father Kircher's. The aural sensations, (for he speaks very accurately concerning the nature of sound) endured to disperse themselves in spheres, but are stopped by the tube, and therefore reundulate towards the axis like waves from a bank, and meeting in the axis, they form a strong undulation a little farther advanced along the tube, which again spreads, is again reflected, and so on, till it arrives at the mouth of the tube greatly magnified, and then it is diffused through the open air in the same manner, as if all proceeded from a very sonorous point in the centre of the wide end of the trumpet. The author distinguishes with great judgment between the prodigious reinforcement of sound in a speaking trumpet and that in the musical trumpet, bugle-horn, conch-shell, &c.; and shows that the difference consists only in the violence of the first sonorous agitation, which can be produced by us only on a very small extent of surface. The mouth-piece diameter, therefore, of the musical trumpet must be very small, and the force of blast very considerable. Thus one strong but simple undulation will be excited, which must be subjected to the modifications of harmony, and will be augmented by using a conical tube (A). But a speaking trumpet must make no change on the nature of the first undulations; and each point of the mouth-piece must be equally considered as the centre of sonorous undulations, all of which must be reinforced in the same degree, otherwise all distinctness of articulation will be lost. The mouth-piece must therefore take in the whole of the mouth of the speaker.

When Sir Samuel Morland's trumpet came to be generally known on the continent, it was soon discovered that the speaker could be heard at a great distance only in the line of the trumpet; and this circumstance was by a Mr Cassegrain (Journ. des Savans, 1672, p.131.) attributed to a defect in the principle of its construction, which he said was not according to the laws of sonorous undulations. He proposed a coneoid formed by the revolution of a hyperbola round its asymptote as the best form. A Mr Hase of Wurttemberg, on the other hand, proposed a parabolic conoid, having the mouth of the speaker

(A) Accordingly the sound of the bugle horn, of the musical trumpet, or the French horn, is prodigiously loud, when we consider the small passage through which the moderate blast is sent by the trumpeter.
Ourselfs of this fact as a mean for enforcing sound, though we cannot explain it in a satisfactory manner. We should expect from it an effect similar to the hearing of the original sound along with another original sound coming from the place from which this reflected sound diverges. If therefore the reflected sound or echo arrives at the ear in the same instant with the original sound, the effect will be doubled; or at least it will be the same with two simultaneous original sounds. Now we know that this is in some sense equivalent to a stronger sound. For it is a fact, that a number of voices uttering the same or equal sounds are heard at a much greater distance than a single voice. We cannot perhaps explain how this happens by mechanical laws, nor assign the exact proportion in which 10 voices exceed the effect of one voice; nor the proportion of distances at which they seem equally loud. We may therefore, for the present, suppose that two equal voices at the same distance are twice as loud, three voices three times as loud, &c. Therefore, if by means of a speaking trumpet, we can make 10 equal echoes arrive at the ear at the same moment, we may suppose its effect to be to increase the audibility 10 times; and we may express this shortly, by calling the sound 10 times louder or more intense.

But we cannot do this precisely. We cannot by any contrivance make the sound of a momentary snap, and those of its echoes, arrive at the ear in the same moment, because they come from different distances. But if the original noise be a continued sound, a man's voice, for example, uttering a continued uniform tone, the first echo may reach the ear at the same moment with the second vibration of the larynx; the second echo along with the third vibration, and so on. It is evident, that this will produce the same effect. The only difference will be, that the articulations of the voice will be made indistinct, if the echoes come from very different distances. Thus if a man pronounces the syllable raw, and the 10 successive echoes are made from places which are 10 feet farther off, the 10th part of a second (nearly) will intervene between hearing the first and the last. This will give it the sound of the syllable thow, or perhaps raw, because r is the repetition of t. Something like this occurs when, standing at one end of a long line of soldiers, we hear the muskets of the whole line discharged in one instant. It seems to us the sound of a running fire.

The aim therefore in the construction of a speaking trumpet may be, to cause as many echoes as possible to reach a distant ear without any perceptible interval of time. This will give distinctness, and something equivalent to loudness. Pure loudness arises from the violence of the single aerial undulation. To increase this may be the aim in the construction of a trumpet; but we are not sufficiently acquainted with the mechanism of these undulations to bring about with certainty and precision; whereas we can procure this accumulation of echoes without much trouble, since we know that echoes are, in fact, reflected like light. We can form a trumpet so that many of these lines of reflected sound shall pass through the place of the hearer. We are indebted to Mr. Lambert of Berlin for this simple and popular view of the subject; and shall here give an abstract of his most ingenious Dissertation on Acoustic Instruments published in the Berlin Memoirs for 1762.
Sound naturally spreads in all directions; but we know that echoes or reflected sounds proceed almost strictly in certain limited directions. If therefore we contrive a trumpet in such a way that the lines of echo shall be confined within a certain space, it is reasonable to suppose that the sound will become more audible in proportion as this diffusion is prevented. Therefore, if we can oblige a sound which, in the open air, would have diffused itself over a hemisphere, to keep within a cone of 120 degrees, we should expect it to be twice as audible within this cone. This will be accomplished, by making the reflections such that the lines of reflected sound shall be confined within this cone. N.B. We here suppose that nothing is lost in the reflection. Let us examine the effect of a cylindrical trumpet.

Let the trumpet be a cylinder ABED, (fig. 1.), and let C be a sounding point in the axis. It is evident that all the sound in the cone BCE will go forward without any reflection. Let CM be any other line of sound, which we may for brevity's sake, call a sonorous or phonic line. Being reflected in the points M, N, O, P, it is evident that it will at last escape from the trumpet in a direction PQ, equally diverging from the axis with the line CM. The same must be true of every other sonorous line. Therefore the echoes will all diverge from the mouth of the trumpet in the same manner as they would have proceeded from C without any trumpet. Even supposing, therefore, that the echoes are as strong as the original sound, no advantage is gained by such a trumpet, but that of bringing the sound forward from C to c. This is quite trifling when the bearer is at a distance. Yet we see that sounds may be heard at a very great distance, at the end of long, narrow, cylindrical, or prismal galleries. It is known that a voice may be distinctly heard at the distance of several hundred feet in the Roman aqueducts, whose sides are perfectly straight and smooth, being plastered with stucco. The smooth surface of the still water greatly contributes to this effect. Cylindrical or prismal trumpets must therefore be rejected.

Let the trumpet be a cone BCA (fig. 2.), of which CN is the axis, DK a line perpendicular to the axis, and DFHI the path of a reflected sound in the plane of the axis. The last angle of reflection IHA is equal to the last angle of incidence FHC. The angle BFI, or its equal CFD, is equal to the angles FHD and FCH; that is, the angle of incidence CFD exceeds the next angle of incidence FHC by the angle FCD; that is, by the angle of the cone. In like manner, FHD exceeds CFD by the same angle FCD. Thus every succeeding angle, either of incidence or reflection, exceeds the next by the angle of the cone. Call the angle of the cone a, and let b be the first angle of incidence PDC. The second, or DFC, is b - a. The third, or FHC, is b - 2 a, &c.; and the nth angle of incidence or reflection is b - n a, after n reflections. Since the angle diminishes by equal quantities at each subsequent reflection, it is plain, that whatever be the first angle of incidence, it may be exhausted by this diminution; namely, when n times a exceeds or is equal to b. Therefore to know how many reflections of a sound, whose first incidence has the inclination b, can be made in an infinitely extended cone, whose angle is a, divide b by -a; the quotient will give the number n of reflections, and the remainder, if any, will be the last angle of incidence or reflection less than a. It is very plain, that when an angle of reflection IHA is equal to or less than the angle BCA of the cone, the reflected line HI will no more meet with the other side CD of the cone.

We may here observe, that the greatest angle of incidence is a right angle, or 90°. This sound would be reflected back in the same line, and would be incident on the opposite side in an angle = 90° - a, &c.

Thus we see that a conical trumpet is well suited for confining the sound: for by prolonging it sufficiently, we can keep the lines of reflected sound wholly within the cone. And when it is not carried to such a length as to do this, when it allows the sounding line GH, for example, to escape without further reflection, the divergence from the axis is less than the last angle of reflection BGC by half the angle BCA of the cone. Let us see what is the connection between the length and the angle of ultimate reflection.

We have sin b - a = sin b = CD : CF, and CF = sin b
CD x sin b - a

and sin b - 2 a = CF:

sin b - a

sin b

sin b - 2 a

sin b

sin b - a

CD x

sin b

sin b - 2 a

sin b - a

&c.

Therefore if we suppose X to be the length which will give us n reflections, we shall have X = CD x

sin b

sin b

Hence we see that the length increases as sin b - n a. Hence we see that the length increases as

sin b - n a. Hence we see that the length increases as

Therefore if we suppose X to be the length which will give the nth reflection, we can give the length which will give the one immediately preceding, whose angle with the side of the cone is a. Let X be this length. We have X = CD x

sin b

sin a

This length will allow every line of sound to be reflected as often, varying once, as if the tube were infinitely long. For suppose a sonorous line to be traced backwards, as if a sound entered the tube in the direction iA, and were reflected in the points h, f, d, D, the angles will be continually augmented by the constant angle a. But this augmentation can never go farther than 90° + 2a. For if it reaches that value at D, for instance, the reflected line DK will be perpendicular to the axis CN; and the angle ADK will be equal to the angle DKB, and the sound will come out again. This remark is of importance on another account.

Now suppose the cone to be cut off at D by a plane perpendicular to the axis, KD will be the diameter of its mouth-piece; and if we suppose a mouth completely occupying this circle, and every point of the circle to be sonorous, the reflected sounds will proceed from it in the same manner as light would from a flame which completely
TRUMPET

[495]

Trumpet. completely occupies its place and is reflected by the inside of the cone. The angle FDA will have the greatest possible sine when it is a right angle, and it
never can be greater than ADK, which is equal to $\frac{a}{2}$.
And since between $90^\circ + \frac{a}{2}$, and $90^\circ - \frac{a}{2}$, there must fall some multiple of $a$; call this multiple $b$. Then, in order that every sound may be reflected as often as possible, saving once, we must make the length of $X = CD \times \frac{b}{S_a}$.

Now since the angle of the cone is never made very great, never exceeding 10 or 12 degrees, $b$ can never differ from 90 above a degree or two, and its sine cannot differ much from unity. Therefore $X$ will be very nearly equal to $CD \times \frac{a}{S_a}$, which is also very nearly equal to $CD = LM (or \ CD_1): \ CM$ and $CM = \frac{CD^2}{DK}$.

But $2S_a : 1 = DK : CD$, and $2S_a : 1 = CD : CM$, therefore $4S_a^2 : 1 = DK : CM$.

And $CM = \frac{DK}{S_a}$ very nearly. And since DK is an inch and a half, we get the length in inches, counted from the apex of the cone $= \frac{3}{2} S_a$, or $\frac{3}{2} S_a$. From this we must cut off the part CD, which:

$\sin 30^\circ = \frac{S_a}{CD}$, and the nearest multiple of $a$ is 84 or 96, both of which are as far removed as possible from 90, and the error is as great as possible, and is nearly $\frac{1}{10}$th of the whole.

This approximation gives us a very simple construction. Let CM be the required length of the trumpet, and draw MI perpendicular to the axis in O. It is evident that $S_a$, MCO: rad. = MO: CM, and CM; or $X = \frac{LM}{S_a} \times \frac{b}{S_a}$, but $X = CD \times \frac{b}{S_a}$, and therefore LM is equal to CD.

If therefore the cone be of such a length, that its diameter at the equal is to the length of the part cut off; every line of sound will have at least as many reflections, save one, as if the cone were infinitely long; and the last reflected line will either be parallel to the opposite side of the cone, or lie nearer the axis than this parallel; consequently such a cone will confine all the reflected sounds within a cone whose angle is $2a$, and will augment the sound in the proportion of the spherical base of this cone to a complete hemispherical surface. Describe the circle DK round C, and making DT an arch of 90, draw the chord DT. Then since the circles described with the radii DK, DT, are equal to the spherical surfaces generated by the revolution of the arc DK, and DKT round the axis CD, the sound will be condensed in the proportion of $DK^2$ to DT.

This appears to be the best general rule for constructing the instrument; for, to procure another reflection, the tube must be prodigiously lengthened, and we cannot suppose that one reflection more will add greatly to its power.

It appears, too, that the length depends chiefly on the angle of the cone; for the mouth-piece may be considered as nearly a fixed quantity. It must be of a size to admit the mouth when speaking with force and without constraint. About an inch and a half may be fixed on for its diameter. When therefore we propose to confine the sound to a cone of twice the angle of the trumpet, the whole is determined by that angle. For in this case LM is equal to CD, we have DK : TRUMPET.

$CD = LM (or \ CD_1): \ CM$ and $CM = \frac{CD^2}{DK}$.

But $2S_a : 1 = DK : CD$, and $2S_a : 1 = CD : CM$, therefore $4S_a^2 : 1 = DK : CM$.

And $CM = \frac{DK}{S_a}$ very nearly. And since DK is an inch and a half, we get the length in inches, counted from the apex of the cone $= \frac{3}{2} S_a$, or $\frac{3}{2} S_a$. From this we must cut off the part CD, which:

$\sin 30^\circ = \frac{S_a}{CD}$, and the nearest multiple of $a$ is 84 or 96, both of which are as far removed as possible from 90, and the error is as great as possible, and is nearly $\frac{1}{10}$th of the whole.

On the other hand, if the length of the trumpet is fixed on, we can determine the angle of the cone. For let the length (reckoned from C) be $L_1$, we have $2S_a = \frac{3}{2} L_1$.

or $S_a = \frac{3}{2} L_1$, and $S_a = \sqrt{\frac{3}{2} L_1}$.

Thus let 6 feet or 72 inches be chosen for the length of the cone, we have $S_a = \sqrt{\frac{3}{144}} = \sqrt{\frac{1}{4}} = 0.1444$.

$\sin 8^\circ 17' = \text{for the angle of the cone}$; and the width at the mouth is $\frac{3}{2} S_a = 10.4$ inches. This being taken from 72, leaves 61.6 inches for the length of the trumpet.

And since this trumpet confines the reflected sounds to a cone of $10^\circ 34'$, we have its magnifying power $= DT^2 : \frac{DK^2}{DK^2}$.

$\sin 30^\circ = \frac{S_a}{CD}$, and the nearest multiple of $a$ is 84 or 96, nearly 10 times farther off. For the loudness of sound is supposed to be inversely as the square of the distance from the centre of undulation.

But before we can pronounce with precision on the performance of a speaking trumpet, we must examine into the manner in which the reflected sounds are distributed over the space in which they are all confined.

Let BKDA (fig. 3) be the section of a conical trumpet by a plane through the axis; let $C$ be the vertex of the cone, and $CD$ its axis; let $TKV$ be the section of a sphere, having its centre in the vertex of the cone; and let $P$ be a sonorous point on the surface of the sphere, and $P a f e$ the path of a line of sound lying in the plane of the section. In the great circle of the sphere take $K Q = K P$, $D Q = D Q$, and $K S = K R$. Draw $Q B$ parallel to $D A$; and draw $P B$, $P D$, $P A$.

Then it is evident that all the lines drawn from $P$, within the cone $A P B$, proceed without reflection, and are diffused as if no trumpet had been used.

2. All

2. All the sonorous lines which fall from P on KB are reflected from it as if they had come from Q.

3. All the sonorous lines between BP and dP have suffered but one reflection; for d a will no more meet DA' so as to be reflected again.

4. All the lines which have been reflected from KB, and afterwards from DA, proceed as if they had come from R. For the lines reflected from KB proceed as if they had come from Q; and lines coming from Q and reflected by DA, proceed as if they had come from R. Therefore draw RAq, and also draw Rg mp parallel to KB, and draw Q e A q, Q b g, P c, and P b. Then,

5. All the lines between b P and e P have been twice reflected.

Again, draw SB p, B r R, r a Q, S x A, R y x, Q y y.

6. All the lines between w P and n P have suffered three reflections.

Draw the tangents TA t, VB v, crossing the axis in W.

7. The whole sounds will be propagated within the cone v W t. For to every sonorous point in the line KD there corresponds a point similar to Q, regulating the first reflection from KB; and a point similar to R, regulating the second reflection from DA; and a point S regulating the third reflection from KB, &c. And similar points will be found regulating the first reflection from DA, the second from KB, and the third from DA, &c.; and lines drawn from all these through A and B must lie within the tangents TA and VB.

8. Thus the centres of reflection of all the sonorous lines which lie in planes passing through the axis, will be found in the surface of the sphere; and it may be considered as a sonorous sphere, whose sounds first concentrate in W, and are then diffused in the cone v W t.

It may be demonstrated nearly in the same manner, that the sonorous lines which proceed from P, but not in the plane passing through the axis, also proceed, after various reflections, as if they had come from points in the surface of the same sphere. The only difference in the demonstration is, that the centres Q, R, S of the successive reflections are not in one plane, but in a spiral line winding round the surface of the sphere according to fixed laws. The foregoing conclusions are therefore general for all the sounds which come in all directions from every point in the area of the mouth-piece.

Thus it appears, that a conical trumpet is well fitted for increasing the force of sounds by diminishing their final divergence. For had the speaker's mouth been in the open air, the sounds which are now confined within the cone v W t would have been diffused over a hemisphere: and we see that prolonging the trumpet must confine the sounds still more, because this will make the angle BWA still smaller; a longer tube must also occasion more reflections, and consequently send more sonorous undulations to the ear at a distance placed within the cone v W t.

We have now obtained a very connected view of the whole effect of a conical trumpet. It is the same as if the whole segment TKDV were sounding, every part of it with an intensity proportional to the density of the points Q, R, S, &c, corresponding to the different points P of the mouth-piece. It is easy to see that this cannot be uniform, but must be much rarer towards the margin of the segment. It would require a good deal of discussion to show the density of these fictitious sounding points; and we shall content ourselves with giving a very palpable view of the distribution of the sonorous rays, or the density (so to speak) of the echoes, in the different situations in which a hearer may be placed.

We may observe, in the mean time, that this substitution of a sounding sphere for the sounding mouth-piece has an exact parallel in optics, by which it will be greatly illustrated. Suppose the cone BKDA (fig. 3) to be a tube polished in the inside, fixed in a wall B, perforated through BA, and that the mouth-piece DK is occupied completely by a flat flame. The effect of this on a spectator will be the same, if he is properly placed in the axis, as if he were looking at a flame as big as the whole sphere. This is very evident.

It is easy to see that the line l e S is equal to the line l e a P; therefore the reflected sounds also come to the ear in the same moments as if they had come from their respective points on the surface of the substituted sphere. Unless, therefore, this sphere be enormously large, the distinctness of articulation will not be sensibly affected, because the interval between the arrival of the different echoes of the same snap will be insensible.

Our limits oblige us to content ourselves with exhibiting this evident similarity of the progress of echoes from the surface of this phonic sphere, to the progress of light from the same luminous sphere shining through a hole of which the diameter is AB. The direct investigation of the intensity of the sound in different directions and distances would take up much room, and give no clearer conception of the thing. The intensity of the sound in any point is precisely similar to the intensity of the illumination of the same point; and this is proportional to the portion of the luminous surface seen from this point through the hole directly, and to the square of the distance inversely. The intelligent reader will acquire a distinct conception of this matter from fig. 4, which represents the distribution of the sonorous lines, and by consequence the degree of loudness which may be expected in the different situations of the hearer.

As we have already observed, the effect of the cone of the trumpet is perfectly analogous to the reflection of light from a polished concave, conical mirror. Such an instrument would be equally fitted for illuminating a distant object. We imagine that these would be much more powerful than the spherical or even parabolic mirrors commonly used for this purpose. These last, having the candle in the focus, also send forward a cylinder of light of equal width with the mirror. But it is well known, that oblique reflections are prodigiously more vivid than those made at greater angles. Where the inclination of the reflected light to the plane of the mirror does not exceed eight or ten degrees, it reflects about three-fourths of the light which falls on it. But when the inclination is 80°, it does not reflect one-fourth part.

We may also observe, that the density of the reflected sounds by the conical trumpet ABC (fig. 4) is precisely similar to that of the illumination produced by a luminous sphere TDV, shining through a hole AB. There will be a space circumscribed by the cone formed by the lines TB and VA, which is uniformly illuminated by the whole sphere (or rather by the segment TDV), and on each side there is a space illuminated by
Trum., a part of it only, and the illumination gradually decreases towards the borders. A spectator placed much out of the axis, and looking through the hole AB, may not see the whole sphere. In like manner, he will not hear the whole sounding sphere: He may be so far from the axis as neither to see nor hear any of it.

Assisting our imaginations by this comparison, we perceive that beyond the point is there no place where all the reflected sounds are heard. Therefore, in order to preserve the magnifying power of the trumpet at any distance, it is necessary to make the mouth as wide as the sonorous sphere. Nay, even this would be an imperfect instrument, because its power would be confined to a very narrow space; and if it be not accurately pointed to the person listening, its power will be greatly diminished. And we may observe, by the way, that we derive from this circumstance a strong confirmation of the justness of Mr. Lambert's principles; for the effects of speaking trumpets are really observed to be limited in the way here described.—Parabolic trumpets have been made, and they fortify the sound not only in the cylindrical space in the direction of the axis, but also on each side of it, which should not have been the case had their effect depended only on the undulations formed by the parabola in planes perpendicular to the axis. But to proceed.

Let BCA (fig. 5.) be the cone, ED the mouth-piece, TEDV the equivalent sonorous sphere, and TBAV the circumscribed cylinder. Then CA or CB is the length of cone that is necessary for maintaining the magnifying power at all distances. We have two conditions to be fulfilled: the diameter ED of the mouth-piece must be of a certain fixed magnitude, and the diameter AB of the outer end must be equal to that of the equivalent sonorous sphere. These conditions determine all the dimensions of the trumpet and its magnifying power. And, first, with respect to the dimensions of the triangle.

The similarity of triangles ECG and BCF gives CG : ED = CF : AB; but CG = BF = 1/4 AB, and CG = 1/4 AB + 1/4 AB; therefore 1/4 AB = ED = GF + AB; therefore 2 GF + ED + AB = AB + AB + AB; therefore 2 GF + ED + AB = AB; therefore 2 GF + ED = AB + ED = AB, and 2 GF + ED = AB, and 2 GF + ED = AB, and 2 GF + ED = AB, and 2 GF + ED = AB, and 2 GF + ED = AB.

And, on the other hand, because AB = EB + AD = 2 GF + ED, we have AB = EB + AD + 1/4 ED = 2 GF + ED + 1/4 ED, or AB = EB + AD + 1/4 ED = 2 GF + ED + 1/4 ED, and AB = 2 GF + ED + 1/4 ED, and AB = 2 GF + ED + 1/4 ED, and AB = 2 GF + ED + 1/4 ED, and AB = 2 GF + ED + 1/4 ED.

Let x represent the length of the trumpet, y the diameter at the great end, and m the diameter of the mouth-piece. Then: 

\[ y = \frac{x - m}{2} \] 
\[ y = \sqrt{\frac{2}{x} + \frac{2}{m} + \frac{2}{x} + \frac{2}{m}} \]

Thus the length and the great diameter may be had reciprocally. The useful case in practice is to find the diameter for a proposed length, which is given by the last equation.

Now if we take all the dimensions in inches, and fix m at an inch and a half, we have 2 x m = 3 x, and 2/3 m = 0.625, and 1/2 = 0.575; so that our equation becomes \[ y = \sqrt{3 + 0.625 + 0.75} \]. The following table gives the dimensions of a sufficient variety of trumpets. The first column is the length of the trumpet in feet; the second column is the diameter of the mouth in inches; the third column is the number of times that it magnifies the sound; and the fourth column is the number of times that it increases the distance at which a man may be distinctly heard by its means; the fifth contains the angle of the cone.

ED in all is = 1.5

The two last columns are constructed on the following considerations: We conceive the hearer placed within the cylindrical space whose diameter is BA. In this situation he receives an echo coming apparently from the whole surface TGV; and we account the effect of the trumpet as equivalent to the united voices of as many mouths as would cover this surface. Therefore the quotient obtained by dividing the surface of the hemisphere by that of the mouth-piece will express the magnifying power of the trumpet. If the chords GF, GE, GT be drawn, we know that the spherical surfaces TGF, TGE, TGD, are respectively equal to the circles described with the radii TG, GE, GT, and are therefore as TGF and TGE. Therefore the audibility of the trumpet, when compared with a single voice, may be expressed by 

\[ \frac{TGF}{TGE} \]

Now the ratio of TGF to TGE is easily obtained.

For if EF be drawn parallel to the axis, it is plain that 

\[ B = \frac{BA - ED}{2} \]

and that EF is to AB as radius to the tangent of BCF; which angle we may call \( \alpha \).

Therefore \( \tan \alpha = \frac{y - m}{x/2} \), and thus we obtain the angle \( \alpha \). But if the radius CE be accounted 1, TG is \( \frac{\sqrt{2}}{2} \), and EG is \( \frac{\sqrt{2}}{2} \). Therefore 

\[ \frac{TGF}{TGE} = \frac{\sqrt{2}}{2} \]

and the magnifying power of the trumpet is 

\[ \frac{2}{4 \sin^2 \frac{\alpha}{2}} \]
The numbers, therefore, in the third column of the table are each
\[ \frac{1}{\sin^2 \alpha} \]
But the more usual way of conceiving the power of the trumpet is, by considering how much farther it will enable us to hear a voice equally well. Now we suppose that the audibility of sounds varies in the inverse duplicate ratio of the distance. Therefore if the distance \( d \), at which a man may be distinctly heard, be increased to \( 2d \), in the proportion of \( EG \) to \( TG \), the sound will be less audible, in the proportion of \( TG^2 \) to \( EG^2 \). Therefore the trumpet will be as well heard at the distance \( 2d \) as the simple voice is heard at the distance \( d \).

Therefore \( \sqrt{2} \) will express the extending power of the trumpet, which is therefore \( \frac{\sqrt{2}}{2} \). In this manner were the numbers computed for the fourth column of the table.

When the angle \( BCA \) is small, which is always the case in speaking trumpets, we may, without any sensible error, consider \( EG \) as \( \frac{ED}{2} \) and \( TG \) as \( TC \).

\[ x \cdot \sqrt{2} = \frac{AB}{2} \sqrt{2} = \frac{y}{2} \]

This gives a very easy computation of the extending and magnifying powers of the trumpet.

The extending power is \( \sqrt{2} \frac{y}{m} \).

The magnifying power is \( 2 \frac{z^2}{m^2} \).

We may also easily deduce from the premises, that if the mouth-piece be an inch and a half in diameter, and the length \( x \) be measured in inches, the extending power is very nearly \( \sqrt{x} \) and the magnifying power \( \frac{x}{\sqrt{2}} \).

An inconvenience still attends the trumpet of this construction. Its complete audibility is confined to the cylindrical space in the direction of the axis, and it is more faintly heard on each side of it. This obliges us to direct the trumpet very exactly to the spot where we wish it to be heard. This is confirmed by all the accounts we have of the performance of great speaking trumpets. It is evident, that by lengthening the trumpet, and therefore enlarging its mouth, we make the lines \( TB \) and \( VA \) expand (fig. 4); and therefore it will not be so difficult to direct the trumpet.

But even this is confined within the limits of a few degrees. Even if the trumpet were continued without end, the sounds cannot be reinforced in a wider space than the cone of the trumpet. But it is always advantageous to increase its length; for this makes the extreme tangents embrace a greater portion of the sonorous sphere, and thus increases the sound in the space where it is all reflected. And the limiting tangents \( TB \), \( VA \) expand still more, and thus the space of full effect is increased. But either of these augmentations is very small in comparison of the augmentation of size. If the trumpet of fig. 5 were made an hundred times longer, its extending power would not be increased one half.

We need not therefore aim at much more than to produce a cylindrical space of full effect; and this will always be done by the preceding rules, or table of constructions. We may give the trumpet a third or a fourth part more length, in order to spread a little the space of its full effect, and thereby make it more easily directed to the intended object. But in doing this we must be careful to increase the diameter of the mouth as much as we increase the length; otherwise we produce the very opposite effect, and make the trumpet greatly inferior to a shorter one, at all distances beyond a certain point. For by increasing the length while the part \( CG \) remains the same, we cause the tangents \( TB \) and \( VA \) to meet on some distant point, beyond which the sound diffuses prodigiously. The construction of a speaking trumpet is therefore a problem of some nicety; and as the trials are always made at some considerable distance, it may frequently happen that a trumpet which is not heard at a mile's distance, may be made very audible two miles off by cutting off a piece at its width end.

After this minute consideration of the conical trumpet, we might proceed to consider those of other forms. In particular, the hyperbolic, proposed by Cassegrain, and the parabolic, proposed by Haase, seem to merit consideration. But if we examine them merely as reflectors of echoes, we shall find them inferior to the conical.

With respect to the hyperbolic trumpet, its inaptitude is evident at first sight. For it must dissipate the echoes more than a conical trumpet. Indeed Mr. Cassegrain proceeds on quite different principles, depending on the mechanism of the aerial undulations: his aim was to increase the agitation in each pulse, so that it may make a more forcible impulse on the ear. But we are too imperfectly acquainted with this subject to decide a priori; and experience shows that the hyperbola is not a good form.

With respect to the parabolic trumpet, it is certain that if the mouth-piece were but a point, it would produce the most favourable reflection of all the sounds; for they would all proceed parallel to the axis. But every point of an open mouth must be considered as a centre of sound, and none of it can be kept out of the trumpet. If this be all admitted, it will be found that a conical trumpet, made by the preceding rules, will dissipate the reflected sounds much less than the parabolic.

Thus far have we proceeded on the fair consequences of the well known fact, that echoes are reflected in the same manner as light, without engaging in the intricate investigation of aerial undulations. Whoever considers the Newtonian theory of the propagation of sound with intelligence and attention, will see that it is demonstrated solely in the case of a single row of particles; and that all the general corollaries respecting the lateral diffusion of the elastic undulations are little more than sagacious guesses, every way worthy of the illustrious author, and beautifully confirmed by what we can most distinctly and accurately observe in the circular waves on the surface of still water. But they are by no means fit for becoming the foundation of any doctrine which lays the smallest claim to the title of accurate science. We really know
know exceedingly little of the theory of aerial undulations; and the conformity of the phenomena of sound to these guesses of Sir Isaac Newton has always been a matter of wonder to every eminent and candid mathematician: and no other should pretend to judge of the matter. This wonder has always been acknowledged by Daniel Bernoulli; and he is the only person who has made any addition to the science of sounds that is worth mentioning. For such we must always esteem his doctrine of the secondary undulations of musical cords, and the secondary pulses of air in pipes. Nothing therefore is more unwarrantable, or more plainly shows the precipitant presumption of modern sciolists, than the familiar use of the general theory of aerial undulations in their attempts to explain the abstruse phenomena of nature (such as the communication of sensation from the organ to the sensorium by the vibrations of a nervous fluid, the reciprocal communication of the volitions from the sensorium to the muscle, nay, the whole phenomena of mind), by vibrations and vibratimcular.

Such attempts equally betray ignorance, presumption, and want of soul. Ignorance of the extent to which the Newtonian theory may be logically carried, is the necessary consequence of ignorance of the theory itself. It is presumption to apply it to the phenomena of the intellectual world; and surely he has an abject soul who hugs and cherishes the humble thought, that his mind is an undulating fluid, and that its all-grasping comprehension, and all its delightful emotions, are nothing more than an ethereal tone.—*Pul me occidisti amen tes.* This which is older than the Harpies: It may be found in Robinet's *Systeme de la Nature.* This by the bye made its first appearance as a discourse delivered by Brother Orateur in the lodge of the grand Orient at Lyons; from which source have proceeded all the cosmopolitan societies in Europe, and that illumination by which reason is to triumph over revelation, and liberty and equality over civil government. We crave pardon of our readers for this ebullition of spleen; and we hope for it from all those who can read Newton, and who esteem his modesty.

Those who have endeavoured to improve the speaking trumpet on mechanical principles, have generally aimed at increasing the violence of the elastic undulations, that they may make a more forcible impulse on the ear. This is the object in view in the parabolic trumpet. All the undulations are converted into others which are in planes perpendicular to the axis of the instrument; so that the same little mass of air is agitated again and again in the same direction. From this it is obvious to conclude, that the total agitation will be more violent. But, in the first place, these violent agitations must diffuse themselves laterally as soon as they get out of the trumpet, and thus be weakened, in a proportion that is perhaps impossible for the most expert analyst to determine. But, moreover, we are not sufficiently acquainted with the mechanism of the very first agitations, to be able to perceive what conformation of the trumpet will cause the reflected undulations to increase the first undulations, or to check them. For it must happen, during the production of a continued sound in a trumpet, that a parcel of air, which is in a state of progressive agitation, as it makes a pulse of one sound, may be in a state of retrograde agitation, as it is part of a pulse of air producing another sound. We cannot (at least no mathe-
The subject is greatly simplified by the circumstances of the case; for the sounds to which we listen generally come in nearly one direction, and all that we have to do is to produce a constipation of them. And we may conclude, that the audibility will be proportional to this constipation.

Therefore let $ACB$, fig. 6, be the cone, and $CD$ its axis. The sound may be conceived as coming in the direction $RA$, parallel to the axis, and to be reflected in the points $A, B, C, D, E, F$ till the angle of incidence increases to $90^\circ$; after which the subsequent reflections send the sound out again. We must therefore cut off a part of the cone; and, because the lines increase their angle of incidence at each reflection, it will be proper to make the angle of the cone an aliquot part of $90^\circ$, that the least incidence may amount precisely to that quantity. What part of the cone should be cut off may be determined by the former principles. Call the angle $ACD$, $\alpha$. We have $C\cdot e = \frac{\sin(\alpha)}{\sin(\frac{2\pi}{n}+1)}$ when the sound gets the last useful reflection. Then we have the diameter of the mouth $AB = 2 \cdot \frac{\sin a}{\sin a}$, and that of the other end $C \cdot e = 2 \cdot \frac{\sin a}{\sin a}$. Therefore the sounds will be constituted in the ratio of $CA$ to $C\cdot e$, and the trumpet will bring the speaker nearer in the ratio of $CA$ to $C\cdot e$.

When the lines of reflected sound are thus brought together, they may be received into a small pipe perfectly cylindrical, which may be inserted into the external ear. This will not change their angles of inclination to the axis nor their density. It may be convenient to make the internal diameter of this pipe $\frac{1}{4}$ of an inch. Therefore $C\cdot e : \sin a = \frac{1}{4}$ of an inch. This circumstance, in conjunction with the magnifying power proposed, determines the other dimensions of the hearing trumpet. For $C\cdot e = \frac{1}{4}\sin a$, and $C\cdot a = \frac{\sin(\frac{2\pi}{n}+1)}{\sin^2 a}$.

Thus the relation of the angle of the cone and the length of the instrument is ascertained, and the sound is brought nearer in the ratio of $CA$ to $C\cdot e$, or of $(\frac{2\pi}{n}+1)\alpha$ to $\sin a$. And seeing that we found it proper to make $(\frac{2\pi}{n}+1)\alpha = 90^\circ$, we obtain this very simple analogy, $1 : \sin a = CA : C\cdot e$. And the size of $\frac{1}{4}$ of the angle of the cone is to radius $1$ to the approximating power of the instrument.

Thus let it be required that the sound may be as audible as if the voice were 12 times nearer. This gives $CA = 12$. This gives $\sin a = \frac{1}{12}$, and $a = 4^\circ 47'\,\prime$, the angle of the cone $= 93.4^\circ$. Then $C\cdot e = \frac{1}{4}\sin a = \frac{1}{4}\times\frac{144}{6} = 24$. Therefore the length of the cone is 24 inches. From this take $C\cdot e = \frac{CA}{12} = 2$, and the length of the trumpet is 22 inches. The diameter at the mouth is 2 $C\cdot e = 4$ inches. With this instrument one voice should be as loud as 144.

If it were required to approximate the sound only four times, making it 16 times stronger than the natural voice...
Trumpet. voice at the same distance, the angle ACB must be 20° 3' A c must be 2 inches, AB must be 1 1/4 inches, and e f must be 3 1/2 inches. It is easy to see, that when the size of the ear-end is the same in all, the diameters at the outer end are proportional to the approximating powers, and the lengths of the cones are proportional to the magnifying powers.

We shall find the parabolic conoid the preferable shape for an acoustic trumpet; because as the sounds come into the instrument in a direction parallel to the axis, they are reflected so as to pass through the focus. The parabolic conoid must therefore be cut off through the focus, that the sounds may not go out again by the subsequent reflections; and they must be received into a cylindrical pipe of one-third of an inch in diameter. Therefore the parameter of this parabola is one-sixth of an inch, and the focus is one-twelfth of an inch from the vertex. This determines the whole instrument; for they are all portions of one parabolic conoid. Suppose that the instrument is required to approximate the sound 12 times, as in the example of the conical instrument. The ordinate at the mouth must be 12 times the 6th of an inch, or 2 inches; and the mouth diameter is 4 inches, as in the conical instrument. Then, for the length, observe, that DC in fig. 7 is 4th of an inch, and MP is 2 inches, and AC is 1 1/4th of an inch, and DC': MP = AC · AP. This will give AP = 12 inches, and CP = 11 1/4ths; whereas in the conical tube it was 23. In like manner an instrument which approximates the sounds four times, is only 4 1/4 inches long, and 1 1/4 inches diameter at the big end. Such small instruments may be very exactly made in the parabolic form, and are certainly preferable to the conical. But since even these are of a very moderate size when intended to approximate the sound only 2 4 times, and as they can be accurately made by any tinsman, they may be of more general use. One of 12 inches long, and 3 inches wide at the big end, should approximate the sound at least 9 times.

A general rule for making them.—Let m express the approximating power intended for the instrument. The length of the instrument in inches is \(m \times \frac{m - 1}{6}\), and the diameter at the mouth is \(\frac{m}{3}\). The diameter at the small end is always one-third of an inch.

In trumpets for assisting the hearing, all reverberation of the trumpet must be avoided. It must be made thick, of the least elastic materials, and covered with cloth externally. For all reverberation lasts for a short time, and produces new sounds which mix with those that are coming in.

We must also observe, that no acoustic trumpet can separate those sounds to which we listen from others that are made in the same direction. All are received by it, and magnified in the same proportion. This is frequently a very great inconvenience.

There is also another imperfection, which we imagine cannot be removed, namely, an odd confusion, which cannot be called indistinctness, but a feeling as if we were in the midst of an echoing room. The cause seems to be this: Hearing gives us some perception of the direction of the sounding object, not indeed very precise,
Mr. Lambert seems aware of some error in his calculation, and proposes another, which leads nearly to this conclusion, but founded on a principle which we do not think is the least applicable to the case of sounds.

TRUMPET-MArine, is a musical instrument consisting of three tables, which form its triangular body. It has a very long neck with one single string, very thick, mounted on a bridge, which is firm on one side, but tremulous on the other. It is struck by a bow with one hand, and with the other the string is pressed or stopped on the neck by the thumb.

It is the trembling of the bridge, when struck, that makes it imitate the sound of a trumpet, which it does to that perfection, that it is scarcely possible to distinguish the one from the other. This is what has given it the denomination of trumpet-marine, though, in propriety, it be a kind of monochord. Of the six divisions marked on the neck of the instrument, the first makes a fifth with the open chord, the second an octave, and so on for the rest, corresponding with the intervals of the military trumpet.

TRUMPET-FLOWER. See BIGNONIA, BOTANY INDEX.
TRUMPETER. See PSOPHIA, ORNITHOLOGY INDEX.

TRUNCATED, in general, is an appellation given to such things as have, or seem to have, their points cut off: thus, we say, a truncated cone, pyramid, leaf, &c.

TRUNCHEON, a short staff or baton used by kings, generals, and great officers, as a mark of their command.

TRUNDLE, a sort of carriage with low wheels, whereon heavy and cumbersome burdens are drawn.

TRUNK, among botanists, that part of the herb which arises immediately from the root, and is terminated by fructification; the leaves, buds, and auxiliary parts of the herb not entering in its description.

TRUNIONS, or TRUNIONS, of a piece of ordnance, are those knobs or bunches of metal which bear her up on the cheeks of the carriage.

TRUSS, a bundle, or certain quantity of hay, straw, &c. A truss of hay contains 56 pounds, or half an hundred weight: 36 trusses make a load.

TRUSS, is also used for a sort of bandage or ligature made of steel, or the like matter, wherewith to keep up the parts in those who have hernias or ruptures.

TRUSS, in a ship, a machine employed to pull a yard home to its respective mast, and retain it firmly in that position.

TRUSTEE, one who has an estate, or money, put or trusted in his hands for the use of another.

TRUTH, a term used in opposition to falsehood, and applied to propositions which answer or accord to the nature and reality of the thing whereof something is affirmed or denied.

TRYpHIOdORUS, an ancient Greek poet, who lived some time between the reigns of Severus and Justinian. His writings were very numerous; yet none of them have come down to us, except an epic poem, on Tryphiodorus, which Mr. Addison has made some entertaining remarks in the Spectator, No. 63.

The first edition of this extraordinary work was published by Aldus at Venice, with Quintus Calaber's Psalmodica, and Coluthus's poem on the rape of Helen. It has been since reprinted at several places, particularly at Frankfort in 1580 by Frischlinus; who not only corrected many corrupt passages, but added two Latin versions, one in verse and the other in prose. That in verse was reprinted in 1742, with the Greek, at Oxford, in 8vo, with an English translation in verse, and Notes, by Mr. Merrick.

TUAM, a town of Ireland, in the province of Connaught, and county of Galway, with an archbishop's see. It was once a famous city, though now it is reduced to a village; but it still retains the title of a city, as being an archiepiscopal see. W. Long. 8. 46. N. Lat. 53. 33.

TUB, in commerce, denotes an indetermined quantity or measure: thus, a tub of tea contains about 60 pounds; and a tub of camphor from 56 to 86 pounds.

TUBE, in general, a pipe, conduit, or canal; a cylinder, hollow within-side, either of lead, iron, glass, wood, or other matter, for the air or some other matter to have a free conveyance through it.

Auricular TUBE, or instrument to facilitate hearing.

See Articulate Trumpet.

TUBERCLES, among physicians, denote little tumors which supplicate and discharge pus; and are often found in the lungs, especially of consumptive persons.

TUCUMAN, a province of Paraguay, in South America, bounded on the north by the provinces of Los Chicas and Chaco; on the east by Chaco and Río de la Plata, on the south by the country of Chichitos and Pampes, and on the west by Chili. The air is hot, and the soil sandy; however, some places are fruitful enough. It now forms part of the republic of Buenos Ayres. See BUENOS AYRES, SUPPLEMENT.

Tufa, a stone consisting of volcanic ashes concreted together with various other species of stones. It is of various colours, blackish gray, bluish gray, and yellow; every colour having a different mixture and solidity: but all of them have the bad quality of mouldering down on long exposure to the weather; notwithstanding which, they have been used in buildings both ancient and modern. The yellow kind resisting the air less than any other.

TULIPA, TULIP; a genus of plants belonging to the class of hexandria; and in the natural system ranging under the 10th order, Coronaria. See BOTANY INDEX; and for the culture of the tulip, see GARDENING.

TULIP-TREE. See LIRIODENDRON, BOTANY INDEX.

TULL, JETHRO, an Oxfordshire gentleman who farmed his own land, and introduced a new method of culture, to raise repeated crops of wheat; from the same land without the necessity of manure: the principles of which he published about 30 years since, in a Treatise on Her-e-hoeing Husbandry.

TUMBBRELLI, TUMBBRELLUM, or Turbiculum, is an engine of punishment, formerly employed for the correction of scolds and unquiet women.

TUMEFACITION, the act of swelling or rising into a tumor.
TUN, a large vessel or cask, of an oblong form, biggest in the middle, and diminishing towards its two ends, girt about with hoops, and used for stowing several kinds of merchandise for convenience of carriage; as brandy, oil, sugar, skins, hats, &c. TUN is also the name of a measure. A tun of wine is four hogsheads; of timber, a square of 40 solid feet; and of coals 20 cwts.

Tun is also a certain weight whereby the burden of ships, &c. is estimated.

TUNBRIDGE, a town of Kent in England, situated on a branch of the river Medway, over which there is a bridge. It is a large well built place, noted for the mineral waters four or five miles south of the town.

TUNE. See MUSIC and TONE.

TUNGSTEIN, one of the metals. See CHEMISTRY and MINERALOGY INDEX.

TURCK, a kind of waistcoat or under garment, in use among the Romans. They wore it within doors by itself, and abroad under the gown. The common people could not afford the togs, and so went in their tunics; whence Heracle calls them populus tunnicatus.

Tunica, in Anatomy, is applied to the membranes which invest the vessels, and divers others of the less solid parts of the body; thus the intestines are formed of five tunics or coats.

TUNIS, a large and celebrated town of Barbary, in Africa, and capital of a kingdom of the same name. It is seated on the point of the gulf of Goleta, about eight miles from the place where the city of Carthage stood. It is in the form of a long square, and is about four miles in circumference, with ten large streets, five gates, and 35 mosques. The houses are all built with stone, though but one story high; but the walls are very lofty, and flanked with several strong towers. It has neither ditches nor bastions, but a good citadel, built on an eminence on the west side of the city. Its population is estimated by Mr. McGill at 100,000, and Mr. Blaquiere at 130,000. The divan, or council of state, assembled in an old palace; and the dyet is the chief of the republic, who resides there. The harbour of Tunis has a very narrow entrance, through a small canal. In the city they have no water but what is kept in cisterns, except one well kept for the bashaw's use. It is a place of great trade, and is 10 miles from the sea. E. Long. 16. 10. N. Lat. 36. 42.

Tunis, a country of Africa, bounded on the north and east by the Mediterranean sea and the kingdom of Tripoli, on the south by several tribes of the Arabs, and on the west by the kingdom of Algiers and the country of Esab; being 300 miles in length from east to west, and 250 in breadth from north to south. This country was formerly a monarchy; but a difference arising between a king and his son, one of whom was for the protection of the Christians, and the other for that of the Turks, in 1574 the inhabitants shook off the yoke of both. From this time it became a republic under the protection of the Turks, but within the last forty years, it has been almost entirely independent. The air in general is healthy; but the soil in the eastern parts is indifferent for want of water. Towards the middle the mountains and valleys abound in fruits; but the western part is the most fertile, because it is watered with rivers. The environs of Tunis are very dry, upon which account corn is generally dear. The inroads of the Arabs oblige the habitants to sow their barley and rye in the suburbs, and to inclose their gardens with walls. However, there are plenty of citrons, lemons, oranges, dates, grapes, and other fruits. There are also olive trees, roses, and odoriferous plants. In the woods and mountains there are lions, wild bebes, ostriches, monkeys, camellos, rabeckas, hares, otter, badgers, rats, foxes, pheasants, partridges, and other sorts of birds and beasts. The most remarkable rivers are the Guadalcarbar, Magrida, Magerada, and Caps. The form of government is by a council, whose president is the dyet. The members of the divan or council are chosen by the dyet, and he in his turn is elected by the divan; which is composed of soldiers, who have more than once taken off the dyet's head. The bashaw who was formerly a Turk, remitted tribute to Constantinople; but since Hammoda Bey ascended the throne in 1787, Tunis has cast off all subjection to the Porte. The common revenues are only 400,000 crowns a-year, because the people are very poor; nor can they send above 40,000 men into the field; nor more than 12 men of war of the line to sea, even upon the most extraordinary occasions. There are generally about 12,000 Christian slaves in this country; and the inhabitants carry on a great trade in linen and woollen cloth. In the city of Tunis alone there are about 3000 clothiers and weavers. They also have a trade in horses, olives, oil, soap, ostriches eggs and feathers. The Moors of this city have 15000 berbers, 30000 vachers, and 65 petty schools. The principal religion is Mahometanism; but the inhabitants consist of Moors, Turks, Arabs, Jews, and Christian slaves. However the Turks, though fewest in number, dominate over the Moors, and treat them little better than slaves. See BARBARY STATES, SUPPLEMENT.

TUNKERS, a religious sect of Baptists in Pennsylvania, so called from the word Tunker, to put a morsel in sauce. They are also called Tumpers, because in performing baptism they plunge the person into the water with the head first. As the Germans sound the letters t and b like d and p, the words Tunkers and Tumblers, have been sometimes written Dunkers and Dumperers. Their church government and discipline are the same with those of the English Baptists, except that every brother is allowed to speak in the congregation, and the best speaker is usually ordained to be their minister. They are a harmless, well-meaning people.

TUNNAGE. See TONNAGE.

TUNNY. See SCORPEN, ICHTHYOLOGY INDEX.

TUNNY-FISHING. See FISHERY.

TURBAN, the head-dress of most of the eastern nations. It consists of two parts, a cap and sash of fine linen or satin, artfully wound in divers plaits about the cap. The cap has no brim, is pretty flat, though roundish at top, and quilted with cotton; but does not cover the ears. There is a good deal of art in giving the turban a fine air; and the making of them is a particular trade. The sash of the Turk's turban is white linen, that of the Persians red woollen. These are the distinguishing marks of their different religions. Sophi, king of Persia, being of the sect of Ali, was the first who assumed the
The time when it was necessary for him to declare that he would not be an ecclesiastic was now arrived. He announced this resolution to his father by letter, showing the motives which induced him to decline the clerical order. His father consented, and he was appointed master of requests. M. Turgot prepared himself for this office by particular application to those parts of science which are most connected with its functions and duties, viz. natural philosophy, agriculture, manufactures, commerce, &c. About this period he wrote some articles for the Encyclopédie, of which the principal are Etymology, Existence, Expanisibility, Fair, and Foundation. He had prepared several others, but the persecution against the Encyclopédie induced him to decline further contributions.

In 1761 M. Turgot was appointed intendant of Limoges, when he gave activity to the society of agriculture; opened a mode of public instruction for female professors of midwifery; procured for the people the attendance of able physicians during the raging of epidemical diseases; established houses of industry, supported by charity (the only species of alms-giving which does not encourage idleness); introduced the cultivation of potatoes into his province, &c. &c. While M. Turgot proceeded with unremitting activity and zeal, in promoting the good of the people over whom he was placed, he meditated projects of a more extensive nature, such as an equal distribution of the taxes, the construction of the roads, the regulation of the militia, the prevention of a scarcity of provision, and the protection of commerce.

At the death of Louis XV, the public voice called M. Turgot to the first offices of government, as a man who united the experience resulting from habits of business to all the improvement which study can procure. After being at the head of the marine department only a short time, he was, Aug. 24, 1774, appointed controller general of the finances. During his discharge of this important office, the operations he carried on are astonishing. He suppressed 23 kinds of duties on necessary occupations, useful contracts, or national compositions. He abolished the corvée, or the labour required from the public for the highways, saving the nation thirty millions of livres annually. He set aside another kind of corvée, which respected the carriage of military stores and baggage. He abated the rigour in the administration of indirect impositions, to the great profit of the contributors, the king, and the financiers; beside many other essential improvements in political economy.

At length, however, by the artifices of the courtiers, he was deprived of his offices; and in retirement he devoted himself to the sciences and the belles lettres, which he had cultivated in his youth. Natural philosophy and chemistry were his favourite pursuits; sometimes he indulged in poetry. He composed, it is said, only one Latin verse, intended for a picture of Dr Franklin.

Eripuit exo fulmen, max sceptra tyrannis.

He died in 1781.

TURIN, an ancient and populous city of Italy, and capital of Piedmont, where the sovereign resides, with an archbishop's see, a strong citadel, and an university. It is seated on a vast plain, at the confluence of the rivers Doria and Po. But the air is unhealthy in the autumn.
Turin, Turkey.

Tunnin and winter on account of the thick fog. One half of this place is lately built; and the streets are straight and clean, being washed by an aqueduct. It contains many elegant buildings. When the plague reigned at Marseilles in 1720, a great number of artificers withdrew to Turin; insomuch that there are now above 37,000 inhabitants, and 48 churches and convents. Turin is very well fortified, and extremely strong; as the French found by experience in 1706, who then besieged it a long while to no purpose. The citadel, which is flanked with five bastions, is without doubt a masterpiece of architecture. There are fine walks on the ramparts, and fine gardens on the sides of the river Po; and the house commonly called La Chartre is remarkable, as there is room for 3000 poor people. The college of the academy is very large and well built, and has a great number of ancient inscriptions. In the royal library are 19,000 manuscripts, besides 30,000 printed books. In December 1798, it was taken possession of by the French, who in June following were driven out of it by the Austrians. But with the rest of Italy it is now under the dominion of the French. It is eminently seat at the foot of a mountain, 62 miles north-east of Genoa, 72 south-west of Milan, and 280 north-west of Rome. L. Long. 4: 45. N. Lat. 44. 50.

Turin is in the heart of the Turinese, situated partly in Europe, and partly in Asia. It is bounded on the north by the empire of Russia, Hungary, and the Black sea; on the west by the Gulf of Venice and the Mediterranean; on the south by the Mediterranean and Arabia; and on the east by Persia. In its present state, we may compute it as extending from the river Unna, in east longitude about 17°, to the mountains which separate it from Persia, in about 50° of east longitude from Greenwich, or about 33° from west to east; from the most southerly point, a little above Bassora, in north latitude 31°, to the confines of European Russia, in north latitude 47°; it occupies a range of 16° of latitude. In British miles its extent is estimated at 750 in length, by a mediad breadth of about 1000, and its area at 652,660 square miles.

Turkey is naturally divided into European and Asiatic, separated from each other by the Black sea, the Archipelago, and the straits by which these are connected. European Turkey is subdivided into 11 provinces, viz.: Moldavia, Bessarabia, Walachia, Bousia, Servia (partially), Bulgaria, Rumaia (including Macedonia and Thrace), Dalmatia, Albania (including Epirus), Croatia (partially), and the Morea, or ancient Greece; while Asiatic Turkey is subdivided into seven provinces, viz.: Natalia (Asia Minor), Dardano (Mesopotamia), Syria (including Judea), Georgia (Iberia), Turcomania (Armenia), Iran-Arabia, and Kurdistan (Asia). See each of these articles in the general alphabet.

Islands.

The islands belonging to Turkey are extremely numerous; comprising those of the Archipelago, or the Cretan islands, and several in the Levant. The most important are Leros, Lesbos or Methana, Scyros, Samos, Cos, Rhodes, Cyprus, Candia, Paros, Delos, Naxia, Santorini, Patmos, Negropon, Andros, Colteri or Salamin, Egina, Zante, Cephalonia, Lecudia, Corfu, and Cerigo or Cythera, which see under their proper heads.

See Persia.

Norse.

The principal rivers of European Turkey is the Da-River, with its tributary streams, the Save, the Morava, the Bosna, and the Pirith; but we may also notice the Marisca or Hebrus, and the Vardan or Axios. In Asiatic Turkey are seen the Kisil-Irmak or Halys, the Sacaria, the Sarabat or Hermus, the Minder or Mender, the Araxes, the Orontes, the Jordan, and the Euphrates.

The lakes of European Turkey are of little importance; and in the Asiatic part there are only three that merit notice. These are the Dead sea and the sea of Galilee in Palestine, and the Van in Armenia.

The climate in the greater part of the Turkish empire is delightful, and the seasons mild and genial. The atmospheric heats of the summer, except in the deserts of Syria, and on the shores of the Black sea, are tempered by the keen winds that blow from the higher regions, and the winter is in general extremely mild. The unhealthiness of the large towns on the coast of Asiatic Turkey, is owing much more to the indolent and dirty habits of the people, than to any insalubrity of the climate.

Turkey affords a most ample field to the naturalist, whether his taste lead him to explore the animal, the botany, vegetable, or the mineral kingdom. In the first of these he will find the lion, a variety of the tiger, the lynx, the jackall, the ibex, the goat and cat of Angora, and many other quadrupeds common in Europe. Among the birds, one of the most numerous and most useful is the stork; partridges of a large size, quails, woodcocks, cranes, and several kinds of prey, are also very common. The Black sea and the Archipelago abound with excellent fish, and contain great variety of curious mollusca, and other marine animals. Among the insects, that destructive animal the locust is a frequent visitant; and Somnii particulars the tarantula, and a monstrous species of spider, which he calls guloide araneoides, or the scorpion spider. Of the domestic animals, the Turks abound in excellent horses, asses of a large size, and that most useful beast of burden, the camel.

To enumerate the vegetable productions of Turkey, would far exceed our scanty limits. The forests of European Turkey, though far less extensive than in ancient times, furnish abundance of the finest timber, especially oak, cedar, larch, walnut, chestnut, and beech, while the olive, the date, the apricot, the pomegranate, the cherry, the orange, the lemon, and the grape, are the natural productions of Asiatic Turkey. Many of the most valuable drugs employed in medicine, are also the produce of this empire, especially opium, rhubarb, cinchona, asafoetida and other fetid gums, scarabey, senna, galls, and coloquintida.

Valleys, and here and there a desert of considerable extent. The plains are watered by numerous large rivers, and, in the Asiatic part, consist chiefly of pasture grounds.

Among the mountains of European Turkey may be the Carpathian chain, which divides it from the Austrian territories; the celebrated mountains of Helms; the Acrocorinian mountains; and the classical hills of Pinthus, Osma, Pelion, and Athos. The most important mountains of Asiatic Turkey are, Mount Caucasia, dividing it from Russia; Mount Taurus, now called Thuron; Olympus; Ida; the mountains of Elivend, and perhaps Mount Arabat, the resting-place of the Ark, dividing it from Persia; and Mount Lebanon, celebrated in scripture for its cedars.

The principal river of European Turkey is the Da-River, with its tributary streams, the Save, the Morava, the Bosna, and the Pirith; but we may also notice the Marisca or Hebrus, and the Vardan or Axios. In Asiatic Turkey are seen the Kisil-Irmak or Halys, the Sacaria, the Sarabat or Hermus, the Minder or Mender, the Araxes, the Orontes, the Jordan, and the Euphrates.

Many of the most valuable drugs employed in medicine, are also the produce of this empire, especially opium, rhubarb, cinchona, asafoetida and other fetid gums, scarabey, senna, galls, and coloquintida.
Turkey.
Both gold and silver mines are found in Turkey, but from the indolence of the natives they are scarcely ever worked. Many of the islands abound in mineral treasures, especially Cyprus, where are found mines of gold, copper, vitriol, and iron; and where rock crystal, jasper, and several precious stones, are occasionally procured. The chief mineral production of Turkey, however, is its marble, of which it furnishes several of the most rare and beautiful varieties. That from the Greek island Paros, is proverbially excellent.

The people whom we now call Turks, and who form the great mass of population of the Turkish empire, are generally believed to be the descendants of the ancient Scyths. These are supposed to have migrated from the Altai mountains in Tartary, about the middle of the sixth century, and to have gradually diffused themselves towards the west, till they reached the lake Maeotis, the modern sea of Azof, near which they settled in Armenia Minor or Cucumania. At this time the Roman empire in the east was sufficiently strong to prevent the invaders from extending beyond the river Ouzon, on the banks of which they established themselves, and soon became a formidable foe to the emperors of Constantinople.

There is little certain or interesting in the history of these barbarians till the reign of the caliph Othman, or Osman, who in the end of the 13th century established what from him has been called the Ottoman empire. He first took the title of sultan, and fixed the seat of his government at Prous, the capital of Bithynia. His successor Orkan was a restless, ambitious, and cruel prince, who, greatly extended the limits of the empire, took possession of Gallipoli, and penetrated into Thrace. Amurath, the grandson of Osman, in 1562, established the famous military bands called janissaries, which still form the chief engines and chief moderators of Turkish despotism. These were first composed of young Christian slaves that had been taken in war, and educated in the Mohammedan religion. They were inured to obedience by severe discipline, and trained to warlike exercise; and as every sentiment which enthusiasm can inspire, and every mark of honour which the favour of the prince could confer, were employed to animate them with martial ardour, and excite in them a sense of their own importance, these janizaries, (as new soldiers) soon became the chief strength and pride of the Ottoman arms.

On the assassination of Amurath in 1389, he was succeeded by his son Bajazet, surnamed Ilderim, or the Thunderbolt, whose reign forms one of the most splendid epochs in the Turkish history.

Early in this reign, viz. in 1396, the Hungarians were defeated at Nicopolis in Bulgaria, and in 1402, was fought the famous battle between Bajazet and Timur or Tamerlane, the chief of the Moguls, between Cesarea and Ancyra, which ended in the captivity of Bajazet, and the temporary humiliation of the Turks. See Moguls, No. 19. and 20.

On the death of Bajazet, his son Mouus became sultan, and in 1412 defeated the emperor Sigismund with great slaughter. Mouus was succeeded by his brother Mohammed I. by whom he had been assassinated. The reign of Amurath II. successor of Mohammed, contributed greatly to increase the splendour of the Turkish empire. In this reign Constantinople was attacked, but for the present escaped pillage. Amurath was successfully opposed in his hostilities against the Christian princes, by the Albanian chief George Castriota, whom the Turks call Scanderbeg.

Amurath was succeeded by Mohammed II. and soon after his accession, viz. in 1453, the city of Constantinople was taken by the Turks, and has ever since remained the capital of their empire. The events of Constantinople, which we have thus drawn the faint outline, are related in the History, No. 111—168.

Three years after the taking of Constantinople, Mohammed laid siege to Belgrade, from which, after an obstinate resistance, he was at length repulsed with considerable loss. Abandoning his attempt on Hungary, the sultan made preparations for an expedition into Greece, where the princes Thomas and Demetrius, brothers of the emperor, still continued to maintain their authority. Alarmed at the progress of the Turkish arms, these princes resolved on retiring into Italy, on which the peninsula was seized by the Albanians. This tribe sent a deputation to Mohammed, offering to give up to him their cities and fortresses, provided they should be allowed to keep the open country; but this offer was rejected by the sultan, who, under the appearance of assisting the Greeks, entered the country with a formidable army, defeated the Albanians, took several cities, and carried off great numbers of the inhabitants.

Mohammed was succeeded by his second son Bajazet II. in 1481, preferred by the janizaries to his elder brother Zizan, who fled for protection to Pope Alexander VI. by whom he is said to have been poisoned, at the instigation of Bajazet, and for the reward of 300,000 ducats. Selim, his youngest son and successor, was a successful prince. He conquered Egypt, Aleppo, Antioch, Tripoli, Damascus, and Gaza, and defeated the Persians. Selim, surnamed the Magnificent, one of the most accomplished, enterprising, and warlike of the Turkish princes, ascended the Ottoman throne in consequence of the death of Selim.

Having quelled some insurrections in Asia, he commenced hostilities against the European princes, and entering Hungary, made himself master of Belgrade, then reckoned the chief barrier of that kingdom against the Turkish power. He next turned his victorious arms against the island of Rhodes, then the seat of the knights of St John of Jerusalem. After incredible efforts of courage and military conduct, the knights obtained an honourable capitulation, and retired to the small island of Malta, where they fixed their residence. See Malta. He afterwards annexed Hungary to the Ottoman empire. His dominions extended from Algiers to the river Euphrates, and from the farther end of the Black sea to the extremity of Greece and Epirus. During the siege of Sigeoth, a city of Hungary, before which the Turks lost above 30,000 men, Solyman expired in the 74th year of his age, and 4l1st of his reign.

His son and successor, Selim II. besieged and took Selin II. Cyprus; but in the famous sea fight at Lepanto, in 1571, the Turkish fleet was utterly destroyed by Don John of Austria. He afterwards invested and took Tunis by storm, putting the garrison to the sword.

On his death, Amurath III. ascended the Ottoman throne, and extended his dominions on both sides of the addition of Raab in Hungary and Tarsis in Persia. His son, Mohammed III. has no claim to notice except
Turkey

except on account of his barbarity. He began his reign by strangling 19 of his brothers, and ordering 12 of his father's wives, whom he suspected to be pregnant, to be drowned. This monster of cruelty had, however, a successful reign of nine years' duration. During the government of his son, Achmet I. the affairs of Turkey underwent a material change for the worse. On his death, the janizaries and the divan elected his brother Mustapha, whom in two months they declared incapable of reigning, and threw him into prison; after this they proclaimed his young nephew, Osman, the son of Achmet, emperor. This prince formed a design of curbing the power of the janizaries, for which he was deposed and murdered; and Mustapha was again called from his prison to the imperial throne, but was soon after deposed.

Under Amurath, or Morad IV. surnamed Casi, the Intrepid, every thing again assumed a new appearance. He was successful in his wars, and took Bagdat from the Persians. A debauch of wine put an end to his life, and dishonoured his memory. His son Ibrahim, who succeeded him, had every vice; he was a weak prince, and wholly destitute of courage. He was strangled by four mutes.

Mohammed IV. succeeded him. His grand vizier Kuploli, who at once directed the councils and conducted the armies of the Porta, took Candida from the Venetians. After carrying on many wars against the Germans, the Poles, the Russians, and other European powers, he was compelled to resign the turban to Solymani II. in 1687, a prince happy in his domestic government, but unsuccessful in his wars. His brother, Achmet II. was likewise unfortunate in his wars. In his reign the Turks were driven out of Hungary and Transylvania. The accession of his nephew, Mustapha II. to the Ottoman throne, gave a new turn to the affairs of the Porte. Possessed of more vigour than his predecessor, he resolved to command his troops in person. He accordingly took the field, passed the Danube, stormed Lippa, seized Rul, and falling suddenly on a body of Imperialists, under Veterei, he killed that officer, dispersed his forces, and closed with success the campaign. He was afterwards defeated by Prince Eugene in an uncommonly bloody battle at Zenta, a small village on the western bank of the Thuya, in the kingdom of Hungary. About 20,000 Turks were left dead on the field, and 10,000 were drowned in the river, endeavouring to avoid the fury of the sword. The magnificent pavilion of the sultan, and all the stores, fell into the hands of Prince Eugene, and soon after this misfortune the haughty Mustapha was dethrown.

His brother and successor, Achmet III. gave an asylum to Charles XII. king of Sweden, at Bender, a Turkish town in Moldavia, after his defeat at the battle of Paltaw (See Russia, No. 116. and Sweden, No. 140.). Being unsuccessful in his war against Kouti Khan and the Persians (see Persia), he was deposed, and succeeded by Mohammed V.

Mustapha III. From the deposition of Achmet III. till the accession of Mustapha III. in 1754, nothing of importance occurs in the history of the Turkish empire. During the reign of this latter sultan was begun and terminated that destructive war with Russia, of which the principal events have been enumerated in the article Russia, No. 143. and 144.

In his reign an extraordinary alarm was excited in Turkey by the sudden appearance of a new prophet in Upper Asia. This man, whose name was Shiek Mansour, new pretended that he was predestined by the eternal immutable decrees of heaven to fill up the measure of divine revelation to mankind; and that, as he was to be the last, so he was the greatest of the prophets. The scene of his ministry was in the wide and desolate regions on the borders of the Caspian sea; and though the first rumour of his proceedings represented him as at the head of a multitude of armed enthusiasts, ready to overturn the established government, and the religion of Mohammed, it was soon discovered that all the military fury of his zeal was directed against the Christians.

About the same time a formidable rebellion broke out in Egypt, which, though it has never properly form. ed a part of the Turkish empire, may be considered as tributary to the Turks, and as constituting the granary of that empire. This rebellion which has been sufficiently noticed under the article Egypt, No. 125, was suppressed chiefly by the wise conduct and intrepid bravery of Hassan Bey, the captain pacha, who at the age of 70, fought with all the ardour of youth, and all the skill of the most consummate general. That veteran, however, was recalled before he was able to carry all his patriotic designs into execution, that he might aid the divan with his counsels, in the critical situation into which the empire was brought by the arrogant claims of the court of Russia. The result of the deliberations was a precipitate declaration of war against that court, contrary to the better judgment of the old pacha. The war commenced in autumn 1787, and the hordes of Tartars which were first brought into the field, headed by the new prophet, were everywhere defeated by the superior discipline of the Russian troops commanded by Prince Potemkin. Some enterprises which were undertaken by the Turks against the island of Taman and the Crimea were attended with as little success as the attempts of the Tartars; while the emperor Joseph declared to the Porte, that he would assist his ally the empress of Russia with an army of 80,000 men. Four Austrian armies were accordingly assembled; one at Carlstadt in Crumia, under the command of General de Vins; another at Peterwaradin in Hungary, commanded by General Langlois; a third on the borders of Lithuania, under General Febris; and the fourth in the Bucowine, under the orders of the prince of Saxe-Cobourg. Two other generals, 10 lieutenant-generals, and 30 major-generals, were all ordered to prepare for active service in the frontier armies.

The war between the Turks and Austrians was carried on with various success. At first the advantage was evidently on the side of the Ottomans, and the imperial Joseph acquired no warlike renown. His declared purpose was to get possession of Belgrade; from which, however, he was repulsed with disgrace. The prince of Saxe-Cobourg in his department of the war displayed indeed prodigies of valour; but being opposed to a superior force, he was long obliged to act only on the defensive. At length being joined by a body of Russian forces under General Saltikoff, preparations were made for commencing in form the siege of Choczin, which was surrendered to the allied armies on Michael-
Tur. was day 1788, after a defence which would have done honour to the ablest general in Europe. Still, however, success seemed to lean to the Turks. The grand visier made a sudden incursion into the Bannat, and spread consternation and dismay to the very gates of Vienna. The Austrian affairs seemed approaching to a very alarming crisis; not only the splendid views of conquest which were held in the imagined partition of a tottering empire had totally disappeared, but had left in their place the sad and gloomy reverse of a discontented and impoverished people, an exhausted treasury, and an army thinned by pestilence and desertion. The first campaign of an invasive war had already produced an impression on the territory of the invader.

In this situation of affairs Marshal Laudohn was with some difficulty drawn from his retirement to take the command of the army in Croatia; and under his auspices fortune began to smile on the Austrian arms. He quickly reduced Dubicza and Nevi, though they were both defended by the most obstinate bravery. He then sat down before Turkish Gradisca; but the autumn rains, falling on with such violence, that the Savinja flowed its banks, he was compelled to raise the siege. During this period the war in the Bannat raged with the utmost violence; torrents of blood were shed on both sides; much desperate valour displayed on the one side, and many brave actions performed on the other; while a very great part of that fine but unfortunate country suffered all the desolation and ruin that fire and sword, under the dominion of vengeance and animosity, could inflict. The inhabitants were objects of commiseration; but the injustice with which the emperor had commenced the war, made his personal losses be considered as nothing more than the due reward of his conduct.

In the midst of these military operations Achmet IV. was deposed, and succeeded by Selim III. the late sultan. The new emperor did not want either courage or prudence, and he continued the war with Russia and Austria, with great spirit and resolution. Those events of this war in which the Russians were more immediately concerned, have been already noticed under the article Russia, No. 156, 158, 160 and 161; so that we have merely to relate the remaining operations of the Austrians.

Marshal Laudohn renewed his attempts upon Gradisca as soon as the season would permit, and after a brave defence it fell into his hands. This, with some other successes, roused the emperor from his inactivity, and made him seriously determine on the attack which he had long meditated on Belgrade. The enterprise was intrusted to Laudohn, who, with that good fortune which seemed constantly to attend him, made himself master of the place in less than a month. The rest of the campaign was little else than a series of the most important successes. While one detachment of General Laudohn's forces took possession of Czernitz in Walachia, another made itself master of Czadova in Servia. Bucharest, the capital of the former of these provinces, fell without opposition into the hands of Prince Cobourg; while Akerman on the Black Sea was reduced by the Russians; and Bender surrendered to Prince Potemkin, not without suspicion of sinister practices, on the 15th of November.

Soon after this, the emperor Joseph died, and his successor Leopold showed a desire for peace. After the re-
The principal title of the sultans is, as we have seen, grand seignior, and the court of Constantinople is usually styled the Porte, or Ottoman Porte, either from the large gate at the entrance of the seraglio, or, what is more probable, from the palace of the viziers, where all the affairs of state are transacted. The principal ministers of the Porte are the grand vizier or prime minister, the mufti, the seis effendi or chief secretary of state, the kislar-agas or chief of the black eunuchs, and the agas of the janizaries.

The revenue of the whole Turkish empire is not accurately known, but has been estimated at 3,000,000l. sterling. It is partly derived from the capitation tax on unbelievers and from the customs, but principally from the tax on land.

The military strength of Turkey is but inconsiderably capable for so large an empire. The number of the land forces are supposed never to exceed 150,000 men, and these are ill disciplined, and now dispirited by successive disastrous wars. The navy is estimated at 30 sail of the line; but the ships are ill built, badly manned, and wretchedly navigated.

The established religion of Turkey is Mahometanism. Religion the tenets of which have been already explained under laws, the articles MAHOMETANISM and ALCORAN. The laws of the empire are entirely founded on the Koran; but in particular cases the judges are guided by certain commentaries on that work, which have acquired the force of laws. The chief of these are the commentaries of Abou-Hanife.

The mufti, or Mohammedan pontiff, resides at Constantinople, but his power has seldom interfered with the civil government. Next to him in rank are the moulahs, who, though esteemed dignitaries of the church, are in fact rather doctors of the law, while the Koran is also a code of civil observance. From the moulahs are selected the inferior muftis and judges throughout the empire, and the cadije eulogies, or chief justices. The next class of divines includes the imams, or parish priests, who perform the service of the mosques, while the cadije are judges annually appointed to administer justice in the towns and villages, and being regarded as churchmen, like the moulahs, have directed their chief attention to the judicial part of the Koran. From this brief view it will be observed, that the ecclesiastical orders of muftis and imams somewhat resemble the Christian bishops and parochial clergy; while the other distinctions arise from the singularity of both religion and laws being united in the Koran, so that a lawyer or judge must be at the same time a skilful divine. The Turks have also their monks, styled dervishes, of four various orders and institutions, dedicated by solemn vows to religious offices, public prayer, and preaching. The Greeks, along with their faith, retain their priests, bishops, archbishops, and patriarchs; but their church is in the last state of degradation, and its dignities openly sold by the Turks; this abomination, however, it must be confessed, partly arises from the miserable ambition and avarice of the Greek ecclesiastics, who think they can atone by idle ceremonies for the neglect of all the invaluable morality of the gospel.

The Turkish language is of far inferior reputation to the Persian or Arabic, being a mixture of several dialects, and possessing neither the force, elegance, nor purity of the

Population of Turkey.

34

Government.

35

The government of Turkey is despotic, but the power of the sultan is by no means so absolute as we are generally led to suppose. Besides, being strictly subject to the laws of the Koran, and thus to the national religion, such obstructions to his absolute will are raised by the power of the mufti, or chief priest and judge, by the frequent insurrections of the janizaries, and the ambition of the pachas, or governors of provinces, that many Christian sovereigns are much more despotic.

39
Turkey. The variety of these two celebrated oriental tongues. Literature, however, is not wholly neglected, and it has been repeatedly attempted to establish a printing-press at Constantinople; but the design failed from the interest of the copyists, who inferred that this art would deprive them of their bread. A late traveller informs us that there are in this capital several butteh-chans, or public libraries, of which the most famous are those of St Sophia, and the Solimante Janamy; but none are so elegant as that founded by the grand vizier Rgshid, which is wholly built of marble in the midst of a square court, and is filled with books chiefly theological. A librarian constantly attends, and there are convenient seats with carpets and cushions. In the neighbourhood is a school founded by the same vizier, in which about 1000 boys are taught to read and write. The market for books is extensive, containing many shops well supplied with oriental manuscripts. The Turks have their ancient poets, historians, and divines; but of little reputation when compared with those of Persia and Arabia. The state of education among the Turks may be conceived to be very low, and ignorance is indeed a chief part of the national character. The only profession which requires a shadow of learning is that of the law, which is intimately connected with their theology. The celebrated doctors have disciples, who are trained up to that department; but there seems nothing that can deserve the name of college or university.

The Turks cannot be regarded as a commercial people, though they admit of an extensive commercial intercourse with the states of Europe, through the medium of Frank and Greek merchants. The chief ports are Smyrna and Constantinople, the former of which is the great centre of the Levant trade, while the latter is concerned chiefly in the trade with Russia, by the Black sea. At both these ports, and indeed throughout the Turkish empire, the trade is nominally carried on by factors from the different European states; but it is managed more immediately by Jew or Armenian brokers, who take numerous advantages of the ignorance of the factors, and seldom fail to enrich themselves at the expense of their employers. The commodities exported from Turkey, chiefly to Britain, Germany, Italy, Holland, and France, consist for the most part of bees wax, boxwood, silk, cotton yarn, walnut planks, sponges, opium, and other drugs enumerated in No 9. madder root, and other dye stuffs, and various dried fruits, such as figs, raisins, and currants. The imports are chiefly tin and tin plates, sugar, shalloons, cotton yarn and cotton goods, muslins, clocks and watches, cutlery and glassware, indigo, gunpowder, pistols and military stores, logwood, rum, coffee, and various spices, especially pepper, ginger, and cinnamon. The exports are principally from Smyrna, where the trade is carried on almost entirely by way of exchange, while at Constantinople the imports are generally paid for by cash or bills. The exchange is commonly against the Turks.

The Turkish money usually employed in commerce is the piaster, which, according to the exchange or agio, is rated at from 13 to 17 in the English pound sterling, so that the average value of the piaster is about 21. 6d. Each piaster is divided into 45 paras, and each para into three aspers. The principal weight employed is the kintal, equal to about one cwt. English, divided into 44 oke, and each oke into 400 drachen.

From their jealousy with respect to strangers, it is extremely difficult to form a true estimate of the national character of the Turks. An intelligent writer, who seems well qualified to direct our judgment in this respect, has thus delineated the Turkish character. The Turks are in general a sagacious, thinking people; in the pursuit of their own interest, or fortune, their attention is fixed on one object, and they persevered with great steadiness until they attain their purpose. They are in common life seemingly obliging and humane, not without appearances of gratitude: perhaps all or either of these, when extended towards Christians, are practiced with a view of some advantage. Interest is their supreme good; where that becomes an object of competition, all attachment of friendship, all ties of consanguinity, are dissolved: they become desperate, no barrier can stop their pursuit, or abate their rancour towards their competitors. In their demeanour they are rather hypochondriac, grave, sedate and passive; but when agitated by passion, furious, raging, unaccountable; big with dissimulation; jealous, suspicious, vindictive beyond conception; perpetuating revenge from generation to generation among the sons of religious tenacity, superstition, and morose. The manners and customs of the Turks are distinguished by the peculiarity of their religion from those of other European nations. On the birth of a child the father himself gives the name, putting at the same time a grain of salt into its mouth. The circumcision is not of the performed till the age of 12 or 14. Marriage is only Türk, a civil contract, which either party may break, and is managed by female mediation, the youth seldom seeing his bride till after the ceremony. The dead are perfumed and embalmed with incense, and buried in a cloth, open at top and ends, bottom, that the deceased may be able to sit up and answer the questions of the angels of death. The burial grounds are near the highways, and stones are often placed at the heads of the graves, with carved turban denoting the sex. As they never intermingle upon a common grave, the cemeteries are very extensive. Indeed the Turks are extremely moderate, and their meals are dispatched with great haste. Rice is the favourite food, and is dressed in three ways. In boiling, the meat is cut into small pieces, and in roasting still smaller, a bit of meat and an onion being placed alternately on a very long spit. The fish of the Archipelago are excellent, and the beef tolerable, except that of the buffalo, which is very hard. The hares, partridges, and other game, are of superior flavour. The meal is usually spread on a low wooden table, and the master of the house pronounces a short prayer. The frugal repast is followed by fruits and cold water, which are succeeded by hot coffee and pipes with tobacco. The houses of the Turks are seldom expensive; the chief furniture is the carpet which covers the floor, and a low sofa on one side of the room. In regard to dress, Tournefort observes that the use of the turban is unhealthy. The shirt is of calico, and the loose robe is fastened by a girdle, in which is stuck a dagger, while the tobacco box, pocket-book, &c. are worn in the bosom. The robe is generally of European broadcloth, trimmed with various furs. The shoes or slippers are slight, and unfit for much exercise. The dress of the women differs little from that of the men, the chief distinction being the head-dress; that of the fair sex consisting of a bonnet like
like an inverted basket, formed of pasteboard covered with cloth of gold, with a veil extending to the eyebrows, while a fine handkerchief conceals the under part of the face. The personal cleanliness of both sexes is highly laudable; but the European eye is not pleased with the female custom of staining the nails with a red tincture. The amusements of the Turks partake of their indolent apathy, if we except hunting, and those of a military description. To recline on an elegant carpet, or in a hot season by the side of a stream, and smoke the delicate tobacco of Syria, may be regarded as their chief amusement. Chess and draughts are favourite games; but those of chance are considered as incompatible with strict morals. The coffee-houses and baths furnish other sources of amusement; and the bairam, or festival which follows their long lent, is a season of universal dissipation.

It appears to be a mistaken notion, that the practice of eating opium, to procure intoxication, is general among the Turks. We are assured by a late traveller, that this practice is confined to a few individuals, who are regarded by the majority of their countrymen with as much contempt as drunkards are in the more polished societies of Europe.

TURNING, the art of forming hard bodies, as wood, ivory, iron, into a round or oval shape, by means of a machine called a lathe.

This art was well known to the ancients, and seems to have been carried by them to a very great degree of perfection; at least, if we believe the testimony of Pliny and several other authors, who tell us, that those precious vases enriched with figures in half relief, which still adorn our cabinets, were turned on the lathe.

The art of turning is of considerable importance, as it contributes essentially to the perfection of many other arts. The architect uses it for many ornaments, both within and without highly finished houses. The mathematician, the astronomer, and the natural philosopher, have recourse to it, not only to embellish their instruments, but also to give them the necessary dimension and precision. In short, it is an art absolutely necessary to the goldsmith, the watchmaker, the joiner, the smith.

Turning is performed by the lathe, of which there are various kinds, and several instruments, as gouges, chisels, drills, formers, screw tais, used for cutting what is to be turned into its proper form as the lathe turns round. The following is a simple kind of lathe (fig. 1.), in which a is the footstool, b the cord, c the frame of the lathe, d d the uppers, e e the points, f the spinning-tree.

The lathe should be fixed in a place very well lighted; it should be immovable, and neither too high nor too low. The puppets should neither be so low as to oblige the workman to stoop in order to see his work properly, nor so high that the little chips, which he is continually driving off, should come into his eyes. The piece to be turned should be rounded (if it be wood) before it be put on the lathe, either with a small hatchet made for the purpose, or with a plane, or with a file, fixing it in a vice, and shaving it down till it is everywhere almost of an equal thickness, and leaving it a little bigger than it is intended to be when finished off. Before putting it on the lathe, it is also necessary to find the centres of its two end surfaces, and that they should be exactly opposite to each other, that when the points of the puppets are applied to them, and the piece is turned round, no side may belly out more than another. To find these two centres, lay the piece of wood to be turned upon a plank; open a pair of compasses to almost half the thickness of the piece; fix one of the legs in the plank, and let the point of the other touch one of the ends of the piece, brought into the same plane with the plank on which the compasses is fixed and very near the fixed leg. Describe four arches on that end at equal distances from each other at the circumference of the end, but intersecting one another within; the point of intersection is the centre of the end. In the same manner must the centre in the other end be found. After finding the two centres, make a small hole at each of them, into which insert the points of the puppets, and fix the piece so firmly as not to be shaken out, and yet loose enough to turn round without difficulty.

The piece being thus fixed, it is necessary in the next place to adjust the cord, by making it pass twice round the piece, and in such a manner that the two ends of the cord, both which is fixed to the spong and to the foot-board, come off on the side on which the turner stands, that the piece may move against the edge of the cutting-tool and be turned. If the lathe be moved by a wheel, the manner of adjusting the cord needs no directions.

If the workman does not choose to be at the trouble to find the two centres of the piece in the manner described above, let him lay, as nearly as he can, the centre of one end upon the point of the left hand puppet, and then let him push forward the right hand puppet, striking it with a mallet till its point is as near as he can in the centre of the other end of the piece; and then fixing the right hand puppet by a gentle blow of the mallet on the key, let him turn round the piece to see by the eye if the centres have been properly found. If any part of it belies out, let him strike that part gently with the mallet till it goes properly; then let him strike one of the puppets pretty smartly to drive the points into the piece, and afterwards fix the puppet by striking the.

If the workman cannot judge by the eye whether the piece be turning properly round its centres or not, he should apply gently the point of an instrument called a triangular graver, leaning it on the rest, and it will mark by a line the place where the piece is out of its centre; and by striking upon this line with a mallet, the piece can easily be placed properly. The rest, of which we have just spoken, ought to be placed upon the two arms of the lathe, and fixed with screws as near the piece as the workman pleases.

The piece being fixed between the two points of the puppets (or, as they are called in Scotland, the heads), the cord adjusted, and the rest fixed as near the work as possible without touching it; the workman is now to take a gouge (fig. 2. in which a is the mouth and b the handle) of a proper size in his left hand, and hold it by the handle a little inclined, keeping the back of the hand
Turning.  hand lowermost. With his right hand, the back of which is to be turned upwards, he is to grasp it as near the end as possible on this side of the rest; then leasing the gouge on the rest, he is to present the edge of it a little higher than the horizontal diameter of the piece, so as to form a kind of tangent to its circumference; then putting the right foot on the foot-board, and turning round the wheel, and holding the gouge firmly on the rest, the piece will be cut neatly. In the same manner are the chisels, formers, and other instruments to be used, taking care that the wood be cut equally, and that the instrument be not pushed improperly, sometimes stronger than others; and taking care also that the instrument used do not follow the work, but that it be kept firmly in the hand without yielding.

The young turner ought to endeavour to acquire the management of the gouge and the chisel, which are the instruments by far the most frequently used, and the most necessary in this art: by them, almost entirely, are the soft woods turned; but as for hard woods and other things, as box, ebony, horn, ivory, and the metals, they are hardly ever turned except by shaving off.

In that case gravers are to be used with square, round, or triangular mouths (fig. 3, 4, 5). They should be held horizontally while applied to the wood, and not obliquely as directed for the gouge and the chisel.

After the work is completely turned, it is next to be polished; and this cannot be done with the instruments hitherto mentioned. Soft woods, as pear tree, hazel, maple, ought to be polished with shark-skin or Dutch rushes. There are different species of sharks; some of which have a greyish, others a reddish skin. Shark-skin is always the better to be a good deal used; at first it is too rough for polishing. The Dutch rush (aquilegia hyemale), which grows in moist places among mountains, and is a native of Scotland. The oldest plants are the best. Before using them they should be moistened a little, otherwise they break in pieces almost immediately, and render it exceedingly difficult to polish with them. They are particularly proper for smoothing the hard woods, as box, lignum vitae, ebony, &c. After having cleaned up the piece well, it should be rubbed gently either with wax or olive-oil, then wiped clean and rubbed with its own rasping or with a cloth a little worn. Ivory, horn, silver, and brass, are polished with pumice-stone finely pounded and put upon leather or a linen cloth a little moistened: with this the piece is rubbed as it turns round in the lathe; and to prevent any dirt from adhering to any part of it, every now and then it is rubbed gently with a small brush dipped in water. To polish very finely, the workmen make use of tripoli, a particular kind of earth, and afterwards of putty or calx of tin. Iron and steel are polished with very fine powder of emery; this is mixed with oil, and put between two pieces of very tender wood, and then the iron is rubbed with it. Tin and silver are polished with a burnisher and that kind of red stone called in France sanguine dure. They may be polished also with a putty, putting it dry into shamoyskin, or with the palm of the hand.

To succeed in turning iron, it is necessary to have a lathe exceedingly strong in all its parts, and exceedingly well fixed. The puppets should be short, and the rest well fixed very near the work: the back of the rest should be two or three lines lower than the iron to be turned.

The lathe and other instruments being prepared, it is necessary to determine the length and thickness of the iron to be turned according to the design which is to be executed, and to make a model of it in wood a little thicker than it ought to be; Then one exact model is to be forged of the best iron that can be procured; that is to say, it must not be new, but well prepared and well beaten with hammers; it must have no flaws, nor cracks, nor pimples. New iron, which has not been well beaten, often contains round drops of cast iron, called by the workmen grains, which blunt the edges of the gouges, chisels, and other instruments used for cutting, break them, or make them slide. The iron being forged according to the model, it should be annealed, that is, heated red hot and allowed to cool slowly on the coals till the fire go out of itself. Some people, to soften the iron, cover it over with clay and allow it to cool. The iron cylinder being thus made, it is next to be put upon the lathe, fitting the centres as formerly directed, and boring a small hole in them that the iron may not escape from the points.

The points should be oiled from time to time to prevent their being excessively heated and spoiled, while the iron is turning. A crochet is then to be applied to the iron to be turned, a little above its centre, pretty gently, and by this means the inequalities of the cylinder will be taken off. Other instruments are then to be applied to mould the iron according to the model; and whenever any of them grow hot, they are to be plunged into a basin of water lying beside the workman. If the iron, after being properly turned, is to be bored like a gun-barrel, one of the puppets is to be removed and another substituted in its place, having a square hole through it into which the collar of the iron is and is fixed firmly, so as not to shake; then borers are to be applied, like those which locksmiths use to bore keys; and beginning with a small one, and afterwards taking larger ones, the hole is to be made as wide and deep as necessary; great care must be taken to hold the borers firm on the rest, otherwise there is danger of not boring the hole straight. The bore must be withdrawn from time to time to oil it and to clean the hole. Since it is difficult to make a bore quite round with borers alone, it is necessary to have also an instrument a good deal smaller than the hole, one of the sides of which is sharp, very well tempered, and a little hollow in the middle. This instrument being fixed in a pretty long handle, it is to be applied with steadiness to the inner surface of the hole, and it will entirely remove every inequality that may have been there before its application.

To cut a screw upon the cylinder, some persons use an instrument consisting principally of a female screw; but this is rather an improper instrument; for if one presses too violently, or inclines it ever so little to the right or left, he runs the greatest risk of spoiling the screw. To avoid this danger, some use it only to trace out the lines of the screw, and afterwards finish it with a file. But the following is a much better way. Take a tap for making a female screw, the threads of which have been cut very accurately, and exactly of the size of the screw which you want; and having put it in the opening which you have traced in the collar of the
TURNING.

Fig. 2.
necessary to round the shell to be moulded of such a size that when moulded, it will be a little higher than the ring of the mould, that there may be no deficiency. The mould is then to be put into a press on a plate of iron, exactly under the screw of the press; put then the shell upon the circle of the mould, so that its centre also is exactly opposite to the place of the screw of the press: then take a piece of wood formed into a truncated cone, and not so thick as the diameter of the circle of the mould, nor so deep as the ring: then put a plate of iron above the cone, and screw down the press gently and cautiously till the whole is well fixed: then plunge the whole into a cauldron of boiling water placed above a fire. In 8 or 10 minutes the shell or horn will begin to soften; screw the press a little firmer that the wooden cone may sink into the softened shell: repeat this from time to time till the cone is quite sunk in the mould; then take out the press and plunge it into cold water. When it is cold, take the box now formed out of the mould, and put into the inside of it a new mould of tin exactly of the form you wish the inside of the box to be; do the same with the outside, put it again into the press and plunge it into boiling water; screw the press gradually till the box receive the desired form.

2. Method of preparing green wood so that it will not split in the turning.—Cut the wood into pieces of a proper size, put them into a vessel full of potash ley. Boil them about an hour; take the cauldron from the fire, allow the ley to cool; and take out the wood and dry it in the shade.

3. Method of giving an ebony-black to hard and fine woods.—After forming the wood into the destined figure, rub it with aquafortis a little diluted. Small threads of wood will rise in the drying, which you will rub off with pumice-stone. Repeat this process again, and then rub the wood with the following composition: Put into a glazed earthen vessel a pint of strong vinegar, two ounces of fine iron filings, and half a pound of pounded gall, and allow them to infuse for three or four hours on hot cinders. At the end of this time augment the fire, and pour into the vessel four ounces of copperas, and a chapron of water having half an ounce of borax and as much indigo dissolved in it; and make the whole boil till a froth rises. Rub several layers of this upon the wood; and when it is dry, polish it with leather, on which you have put a little tripoli.

4. Method of giving to plum-tree the colour of brass wood.—Slake lime with urine, and bedaub the wood over with it while it is hot: allow it to dry; then take off the coat of lime, and rub it with shamin skin well oiled. Or, steep the wood in water, having a quantity of alum dissolved in it: then, having allowed brazil wood to dissolve in water five or six hours, steep the wood in it, kept lukewarm during a night; and when it is dry, rub it, as before directed, with shamin skin well oiled.

5. Method of giving a fine black colour to wood.—Steep the wood for two or three days in lukewarm water in which a little alum has been dissolved; then put a handful of logwood, cut small, into a pint of water, and boil it down to less than half a pint. If you then add a little indigo, the colour will be more beautiful. Spread a layer of this liquor quite hot on the wood with a pencil, which will give it a violet colour.
TURPENTINE, a transparent viscous substance, flowing either naturally or by incision from several resinous trees; as the terebinthus, pine larch, fr., &c. See Pinus, Botany Index. See also Chemistry and Materia Medica Index.

Oil of Turpentine. See Chemistry and Materia Medica Index.

TURPETH, the cortical part of the root of a species of convolvulus. See Materia Medica Index.

TURQUOISE, is the tooth of an animal penetrated with copper ore.

TURRITIS, Tower mustard; a genus of plants belonging to the class tetradynamia; and in the natural system ranging under the 39th order, Silphioseae. See Botany Index.

TURTLE. See Testudo, Ephemeroidea Index.

Turtle Dove. See Columba, Ornithology Index.

TUSCAN ORDER, in Architecture. See Architecture, No 42.

Tuscan Earth, a yellowish kind of soil found in many parts of Italy, and particularly about Florence, where there is a stratum eight or ten feet thick, at the depth of five or six feet from the surface. It is supposed to have an astringent property.

TUSCANY, a duchy of Italy, which makes part of the ancient Heturian, and, excepting some detached parts, is encompassed by a part of the Mediterranean, called the Tuscan sea; the ecclesiastical state; the duchy of Modena; and the republic of Lucca; its extent from north to south being about 116 English miles, and from east to west about 80; its area 8400; and in 1815 it was estimated to contain 419,500 inhabitants.

Though some parts of it are mountainous, yet both the hills and dales are covered with vines, olives, citrus, lemon, and orange trees, &c. The mountains yield also copper, iron, alum, &c, and some of the finest marble. Here is also plenty of corn, rice, saffron, honey, wax, wool, flax, hemp, with mineral waters, rich pasture, salt-pits, sulphur, alabaster, calcedony, lapis lazuli, borax, anhydrites, carnelians, and jaspers. In some places the elms and ashes yield manna.

The principal river in Tuscany is the Arno, which has its source in the Apennine mountains, and falls into the sea below Pisa. There are some other smaller rivers.

This ducy fell under the dominion of the Romans about 455 years before Christ. The Ostrogoths possessed themselves of it in the fifth century, and after them the Lombards, who were expelled by Charlemagne anno 829; in consequence of which it became subject to the German emperors, who appointed governors over it. At last the cities of Florence, Pisa, Siena, and some others, during the contiguities between the pope and the emperor, and their respective adherents, the Guelphs and Gibelinals, withdrew themselves from the dominion of both, and erected themselves into separate commonwealths. In that of Florence, John de Medici, a popular nobleman, so insinuated himself into the favour of his countrymen, that they invested him with sovereign power. Pope Pius V. confirmed the title of grand duke on Cosmo de Medicis anno 1577, in whose family the duchy continued until the death of Gaston de Medicis, who died anno 1737. The duchy was then transferred to the duke of Lorraine, afterwards the emperor.
TYMPANUM, in Mechanics, a kind of wheel placed round an axis or cylindrical beam, on the top of which are two levers or fixed staves for the more easily turning the axis in order to raise a weight required.

TYMPANUM, in Anatomy. See Anatomy, No 144. TYPANY, or TYPANNITES, in Medicine. See Medicine, No 337, and Surgery Index.

TYNDALE, William, a zealous English reformer, and memorable for having made the first English version of the Bible, was born on the borders of Wales some time before 1500. He was of Magdalen-hall in Oxford, where he distinguished himself by imbibing early the doctrines of Luther, and by zealously propagating them. Afterwards he removed to Cambridge, and from thence went to live with a gentleman in Gloucestershire in the capacity of tutor to his children—While he continued there, he showed himself so furious for Luther, and so inveterate to the pope, that he was forced, merely for the security of his person, to leave the place. He next endeavoured to get into the service of Tonstall bishop of Durham, but did not succeed. His zeal for Lutheranism made him desirous to translate the New Testament into English; and as this could not safely be done in England, he went into Germany, where, setting about the work, he finished it in 1527. He then began with the Old Testament, and finished the five books of Moses, prefixing discourses to each book, as he had done to those of the New Testament. At his first going over into Germany, he went into Saxony, and had much conference with Luther; and then returning to the Netherlands, made his abode chiefly at Antwerp. During his peregrinations from one country to another, he suffered shipwreck upon the coast of Holland, and lost all his books and papers. His translations of the Scriptures being in the mean time sent to England, made a great noise there; and, in the opinion of the clergy, did so much mischief, that a royal proclamation was issued, prohibiting the buying or reading them. But the clergy were not satisfied with this, they knew Tyndale capable of doing infinite harm, and therefore thought of nothing less than removing him out of the way. For this purpose one Philips was sent over to Antwerp, who insinuated himself into his company, and under the pretext of friendship betrayed him into custody. He was sent to the castle of Fiford, about 18 miles from Antwerp; and though the English merchants at Antwerp did what they could to procure his release, and letters were also sent from Lord Cromwell and others out of England, yet Philips bestirred himself so heartily, that he was tried and condemned to die. He was first strangled by the hands of the common hangman, and then burned near Fiford castle, in 1536. While he was tying to the stake, he cried with a fervent and loud voice, “Lord, open the king of England’s eyes.”

TYPE (type), an impression, image, or representation of some model, which is termed the antitype. In this sense the word occurs often in the writings of divines, who employ it to denote that prefiguration of the great events of man’s redemption which they have found or fancied in the principal transactions recorded in the Old Testament.

Type, among letter-founders and printers, the same with letter.
TYR is also used to denote the order observed in the
intention and remission of fevers, pulses, &c.

TYPHA, Cat’s tail; a genus of plants belonging
to the class of monoezia, and in the natural system arranged
under the 3d order, Calemariae. See Botany Index.

TYPHON. See Whirlwind.

Typhon, the devil of the ancient Egyptians. See Polytheism, No. 29.

Typography, the art of printing. See Printing.

Tyrrant, among the ancients, denoted simply a
king or monarch; but the ill use which several persons
invested with that sacred character made of it, has altered
the import of the word; and tyrant now conveys the
idea of an unjust or cruel prince, who rules in a
more despotic manner than the laws allow.

Tyre, formerly a celebrated city of Asia, on the
eastern coast of Syria, situated under the 34th degree of east
longitude, and 32d of north latitude. It was built,
according to some writers, 2750 years before the Christian
era. There were two cities of that name; the one
called Palæturus, situated on the continent; and the
other the city of Tyre, built on an island about half a
mile from the shore. It was about 19 miles in circum-
ference, including Palæturus; the town on the island
was about four miles square. The buildings of Tyre
were very magnificent; the walls were 150 feet high,
broad in proportion. The city was at one period
the most famous commercial city in the world. Of its
commercial transactions, the most particular account
that is to be found in any ancient writer has been given
by the prophet Ezekiel, which at the same time con-
veys a magnificent idea of the extensive power of that
state. It resisted Nebuchadnezzar king of Babylon for
13 years; at the end of which, wearied with fruitless
efforts, the inhabitants resolved to place the sea be-
tween them and their enemy, and passed accordingly in-
to the island. The new city stood out against Alex-
ander the Great for seven months; and before he could
take it, he was obliged to fall up the strait which sepa-
rated the island from the continent. It was repaired af-
terwards by Adrian, and became the metropolis of the
province. It afterwards fell into the hands of the A-
rabs; and after being taken by Baldwin II. king of Je-
rusalem, it was destroyed by the sultan of Egypt in
1289, and abandoned. An excellent account of its
modern state may be found in Volney’s Travels, vol. ii.
It now consists of a small village, composed of fisher-
men’s huts, and containing about 50 or 60 poor families.

Tyrion dye. See Morex, Conchology In-
der.

Tyrone, a county of Ireland, in the province of
Ulster, 46 miles in length and 37 in breadth; bounded
on the north by Londonderry, on the east by Antrim
and Lough Neagh, on the south by Fermanagh, and
on the west by Donegal. It is a rough and rugged
country, but tolerably fruitful; contains 12,683 houses,
30 parishes, 4 baronies, 4 boroughs, and formerly 10
members to the Irish parliament. The principal town is
Dungannon.

V, U.

V, or u, the 20th letter and 5th vowel of our alpha-
bet, is formed in the voice by a round configuration
of the lips, and a greater extrusion of the under
one than in forming the letter 0, and the tongue is also
more camouflated. The sound is short in curt, must, tun,
tub; but is lengthened by a final e, as in tune, tube, &c.
In some words it is rather acute than long; as in brute,
bluff, flute, &c. It is mostly long in polysyllables; as in
union, curious, &c.; but in some words it is obscure,
as in nature, venture, &c. This letter in the form of V
or v, is properly a consonant, and as such is placed
before all the vowels; as in vacant, vacant, vibrant, &c.
Though the letters v and u had always two sounds, they
had only the form v till the beginning of the fourth
century, when the other form was introduced, the incon-
invenience of expressing two different sounds by the
same letter having been observed long before. In nu-
merals V stands for five; and with a dash added at top,
thus V, it signifies 5000.

In abbreviations, amongst the Romans, V. A. stood
for veni aequi assignati; V. B. viro bono; V. B. A. viri
boni orbis terrae; V. B. F. viri bone sedit; V. C. viri
consagurati; V. C. C. E. vole, confusus carissimus, feliciter;
V. D. D. voto dedicatus; V. G. verbi gratia; V. V. ve-
ingo vestalis; V. L. videlicet; V. N. quinto nonarum.

Vaccinium, the Whortle-berry, or Bilberry, Vaccinium
a genus of plants belonging to the class octandria, and
arranged in the natural system under the 18th order,
Bicornus. See Botany Index.

Vacuum, in Philosophy, denotes a space devoid of
all matter or body.

It has been greatly disputed whether there be in na-
ture a perfect vacuum, or space void of all matter; but
if bodies consist of material solid atoms, it is evident
that there must be vacuities, or motion would be im-
possible (See Metaphysics, No. 192). We can even
produce something very near a vacuum in the receiver
of an air-pump and in the Torricellian tube (see pneu-
matics, vacuum).

Vadium, a pledge in law, is either suum or mortu-
orum.

Vadium. Vadium, or Living Pledge, is when a man
borrows a sum (suppose 200l.) of another; and grants
him an estate, as of 20s. per annum, to hold till the
rents and profits shall repay the sum so borrowed. This
is an estate conditioned to be void as soon as such sum
is raised. And in this case the land or pledge is said
to be living: it subsists, and survives the debt; and,
immediately on the discharge of that, reverts to the
borrower.

Vadium
and idols are said to abound among them more than in any other place of the globe. They are naturally hardy, enterprising, and good-natured. Veliaia is surrounded on all sides by very high mountains, most of which are covered with perpetual snow. The soil is fertile in corn, wine, and fruits. The muscat-wine, which is produced here, is excellent, and well known all over Europe. This country comprehends 55 large parishes, with one bishop. The religion is the Roman Catholic.

VALANTIA, a genus of plants belonging to the class polygamiæ, and in the natural system arranged under the 21st order, Superfideæ. See Botany Index.

VALENCA, a province of Spain, which bears the title of a kingdom; and is bounded on the east and south by the Mediterranean sea, on the north by Catalonia and Aragon, and on the west by New Castile and the Kingdom of Murcia. It is about 165 miles in length, and 63 in breadth, and in 1788 contained 783,000 inhabitants. It is one of the most agreeable parts of Spain, enjoying almost a perpetual spring. The great number of rivers whereby it is watered renders it extremely fertile. There are very rugged mountains in it, which contain mines of alum and other minerals.

VALENCE, a city of Spain, and capital of the kingdom of the same name. It contains, according to La Borde, 20,000 houses, and 100,000 inhabitants. It has an university, and an archbishop's see; and was taken from the Moors by the Christians in the 13th century. The town is handsome, and adorned with very fine structures. It is not very strong, though there are some bastions along the sides of the walls. They have manufactures in wool and silk, which bring in great sums to the inhabitants. It is seated on the river Guadalquivir, over which there are handsome bridges; and it is about three miles from the sea, where there is a harbour, 110 miles north of Murcia, and 165 east by south of Madrid. This city surrendered to the earl of Peterborough in the year 1705, and suffered dreadfully when taken by Marshal Buchet in 1811. W. Long. 0. 10. N. Lat. 39. 27.

VALENCOINES, an ancient, strong, and considerable city of France, in the department of the North, containing about 17,000 inhabitants in 1800. The Scheldt divides it into two parts. It is a very important place: the citadel and fortifications, the work of Vauban, were constructed by order of Louis XIV, who took this town from the Spaniards. It was confirmed to him by the treaty of Nimeguen, in 1678. In 1793, it surrendered to the allies after a severe siege; but was afterwards abandoned; and is now in possession of the French. Besides lace, this city is noted for manufactories of woollen stuffs and very fine linens. It is 20 miles west-south-west of Mons, 17 north-east of Cambray, and 120 north-east by north of Paris. E. Long. 3. 37. N. Lat. 50. 27.

VALES, Flavius, emperor of the East, a great patron of the Arts. Killed by the Goths in the year 379. See Constantinople, No. 76.

VALENTINIAN I. emperor of the West, a renowned warrior, but a tyrant over his subjects. See Rome, No. 523.

VALENTINIAN II. emperor of the West, a prince celebrated for his virtues, and above all for his moderation; yet a conspiracy was formed against him by Arians, bagatery,
Mathematical on the Variation of the Magnetical Needle, Variation

by Mr Henry Gillebrand, Gresham professor of astronomy. He had compared the variations observed at London by Burroughs, Gunter, and himself, and found that the north end of the mariner's needle was gradually drawing more to the westward. For Norman and Burroughs had observed it to point about 11° to the east of north in 1582; Gunter found its deviation only 6° in 1622, and he himself had observed only 4° in 1634; and it has been found to deviate more and more to the westward ever since, as may be seen from the tables given under Magnetism.

Mr Bond, teacher of mathematics in London, and employed to edit and improve the impressions of the popular treatises of navigation, about 1650, declared, in a work called the "Seaman's Kalendar," that he had discovered the true progress of the deviation of the compass; and published in another work, called "the Longitude Found," a table of the variation for 50 years. This was, however, a gratuitous prognostication, not founded on any well-grounded principles; and though it agreed very well with the observations made by Bond, which showed a gradual motion of the point of the needle towards the south at the rate of 1° 12' annually, no means agreed with the observations made in other places. See Phil. Trans. 1668.

But this news soon lost its credit: for the inconsistency with observation appeared more and more every day, and all were anxious to discover some general rule, by which a near guess at least might be made as to the direction of the needle in the most frequented seas. Halley recommended the matter in the most earnest manner to the attention of government; and, after much unwarranted solicitation, obtained a ship to be sent on a voyage of discovery for this purpose. He got the command of this ship, in which he repeatedly traversed the Atlantic ocean, and went as far as the 50th degree of southern latitude. See his very curious speculations on this subject in the Phil. Trans. 1683 and 1692.

After he had collected a prodigious number of observations made by others, and compared them with his own, he published in 1700 a synoptical account of them in a very ingenious form of a sea chart, where the ocean was crossed by a number of lines passing through those planes where the compass had the same deviation. Thus, in every point of one line there was no variation in 1700; in every point of another line the compass had 20° of east variation; and in every point of a third line it had 20° of west variation. These lines have since been called Halleyan lines, or curves. This chart was received with universal applause, and was undoubtedly one of the most valuable presents that science has made to the arts.

The polarity of the magnetic needle, and a general though intricate connection between its positions in all parts of the world, naturally makes the philosopher speculate about its cause. We see that Cortez ascribed it to the attraction of an eccentric point, and that Bond thought that this point was placed not in the heavens, but in the earth. This notion made the basis of the famous Theory of Magnetism of Dr Gilbert of Colchester. See Magnetism, No 71.

Gilbert's theory may be understood from the following general proposition.

Let NS (fig. 29) be a magnet, of which N is the north
Therefore the needle of the mariner's compass in Variation.

every part of the world arranges itself in the magnetic
direction, so that if poised as a dipping needle should be,
it will be a tangent to one of the curves NeS of fig. 1.
The horizontal needle being so poised as to be capable
of playing only in a horizontal plane, will only arrange
itself in the plane of the triangle NeS. That end of it
which has the same magnetism with the south pole S of
the great magnet included in the earth will be turned
towards its north pole N. Therefore what we call the
north pole of a needle or magnet really has the magnes-
tism of the south pole of the great primitive magnet.

Dr Halley's first thought was, that the north pole of
the great magnet or loadstone which was included in the
bowels of the earth was not far from Baffin's bay, and
its south pole in the Indian ocean south-west from New
Zealand. But he could not find any positions of these
two poles which would give the needle that particular
position which it was observed to assume in different
parts of the world; and he concluded that the great
terrestrial loadstone had four irregular poles (a thing not
unfrequent in natural loadstones, and easily producible
at pleasure), two of which are stronger and two weaker.

When the compass is at a great distance from the two
poles, it is affected so as to be directed nearly in
a plane passing through the strongest. But if we make
it approach much more to the weakest, the greater vicin-
ity will compensate for the smaller absolute force of the
weak pole, and occasion considerable irregularities. The
appearances are favourable to this opinion. If this be
the real constitution of the great magnet, it is almost a
desperate task to ascertain by computation what will be
the position of the needle. Halley seems to have de-
seried: for he was both an elegant and a most expert
mathematician, and it would have cost him little trouble
to ascertain the places of two poles only, and the
direction which these would have given to the needle.

But to say what would be its position when acted on by
four poles, it was necessary to know the law by which
the magnetic action varied by a variation of distance;
and even then, the computation would have been ex-
ceedingly difficult.

In order to account for the change of variation, Dr
Halley supposes this internal magnet not to adhere to the
external shell which we inhabit, but to form a nu-
cleus or kernel detached from it on all sides, and to be
so poised as to revolve freely round an axis, the position
of which he hopes to discover by observation of the
compass. Dr Halley imagined that the nucleus revol-
ved from east to west round the same axis with the earth.

Thus the poles of the magnet would change their pos-
tions relatively to the earth's surface, and this would
change the direction of the compass needle.

The great Euler, whose delight it was always to en-
gage in the most mathematical researches and compu-
tations, undertook to ascertain the position of the
needle in every part of the earth. His dissertation on
this subject is to be seen in the 14th volume of the Me-
moirs of the Royal Academy of Berlin, and is exceed-

Vol. XX. Part II.
Variation. ing beautiful, abounding in those analytical tours d’adresse in which he surpassed all the world. He has reduced the computation to a wonderful simplicity.

He found, however, that four poles would engage him in an analysis which would be excessively intricate, and has contented himself with computing for two only; observing that this supposition agrees so well with observation, that it is highly probable that this is the real constitution of the terrestrial magnet, and that the coincidence would have been perfect if he had hit on the due positions of the two poles. He places one of them in lat. 56° north, and long. 96° west from Teneriffe. The south pole is placed in lat. 58° south, and long. 158° west from Teneriffe. These are their situations for 1777.—Mr Euler has annexed to his dissertation a chart of Halleyan curves suited to these assumptions, and fitted to the year 1757.

It must be acknowledged, that the general course of the variations according to this theory greatly resembles the real state of things; and we cannot but own ourselves highly indebted to this great mathematician for having made so fine a first attempt. He has improved it very considerably in another dissertation in the 22d volume of those memoirs. But there are still such great differences, that the theory is of no use to the navigator, and it only serves as an excellent model for a further prosecution of the subject. Since that time another large variation chart has been published, fitted to a late period; but the public has not sufficient information of the authorities or observations on which it is founded.

The great object in all these charts is to facilitate the discovery of a ship’s longitude at sea. For the lines of variation being drawn on the chart, and the variation and the latitude being observed at sea, we have only to look on the chart for the intersection of the parallel of observed latitude and the Halleyan curve of observed variation. This intersection must be the place of the ship. This being the purpose, the Halleyan lines are of great service; but they do not give us a ready conception of the direction of the needle. We have always to imagine a line drawn through the point, cutting the meridian in the angle corresponding to the Halleyan line. We should learn the general magnetic affections of the globe much better if a number of magnetic meridians were drawn. These are the intersections of the earth’s surface with planes passing through the magnetic axis, cutting one another in angles of 60° or 10°. This would both show us the places of the magnetic poles much more clearly, and would, in every place, show us at once the direction of the needle. In all those places where these magnetic curves touch the meridians, there is no variation; and the variation in every other place is the angle contained between these magnetic meridians and the true ones.

The program of a work of this kind has been published by a Mr Churchman, who appears to have engaged in the investigation with great zeal and considerable opportunities. It is pretty certain that the north magnetic pole (or point, as Mr Churchman calls it) is not far removed from the stations given it by Halley and Euler; and there seems no doubt but that in the countries between Hudson’s bay and the western parts of North America the needle will have every position with respect to the terrestrial meridian, so that the north end of a compass needle will even point due south in several places. Almost every thing that can be desired in this inquiry would be obtained by a few well-chosen observations made in those regions. It would be of immense advantage to have the dips ascertainment with great precision. These would enable us to judge at what depth under the surface the pole is situated; for the well-informed mechanician, who will study seriously what we have said about the magnetic curves, will see that a compass needle, when compared with the great terrestrial magnet, is but as a particle of iron filings compared to a very large artificial magnet. Therefore, from the position of the dipping needle, we may infer the place of the pole, if the law of magnetic action be given; and this law may be found by means of other experiments, which we could point out. See Magnetism, No. 80, et seq.

Mr Churchman has adopted the opinion of only two poles. According to him, the north pole was (in 1600) in lat. 36° N. and Long. 135° W. from Greenwich, very near Cape Fairweather; and the south pole lies in lat. 35° S. and Long. 165° E. from Greenwich. He also imagines that the north pole has moved to the eastward on a parallel of latitude, about 65 since the beginning of the 19th century (from 1600), and concludes that it makes a revolution in 1029 years. The southern pole has moved less, and completes its revolution in 2289 years. This motion he ascribes to some influence which he calls magnetic tides, and which he seems to consider as celestial. This he infers from the changes of variation. He announces a physical theory on this subject, which, he says, enables him to compute the variation with precision for any time past or to come; and he even gives the process of trigonometrical computation illustrated by examples. But it is to this publication (entitled The Magnetic Atlas), published for the author, by Darton and Harvey, 1794, is only a program, he expresses himself obscurely, and somewhat enigmatically, respecting his theory. He speaks of the influence of one pole being greater than that of the other; and says, that in this case the magnetic equator, where the needle will be parallel to the axis, will not be in the middle between the poles. This is true of a common magnet. He must therefore abide by this supposition in its other consequences. The magnetic meridians must be planes passing through this axis, and therefore must be circles on the surface of the earth. This is incompatible with the observations; nay, his charts are so in many places, particularly in the Pacific ocean, where the variations by his chart are three times greater than what has been observed.—His parallels of dip are still more different from observation, and are incompatible with any phenomena that could be produced by a magnet having but two poles. His rules of computation are exceedingly exceptionable. He has in fact but one example, and that so particular, that the mode of computation will not apply to any other. This circumstance is not taken notice of in the enunciation of his first problem; and the reader is made to imagine that he has got a rule for computing the variation, whereas all the rules of calculation are only running in a circle. The variation computed for the port of St Peter and Paul in Kamtschatka, by the rule, is ten times greater than the truth.

For our own part, we have little hopes of this problem ever being subjected to accurate calculation. We believe,
All this refers only to the thin crust through which variation, the human eye has occasionally penetrated. Of what may be below we are ignorant; but when we see appearances which tally so remarkably with what would be the effects of great masses of magnetic bodies, modifying the general and regularly progressive action of a primitive magnet, whose existence and motion is inconsistent with nothing that we know of this globe, this manner of accounting for the observed change of variation has all the probability that we can desire. Nay, we apprehend that very considerable changes may be produced in the direction of the compass needle, even without the supposition of any internal motion. If the great magnet resembles many loadstones we are acquainted with, having more than two poles, we know that these poles will act on each other, and gradually change each other's force, and consequently the direction of the compass. This process, to be sure, tends to a state of things which will change no more.—But the period of human history, or of the history of the race of Adam, may make but a small part of the history of this globe; and therefore this objection is of little force.

There can be no doubt of the operation of the general terrestrial magnetism on every thing susceptible of magnetic properties; and we cannot hesitate to explain in this way many changes of magnetic direction which have been observed. Thus, in Italy, Father de la Torre observed, that during a great eruption of Vesuvius the variation was $16^\circ$ in the morning, at noon it was $14^\circ$, and in the evening it was $10^\circ$, and that it continued in that state till the lava grew so dark as no longer to be visible in the night; after which it slowly increased to $13^\circ$, where it remained. Daniel Bernoulli found the needle changed its position $45^\circ$ by an earthquake. Professor Muller at Mannheim observed that the declination of the needle in that place was greatly affected by the earthquake in Calabria. Such streams of lava from Helia in the last dreadful eruption must have made a transference of magnetic matter that would considerably affect the needle. But no observations seem to have been made on the occasion; for we know that common ironstone, which has no effect on the needle, will, by mere cementation with any inflammable substance, become magnetic. In this way Dr Knight sometimes made artificial loadstones. But these are partial things, and not connected with the general change of variation now under consideration.

We have said so much on this subject, chiefly with the view of cautioning our readers against too sanguine expectations from any pretensions to the solution of this great problem. We may certainly gather from these observations, that even although the theory of the variation should be completed, we must expect (by what we already know of magnetism in general) that the disturbances of the needle, by local causes intervening between it and the great influence by which it is chiefly directed, may be so considerable as to affect the position of the compass needle in a very sensible manner: for we know that the metallic substances in the bowels of the earth are in a state of continual change, and this to an extent altogether unknown.

There is another irregularity of the mariner's needle that we have noticed under Magnetism, page 365, namely, the daily variation. This was first observed by...
Variation by Mr. George Graham in 1722 (Philosophical Transactions, N° 383.), and reported to the Royal Society of London. It usually moves (at least in Europe) to the westward from 8 morning till 2 P.M., and then gradually returns to its former situation. The diurnal variations are seldom less than 6° 5', and often much greater. Mr. Graham mentions (Philosophical Transactions, N° 428.) some observations by a Captain Hume, in a voyage to America, where he found the variation greatest in the afternoon. This being a general phenomenon, has also attracted the attention of philosophers. The most detailed accounts of it are met with are those of Mr. Canton (see Magnetism), in Philosophical Transactions, vol. li. part i. p. 399, and those of Van Swinden, in his Treatise on Electricity and Magnetism.

Mr. Canton attempts to account for these changes of position, by observing that the force of a magnet is weakened by heat. A small magnet being placed near a compass needle, ENE from it, so as to make it deflect 45° from the natural position, the magnet was covered with a brass vessel, into which hot water was poured. The needle gradually receded from the magnet 45°, and returned gradually to its place as the water cooled. This is confirmed by uniform experience.

But, besides this regular diurnal variation, there is another, which is subjected to no rule. The aurora borealis is observed (in Europe) to disturb the needle exceedingly, sometimes drawing it several degrees from its position. It is always observed to increase its deviation from the meridian, that is, an aurora borealis makes the needle point more westerly. This disturbance sometimes amounts to six or seven degrees, and is generally observed to be greatest when the aurora borealis is most remarkable.

The observation of the connection of the polarity of the needle with the aurora borealis occurred to the late Professor Robinson in 1759, when a midshipman on board the Royal William in the river St. Lawrence. The point of the heavens to which all the rays of light converged was precisely that which was opposite to the south end of the dipping needle.

This is a very curious phenomenon, and we have not been able to find any connection between this meteor and the position of a magnetic needle. It is to be observed, that a needle of copper or wood, or any substance except iron, is not affected. We long thought it an electric phenomenon, and that the needle was affected as any other body balanced in the same manner would be; but a copper needle would then be affected.

We see the needle frequently disturbed both from its general annual position, and from the change made on it by the diurnal variation. This is probably the effect of aurora borealis which are invisible, either on account of thick weather or daylight. Van Swinden says, Variation he seldom or never failed to observe aurora borealis immediately after any anomalous motion of the needle; and concluded that there had been one at the time, though he could not see it. Since no needle but a magnetic one is affected by the aurora borealis, we may conclude that there is some natural connection between this meteor and magnetism. This should further incite us to observe the circumstances above mentioned, viz. that the south end of the dipping needle points to that part of the heavens where the rays of the aurora appear to converge. We wish that this were diligently observed in places which have very different variation and dip of the mariner's needle.

Another species of variation of great importance has lately been discovered. This arises from the action of the mass of the ship on the needle, and is found in some cases to amount to five degrees, so that when bearings are taken with the ship's head first on one side of the magnetic meridian, and then on the other, a difference will be found of ten degrees. Anomalies arising from this source had been often observed, and had greatly perplexed nautical men: they were often attributed to the defects of the compass. Captain Flinders seems to have been the first who detected the true cause of these irregularities, by ascertaining that the mean variation taken with five different compasses at the binnacle, was 4° 37' greater than at the booms. This subject, however, was first fully investigated and explained by Mr. William Bain, a nautical gentleman, in a small tract published at Edinburgh in 1817. Mr. Bain having detected the effects of the local attraction of the ship by his own observations in 1811, has, by means of this principle, satisfactorily explained many facts recorded by former navigators, which appeared hitherto inexplicable. He shows, that in the short course from Plymouth to Cape Finisterre, by neglecting this local attraction, an error of 12 miles may be committed in latitude, and of 35 in longitude. In the course from St. John's Newfoundland to England, the error from the same cause may amount to 64 miles in latitude, and 198 in longitude. He observes also, that in beating to windward, and tacking pretty often, all seamen have remarked, that every time the ship was put about, the wind came round some points with the ship. This change in the wind, however, is merely apparent, and is simply the effect of the attraction of the ship upon the needle. When the head is westerly, the north end of the needle is drawn half the difference westward; when the head is easterly, it is drawn half the difference eastward. He has also shown, that many of the irregularities ascribed to currents are truly owing to this cause. The amount of the local variation caused by the ship must depend on her construction, and in a merchant vessel on her cargo. It will therefore most probably vary in different ships, and in the same ship, at different times. Mr. Bain thinks that it would be advisable for every merchant vessel before she leaves the port, to ascertain by observations made on some fixed object at a distance, the precise amount of this local attraction; and when this is once known, she may steer her course with much greater confidence and security. For further particulars the reader may consult Mr. Bain's excellent little work, entitled, "An Essay on the Variation of the Compass."
Variation: Compass. Edinburgh, 1817. The discovery of this species of variation well deserves to be regarded as an important step in the improvement of navigation.

For the dinna and this irregular variation, consult the Dissertations of Celsius and of Horler, in the Memoirs of Stockholm; Wargentus, Philosophical Transactions, vol. viii.; Braun (Comment. Petropol. Novi, tom. v. vii. ix.); Graham and Cauton as above.

Variety, a change, succession or difference, in the appearance or nature of things; in opposition to uniformity.

Variety, in Botany, is a change in some less essential part of the species, than genus, or subgenus, or age.

Exteriorly; by the paiing or interweaving of the branches—by budding or grafting of several stalks into one broad flat one; by the greater breadth or narrower, or curving of leaves—by becoming awnless, or smooth, or hispate. Internally; by being mutilated in the corolla; or having one larger than ordinary—by luxuriance, multiplication, or fulness—by becoming proliferous, or crested—by bearing buds instead of seeds—or being viviparous.

The usual causes of variation are, climate, soil, exposure, heat, cold, winds, culture.

Variola, the Smallpox. See Medicine, No. 223—224.

Varix, in Medicine, the dilatation of a vein, arising from the too great abundance or thickness of the blood.

Varnish, a clear limpid fluid, capable of hardening without losing its transparency, used by painters, gilders, &c. to give a lustre to their works, to preserve them and defend them from the air.

A coat of varnish ought to possess the following properties: 1. It must exclude the action of the air; because wood and metals are varnished to defend them from decay and rust. 2. It must resist water; for otherwise the effect of the varnish could not be permanent. 3. It ought not to alter such colours as are intended to be preserved by this means. It is necessary therefore that a varnish should be easily extended or spread over the surface, without leaving pores or cavities; that it should not crack or scale; and that it should not peel. Now resins are the only bodies that possess these properties. Resins consequently must be used as the bases of varnish. The question which of course presents itself must then be, how to dispose them for this use? and for this purpose they must be dissolved, as minutely divided as possible, and combined in such a manner that the imperfections of those which might be disposed to scale may be corrected by others.

Resins may be dissolved by three agents: 1. By fixed oil. 2. By volatile oil. 3. By alcohol. And accordingly we have three kinds of varnish; the fat or oil varnish, essential varnish, and spirit varnish. Before a resin is dissolved in a fixed oil, it is necessary to render the oil drying. For this purpose the oil is boiled with metallic oxides; in which operation the mucilage of the oil combines with the metal, while the oil itself unites with the oxygen of the oxide. To accelerate the drying of this varnish, it is necessary to add oil of turpentine. The essential varnishes consist of a solution of resin in oil of turpentine. The varnish being applied, the essential oil flies off, and leaves the resin. This is used only for paintings. When resins are dissolved in alcohol, the varnish dries very speedily, and is subject to crack; but this fault is corrected by adding a small quantity of turpentine to the mixture, which renders it brighter, and less brittle when dry.

We shall now give the method of preparing a number of varnishes for different purposes.

A Varnish for Toilet-boxes, Cases, Fans, &c.—Dissolve two ounces of gum mastich and eight ounces of gum sandarach in a quart of alcohol; then add four ounces of Venice turpentine.

A Varnish for Chairs, Canes, Iron-chairs, Grates.—Dissolve in a quart of alcohol eight ounces of gum sandarach, two ounces of gum lac, four ounces of rosin; then add six ounces of Venice turpentine. If the varnish is wished to produce a red colour, more of the lac and less of sandarach should be used, and a little dragon’s blood should be added. This varnish is so thick that two layers of it are equal to four or five of another.

A Varnish for Fiddles, and other Musical Instruments.—Put four ounces of gum sandarach, two ounces of lac, two ounces of gum mastich, an ounce of gum elemi, into a quart of alcohol, and hang them over a slow fire till they are dissolved; then add two ounces of turpentine.

Varnish in order to employ Vermilion for painting Equine figures.—Dissolve in a quart of alcohol six ounces of sandarach, three ounces of gum lac, and four ounces of rosin; afterwards add six ounces of the cheapest kind of turpentine; mix with it a proper quantity of vermilion when it is to be used.

Gold-coloured Varnish.—Pound separately four ounces of stick lac, four ounces of gamboge, four ounces of dragon’s blood, four ounces of salicron; put each of them separately into a quart of alcohol, and expose them for five days in a narrow-mouthed bottle to the sun, or keep them during that time in a very warm room, shaking them every now and then to hasten the solution. When they are all melted, mix them together. More or less of each of these ingredients will give the different tints of gold according as they are combined. In order to make silver imitate gold exactly when covered with this varnish, the quantity of ingredients must be somewhat greater. The method of gilding silver-leaf, &c., with this varnish is as follows: The silver-leaf being fixed on the subject, in the same manner as gold-leaf, by the interposition of proper glutinous matters, the varnish is spread upon the piece with a brush or pencil. The first coat being dry, the piece is again and again washed over with the varnish till the colour appears sufficiently deep. What is called gilt leather, and many picture frames, have no other than this counterfeit gilding. Washing them with a little rectified spirit of wine affords a proof of this; the spirit dissolving the varnish, and leaving the silver-leaf of its own whiteness. For plain frames, thick tinfoil may be used instead of silver. The tin-leaf, fixed on the piece with glue, is to be burnished, then polished with emery and a fine linen cloth, and afterwards with putty applied in the same manner: being then lacquered over with the varnish five or six times, it looks very nearly like burnished gold. The same varnish, made with a less proportion of the colouring materials, is applied also on works of brass; both for heightening the colour of the metal to a resemblance with that of gold,
VARNISH (526)

Varnish, and for preserving it from being tarnished or corroded by the air.

Oil Varnishes.—Gum copal and amber are the substances principally employed in oil varnishes; they possess the properties necessary for varnishes, solidity and transparency. The copal being whitest, is used for varnishing light, the amber for dark colours. It is best to dissolve them before mixing them with the oil, because by this means they are in less danger of being scorched, and at the same time the varnish is more beautiful. They should be melted in a pot on the fire; they are in a proper state for receiving the oil when they give no resistance to the iron spatula, and when they run off from it drop by drop. The oil employed should be a drying oil, and perfectly free from grease. It should be poured into the copal or amber by little and little, constantly stirring the ingredients at the same time with the spatula. When the oil is well mixed with the copal or amber, take it off the fire; and when it is pretty cool, pour in a greater quantity of the essence of turpentine than the oil that was used. After the varnish is made, it is should be passed through a linen cloth. Oil varnishes become thick by keeping; but when they are to be used, it is only necessary to pour in a little essence of turpentine, and to put them for a little on the fire. The turpentine is necessary in oil varnishes to make them dry properly; generally twice as much of it is used as of oil. Less is necessary in summer than in winter. Too much oil hinders the varnish from drying; but when too little is used, it cracks and does not spread properly. We shall subjoin the most useful oil varnishes:

White Copal Varnish.—On 16 ounces of melted copal pour six, or eight ounces of linseed oil, boiled and quite free from grease. When they are well mixed, take them off the fire (not forgetting to stir them properly); and when pretty cool, pour in 16 ounces of the essence of Venice turpentine. Pass the varnish through a cloth. Amber varnish is made in the same way.

Black Varnish for Coaches and Iron Work.—This varnish is composed of bitumen of Palestine, rosin, and amber, melted separately, and afterwards mixed: the oil is then added, and afterwards the turpentine, as directed above. The usual proportions are, 12 ounces of amber, two ounces of rosin, two ounces of bitumen, six of oil, and 12 of the essence of turpentine. Golden-coloured varnish may be made also by substituting linseed oil for alcohol.

Essential Oil Varnishes.—The only essential oil varnishes used are for pictures. Picture varnishes should be white, light, and quite transparent, which will preserve the colours without giving them any disagreeable tint; and it should be possible to take them off the picture without injuring them. They are usually made of gum mastic and turpentine dissolved together in some essential oil. The varnish is passed through a cloth, and allowed to clarify. It is applied cold to the picture.

Varnish for Glass in order to preserve it from the agant, and let it dissolve for 24 hours in the white of eggs well beat up; then rub it gently on the glass with a brush.

Varnishes before they are used should be carefully kept from dust, which would spoil them; and they should be kept in a vessel quite clean and dry. When used, they should be lifted lightly with a brush, and spread upon a ground altogether free from dirt and moisture. The substance, after being varnished, should be exposed to the heat of the sun, or placed in a warm room covered with a glass case, to keep out all fih. Oil varnishes require more heat than alcohol varnishes. The varnish should be put on very quickly, making great strokes with the pencil or brush, taking care that these strokes never cross one another; it should be spread equally, and never thicker than a leaf of paper; a second coat should never be put on till the first is quite dry. If the varnish, after being put on, becomes dull and uneven, it must be taken off entirely, and new varnish put on.

When wainscot is to be varnished, it is first painted of a wooden colour. This colour is made by infusing in water either red or yellow ochre (according to the colour wished for), terra umber (a kind of ochre) and white lead; into this as much as necessary is put of parchement paste. Two or three coats of this are to be put on, and, after they are quite dry, the varnish.

Varnishes are polished with pumice-stone and tripoli earth. The pumice-stone must be reduced to an impalpable powder, and put upon a piece of serge moistened with water; with this the varnished substance is to be rubbed lightly and equally. The tripoli must also be reduced to a very fine powder, and put upon a clean woollen cloth moistened with olive oil, with which the polishing is to be performed. The varnish is then to be wiped with soft linen, and, when quite dry, cleaned with starch or Spanish white, and rubbed with the palm of the hand or with a linen cloth.

To recover colours or varnish, and to take off the dirt and filth which may adhere to them, a ley is used made of potash and the ashes of less of wine. Take 18 ounces of potash, and 16 of the above-mentioned ashes, and put them into six quarts of water, and the ley is made: instead of the ashes an equal quantity of potash would probably do as well. To clean dirty colours, dilute some of this ley with four times its quantity of water, and rub the picture with it; then wash it with river water; and when dry, give it a coat or two of varnish. In order to take off a varnish, wash it with the above-mentioned ley, then with water, and then lift it off the substance on which it was with any iron instrument. We shall finish this article with a description of the famous Chinese varnish.

The Chinese varnish is not a composition, but a resin which exudes from a tree called in China tsu-chu, "varnish tree." This tree grows in several provinces of the southern parts of China. The Chinese take the following method of propagating this tree: In spring they choose a vigorous shoot about a foot in length, which proceeds immediately from the trunk; and coat over the lower part, by which it adheres to the tree, with a kind of yellow earth, at least three inches in thickness. This coat is carefully covered with a mat, to defend it from rain and the injuries of the air. Towards the autumnal equinox they detach a little of the earth, to observe in what condition the small roots are, which begin to spring forth from the shoot. If they find that the filaments which compose them are of a reddish colour, they judge it is time to make an amputation; but they defer it if the roots are white, because this colour shows
The season of collecting varnish being ended, the merchants put it into small casks closely stopped. A pound of it newly made costs him about one shilling and eight pence sterling; but he gains cent. per cent. upon it, and sometimes more, according to the distance of the place to which he transports it.

Besides the lustre and beauty which varnish gives to many of the Chinese manufactures, it has also the property of preserving the wood upon which it is laid, especially if no other matter be mixed with it. It prevents it from being hurt either by dampness or worms.

Every workman has a particular art and method of using the varnish. This work requires not only much skill and dexterity, but also great attention, to observe the proper degree of fluidity which the gum ought to have, as it must be neither too thick nor too liquid when it is laid on. Patience above all is necessary in those who wish to succeed. To be properly varnished, a work must be done at leisure; and the whole summer is scarcely sufficient to bring it to perfection. It is therefore rare to see any of those cabinets which are imported to us from Canton so beautiful and durable as those manufactured in Japan, Tong-king, and Nang-king, the capital of the province of Kiang-nan; not that the artists do not employ the same varnish; but as they work for Europeans, who are more easily pleased, they do not take the trouble of giving the pieces which come from their hands all the polish they are capable of receiving.

There are two methods of laying on the varnish; the simplest is, when it is immediately laid on the wood. The work is first polished, and then daubed over with a kind of oil which the Chinese call long-yeow. When this oil is dry, it receives two or three coats of varnish; which remain so transparent that all the shades and veins of the wood may be seen through them. If the artist is desirous of entirely concealing the substance on which they are laid, nothing is necessary but to add a few more coats; these give the work a shining surface, the smoothness of which equals that of the most beautiful ice. When the work is dry, various figures are painted upon it in gold and silver, such as flowers, birds, trees, temples, dragons, &c. A new coat of varnish is then sometimes laid over these figures, which preserves them, and adds much to their splendour. The second method requires more preparation. The Chinese workmen fix the wood by means of glue a kind of pasteboard, composed of paper, hemp, lime, and other ingredients, well beaten that the varnish may incorporate with them. Of this they make a ground perfectly smooth and solid, over which the varnish is laid in thin coats, that are left to dry one after the other.

It often happens, that the lustre of varnished tables and other pieces of furniture is insensibly destroyed by tea and warm liquors. "The secret of restoring to varnish its shining black colour (as a Chinese author) is to expose it for one night to a white hoar-frost, or to cover it some time with snow." For a method of imitating Chinese varnish, see TURNING.

VARNISH also signifies a sort of shining coat, whereof potters-ware, delft-ware, china-ware, &c. are covered, which gives them a smoothness and lustre. Melted lead is generally used for the first, and small for the second. See GLAZING.
VARNISH, among medalists, signifies the colours antique medals have acquired in the earth.

The beauty which nature alone is able to give to medals, and art has never yet attained to counterfeit, enhances the value of them: that is, the colour which certain soils in which they have a long time lain tinges the metals withal: some of which are blue, almost as beautiful as the turquoise; others with an inimitable vermilion colour; others with a certain shining polished brown, vastly finer than Brazil figures. The most usual varnish is a beautiful green, which hangs to the finest strokes without effacing them, more accurately than the finest enamel does on metals. No metal but brass is susceptible of this; for the green rust that gathers on silver always spoils it, and it must be got off with vinegar or lemon juice.

False ones of medals have a false or modern varnish, which they use on their counterfeits, to give them the appearance or air of being antique. But this may be discovered by its softness.

VARRO, MARCUS TULLIUS Ciceronis, the most learned of all the Romans, was born 28 years B.C. He was a senator of the first distinction, both for birth and merit; and bore many great offices. He was an intimate friend of Cicero; and this friendship was confirmed and immortalized by a mutual dedication of their learned works to each other. Thus Cicero dedicated his Academic Questions to Varro; and Varro dedicated his treatise on the Latin tongue to Cicero. In the civil wars he was zealously attached to Pompey; but after his defeat soon submitted to Caesar, who was reconciled to him. Afterwards he applied his whole time to letters, and had the charge of the Greek and Latin libraries at Rome. He was above 70 when Antony proscribed him; however, he found means to escape and save his life, though he could not save some of his works and his library from being plundered by the soldiers. After this storm was over, he pursued his studies as usual, and Pliny relates, that he continued to study and to write when he was 88 years of age. He was 63 when he wrote his three books De re Rustica, which are still extant. Five of his books De lingua Latina, which he addressed to Cicero, are all extant. There remain, too, divers fragments of his works, particularly of his Menippous Satires, which are medleys of prose and verse; and Scaliger has collected some of his epigrams from among the Catalept Virgilii. His books De lingua Latina, and De re Rustica, were printed with the notes of Joseph Scaliger, Turenbus, and Victorinus, by Henry Stephens at Paris, 1573, in 8vo, and have been published separately since among the Auctores de lingua Latina, and the Auctores de re Rustica.

There was another Varro of antiquity called Atacius, a poet, who was born about 10 years after the first, at a small town near Narbonne. His chief works were: A poem on the war with the Sequani, a people of Gaul; and the Astronomics, that went under the name of Planciades the grammarian. But the Argonautics, in four books, was what gained him the greatest reputation: and though indeed nothing but a translation of Apollonius Rhodius, yet was so well done as to be commended by Quintilian.

VARRONIA, a genus of plants belonging to the class pentandris, and arranged in the natural system under the 41st order, Asperifolies. See Botany Index.

VASCULAR, something consisting of divers vessels, as arteries, veins, &c.

VASE, a term frequently used for ancient vessels dug from under ground, or otherwise found, and preserved in the cabinets of the curious. In architecture, the appellation vase is also given to those ornaments placed on cornices, foycales, or pedestals, representing the vessels of the ancients, particularly those used in sacrifice, as incense-pots, flower-pots, &c. See Porr.

VASSAL, in our ancient customs, signified a tenant or feuodatory; or person who vowed fidelity and homage to a lord, on account of some land, &c. held of him in fee; also a slave or servant, and especially a domestic of a prince.—Vassallus is said to be quasi inferior sucius; as he is inferior to his master, and must serve him; and yet he is in a manner his companion, because each of them is obliged to the other. See Feodal System.

VATICAN, a magnificent, palace of the pope in Rome, which is said to consist of several thousand rooms: but the parts of it most admired are the grand staircase, the pope's apartment, and especially the library, which is one of the richest in the world, both in printed books and manuscripts.

VAUBAN, SEBASTIEN LE PRESTRE, SEIGNEUR DE, marshal of France, and the greatest engineer that country ever produced, was born in 1633. He displayed his knowledge of fortification in the course of many sieges, and his services were rewarded with the first military honours. He was made governor of Lisle in 1668, commissary general of the fortifications of France in 1678, governor of the maritime parts of Flanders in 1689, and a marshal of France in 1703. He died in 1707, after having brought the arts of attacking and defending fortified places to a degree of perfection unknown before. His writings on these subjects are in great esteem.

VAUCLUSE, a department in the south-east of France, lying between the eastern side of the Rhone, and the branches of the Alps. The soil is various, in the north chiefly calcareous, in the west sandy, and in other parts covered with flinty pebbles. Agriculture is in a very rude state, the corn raised is not sufficient for internal consumption, and leguminous plants do not thrive here. The climate admits of the vine, the olive, and the mulberry, but none of them are cultivated with any degree of spirit. There are mines of coal, but of a kind extremely sulphurous. The manufactures are trifling. The extent of this department is 234,360 hectares, and the population in 1817 was 205,862. Avignon is the chief town.

VAUDOIS, VALDENSES, or Waldenses, in ecclesiastical history, a name given to a sect of reformers, who made their first appearance about the year 1160.

The origin of this famous sect, according to Mosheim, was as follows: Peter, an opulent merchant of Lyons, surnamed Valdensis, or Valditius from Vaux or Waldum, a town in the marquisate of Lyons, being extremely zealous for the advancement of true piety and Christian knowledge, employed a certain priest called Stephanus de Vaux, about the year 1160, in translating from Latin into French the four Gospels, with other books of Holy Scripture, and the most remarkable sentences of the ancient doctors, which were so highly esteemed.
UBIQUITY, OMNIPRESENCE; an attribute of the Deity, whereby he is always intimately present to all things; gives the esse to all things; knows, preserves, and does all in all things.

UDDER, in comparative anatomy, that part in brutes wherein the milk is prepared, answering to the mammary or breasts in women. See ANATOMY, COMPARATIVE.

VEDAS, the sacred books of the Hindoos, believed to be revealed by God, and called immortal. They are considered as the fountain of all knowledge human and divine, and are four in number; of which we have the following account in the first volume of the Asiatic Researches: the Rigveda consists of five sections; the Yajurveda of eighty-six; the Samaveda of a thousand; and the Atharvaveda of nine; with eleven hundred sacha's, or branches, in various divisions and subdivisions. The Vedas in truth are infinite, but have been long reduced to this number and order; the principal part of them that which explains the duties of man in a methodical arrangement; and in the fourth is a system of divine ordinances.

From these are reduced the four Upavedas, the first of which was delivered to mankind by BRAHMA, INDRA, DHANWANTARI, and five other deities; and comprises the theory of disorders and medicines, with the practical methods of curing diseases.

The second consists of music, invented for the purpose of raising the mind by devotion to the felicity of the Divine nature; the third treats of the fabrication and use of arms; and the fourth of sixty-four mechanical arts. Of however little value we may esteem the mechanical arts of the Hindoos, and however despicable their theological system may really be, the Upaveda, which treats of diseases and the method of curing them, surely deserves to be studied by every European physician practising in India. There are indeed a great number of medical books in the Sanscrit language worthy of attention; for though the theories of their authors may be groundless and whimsical, they contain the names and descriptions of many Indian plants and minerals, with their uses, discovered by experience, in the cure of diseases.

VEDETTE, in War, a centinel on horseback, with his horse's head towards the place whence any danger is to be feared, and his carabine advanced, with the butt-end against his right thigh. When the army has encamped, there are vedettes posted at all the avenues, and on all the rising grounds, to watch for its security.

To VEER AND HAUL, to pull a rope tight, by drawing it in and slackening it alternately, till the body to which it is applied acquires an additional motion, like the increased vibrations of a pendulum, so that the rope is strained to a greater tension with more facility and dispatch. This method is particularly used in hauling the bowlines.

The wind is said to veer and haul when it alters its direction, and becomes more or less fair. Thus it is said to veer aft and to haul forward.
VEER, Ter-Veer, anciently Camp-Veer, a town of
Zeeland in the United Provinces, standing at the mouth
of the East Schelde, about four miles from Middle-
burgh, and eight from Flushing. Veer, in Dutch, sig-
nifies a passage or ferry over an arm of the sea or a
river; and as there was once a ferry here over the
Schelde to the village of Compen, on the island of
North Beveland, the town thereby got the name of
Veer, Camp-Veer, and Ter-Veer. It is well fortified,
and formerly enjoyed a good trade, especially to Scot-
land; the natives enjoying particular privileges here.
The harbour is very good, and the arsenal the best fur-
nished in the world. Hence the Veres, anciently earls
of Oxford, are said to have derived both their origin
and name.

VEERING, or WEARING, the operation by which
a ship, in changing her course from one board to the
other, turns her stern to windward. Hence it is used
in opposition to TACKING, where the head is turned
to the wind and the stern to leeward. See SEAMANSHIP.

VEGA, LOPÉZ DE, a celebrated Spanish poet. He
was the son of Félix de Vega and Francisca Fernandez,
who were both descended from honourable families,
and lived in the neighbourhood of Madrid. Our poet
was born in that city on the 25th of November 1562. He
was, according to his own expression, a poet from his
cradle; and beginning to make verses before he had
learned to write, he used to browse his elder school-fell
ows with part of his breakfast, to commit to paper the
lines he had composed. Having lost his father while he
was yet a child, he engaged in a frolic very natural
to a lively boy, and wandered with another lad to vari-
ous parts of Spain, till, having spent their money, and
being conducted before a magistrate at Segovia for of-
fering to sell a few trinkets, they were sent home again
to Madrid. Soon after this adventure, our young poet
was taken under the protection of Geronimo Manrique,
bishop of Avila, and began to distinguish himself by his
dramatic compositions, which were received with great
applause by the public, though their author had not yet
completed his education: for, after this period, he be-
came a member of the university of Alcala, where he
development himself for four years to the study of philo-
sophy. He was then engaged as secretary to the duke
of Alva, and wrote his Arcadia in compliment to that
patron: who is frequently mentioned in his occasional
poems. He quitted that employment on his marriage
with Isabel de Urbina, a lady (says his friend and bio-
grapher Perez de Montalvan) beautiful without arte-
face, and virtuous without affectation. His domestic
home was soon interrupted by a painful incident:
Having written some lively verses in ridicule of a person
who had taken some injurious freedom with his charac-
ter, he received a challenge in consequence of his wit;
and happening, in the duel which ensued, to give his
adversary a dangerous wound, he was obliged to fly
from his family, and shelter himself in Valencia. He
resided there a considerable time; but comunal affec-
tion recalled him to Madrid. His wife died in the year
of his return. His affliction at this event led him to
renounce his favourite studies, and embark on board the
Armada which was then preparing for the invasion of
England. He had a brother who served in that fleet as
a lieutenant; and being shot in an engagement with
some Dutch vessels, his virtues were celebrated by our
afflicted poet, whose heart was peculiarly alive to every
Dutchman generous affection. After the ill success of the Armada,
the disconsolate Lopez de Vega returned to Madrid,
and became secretary to the marquis of Majoza, to
whom he has addressed a grateful sonnet. From the
service of this poet and of the household of the
count of Lemos, whom he celebrates as an illustrious
poet. He was once more induced to quit his attendance
on the great, for the more inviting comforts of a mar-
ried life. His second choice was Juana de Guardi, of
noble birth and singular beauty. By this lady he had
two children, a son who died in his infancy, and a
daughter named Feliciana, who survived her father.
The death of his little boy is said to have hastened that
of his wife, whom he had the misfortune to lose in about
seven years after his marriage. Having now experi-
enced the precariousness of all human enjoyments, he
devoted himself to a religious life, and fulfilled all the
duties of it with the most exemplary piety: still contin-
uing to produce an innumerable variety of poetical com-
positions. His talents and virtues procured him many
unsolicited honours. Pope Urban VIII sent him the
cross of Malta, with the title of Doctor in Divinity,
and appointed him to a place of profit in the Apostolic
Chamber: favours for which he expressed his gratitude
by dedicating his Coroa Tragic6 (a long poem on the
fate of Mary queen of Scots) to that liberal pontiff. In
his 73d year he felt the approaches of death, and pre-
pared himself for it with the utmost composure and de-
votion. His last hours were attended by many of his
intimate friends, and particularly his chief patron the
duke of Sessa, whom he had made his executor: leaving
him the care of his daughter Feliciana, and of his vari-
ous manuscripts. The manner in which he took leave of
those he loved was most tender and affecting. He
said to his disciple and biographer Montalvan, That
true fame consisted in being good: and that he would
willingly exchange all the applause he had received to
add a single deed of virtue to the actions of his life.
Having given his dying benediction to his daughter,
and performed the last ceremonies of his religion, he
expired on the 25th of August 1635.

VEGETABLE PHYSIOLOGY.—Under the article
BOTANY, and also under PLANT, we have already de-

ivered some of the commonly received doctrines on this
subject. But as some late investigations seem to lead
to new views with regard to the structure and nature
of vegetables, we have thought it necessary to resume
the subject, and to give as full a detail of the experiments
and observations to which we allude as our limits will
permit; we shall first treat of the structure, and se-
condly of the physiology of plants.

I. STRUCTURE OF PLANTS.—In considering the
structure or anatomy of plants, we shall treat, 1st, of
the root; 2d, of the stem and branches; 3d, of the
leaves; and 4th, of the flowers; in the order in which
they are now enumerated.

1. The Root.—The root is that organ belonging to
vegetables by which they are supplied with nourish-
ment, and by which they are fixed and insensible
situation.

It was formerly supposed to be composed of exterior
and inner bark, of wood, and of pitch; but Mrs. Dibetan, who
has lately communicated to the public the results of an
elaborate in-
VEG  [ 531 ]  VEG

Vegetable. elaborate series of experiments on this subject, thinks
Physiology. that it is wholly composed of the rind much thickened,
with perhaps a very little of the outer bark, but no inner
bark; of a quantity of wood, hardly any pith, and
no spiral vessels. Mrs Ibbetson searched in vain for the
larger vessels of the inner bark, till it occurred to her
that the want of this bark accounted for there being no
leaves on the root. Mrs Ibbetson had often been as-
sured that roots were found bearing leaves, but on dis-
section of these supposed roots, she found that they were
branches which crossed the root.

The root consists of the caudex, stock or main body,
and of the radicle or fibres which arise from the caudex,
and are the organs by which the moisture is im-
mEDIATELY imbibed.

In botanical terminology, we generally consider all
that part of a plant which is under ground as the root;
but Linæus comprehends under his definition, what we
term the body or trunk of the plant, and be so
far as to call the stems of trees "roots above ground,"
but as Dr Smith justly remarks, this seems paradoxical
and scarcely correct. Dr Smith adds, that it would
be more accurate to call the caudex a "subterra-
naneous stem"; although he is rather inclined to think
that it has functions distinct from the stem, analogous to
digestion; for there is evidently a great difference in many
cases, between the fluids of both, at least the secre-
ted ones, and those of the rest of the plant.

In botanical botany, by the term root, so often un-
derstood the parts only which serve to keep the plants
firm in the ground: thus the bulbous and fleshy roots
as they are called, are, strictly speaking, not roots; the
radicle or fibres being the real roots. The duration of
roots is various; they are either annual, biennial, or
perennial.

2. The Stems and Branches.—Linæus long ago di-
sected the stems of trees into four parts; the rind, the
bark, the wood and the pith: and nearly a similar divi-
sion has been adopted by most vegetable physiologists
till the present time.

Mrs Ibbetson (aided by a powerful solar microscope),
however, thinks that nature points out a more regular
division, a division marked not only by the form, but
by the difference of the woody parts, with which the parts
are

Mrs Ibbetson divides the stem of trees into six parts;
1. The rind; 2. The bark and inner bark; 3. The
wood; 4. The spiral vessels; 5. The nerves or circle of
dife (corona of Hill); and, 6. The pith.

Of the rind.—Mrs Ibbetson conceives the rind to be
merely an outward covering to the tree, which pre-
vents its juices from being evaporated by the influence
of the sun’s heat. The rind is continued under ground:
but it may be as useful there to prevent the entrance of
the root, and earth, the pressure of stones, or the injury
of insects.

The rind is composed of two rows of cylinders, with
a single line to divide them. The cylinders are filled
with a pellucid liquor. There are seldom more than
four or five layers of vessels in the rind; but it is in
general so covered with parasitic plants, as powdery li-
chen, &c. that its thickness is often more than dou-
bled.

The rind does not appear to be necessary to plants in
general, as there are many in which the bark serves
as a covering in its stead; but it seems to form an es-
sential part of trees.

2. Of the bark and inner bark.—These parts, though
certainly different as to form, contain the same kind of
juice; and being so nearly allied, may be treated of as
one. From the bark and inner bark the leaves take
their origin, as will be shown when we come to treat of
the formation of the leaf-bud. Mrs Ibbetson conceives
that the juice of the bark is the blood of the tree.

In the bark alone are produced the galls, the resins,
the oil, the milk, &c. in short that belongs to the
tree; gives taste to it; all that makes one plant differ
from another, and all its virtues, if the expression may
be used. The bark is generally green; the inner bark
white, yellow, or green. The former consists of vessels
crossing each other; the latter of bundles of vessels of
two sizes. The large vessels consist of broad cylinders,
having a bottom with a hole in it, through which the
liquid passes, though not with perfect ease.

Mrs Ibbetson says that on exposing several pieces of
the inner bark to the solar microscope, the moment she
turned the light on the specimen, the juice, which had
before proceeded up the pipes rather slowly, was sud-
denly propelled forward with a force truly astonishing.

When the heat and light were increased by causing the
focus of the rays to fall on the vessels, the side divi-
sions of the vessels were broken through, thus inundat-
ing the specimen; but when a proper degree of light
and heat was kept up, it was curious to observe the li-
quid passing from pipe to pipe, in one regular and easy
flow, making only a short stop as it issued through the
straitened apertures at the bottom of the vessels. Mrs
Ibbetson has often stood for more than an hour watch-
ing the current, (which passes, however, much slower
than the sap does), nor could she perceive while the
heat and light were on it, that it required any addi-
tional expedient to hasten its momentum; but during
the cold and darkness of night, she supposes that the
pressure of the bastard grain mentioned by Mr Knight,
may very likely assist its flow, as it is at night that the
bastard grain is pressed against the cylinders.

The bastard grain is found however only in the wood;
but the contraction at the bottom of the large vessels of
the inner bark, may probably serve the same purpose,
the impetus of the current being increased by the less-
ing of the apertures of the vessels.

The vessels of the inner bark are very thick in pro-
portion to their size, and there is placed in them a pe-
culiar circular body, which resembles a cullender full of
holes so small that no liquid could pass them. In view-
ing the thick juice which runs through these pipes, Mrs
Ibbetson observed many bubbles of air, the size of which
was increased or diminished according to the tempera-
ture; and as their size varied, so was the flow of the
liquid accelerated or retarded. To see these vessels
well, the specimens may be placed in a basket which is
to be fastened in a running stream for some time, or
boiled thoroughly, and then thrown into green wax
perfectly melted.

Mirbel says that “some plants have the same juices
in every part of them:” but Mrs Ibbetson does not coin-
cide with his idea, for she did not find it to be so; though
the potent smell of the liquid belonging to the bark of-
ten extends to other parts of the plant, yet it general-
ly vanishes if kept separate for a day, or becomes so
faint.
Vegetable

Mirbel says that the cylinders of the inner bark are merely vacancies of the ordinary vessels; but Mrs. Ibbetson states that they are exactly the same as these vessels, and occupy the same place.

They have a peculiar shape, being unlike any other vessels of the tree, and they perform a particular office.

The vessels of the bark are smaller, and more simple than those of the inner bark, and are divided by a line or two, running longitudinally between them.

3. Of the Wood.—This is a very obvious part. Place the stem of any plant in a coloured liquid, and every vessel which conveys the sap from the earth to the top of the tree will be tinged.

The sap is a thin watery liquor, probably medicated from the earth, in order to become suitable for the life of vegetables.

Mrs. Ibbetson supposes that the sap may vary with the soil, though on trial she has never found that change which might have been suspected.

If we make a transverse section of the stem of a tree, two different kinds of layers present themselves in the wood; some running in a circular manner, which timber merchants call the silver grain; and others from the circumference to the centre, which they denominate the bastard grain. Linne long ago believed that one of the circular layers was added to the tree each year. This opinion has often been controverted, and among others by Duhamel and Mirbel; but Mrs. Ibbetson has had an opportunity of verifying the accuracy of Linne’s opinion. She also observed that the layer was large or small according to the exposure of the tree, and the favourableness of the season; thus in exposed situations, the circles taken as a whole, were much narrower than in trees not exposed. In some trees she noticed only half a circular layer.

Mrs. Ibbetson thinks the bastard stripe consists of two lines or strings with a little scale between them; and they appear, from their extreme susceptibility, to be formed of the same leather-like substance as the spiral vessels, which we are immediately to notice.

Mr. Knight merely calls them scales; but as he mentions their pressing close (which they certainly do) to the cylinders at night, and during cold weather, it is obvious (whichever of the opinions we adopt) that the bastard grains are capable of supplying the place of the sun’s rays, by their pressure.

The wood-vessels are far more simple in structure than those of the bark; they are very narrow cylinders, and the two rows next to the corona are covered by the spiral vessels.

It is indeed difficult to determine the exact extent of the spiral vessels even with the assistance of the solar microscope, for it is by surrounding them alone that they can be known; and their extreme fineness confuses, in consequence of which they have been taken for sap vessels. Neither Mr. Knight nor Mirbel was led into this mistake, and Mrs. Ibbetson thinks that there can be no doubt that these vessels (formerly so called) are solid strings which hold no liquid.

The vessels of the wood may be best seen in slices of the stems of young trees; and if not very visible when recently cut, they will soon become so if the slices are kept in a dry place.

If the wood-vessels are cut longitudinally and observed with a high magnifier, as soon as the light is permitted to come on the glass, the flow of sap will be accelerated, and with perfect ease will run up vessels so diminutive that to measure them is almost impossible.

A few of the wood-vessels are separated and run with the spiral vessels to each leaf, in order to nourish it, as will be more particularly noticed, when we come to treat of the leaf-bud.

But little of the sap, however, passes off in this way from the principal current, which flows on; its chief purpose being to form the stamens and the pollen appertaining to it, and afterwards to lend its principal aid to the formation of the fruit and seed.

4. The spiral vessels are a quantity of solid strings coiled up into a spiral form. Mrs. Ibbetson supposes them to be formed of a leather-like substance, and, as already mentioned, to be rolled round the wood. In this spiral manner they run up the stems of trees and plants of every kind (with a few exceptions), and from thence into every leaf and flower. These spiral cords are singly too small to be observed by the naked eye. They run into every fibre of the leaf, and are fastened to its edge, thus crossing among the vessels in every direction like a spider’s web; by which disposition they can draw the leaves in any way that is necessary for them.

The larger of the interior wood-vessels are each supplied with sets of ten or twelve spiral cords, but the smaller of these have only three or four to each.

In the cabbage leaf and in the burdock, the spiral cords may be found in bundles almost as thick as a packthread, but in smaller leaves they are properly proportioned. These spiral cords, Mrs. Ibbetson thinks, are the cause of the motions of plants. See PLANT, p. 601, where these cords are called air-vessels.

5. Of the corona or circle of life.—The next part to be noticed is the small circle of vessels situated between the wood and the pith, the importance of which, in the formation of the seed, will be noticed under Imprimatur of the Seed; where are also related strong proofs to show that a plant cannot exist a day without the corona, and that if a young plant be deprived of this part, it will not grow again, though it will certainly do so if the plant be somewhat old. It is very curious that almost every botanical anatomist should have figured this part, without giving it a name, or noticing it particularly; and that these anatomists should have attributed all its powers to the pith, which, from the short term of its existence, and its being perpetually impeded in its progress to make way for the flower-bud, can evidently have but little influence. The circle of life, however, has not escaped the notice of Hill, who termed it the corona.

The circle of life consists of rows of little cylinders which have their own peculiar juice, generally of a more austere quality. From the corona all branches take their rise, and from it all wood threads grow. The cylinders of which it is composed run up into all flower-buds, but never approach the leaf-bud as is represented by fig. 1. and 2; when these cylinders enter the flower-bud, they make their way distinctly to each separate flower.
Vegetable flower, forming the pistil, and after depositing in each side the line, which is the first origin of life, they are afterwards impregnated, or acquire the power of giving life by the juice of the stamen, which runs through the same string into the seed.

That the principal vitality of the plant resides in the corona, we think is proved by the experiments and observations of Mrs Isbister under Impregnation of seed, and seems to be further confirmed by the following remarks.

When a branch is cut from a tree, or a tree is torn up, the corona or circle of life is the first part that dies; and if, after a sudden frost, we examine the flowers of a fruit tree, we shall find that neither the calyx, the corolla, the stamens, nor the seeds are hurt, but that the pistils are destroyed. And if we now observe the pistils with care, we shall see that it is the line of life which is decayed, and that this is the first part in which mortification commences. The peculiar liquor of the pistil acquires a blood-red colour, and the vessels which run up to the stigma become black, instead of their natural yellow colour.

If in wood, this line is injured (either by the decay of the bark or other means) the circle will undulate into a thousand forms, for the purpose of regaining a healthy situation in which it may pursue its course.

Mrs Isbister, to prove the power of the circle of life, relates the following observations respecting the boa reptans.

She had often measured in winter, seven or eight yards of this grass, which appeared perfectly dead; and yet in May or June, she perceived life in it at the most distant end from the stalk. Next spring she took up two of these creeping branches which were much alike; and on dissecting one of them through its whole length, she found in it a collection of little vessels not thicker than a very fine thread.

This collection of vessels had run about half way the length of the branch, which was about three yards.

Mrs Isbister having merely opened the cover of the grass, laid it down again, and the little vessels continued increasing till they reached the end of the branch, when they made a stop, and it was perceived that the grass began to thicken; and at the end nearest the roots, the dead part became inflamed with juice, lost by degrees its dead appearance, thickened about the joints within, and at last shot forth fresh leaves and fresh roots from every joint.

Mrs Isbister has since watched with the greatest care, and found that the fine thread which runs through the grass protected by the dead scale, was the circle of life. When this thread is stopped by the covers decaying, it waits till the season permits the rest of the plant to grow. From what has been said, it is evident that the dead matter may be inflamed with a living juice, and live itself again, provided the life near the stem of the plant be not extinguished. Mrs Isbister has observed this to happen in many plants, as in hydrangea, in which the stalks apparently lie down and are inflamed again, or at least a part of them.

6. Pith.—Linnaeus considered the pith of plants as of equal importance with the spinal marrow of animals; but Mrs Isbister thinks this part of but little consequence, and transfers this importance to the circle of life, which she compares to the brain and spinal marrow. She conceives that the pith forms merely a nutritive source of moisture for the plant when required. The pith stops with every flower-bud, and begins again to grow as soon as the bud is past; it decreases as the strength and size of the tree increase; it is the only part of the tree which is devoid of vessels; it is merely a net, not a bundle of cylinders, and is commonly of a remarkably splendid or silver white colour.

It has been said that the pith assumes a variety of figures, but Mrs Isbister thinks this is a mistake, though she admits a few different sorts.

All young trees and shrubs are provided with pith, but in the progress of their growth they lose it; or no longer, the wood being a good substitute. On the same account, in general, we find no pith in water plants, which have a hollow stem, and rarely suffer from drought.

Linnaeus thought that the pith was the seat of life and the source of vegetation; or in a word, the primary part of the plant. Duhamel considered it as of but little importance at all. Wildensow and Knight concur with Mrs Isbister in regarding it as a reservoir of moisture for the young plants; and Dr Smith holds a moderate opinion between that of Linnaeus and the other authors just named.

He says "there is in certain respects an analogy between the medulla of plants, and the nervous system of animals; it is no less assiduously protected than the spinal marrow; it is brachied off and diffused through the plant, as nerves through the animal. Hence it is not absurd to presume that it may in like manner give life and vigour to the whole, though by no means, any more than nerves, the organ or source of nourishment."

We were somewhat surprised to find that Mrs Isbister had not particularly noticed the cellular tissue as a distinct part to be seen in the steus of trees, as it has been long known; we shall therefore subjoin a description of it. It is a succulent cellular substance, generally of a green colour, at least in the leaves and branches. Duhamel long ago called it envelope cellulair, and Mirbel, more lately, tissu herbacet.

Duhamel supposed that the cellular tissue formed the cuticle, or epidermis; but this is not very probable, as his own experiments show when the cuticle is removed, the cellular integument exfoliates, at least in trees, or is thrown off in consequence of the injury, and a new cuticle, covering a new layer of the cellular tissue, is formed under the old one. This substance is very universal, even in mosses and ferns. Leaves consist almost entirely of a plate of this substance, covered on each side by the cuticle. The stems and branches both of annual and perennial plants are invested with it; but in woody plants it is dried up, and reproduced almost continually, such parts only having that reproductive power. The old layers remain, are pushed outward by the new ones, and form at length the thickened dry dead covering of the old trunks of trees. The cellular integument is a part of plants of the greatest importance; for in it the juices of plants are operated on by light, air, &c.

With regard to the branches of trees it has been already noticed, that they derive their origin from the corona, and they are composed exactly of the same parts as the trunks from which they arise.

3. The Leaves.—Mrs Isbister has, with the assistance
Vegetable sense of the solar microscope, and by great attention to the natural process, being enabled to give some new and interesting views on this subject. Her opinion respecting the formation of the leaf-bud is, “That leaves are formed or woven by the vessels or cotton that is generally supposed by botanists (to be) placed there to defend the bud from the severities of winter; that these vessels (or cotton) are a continuation of those of the bark and inner bark in the stem of the plant; that these vessels compose the various interlacing branches of the leaf, which are soon filled up by the concentrated and thickened juices of the inner bark, which form the pabulum of the leaf.”

Mrs. Ibbetson says the truth of her assertion may be easily seen by dissecting early buds, in which, except two or three, nothing but the cotton-like vessels will be found. She asks then what could the use of these vessels be, and answers, that to put them within the bud to keep the outside warm is against nature, for it is contrary to nature. The leaf-bud in its first state consists of two or three scales, enclosing a parcel of vessels, which appear like very moist coarse cotton, but when drawn out and placed in the solar microscope, they show themselves to be merely the vessels of the bark and inner bark elongated and curled up in various forms.

These vessels are of three kinds like the bark, &c.

First, three or four short thick ones which appear to grow from the larger vessels of the inner bark, and through which the thickened juice flows, but with this difference, that the holes are not there.

Then there are two smaller sized vessels, which exactly resemble the smaller vessels of the bark.

Mrs. Ibbetson has always found the short thick kind of vessels to form the mid-rib of the leaves, and the smaller sized vessels to compose the interlacing fibres (or vessels) of the other parts of the leaves; and from often comparing the full-grown leaf with the leaf of the bud, she feels the most thorough conviction that the latter takes its origin as above noticed. The pabulum of the leaf which lies between the vessels, is composed of that thick juice which runs in the bark or inner bark of the tree, and which does not exist in any other part of it. The pabulum differs essentially from the sap, and may be called the blood of the tree, as it possesses peculiar properties in different trees; thus it is of a gummy nature in one, of a resinous in a second, and of an oily nature in a third, &c.

Mrs. Ibbetson is not certain whether the pabulum both flows forwards and in a retrograde direction; but she is convinced that the greatest part of it is taken up in forming the leaves. The pabulum of the leaf, after the vessels are arranged and crossed, grows over in bladders, making alternate layers with the smaller pipes (vessels), and with the branches of the leaf.

Mrs. Ibbetson states, that she does not know any tree which gives a more convincing proof of the formation of the leaves in the bud, than may be seen in the horse chestnut (Aesculus hippocastanum) about the month of November or December.

Several different mid-ribs may be taken out at once from the same leaf-bud, which have an innumerable number of extremely fine silken vessels fastened to or growing up from each side of them. When these vessels have become sufficiently interlaced with each other, the pabulum will begin to grow over them, in form of small bladders full of a watery juice; and then larger vessels will cross over them, which will soon be followed by another row of bladders; and a similar process will go on until the leaf has attained its proper thickness. The leaves thus formed are very small, but when once their shape is completed every part of them continues to increase in size. Fig. 6. represents the leaf-fig. 6. bud of the horse-chestnut, as it was examined by Mrs. Ibbetson about the month of January.

Mrs. Ibbetson next notices the arrangement of the leaves in the buds of different trees; but we shall consider them by and bye.

The rolling, folding, or plaiting, &c. of the leaf-bud, it is observed, does not merely take place at once; but to complete the process of budding, it appears that this arrangement of the leaves is repeated several times. During this arrangement the bolder leaves are immersed in the glutinous liquor which runs in the bark (and forms the pabulum); and the pressure of the leaves is very great. By this pressure and the rolling, &c. the leaves are completed; for if a leaf be taken from the bud before this process commences, it may be compared to a piece of cloth before it is dressed; for its back will be obscured by the edges of vessels, which had it remained in situ, would have been all rubbed off, except the hairs which remain on many plants.

We come now to the formation of the edge of the leaf, a curious and beautiful process.

The bud if opened will appear full of the glutinous liquor which forms the pabulum, and the leaves arranged in the manner proper to the particular tree from which the bud is taken. If one of the leaves be taken out, the edges (in whatever manner folded) will exhibit a perfect double row of bubbles, following the scallop of the edge of the leaf; and it will appear as if it were set with brilliants.

Things being in this state, all that is wanting for the completion of the leaf is the formation of the pores, now to be mentioned. Mrs. Ibbetson states that in many hundred forming leaves which she exposed to the solar microscope, she had never once been able to see the pores; which she has often observed after the leaves have completely quit the bud; and she is uncertain whether this is owing to the greater thickness of the young leaf, and its being covered with more hair than it is afterwards, which obscure or conceal the pores; or whether it be caused by the upper net-work of the leaf growing last. While the upper and under cuticles of the leaf are growing, the edge of it is completing; the bubbles generally divide, and partly dry up, leaving horny points on their stead. When the edges of the leaves are completely formed, they burst from the bud and assume a different aspect.

The vessels of the leaves (those confined within the mid ribs and side ribs of the leaves) are of two sorts, the spiral, and the nourishing. The spiral vessels are those cork-screw-like wires which surround the two last rows of the sap vessels. The nourishing vessels are the only parts formed of the wood. They convey the sap necessary for the support of the leaves, and run on each side of the spiral vessels.

To prove that she has given a fair and accurate account of the formation of the leaf, Mrs. Ibbetson
The leaves of such plants are more woody than any others, as every one may know on breaking them. In such plants also the circle of life may be traced as leading from one flower to another.

Mrs Ibseton also thinks that all those parts which concur in forming the flower also join in forming the fruit and seed.

Mrs Ibseton then adverts to the opinion of Wilde-now, when he says, "we find in the springing flower, elongations of air-vessels, but we never see the elongations from each particular part, one forming the future calyx, another the corolla, and so forth." "For instance, in the common sun-flower (Helianthus annuus), where in an immense large receptacle, numerous small flowers are placed, how should these elongations be able to unfold themselves into florets from the bark, inner bark, &c. through such a receptacle? There would arise a confusion amongst these small parts which is never met with."

"How should, besides, the stamens be formed in herbs, which are not ligneous, or the pistil in plants which have no pith? Every one may therefore (though I do not see it), that this must be a mere hypothesis, which may be refuted, even without the aid of anatomical dissection."

Mrs Ibseton attacks Wilde-now's opinion, and says: that he addsuces the syngenensis class to prove the accuracy of it, the class which contains the very plants that would have proved the mistake of his argument, had he dissected them.

Mrs Ibseton then proposes the following questions to Wilde-now. Why, if the nonripening of each part of the stem be not confined to the flower, does the whole arrangement of the parts alter, the moment it gets to the flower-stalk?

Why are there particular vessels to convey and carry the juice to each peculiar part, if it were not of consequence that this juice should touch no other places? For what purpose is the curious and artificial management in the bottom and top of a seed-vessel, which enables the dissector to say, that "there are five divisions of little vessels proceeding from the wood; I know, therefore (though I do not see it), that this must be a pentandrian flower; here is but one middle vessel proceeding from the circle of life (for the pith stops), it is therefore of the order monogynia; here are five divisions of little vessels proceeding from the inner bark, it must therefore have five petals?"

Mrs Ibseton wishes others to be convinced of these facts as well as herself. If a cut be made above or below the seed-vessel of a lily, a violet, or a tulip, she thinks conviction of her accuracy will follow. Why in cutting above or below the seed-vessel of a syngenensis flower can you directly tell, whether it belongs to the order superfius, equalis, or segregata? Look at the bottom of the seed-vessel of the monches; every pin hole of the vessel of the male is carried up by corresponding vessels in the outward cuticle of the seed, till it meets and joins the ligature of the males; and the female liquor is protruded through the inside of the seed, and is perhaps one of the strongest proofs of the impregnation of the female. In the syngenensis class (see fig. 12.), the delicacy of the vessels, which may be supposed too small for a liquid to flow through them, must not impede the belief that it does so, when we consider.
Vegetable sider the circulation of blood in the diminutive animal
Physiology that torments the body of the flea or louse. Mrs Ibbetson says she has seen the liquor run up with the utmost celebrity through the upper cuticle of a very small seed of a plant belonging to the synnesian class, till it met the male and continued its course. It is to be understood that the juice from the corolla flows in the rest of the cuticle, and that the largest vessels are those for

Fig. 12, 13. — the male liquor. See fig. 12, 13.

11. Physiology of Plants.—In treating this part of the subject, we propose to consider, first, the impregnation of seeds; and, second, the irritability of vegetables.

1. The impregnation of the seed.—The investigation of what is included under this title, forms one of the most beautiful and interesting pursuits of the vegetable physiology. Mrs Ibbetson has communicated some curious observations on this subject. Provided with a powerful solar microscope for opaque objects, she proceeds to an examination of the seed, and the first shooting of the infant plant, or rather of the germ or vessel which precedes it; and she remarks that it is almost impossible to ascertain the exact time when the seed is first formed in the pericarp; but that she has always found it in the winter buds when they were large enough for dissection.

It is curious to observe the vessels, which, she says, may properly be called the life, tracing their way to each flower-bud: for a seed may be said to depend for perfection on two separate moments: the one in which the life first enters the seed, when the whole outward form appears to be perfected; and the second, when the impregnation of the seed takes place, by the ripening of the pollen.

But when the life enters, it leaves a little string, and remains for a long time afterwards in a torpid state. This string crosses the corculum, or heart of the seed, so called because it is the cradle of the infant plant. She then states that the seed is attached to the seed-vessel by two distinct organs, termed by the botanists the umbilical cord, but as she thinks improperly, since they do not convey nourishment to the infant plant, which is wholly the office of the second set of vessels. We cannot agree with Mrs Ibbetson in her opinion; for although the umbilical cord of an infant contains nourishing vessels, it also contains nerves, and yet we would never think of restricting this term alone to the arteries.

The first of the connecting organs Mrs Ibbetson conceives to be the circle of life, first, because without it the plant dies; and, second, because although every other part be eradicated by degrees and the circle of life be uninjured, the plant will grow again.

She has made these experiments many thousand times and with the above results. The circle of life consists of delicate simple vessels, which carry a juice of a particular nature, and may be traced in every part lying between the wood and the pith. These vessels are not to be found in the leaf-bud; for they pass by it to the female flower, where they establish a new life in the

(a) In the journal it is said "to the pointal;" but certainly stigma is meant, for pistil and pointal are synonymous.

(b) In the journal it is called pollen, but anther must be meant.
Vegetable Physiology.

So cutting off their communication; but did not touch o, o, which she thinks is the nourishing vessel.

The consequence was, that the seeds of this flower were never impregnated. Mrs Ibbetson next tried the effect of taking the nerve of life from the chestnut, the walnut, acorn, &c.; first opening a seed without touching the nerve, that she might be certain that the opening was not the cause of its death. Fig. 17 represents Fig. 17, the heart taken out of a seed of the chestnut; i is the circular hook already described; o is the nourishing vessels, and i/ the line of life, which was taken out from some seeds where it crosses the heart at m. Fig. 18, fig. 18, is the seed of the gooseberry; o is the nourishing vessels, e the line of life, and m the corculum or heart.

She found that all those seeds from which she took the nerve of life died; and that the others, which had been merely laid open, lived. She remarks that it is only at the beginning of life, that the plant can be killed by this process; for when older, if the nerves of life decay, they shoot out above the declining part, and run into any part of the stem that is pure, to preserve themselves. Mrs Ibbetson then states that this nerve is the source of life in very decayed trees, and is also the cause of a double pith, or at least the appearance of it, in many trees.

To observe this line of life, seeds must be examined in their first formation; for when it has done its office, it detaches itself. When the seed is boiled, the line of life and nourishing vessels mark themselves by becoming of a dark colour.

Irritability of vegetables. In entering upon this subject, we ought to warn our readers, that very opposite opinions have been entertained respecting it; some physiologists of the greatest eminence allowing that we have satisfactory proofs of the irritability of vegetables in a variety of plants, but more particularly in the motions of the mimosa, dionaea, &c.; while others of no less respectability ascribe these motions to the influence of light, heat, or some other mechanical agent.

As neither muscles nor nerves have ever been demonstrated in the vegetable structure, of course the proofs of the irritability of vegetables are drawn from the intimate analogy which seems to exist between the motions of some plants and those of animals. Some physiologists, from observing the similarity of motions in the two kingdoms, were naturally led to ascribe them to the same cause; others, from not being able to observe the same motive organs, namely, muscles, in both kingdoms, denied that plants could possess irritability; a third set, waving the idea of irritability in the vegetable kingdom, have laboured to shew that the motions of plants depend on mechanical causes alone.

We shall first notice the observations of Mrs Ibbetson, who ascribes the motion of plants to the spiral wires which we have described. Her opinion is founded upon a number of new observations made with the solar microscope, which we shall proceed to relate.

1st. The spiral vessels are not to be found in any plants to which motion is unnecessary.

She could not observe these vessels in any of the first, in any of the plants which spread their leaves upon the surface of the water, in any of the sea weeds (c), of the lichens, or of the grasses; and she does not think that

(c) She afterwards excepts the conservar, which have motion.
We would here observe that if these observations were completely true, they would certainly afford a strong proof in confirmation of her opinion; but we suspect that they are not altogether just, especially as we observe a discrepancy in the papers of Mrs. Ibbetson. Thus at one part she has given us a very minute description of the spiral vessels in the runners of the *poa reptans*, and now she says they are not to be found in the grasses (b).

Mrs. Ibbetson's second argument is, that if a plant whose leaves present their faces to the light, be turned so that the backs are to the sun, the leaves in a few hours will regain their former position; but if this be often repeated, although the plant will not suffer, yet the leaves will be longer at every repetition in returning to their former situation, or will cease to move at all. She accounts for this by saying, that the spiral-like elastic vessels are relaxed by the operation, and lose their power of coiling into their usual form.

Others would account for the above fact by saying that the irritability of the plant was exhausted by these repeated and unnatural actions; in the same manner as the mimosa becomes gradually less sensible to impressions when too often renewed.

Mrs. Ibbetson's third argument is, that those leaves which have most motion, are provided with most spiral vessels, and have these vessels most twisted; as in the *populus tremula*.

Fourth proof. Mrs. Ibbetson divided the spiral vessels of a vine leaf while growing, without touching the nourishing vessels; and from that moment it never contracted, and when placed with its back to the light, it did not alter its position, though it was long before it decayed. Both electricity and galvanism cause those leaves to contract, by affecting the spiral wires (not the cuticle), for when the leaf is deprived of these vessels it does not contract at all.

We would here remark that we suspect much, in the above experiment, that more than the spiral vessels was divided; at any rate there is very great discordance between Mrs. Ibbetson's experiments and that of M. Calandrini, who found that vine leaves turned to the light when they were separated from the stem and suspended by a thread.

Fifth argument. Mrs. Ibbetson observed, when she placed some of the spiral vessels taken from a cabbage leaf upon one end of a long netting needle, and caused a candle to approach, that they were much agitated, and at last flung themselves off the needle. We think no conclusion can be drawn from what is here stated.

The fresh water *convera* and the dodder tribe, are the only plants, without leaves, that Mrs. Ibbetson is acquainted with, which have spiral vessels.

Mrs. Ibbetson says that the spiral vessels are so tough, and so very tightly coiled, in the leaf stem (*petiole*) of the *geranium cordifolium*, that she has by means of them been enabled to draw up the leaf; but it is difficult to be done.

The sixth proof is drawn from the effect produced by moisture on Captain Kater's hygrometer, which will be noticed soon.

(b) She found the spiral vessels also in the *andropogon contortum*. General Observations.—Mrs. Ibbetson says the spiral wires may be considered as a secondary cause of motion, as they are primarily acted upon by light and moisture. By means of the spiral wire, all the movements of plants are made; by it, flowers open in the morning and shut in the evening; the leaves turn, and the creeping plants wind in their regular order. Mrs. Ibbetson says, the opening of the flower at a different time of the day, or its turning in a different manner, does not militate against the above statement; as strong light and dry weather produce a contraction of the wire, while darkness and moisture effect a dilatation of it. It depends wholly upon the position in which the spiral wire is placed, whether by its dilatation the flowers shall be opened or shut, as in mechanics the same spring may be made to turn to the right or to the left, to open or to shut a box. Most of the flowers which Mrs. Ibbetson has observed to close at noon, have an extremely limber corolla, formed only of a double cuticle without pubescence; and hence they are soon overcome by heat, and relaxation directly takes place; as in the *condula mar*, the evening or tree primrose, &c.

We must add, however, that we regard this account of the spiral vessels with some degree of doubt. We suspect that the spiral wires, if they have the power of opening or shutting a flower, will always act in one uniform manner; i.e. if they are able to open it, they will always do so, and vice versa.

The *symphyce alba* raises itself out of the water, and expands, about seven o'clock in the morning; and closes again, reposing upon the surface, about four in the evening. Now its petals are much thicker than those of the *lentodon taraxacum*, which shuts up its flowers between eight and nine in the evening.

We could multiply instances; but we conceive we have said enough to shew, that the flowers with the most slender corolla are not uniformly those which soonest close.

Mrs. Ibbetson says, contrary to the opinion of M. Belin, that the case in which the spiral vessels are involved is capable of being stretched; indeed it is formed of so thin (or rather so loose) a substance, as plainly to be intended to dilate and contract. The case is composed of a very few thin vessels, interlaced with an extremely fine spiral wire; while the large spiral vessels fill up the case in an irregular manner, the nourishing vessels form a regular circle of tubes around it. See fig. 29. and 30.

Of the *Indian grass* (*andropogon contortum*) of Louisiana, of which Captain Kater's hygrometer is formed.

—The chief part of it is made with the spiral awn of an Indian grass, which readily untwists in a moist atmosphere, and vice versa. Now Mrs. Ibbetson asks, if the most trifling change of moisture can untwist one sort of vegetable fibre, and by this means manage an instrument, why should not a quantity of similar formed fibres or spiral vessels produce the same effect on leaves and flowers? She says, Captain Kater's hygrometer moves very sensitively if a finger be placed within half an inch of the fibre (awn). Now, the most sensitive plant we have will not move but with the touch.

We are quite aware of the effects of moisture on some vegetables.
Vegetable vegetables. We have strong proofs of it in some of the
physiology, mosses, as in the bryum hygrometricum, which, if the
fruitstalk be moistened at the bottom, makes three or four
revolutions; if the upper part be moistened, it
turns the contrary way.

We can scarcely compare these motions with those of
the mimose; for it is quite evident that they are pro-
duced by moisture: but as we are to speak of the
motions of the mimose in a little, we would only observe,
that when Mrs Ibbon says "the sensitive plant will
not move but with the touch," she argues against her-
self; for this shows that it is acted upon by the same
causes as animal muscles, and that it is not governed by
moisture alone.

The only sensitive part of the Indian grass is the awn,
which is formed of a leather-like substance, infinitely
thicker and stronger than the usual spiral vessels in
plants. The awn is formed of two apparently flat
pieces, with a cylindric hollow running through the
middle, which is filled with a thick spiral wire. Fig.
21. 22. 23. and 24. Each side of the awn is bristled;
but the bristles do not add to its sensibility.

Of the Nettle.—The awn or sting of the nettle is
a long pipe with a bag at the end divided into two
parts; the smaller contains the poison, and the larger
is situated below it. This bag seems also to be com-
posed of a leather-like substance, and it is likewise
affected by light and moisture.

The moment the upper part of the pipe is touched,
the under part of the bag swells up, breaks the poison
bladder, and throws its contents violently up the pipe,
burning the person who touches it.

Light thrown upon the bag by means of the solar
microscope produces the same effect as touching it.
The poisonous liquor is protruded up the pipe with
great force, till it issues out at the minute aperture
at the point; but before it does so, the pipe is bent
down with a jerk, by means of the spiral wire.

The spiral wire winds round the bag at the bottom
of the pipe; and it is by the action of this wire that
the bag is made to contract. The nettle lays down its
stings every evening, just as the sensitive plant does its
branches. See fig. 19. and 20.

Mimose Senstiva.—The motions of this plant are re-
gulated not only by the spiral wire, but also by a bag
of a leather-like substance, which is capable of contrac-
tion and dilatation.

We shall next give Mrs Ibbon's plate respecting
the structure of this plant, with her description.

Fig. 25. is a representation of the springs which gov-
ern each leaf; d, d is the stalk. Each leaf has a
base c, c, which serves to concentrate the spiral wires.
These passing over in every direction, being drawn
through the narrowest parts of the stem b b b b, press
the stem together; and, when touched, lie the leaves,
one on the other, the whole way down the leaf-stalk.

But, before the stimulus is applied, the stem is flat-
tened in a contrary direction. The ball of the leaf
is hollow and filled with oil. The parts e e and p p
(fig. 26.) are made of that leathery substance, which
forms the cuticle, and is contracted by the light in
the solar microscope. The parts e e contain the oil
which serves to lubricate the knots (we suppose),
and enable them to slip over each other; beside, probably,
acting some important part in the formation of the va-
rious gasses and juices in the composition of the plant.

When touched, the whole string relaxes at o o, and
lets the branch fall. This it would also do at n, if it
were not supported by the wood-vessels turning into the
leaf. Fig. 27. is the part e e p p uncut, and in its na-
tural state. Mrs Ibbon thinks that not only the mo-
tions of this plant, but of all others, depend upon the
spiral wires which contract and dilate by the action of
light and moisture. She adds, that there are no spiral
wires in the seminal leaves of the mimose sensitiva,
and that the seminal leaves have no motion whatever.

In further illustration of this subject, we shall next
present our readers with some observations by Mr Loyall,
lately published in Nicholson's Journal; respecting
the irritability of the mimose pudica, and some other gi-

It is well known (he observes), if we take a leaf
of this plant, similar to what is represented (fig. 31.),
and then, by means of a pair of asciars (completely
dry), cut off half the pinula A, this pinula will con-
tract at its joint, either immediately, or in a few se-
conds; its neighbour, or opposite pinula, B, closing
at the same time, or soon after.

The pinula A and B having come into contact,
there is a pause, or a short cessation, of motion; but
in the course of a few more seconds, the next pair of
pinulae, CC, will also shut up, and the same will hap-
pen with every pair of pinulae of that pinula succes-
ively; only with this difference, that the intervals be-
tween the shutting up of each pair of pinulae will be
shorter, the farther it is from the pinula that was cut.
After the whole of the pinulae of this pinula have com-
pletely closed, and a little interval, then the joint D
will bend so as to allow the pinna to drop consider-
ably.

Nevertheless, the motion is often not so obvious in
this joint, as in that to be mentioned.

A longer pause will now intervene, in some cases
so long as to make us suppose that all motion is at an
end; but at length the joint E suddenly bends, and
astonishes the beholder.

The petiole F, now, instead of forming an acute
angle with the stem above the joint, forms a very ob-
tuse angle with it.

We shall now have another cessation of motion,
and then the joint, H, will slightly bend; then another
pause, then a shutting up of the pair of pinulae, H i,
and so on with the other pinulae; till the whole pinula
is closed. The motions, however, will not be so regu-
lar in this pinula as they were in the other; for as the
pinulae n approach, they press forward the next pair,
and so on with all the rest.

These motions, the author supposes, are not occasion-
ated by impulse; for a bit of the pinula may be cut off
almost without producing any motion.

But allowing that a little motion were produced, it
comes naturally as a question. Why does the motion
become so extensive? how is the impulse communicated
to the origin of the petiole? The author does not think
that these questions will ever be satisfactorily answered
upon mechanical principles.

He admits indeed, that a structure exists in the mi-
mosa sensitiva, corresponding to what Mrs Ibbon has
3 Y 2 described;
Vegetable described; although he seems to have some doubts respecting it. He then proceeds to inquire, whether by such a structure, acted upon by heat, light, or moisture, we could possibly explain the motions of the mimosa pudica. On the experiments above related, (he observes), I presume no one would say, that moisture was the cause of motion, as the scissors were quite dry.

It is to be remembered also, that this plant will perform its motions under water.

As there was no change of light, consequently this had no share in the effect. Besides, when moisture is produced (Mr. Lyall certainly means darkness) in consequence of the abstraction of light, all the pinnule shut up at the same time; not, however, in the regular order mentioned in the experiment. Neither does the motion take place from change of temperature, for the temperature was not altered.

A great many questions will here suggest themselves, as, How does it happen that the motion is produced? how does it become so extensive? how comes it that there are regular motions and pauses, &c. &c.

The author concludes, by saying, that it is vain to attempt any mechanical solution of the phenomenon mentioned above, "which would seem to depend on an exquisite irritability in the plant itself."

Dionaea Muscipula.—Mr. Lyall does not think that the motions of this plant are to be explained in the manner spoken of by Brussouzet, who ascribed them to the evacuation of a fluid from the leaf, which will be noticed when we speak of the drosera. For the leaf may be touched without causing any efflux of fluid whatever, and yet it will contract completely.

Comparetti’s explanation respecting the motion of this plant is not admitted; because it seems improbable, is contrary to analogy, and inadequate to explain the phenomenon.

Of the Drosera Longifolia and Rotundifolia.—As many of the muscles of the animal system, as the heart, diaphragm, &c. act quite independent of the will, and as these parts are highly irritable, Mr. Lyall wishes to show, that a voluntary command of a muscular force should not be taken into the definition of the word irritability, as has been done by some. Mr. Lyall says, "By irritability, I understand, that property inherent in some bodies (or rather parts of bodies), by which, when a stimulus is applied, they are enabled to contract."

The leaves of the drosera rotundifolia, when properly unfurled, lie round the stem in a stellated manner. The footstalks of the leaves vary in length from half an inch to an inch and a half. The leaves are covered on their upper surface by a number of hairs, varying also in length from one line to three-eighths of an inch, and are each terminated by a little gland, which gland is covered by a transparent viscid fluid, presenting a fine appearance.

The chief difference between the drosera longifolia and rotundifolia is in the shape of the leaves; those of the former being obovate, while those of the latter are of an orbicular shape.

Mr. Lyall mentions the observations of Mr. Whatley, who, it would appear, was the first in this kingdom who described the contractions of the drosera when irritated.

Mr. Whately and Mr. Gardom had observed some insects imprisoned in the leaves of this plant, and hence they were led to press with a pin the centre of other leaves in their natural and expanded form, when they very suddenly contracted, and, as it were, encircled the pin.

Roth had noticed, in 1779, that the leaves of the drosera moved, when irritated. He placed an ant upon the middle of a leaf of the drosera rotundifolia, but so as not to disturb the plant. The ant endeavoured to escape, but was held fast by the clammy juice of the points of the hairs, which was drawn out by its feet into fine threads; in some minutes the short hairs on the disk of the leaf began to bend, then the long hairs, and laid themselves upon the insect. After a while the leaf itself began to bend, and in some hours the end of the leaf was so bent inwards as to touch the base. The same happened when the experiments were made on the drosera longifolia, but more rapidly.

Roth also found that the hairs bent themselves when he touched them with the point of a needle, with a dog’s bristle, or when he placed a very small piece of wood the weight of an ant upon the leaf. He says, that all these give us an account of his own experiments. He says, "that for five months, he almost, every day, had the species of drosera under his eye, either at home or in the country; and he confesses, that he never saw such a rapid contraction of the leaves of the drosera rotundifolia, as had been noticed by Mr. Whatley and Gardom; but in all his experiments an hour was necessary for the complete bending of all the hairs; and it required some hours for the perfect shutting up of the leaves. Hence it is evident, that whoever has a wish to notice the motions of the drosera, must not set out with the expectation of seeing a rapid motion, similar to what happens in the mimosa, follow the application of a stimulus; but, to observe the ultimate effects, must watch with an attentive eye, for at least 20 minutes.

In accounting for the manner in which these motions are performed, various opinions have been held. Brussouzet suspects that the disengagement of some fluids influences them. He says, that the insect, by absorbing the fluid which is on the points of the hairs, empties the vessels of the leaf, which folds upon itself; and the quickness of the action is proportional to the number of hairs touched by the insect.

Our author observes, that "this theory, at first sight, does not appear even to be plausible; for, how is it possible that an insect can absorb a thick tenacious fluid? No doubt, however, part of this fluid will be attached to the part of the insect which touches it; but this seems quite unconnected with the contraction of the leaf. On the 30th of July, 1844, Mr. Lyall brought from the country a number of plants of the drosera rotundifolia, and, on inspecting them, he found many of the hairs of the leaf deprived of their viscid fluid; but yet both they and the leaf remained quite expanded and in good condition. Next day, about four o’clock, he placed a small bit of sulphate of copper, in the disk of one of these expanded leaves, and by that o’clock most of the hairs on one side of the leaf, even the outermost, had bent themselves over the bit of copper; this seems
Vegetable Physiology

Vegetable to prove the inaccuracy of Broussonet's theory. In other experiments, he placed small bits of bread or wood, or three or four of the central hairs, without touching the other hairs, or the viscid fluid on their ends; and in a few hours he found that all the hairs had contracted around the foreign body. In some plants, the sulphate of copper was placed upon some of the small hairs in the disk of the leaf, without touching the leaf itself; yet the bending of the hairs and leaf was complete.

"We have here proof (be it added), 1st, That the leaves do not contract when deprived of their viscid fluid, which ought to have been the case if Broussonet's theory had been true. 2dly, That the contraction takes place even when the viscid fluid does not cover the little glands. 3dly, That the contraction follows, although the foreign body is not brought into contact with all the hairs.

The opinion of Sennebier, who appears to have ascribed the motions of the droserea to the effect of pressure is next examined. "Sennebier seems (it is observed) sensible, that the contractions of the leaves take place even when light bodies are placed on them, which circumstance of itself would lead us to suspect, that pressure is not alone the cause. But (it is added), that, if we press on the centre of a leaf with a pin, &c. we may cause its margin to approximate the pin; and this certainly would be owing to a mechanical cause. But, suppose we see the contraction take place, as I have done, when a body specifically lighter than the leaf itself is placed in the centre, as a bit of rotten wood; should we be still inclined to ascribe it to a mechanical cause? Admit that it is the case. Suppose, then, we place the same bit of wood on the margin of the leaf, what effect ought to follow? If it were owing to a mechanical cause, or the weight of the foreign body, as in the last mentioned case, then we should expect, that the part of the margin of the leaf, on which the bit of wood rested, would be depressed; which undoubtedly is not the case: but, on the contrary, the margin rises, and then contracts towards the foreign body, or towards the footstalk of the leaf.

"That this motion does not depend on pressure, may be still better illustrated, by placing a fly, or some other body, on the apex of a leaf of the droserea longifolia. The hairs near the foreign body will contract around it, and then the apex of the leaf will rise upwards, and turn inwards, until it touches the base. Or, if the offending body is small, the leaf will become convoluted around it."

From the result of his experiments, the author thinks, that the motions of the leaves of the droserea cannot be explained on mechanical principles. He conceives, that these motions are performed, if not by muscles, at least by something which is equivalent to muscles in the animal body.

It is observed, that the leaves of the droserea rotundifolia and longifolia remain completely expanded during the hottest sunshine and driest weather; during the coldest and wettest weather; during the greatest darkness, and, finally, during the brightest light of day. This, however, is to be taken in a limited sense, i.e., only during the expansion of the leaves, not during the cold of winter. "Here, then, neither heat, cold, dryness, dampness, darkness, nor light in general, at all affect the leaves; but, if a foreign body be applied to the leaf so as Vegetable to stimulate, then it will shut up" in the manner we have already described. See Vegetable Anatomy.

Fig. 17. Represents the heart taken out of the seed of a chestnut. l, l, the circular hook; o, o, the nourishing vessels; l, l, the line of life, which was taken out where it crosses the heart at m.

Fig. 18. The seed of the gooseberry. o, the nourishing vessels; l, l, the line of life; m, the corculum or heart.

Fig. 19. The stinging nettle, as viewed with the polar microscope; n, the bag of poison; x, the spiral wire.

Fig. 20. The stinger after the poison has been thrown to the point; n, the spiral wire contracted.

Fig. 21. Indian grass greatly magnified, showing the manner in which it is formed.

Fig. 22. Awn of the grass.

Fig. 23 and 24. The grass twisted.

Fig. 25. Leaf of the mimosa sensitiva.

Fig. 26. A longitudinal section of the leaf-stalk of the mimosa sensitiva, the middle part containing five cases of spiral wire, and each extremity only three.
VELITES, in the Roman army, a kind of ancient soldiery, who were armed lightly with a javelin, a cask, cuirass, and shield.

VELLIUS PATERCULUS. See Paterculus.

VELLUM, is a kind of parchment, that is finer, evener, and more white than the common parchment. The word is formed from the Latin vellus, "belonging to a calf."

VELOCITY, in Mechanics, swiftness; that affection of motion whereby a moveable is disposed to run over a certain space in a certain time. It is also called celerity, and is always proportional to the space moved. See Quantity No. 11 and 14, &c.

VELVET, a rich kind of stuff, all silk, covered on the outside with a close, short, fine, soft shag, the other side being a very strong close tissue. The nap or shag, called also the reticling, of this stuff, is formed of part of the threads of the warp, which the workman puts on a long narrow-channeled roller or needle, which be afterwards cutts, by drawing a sharp steel tool along the channel of the needle to the ends of the warp. The principal and best manufactory of velvet are in France and Italy, particularly in Venice, Milan, Florence, Genoa, and Lucca: there are others in Holland, set up by the Dutch refugees; whereas that at Haerlem is the most considerable: but they all come short of the beauty of those in France, and accordingly are sold for 10 or 15 per cent. less. There are even some brought from China; but they are the worst of all.

VENAL, or Venous, in Anatomy, something that bears a relation to the veins. This word is also used for something bought with money, or procured by bribes.

VENEERING, Veneering, or Finering, a kind of marquetry, or inlaying, whereby several thin slices or leaves of fine wood, of different kinds, are applied and fastened on a ground of some common wood.

There are two kinds of inlaying: the one, which is the more ordinary, goes no farther than making of compartments of different woods; the other requires much more art, and represents flowers, birds, and the like figures. The first kind is what we properly call veneering: the latter we have already described under MARQUETRY.

The wood intended for veneering is first sawed out into slices or leaves, about a line thick: in order to saw them, the blocks or planks are placed upright in a kind of vice or sawing press: the description of which kind may be seen under the article just referred to. These slices are afterwards cut into slips, and fashioned divers ways, according to the design proposed; then the joints being carefully adjusted, and the pieces brought down to their proper thickness, with several planes; for the purpose, they are glued down on a ground or block of dry wood, with good strong English glue. The pieces thus joined and glued, the work, if small, is put in a press; if large, it is laid on the bench, covered with a board, and pressed down with poles, or pieces of wood, one end whereof reaches to the ceiling of the room, and the other bears on the boards. When the glue is quite dry they take it out of the press and finish it; first with little planes, then with divers scrapers, some whereof resemble raps, which take off dents, &c. left by the planes. When sufficiently scraped, the work is polished with the skin of
VEN

VENERAL, something belonging to venery; as the lues venerea, &c. See MEDICINE INDEX.

VENERY, is commonly used for the act of copulation, or coition, between the two sexes; it has also been employed by old writers as applicable to hunting or the chase, as beasts of venery.

VENESECTION, or PHLEBOTOMY, in Surgery. See SURGERY Index.

VENETIAN BOLE, a fine red earth used in painting, and called in the colour shops Venetian red. -It is the sinuous form, and sent from Venice to all parts of the world; but the use of it is much superseded by a bright-coloured vitrul.

VENICE, STATE OF, formerly a celebrated republic, which for nearly ten centuries formed one of the most powerful maritime states of Europe. Its dominions lay chiefly along the coasts at the head of the Adriatic sea, comprehending not only a considerable tract round the city of Venice, but several districts both to the east and west of that sea, together with the islands of Corfu, Zante, Cephalonia, Cerigo, and some others of less note in the Archipelago. It was bounded to the north by the Alps, to the west by the duchy of Milan, and to the east by Corinth, a province of Turkey in Europe.

The republic of Venice is said to have taken its rise from a small Italian colony, who in the middle of the 6th century were driven by Attila king of the Huns from the cities of Aquileia, Verona, Mantua, &c. and took refuge in the group of small islands where now stands the city of Venice. Here they established themselves, and formed a small independent state, adopting the regular form of government which had so long prevailed at Rome. By the end of the 6th century they had become of consequence, and were able to raise and maintain a fleet and a small army. They engaged in war with the Lombards, and distinguished themselves against the Istrian pirates, and the inhabitants of the neighbouring port of Trieste. They also assisted Justinian in his contest with the Goths, and received from him and his general Narses, many marks of favour and distinction.

About the year 607, the tributary power, which had prevailed in Venice from the end of the 5th century, was abolished, and the states elected a supreme magistrate, whom they called doge, or duke. He was to represent the honour and majesty of the state; to assemble and preside at the great council, where he had a casting vote in all disputed points; to nominate to all offices, places, and preferments, and to enjoy the same authority in the church as in the state. Excepting a short intermission of about five years, the power of the doges continued till the fall of the republic.

Under the doges, the power and wealth of the republic continued to increase. In 762, the Heraclids and Gezalans, subjects of the republic, revolted, and threw themselves on the protection of the emperor Charlemagne. That emperor settled them for the present at Malamoe, in the neighbourhood of the Venetian capital; but from this asylum they were quickly driven by the forces of the republic. Incensed at this affront committed against his authority, Charlemagne ordered his son Pepin to declare war against the Venetians; but as

Astołphus king of the Lombards was then laying waste the territories of the church, the troops of Pepin were, by the intrigues of the pope, dispatched against that powerful monarch; and though, on the defeat of Astolphus they marched against the Venetians, it does not appear that the enterprise was productive of either honour or success. The war with Pepin was renewed in 824, on occasion of Obelerio, the doge of Venice, shewing an inclination to favour the Greek emperor Nicephorus against Pepin. Obelerio was related to the French monarch, having married his sister; and as on this account the Venetians were jealous of the attachment of their doge, he was superseded, and Valentin nominated commander in his place. Pepin had collected a numerous and well appointed army, and had fitted out a fleet to act against the Venetians by sea. With this formidable force he advanced directly to Venice, but here he was opposed with all the valor of independent citizens fighting for their liberties.

The Venetians, however, notwithstanding the most intrepid obstinate defense, the most vigorous sallies, and their success in selling every inch of ground at an incredible expense of blood, were at length reduced to that part of the city south of the Rialto (see the next article); this stream and their own bravery, being now their only defense. While Pepin was preparing to throw a bridge over the canal, they resolved, as a last effort, to attack Pepin's fleet, and to vanquish or die in defense of their liberty. Embarking all the troops they could spare, they bore down with the advantage of the wind and tide, upon the enemy, and began the attack with such fury, as obliged the French admiral to give way. The lightness of their ships, and the knowledge of the soundings, gave the Venetians every advantage they could wish: the enemy's fleet was run aground, and the greater part of their troops perished in attempting to escape; the ships were all to a few either taken or destroyed. During this action at sea, Pepin resolved to assault the city by land, not doubting but the garrison was so weakened by the number of forces they had sent on board the fleet, as to be able to make but a slight resistance. Having for this purpose thrown a bridge over the Rialto, he was marching his troops across it, when he found himself attacked on every side by the Venetians from their boats, and others who had posted themselves on the bridge.

The battle was long, bloody, and doubtful, until the Venetians employed all their power to break down the bridge; which at last yielding to their obstinate endeavours, a prodigious slaughter of the French ensued; they fought, however, like men in despair, seeing no hopes of safety but in victory; but all communication being cut off with the troops on shore, they were to a man either killed or drowned. The number of slain was so great that the space between the Rialto and Malamoe was covered with dead bodies, and has ever since gone by a name expressive of the prodigious slaughter. Pepin was so struck with the intrepidity of the Venetians, that he raised the siege, abandoned the enterprise, and concluded peace with the republic.

In 839, the Venetians engaged in an offensive and venetian defensive alliance against the Saracens, with the Greek ex- emperor Michael, to whose assistance they sent a fleet of fifty to sixty galleys. In an engagement which took place be- tween the allied fleets and that of the Saracens, the for-
Venice. The Venetian galleys were either taken or destroyed. On the news of this defeat, the capital was thrown into the greatest consternation, justly dreading an attack from the victorious Saracens. This alarm, however, soon subsided, on finding that the barbarians had turned off on the side of Ancona. The city now became a prey to internal dissension. Popular tumults were frequent, and in one of these the doge was murdered. By the prudent and vigorous administration of a succeeding doge, Orso Participato, good order was re-established, and at the commencement of the 11th century, the reputation of the republic for military prowess was much advanced by a victory gained over the Huns, who had invaded Italy, and defeated Berengarius.

Towards the close of the 11th century, Venice began to make a considerable figure among the states of Europe, having acquired the sovereignty of Dalmatia and Croatia, with which in 1084 they were formally invested by the Constantinopolitan emperor.

About this time a crusade, or holy war against the Saracens, was preached up by the emissaries of the pope, and the Venetian republic engaged in the undertaking with such ardour, as to equip a fleet of 200 sail, under the command of the doge Vitalis Michael. Before he sailed for the coast of Asia, however, the doge found it necessary to chastise the Pisans, whom he defeated in a terrible engagement. He then sailed for Askalon, at that time besieged by the Christian forces, and it was chiefly by his valour that that city, as well as Caesarea and Tiberias, fell into the hands of the Christians. From these victories he was recalled to repel an invasion of Dalmatia by the Normans, whom he also defeated, carrying off considerable booty. His successor assisted Baldwin in the conquest of Ptolemais, but was defeated and killed in attempting to quell a rebellion of the Croatians.

Under the government of Domenico Micheli, who succeeded Ordelapho, the pope's nuncio arrived at Venice, and excited such a spirit of enthusiasm among all ranks and degrees of men, that they strove whose names should be first enrolled for the holy war. The doge, having fitted out a fleet of 60 galleys, sailed with it to Joppa, which place the Saracens were at that time besieging. The garrison was reduced to the last extremity when the Venetian fleet arrived, which surprised and defeated that of the enemy with great slaughter; soon after which the Saracens raised the siege with precipitation. Tyre was next besieged, and soon was obliged to capitulate; on which occasion, as well as on the taking of Ascalon, the Venetians shared two-thirds of the spoils. While the doge was absent on those important affairs, the emperor of Constantinople, jealous of the growing power of the Venetians, resolved to take advantage of their apparent incapacity to resist an attack at home. The Venetians, however, had timely notice of his approach, and instantly recalled the doge, who on his return laid waste and destroyed the country round Chios, seized on the islands of Samos, Lesbos, and Andros, then belonging to the emperor, and reduced several places in Dalmatia which had revolted.

In 1173, the republic ventured to oppose Frederick Barbarossa in his attack on the pope. Frederick, after a haughty reply to an embassy sent him by the Venetians, dispatched against them his son Otho, who soon arrived before the city with 75 galleys. The doge Venex, Sebastiano Ziani sailed out with the few vessels he had got equipped, to give the enemy battle. The fleets met off the coast of Istria, and a terrible engagement ensued, in which the imperial fleet was totally defeated; Otho himself taken prisoner, and 48 of his ships destroyed. On the doge's return, the pope went out to meet him, and presented him with a ring, saying, "Take this, Ziani, and give it to the sea, as a testimony of your dominion over it. Let your successors annually perform the same ceremony, that posterity may know that your valour has purchased this prerogative, and subjected this element to you, even as a husband subjected his wife." Otho was treated with the respect due to his rank, and soon conceived a great friendship for Ziani. At last, being permitted to visit the imperial court, on his parole, he not only prevailed on his father to make peace with the Venetians, but even to visit their city, so famed for its commerce and naval power. He was received with all possible respect, and on his departure attended to Ancona by the doge, the senate, and the whole body of the nobility. During this journey he was reconciled to the pope; and both agreed to pay the highest honours to the doge and republic.

In the beginning of the 13th century, the Venetians, in conjunction with the French, besieged and took Constantinople, as has been related under the article Con- stantinople, in STANTINOPOLITAN HISTORY, No. 144—146, which they held till the year 1261.

In the mean time the Genoese, by their successful wars with application to commerce, having raised themselves in the Go- no such a manner as to be capable of rivalling the Venetians, a long series of wars took place between the republics; in which the Venetians generally had the advantage, though sometimes they met with terrible overthrow. These expensive and bloody quarrels undoubtedly contributed to weaken the republic notwithstanding its successes. In the year 1348, however, the Genoese were obliged to protect the protection of Visconti duke of Milan, in order to support them against their implacable enemies the Venetians. Soon after this, in the year 1352, the latter were utterly defeated with such loss, that it was thought the city itself must have fallen into the hands of the Genoese, had they known how to improve their victory. This was in a short time followed by a peace; but from this time the power of the republic began to decline. Continual war with the states of Italy, with the Hungarians, and their own rebellious subjects, kept the Venetians employed, so that they had no leisure to oppose the Turks, whose rapid advances might have alarmed all Europe. After the destruction of the eastern empire, however, in 1453 the Turks began more immediately to interfere with the republic. Whatever valour might be shown by the Venetians, or whatever successes they might boast of, it is certain the Turks ultimately prevailed; so that for some time it seemed scarcely possible to resist them. What also contributed greatly to the decline of the republic, was the discovery of a passage to the East Indies by the Cape of Good Hope in 1497. Till then the greatest part of the East India goods imported into Europe passed through the hands of the Venetians; but as soon as the Cape was discovered, the conveyance by the way of Alexandria almost entirely ceased. Still, however, the Venetian power
power was strong; and in the beginning of the 16th century they maintained a war against almost the whole force of France, Germany, and Italy, associated against them in what has been called the League of Cambray.

After this, nothing of importance occurs in the history of the Venetian republic till the year 1645, when the republic was involved in a new and sanguinary conflict with the Turks, in defence of the important island of Candia. The transactions to which this war gave rise, and the spirit and bravery displayed by the Venetians, in defending their colonial possessions, are amply detailed under the article CANDIA.

At the end of the 17th century, the Venetians obtained an important acquisition of territory by the conquest of the Morea, which at the peace of Carlowitz in 1699, was formally ceded by Turkey to the state of Venice.

During the war of the Succession, the states of Venice observed a strict neutrality. They considered that dispute as unconnected with their interests; taking care, however, to keep an foot on their frontiers in Italy, of sufficient force to make them respected by the belligerent powers. But soon after the peace of Utrecht, the Venetians were again attacked by their old enemies, the Turks, who, being the great European powers exhausted by their late efforts, and unable to assist the republic, thought this the favourable moment for recovering the Morea, which had been so lately ravished from them. The Turks obtained their object, and at the peace of Passarowitz in 1715, which terminated this unsuccessful war, the Venetian states yielded up the Morea; the grand seignior on his part restoring to them the small islands of Cerigo and Cerigo, with some places which his troops had taken during the course of the war in Dalmatia.

The state of Venice becomes a province of Austria.

From the peace of Passarowitz to the conclusion of the 18th century, the affairs of Venice ceased to form an interesting part of the history of Europe. Ever since the league of Cambray, the republic, weakened by its continual struggles with Turkey, had declined in power and in consequence, and was incapable of opposing a barrier to the encroachments of its more powerful neighbours. During the first war which the French republic maintained against the emperor in Italy, the states of Venice afforded a tempting object to each of the contending parties; and in May 1797, the capital was occupied by a body of French troops, who under pretence of quelling a tumult that had arisen in the city, took possession of the forts, and subverted the existing authorities. By the treaty of Campo Formio, concluded in October of the same year, the French consented that the emperor should take possession of the Venetian territory, with the islands in the Archipelago, which had been subject to the Venetian republic. At the treaty of Presburg in 1805, Austria was compelled to cede the Venetian states to the kingdom of Italy, of which these states continued to form a part till the overthrow of the French power in 1814, when they reverted to Austria.

It is not necessary for us to be very minute in our account of the late constitutions and government of Venice. The government was strictly aristocratical, being vested in the great council or senate, in which each of the nobility had a seat. The nobility were extremely numerous, being computed at not fewer than 2000, whereas the whole population of the state did not exceed 2,000,000. Besides the great council, or il consiglio grande, there were four others; one composed of the doge and six councillors, called la signoria; another called il consiglio du pregodi, consisting of about 250 of the nobility; a third united to la signoria, consisting of 28 assessors, or great sages, which gave audience to ambassadors; and a fourth, composed of 10 councillors, who took cognizance of all criminal matters, and before whom even the doge himself must appear, if accused. The secret business of the state was often carried on by spies and informers; and there were in the ducal palace several statues of lions with open mouths, which formed so many receptacles for secret and anonymous information.

The office and privileges of the doge of Venice have been already mentioned under the article DOGE. Of late this office was little more than nominal; and the doge was a mere state puppet, without authority and without power. His establishment, however, was splendid, and his revenue not contemptible. The mode of electing the doge deserves notice, as it was well calculated to prevent bribery, or the exertion of party influence. He was elected by a plurality of voices, and held his dignity for life. In his election they made use of gold and silver balls, which were put into a vessel, and served for balloting. Those who drew the golden balls, first elected 40 councillors, who drew 12 others, and elected 25 in addition. Of this number nine persons, who had drawn golden balls, chose 40 more; 11 of those, appointed in the same way, chose 41 councillors, who finally proceeded to the election, till 25 votes or more fell upon the same person, who was then declared doge. After this election they placed the ducal cap upon his head, upon which he took possession of the doge's palace. He never uncovered his head to any person, because he did not wear the cap in his own name, but in that of the republic.

The military strength of the Venetians consisted of nearly 50,000 land forces, under the command of a capitano, who was always a foreigner of distinction; besides a considerable fleet, which they boasted could, in time of war, be increased to 60 men of war, and above 100 galleys. The ordinary revenues of the state have been computed at rather more than 1,000,000l. sterling, a considerable part of which arose from the customs, and the duty on salt made at Corfu and Chiassa. Venice, the city which was the seat of government of the Venetian republic, is built on 72 small islands at the head of the Adriatic or gulf of Venice, about five miles from the main land. That part of the gulf which lies between the city and the continent forms a kind of laguna or lake, which, at low water, is very shallow, and on the opposite side of the islands there are numerous shallows, the channels between which are marked by stakes, to direct ships in entering the port. The lagoons that lie between the islands form so many canals that intersect the city in all directions, and over these the streets communicate by not fewer than 300 bridges. The principal or great canal is broad, and has a serpentine course through the middle of the city, but the others are narrow and crooked. The streets are also narrow and winding, but clean and neat. The houses are built on piles, and have each a door opening to the

adjacent canal, and another to the street. As the narrowness of the streets but ill adapts them for walking in, the only places of resort on land are the Rialto, a noble bridge across the great canal, bordered with booths and shops and the great square of St Mark, or Piazzetta di St Marco, an irregular quadrangle, formed of several buildings some of which are magnificent. Of these, the Ducal palace where the business of the state used to be transacted; the patriarchal church of St Mark; the steeple of St Mark, at a little distance from the church; the church of St Geminiano; and the new and old Procuratories, are most deserving the notice of travellers. The canals form the great medium of communication, as well as the principal scene of relaxation and amusement to the inhabitants. Here ply numerous gondolas, (see Gondola, and Macgill’s Travels, vol. i.) which are rowed with admirable speed and dexterity by the gondoliers; and here are occasionally held races, or rather rowing matches. As the canals are, of necessity, the receptacles of all the filth of the city, they become, in hot weather, very offensive. The whole city is about six miles in circumference, and the inhabitants were formerly estimated at 162,000, but have been continually decreasing since it lost its independence; at present they are not supposed to exceed 100,000.

The inhabitants of Venice formerly carried on a flourishing trade in silk manufactures, gold lace, mirrors, and other articles of glass, besides military stores and implements of war. At some distance from the city there is a large and commodious lazaretto, where ships coming from the Levant unload their goods, and perform quarantine from 20 to 40 days.

This celebrated city, once the seat of power, opulence and the fine arts, whose carnival revelries have been the subject of so many animated descriptions, has undergone a melancholy change. Her streets and canals no longer re-ound with the strains of the musician and the serenades of watchful lovers, and her gay gondolas, which were formerly occupied by fashionable groups and parties of pleasure, are now become the vehicles of trade, or serve for the accommodation of the soldier and the mechanic. The trade of the city, which had long declined, has, since the cession of the Venetian territory to Austria, been almost entirely transferred to Trieste. Venice is 72 miles E. by N. of Mantua; 115 N. E. of Florence; 120 E. of Milan; 212 N. of Rome, and 300 N. by W. of Naples. E. Long. 12° 33′. N. Lat. 4° 26′.

VeniRe FaciAs, in Law, is a judicial writ lying where two parties plead and come to issue, directed to the sheriff, to cause 12 men of the same neighbourhood to meet and try the same, and to say the truth upon the issue taken.

VenTori, signifies the bully; but it is also used for the children by a woman of one marriage: there is in law a first and second venetier, &c. where a man hath children by several wives, and how they shall take in descent of lands.

VentILAToR, a machine by which the noxious air of any close place, as an hospital, geol. ship, chamber, &c. may be discharged and changed for fresh. The noxious qualities of bad air have been long known; and no one has taken greater pains to set the mischiefs arising from foul air in a just light than Dr Hales; who has also proposed an easy and effectual remedy by the use of his ventilators; his account of which was read to the Royal Society in May 1741. In the November following M. Triewald, military architect to the king of Sweden, informed Dr Mortimer secretary to the Royal Society, that he had in the preceding spring invented a machine for the use of his majesty’s men of war, in order to draw out the bad air from under their decks, the least of which exhausted 26,172 cubic feet in an hour, or at the rate of 21,732 tons in 24 hours. In 1742 he sent one of them, formed for a gun-ship to France; which was approved of by the Royal Academy of Sciences at Paris; and the king of France ordered all the men of war to be furnished with the like ventilators.

The ventilators invented by Dr Hales consist of a square box ABCD (fig. 1.) of any size; in the middle of one side of this box a broad partition or midriff is fixed by hinges X, and it moves up and down from A to C, by means of an iron rod ZR, fixed at a proper distance from the other end of the midriff, and passing through a small hole in the cover of the box up to B. Two boxes of this kind may be employed at once, and the two iron rods may be fixed to a lever FG (fig. 2.) moving on a fixed centre O; so that by the aid of raising and pressing down of the lever FG; the midriffs are also alternately raised and depressed, whereby these double-bellows are at the same time both drawing air, and pouring it out, through apertures with valves made on the same side with, and placed both above and below the hinges of the midriffs. In order to render the midriffs light, they are made of four bars lengthwise, and as many across them breadthwise, the vacant space being filled up with thin pannels of fir board; and that they may move to and fro with the greater ease, and without touching the sides of the boxes, there is an iron regulator fixed upright to the middle of the end of the box AC (fig. 1.) from N to L, with a notch cut into the middle of the end of the midriff at Z; so that the midriffs, in rising and falling, will meet without any friction than what is made between the regulator and the notch. Moreover, as the midriff ZKX moves with its edges only one-twentieth of an inch from the sides of the box ABCDF, very little air will escape by the edges; and therefore, there will be no need of leather sides as in the common bellows. The end of the box at AC is made a little circular, that it may be better adapted between A and C to the rising and falling midriff; and at the other end of the midriff a slip of leather may be nailed over the joints if needful. The eight large valves through which the air is to pass, are placed at the hinge-end of the boxes BK (fig. 2.) at 1, 2, 3, &c. The valve 1 opens inward to admit the air to enter, when the midriff is depressed at the other end by means of the lever FG. And at the same time the valve 3 in the lower ventilator is shut by the compressed air which passes out at the valve 4. But when that midriff is raised, the valve 1 shuts, and the air passes out at the valve 2. And it is the same with the valves 5, 6, &c. of the other box; so that the midriffs are alternately rising and falling, and two of the ventilators drawing in air, and two blowing it out; the air entering at the valves 1, 3, 6, 8, and passing out at the valves 2, 4, 5, 7. Before these last valves there is fixed to the ventilators a box QQNM (fig. 3.) as a common receptacle for all the air which comes out of these valves; which

VENUS’s Fly-trap. See Dionaea Muscipula, Botany Index.

VENUS, a genus of shell-fish. See Conchology Index.

Vepreculæ, diminutive from repres, “a briar or bramble;” the name of the 31st order in Linnaeus’s Fragments of a Natural Method. See Botany Index.

Veracruz, a sea port town of North America, in New Spain. This city is almost the sole channel of communication between Mexico and the mother country. It is beautifully and regularly built, and is situated in an arid plain, destitute of running water, on which the north winds have formed hills of moving sand. Near the town are considerable marshes and stagnant pools, which occasion intermittent fever among the inhabitants. The population of Veracruz in 1803 amounted to 16,000. The port is not very secure; though it is the best on the Mexican coast. The trade of this town is very extensive: the exports consist of gold and silver in ingots, cochineal, sugar, flour, indigo, salted provisions, tanned hides, vanilla, soap, camphany wood, &c. and amount annually, according to Humboldt, to 4,620,000. sterling; while the imports, consisting of linens, woollens, cottons, paper, mercury, iron, brandy, wine, &c. amount only to 3,150,000.

W. Long. 95. 15. N. Lat. 10. 12.

Veraguas, a province of New Spain, bounded on the east by that of Costa Rica, on the west by Panama, on the north by Darien and the gulf of Mexico, and on the south by the South sea. It is about 250 miles in length from east to west, and 62 in breadth from north to south. It is a mountainous barren country; but has plenty of gold and silver. Conception is the capital town.

Veratrum, a genus of plants belonging to the class Polygamos, and in the natural system arranged under the 10th order, Coronariae. See Botany and Materia Medica Index.

Verb, in Grammar. See Grammar, chap. iv.

Verbascum, a genus of plants of the class pentandria, and in the natural system arranged under the 28th order, Lerideae. See Botany Index.

Verbena, a genus of plants of the class diandria, and in the natural system arranged under the 40th order, Personatae. See Botany Index.

The islands of Cape de Verd are seated in the Atlantic ocean, about 400 miles west of the Cape. They are between the 13th and 15th degree of latitude; and the principal are 12 in number, lying in a semicircle. Their names are, St Antony, St Vincent, St Lucia, St Nicholas, the isle of Sal, Bona Vista, Mayo, St Jago, Fuego, and Bravo.

Verdict, (Pere dictum), is the answer of the jury given to the court concerning the matter of fact, in any case civil or criminal, committed by the court to their trial and examination. See Law, No. clxxvi. 51. and Trial.

Verdigrise, the acetate of copper, much used by painters as a green colour. See Copper, Chemistry Index.

Verditer, or Verdater, a preparation of copper, sometimes used by painters, &c. for a blue; but
VERGIL, Polydore. See Virgil.

VERJUICE, a liquor obtained from grapes or apples, unfit for wine or cyder; and chiefly used in sauces, ragouts, &c.

VERMES, the sixth class of animals in the Linnean system, comprehending five orders. See Natural History, and Conchology and Helminthology Index.

VERMICELLI, or Vermicheley, a composition of flour, cheese, yolks of eggs, sugar, and saffron, reduced to a paste, and formed into long slender pieces like worms, by forcing it with a piston through a number of little holes. It was first brought from Italy; and is chiefly used in soups and pottages.

VERMICULAR, an epithet given to any thing that bears a relation or resemblance to worms.

Vermiformis, in Anatomy, a term applied to various parts in the human body, bearing some resemblance to worms.

VERMILION, a bright and beautiful red colour, composed of quicksilver and sulphur, in great esteem among the ancients under the name of minium. See Chemistry, No. 1701, and 1713; but what goes by the name of minium amongst us, is a preparation of lead, known also by the name of red-lead. See Chemistry, No. 1832.

VERMIN is a general term, denoting those animals which are either directly or indirectly injurious to mankind, the inferior animals, or the fruits of the earth; as flies, caterpillars, fies, worms, &c.

VERMIN, Destruction of. As we propose in this article to point out the means of destroying some of those animals that are hurtful or troublesome to man, we shall employ the term vermin, in a more extended sense, including also under it, mice, rats, moles, &c. We shall endeavour to collect the most useful observations that have been made on the means of diminishing or extirpating such animals as are obviously injurious. We cannot avoid here remarking, that although the seemingly excessive increase of one species of animals is hurtful or inconvenient to another, or to man himself, and their existence is attended with great loss and damage, by their infesting and destroying grains and other fruits of the earth destined for the food of man or those animals that are subservient to him; we are not of opinion that this excess ought to be considered merely as a useless excescence in the great scale of being; nor are we of opinion that their numbers ought not to be reduced, because we are too short-sighted to compre-

hend the wise purposes for which they are called into life. We have heard such a doctrine held up, although we are inclined to suspect that it is founded on a love of singularity, or indolence, rather than proceeding from pure motives of benevolence. But we must abstain from such discussions, and occupy the limits allotted to the proper subject of consideration.

Rats and Mice.—Various methods have been proposed for the destruction of these vermin. The following preparation has been recommended as very effectual. Take of the seeds of stavesacre (delphinium staphiatricum), or of mousewort (pedicularis palustris), powdered, more or less as the occasion requires, one part; of oat meal, three parts: mix them well, and make them up into a paste with honey. Lay pieces of this paste in the holes, and on the places where mice and rats frequent; and it will effectually kill or rid the places of those kind of vermin by their eating of it.

Some time ago the society for encouraging arts proposed a premium of 50l. for a preparation capable of alluring or fascinating rats so that they might be taken alive. In consequence of this, a great number of new traps, &c. were invented, and the following method of alluring the rats to a certain place was published. One of the methods which is most easily and efficaciously practised, is the trailing of some pieces of their most favourite food, which should be of the kind which has the strongest scent, such as toasted cheese or boiled red herrings, from the holes or entrances of the closet to their recesses in every part of the house or contiguous building. At the extremities, and at different parts of the course of this trailed track, small quantities of meal, or any other kind of their food, should be laid to bring the greater number into the tracks, and to encourage them to pursue it to the place where they are intended to be taken; at that place, when time admits of it, a more plentiful repast is laid for them, and the trailing repeated for two or three nights.

Besides this trailing and vessel-baiting, some of the most expert of the rat-catchers have a shorter, and perhaps more effectual method of bringing them together; which is the calling them, by making such a whistling noise as resembles their own call; and by this means, with the assistance of the way-baits, they call them out of their holes, and lead them to the repast previously prepared for them at the places designed for taking them. But this is much more difficult to be practiced than the art of trailing; for the learning of the exact notes or cries of any kind of beasts or birds, so as to deceive them, is a peculiar talent which is attained only by few.

In practising either of these methods of trailing or calling, great caution must be used by the operator to suppress and prevent the scent of his feet and body from being perceived; which is done by overpowering that scent, by other scents of a stronger nature. In order to do this, the feet are to be covered with cloths rubbed over with assafoetida, or other strong smelling substances; and even oil of rhodium is sometimes used for this purpose, but sparingly, on account of its high price, though it has a very alluring as well as disgusting effect. If this precaution of avoiding the scent of the operators feet, near the track, and in the place where the rats are proposed to be collected, be not properly observed, it will very much obstruct the success of the at-
Vernia. tempt to take them; for they are very shy of coming
where the scent of human feet lies very fresh, as it intimates
to their sanguous instinct the presence of human
creatures, whom they naturally dread. To the above
mentioned means of alluring by trailing, way-baiting
and calling, is added another of very material efficacy,
which is the use of oil of rhodium, which, like the marum
syriacum and valerian in the case of cats, has a very ex-
traordinary fascinating power on these animals. This oil,
as it is extremely dear, is therefore sparingly used. It is
exalted in a small quantity in the place, and at the ent-
rance of it, where the rats are intended to be taken,
particularly at the time when they are to be last brought
together, in order to their destruction: and it is used
also by smearing it on the surface of some of the imple-
ments used in taking by the method below described;
and the effect it has in taking off their caution and
dread, by the delight they appear to have in it, is very
extraordinary.

It is usual, likewise, for the operator to disguise his
figure as well as scent, which is done by putting a sort
of gown or cloak, of one colour, that hides the natural
form, and makes him appear like a post, or some such
inanimate thing, which habit most likewise be scented
as above, to overpower the smell of his person; and be-
sides this, he is to avoid all motion till he has secured
his point of having all the rats in his power.

When the rats are thus enticed and collected, where
time is afforded, and the whole in any house and out-
buildings are to be cleared away, they are suffered to
regale on what they most like, which is ready prepared
for them, and then to go away quietly for two or three
nights; by which means those that are not allured the
first night, are brought afterwards, either by their fel-
lowers, or the effects of their trailing, &c. and will
not fail to come duly again, if they are not disturbed or
molested. But many of the rat-catchers make shorter
work, and content themselves with what can be brought
together in one night; but this is never effectual, unless
where the building is small and entire, and the rats but
few in number.

The means of taking them when brought together are
various. Some entice them into a very large bag, the
mouth of which is sufficiently capacious to cover nearly
the whole floor of the place where they are collected;
which is done by smearing some vessel, placed in the
middle of the bag, with oil of rhodium, and laying in
the bag baits of food. This bag, which before lay flat
on the ground with the mouth spread open, is to be
suddenly closed when the rats are all in. Others drive
or frighten them, by slight noises or motions into a bag of
a long form, the mouth of which, after all the rats are
come in, is drawn up to the opening of the place by
which they entered, all other ways of retreat being
secured. Others, again, intoxicate or poison them, by
mixing with the rest prepared for them, the coc-
lus, or the nux vomica. They direct four ounces of
cocculus indicus, with 12 ounces of oat-meal, and two
ounces of treacle or honey, made into a moist paste
with strong beer; but if the nux vomica be used, a
much less proportion will serve than is here given of the
cocculus. Any similar composition of these drugs, with
that kind of food the rats are most fond of, and which
has a strong flavour to hide that of the drugs, will
equally answer the end. If indeed cocculus indicus
be well powdered, and infused in strong beer for some
time, at least half the quantity here directed will serve
as well as the quantity before mentioned. When the
rats appear to be thoroughly intoxicated with the coc-
lus, or sick with the nux vomica, they may be taken
with the hand and put into a bag or cage, the door of
the place being first shut, lest those who have strength
and sense remaining should escape.

In destroying rats, advantage may be taken of that
remarkable degree of instinct which they possess of de-
serting one place, where they find themselves disturbed
or harassed, and retiring to new haunts. It is well
known, that after one or two rats are poisoned, or ta-
taken in traps, or wounded or otherwise injured, and af-
terwards permitted to escape, the whole colony imme-
diately disappears. The practice, however, of destroy-
ing rats that frequent dwelling-houses, by poison, should
be as much as possible avoided; for they retire to places
behind the wainscots, &c. from which, after death, their
putrid bodies emitting a most offensive smell cannot be
removed. But it is far less difficult than is generally
imagined to secure the different apartments of a dwell-
ing house, and even the cellars, from the intrusions of rats
and mice, and thus to prevent their unwelcome visits,
by shutting up the passages through which they enter.
Stone and lime, when they can be applied, are effec-
tual; but common plaster, by introducing pieces of
broken pottery ware or glass, along with it, will also
answer the purpose; and even a piece of cork, with a
pin or two stuck through it to prevent them from eating
it away, is a complete barrier to mice entering through
a hole in wood, and may even prevent the entrance of
rats.

I have seen this method of shutting up the holes, as
soon as they were opened by the industry of the enemy,
steadily pursued for some time, attended with the fullest
success, even in an old house of considerable extent, and
finished from top to bottom with wood, some of which
was much decayed.

Often for the sake of food, rats and mice frequent
gardens, fields, and woods, in the summer season; but,
on the approach of winter, they return to their former
haunts in the habitations of man; and, accordingly, it
is observed, that houses which are free from those ver-
min during the summer, swarm with them about the end
of harvest. Attention to this circumstance in the
habits of these animals, may be the means of securing
us from their visits and depredations: for if, at the time
alluded to, every hole and cranny through which rat or
mouse can enter, be shut up, and carefully kept close
and secure, the perseverance of the foe is exhausted and
overcome by repeated and constant resistance, and thus
he is forced to abandon the unequal contest, and to re-
tire to other haunts where his motions are less inter-
rupted.

Vernia. other methods have been proposed for the
destruction of rats; and although we have thrown out
a hint against the use of arsenic for this purpose, in
dwelling-houses; yet where it can be employed with
perfect safety, and without risk of the nuisance alluded
to, as in cellars and outhouses, it is undoubtedly one of
the most effectual to which we can have recourse.

Suffocating these vermin by means of the fumes of sul-
phur, as on board of ships, in granaries, and other
buildings, which can be shut up, is sometimes also suc-
cessfully.
Vermin. cessfully practised. Rats and other vermin have also been effectually destroyed and eradicated by burning wood in close apartments, thus producing fixed air or carbonic acid gas, by which they are also suffocated.

Moles.—Various methods have been proposed for the destruction of these animals. But the following observations on this subject, which we shall give in the words of the author, seem to be more satisfactory than anything we have met with.

"The great damage (says he) which moles occasion in cultivated land, and particularly gardens, is well known; and the best means of remedying this evil is by destroying all those that make their appearance, as far as possible. The secrets which quack and sell for exterminating these destructive animals are of very little avail; and even poison produces no effect, as the mole does not drink, and lives only on roots and worms. In regard to gins and traps, the moles must be enticed to them by some kind of bait, which does not always produce the intended effect. Buffon advises a trench to be dug round the hills under which they conceal themselves, and thus to cut them off from all communication with the neighbouring ground. This method requires three or four people to dig trenches; and though it may prove effectual, it is attended with too much trouble. The other methods proposed by different naturalists are neither easier nor more certain.

"It is well known that this animal lives under the earth; and if at any time it comes forth from its holes, it is only when compelled to do so, in consequence of large quantities of water accumulated after the heavy rains which fall in summer, or when the earth is so much parched and dried by the continued drought, that it can no longer continue its labour: but it again creeps back into the earth when it finds a spot convenient for its purpose.

"This animal, as already remarked, feeds upon roots and worms, and for this reason is generally found in rich fertile soil; but never in that which is marshy or stony. In the winter time it retires to elevated places, because it is there best secured from inundations. In summer, however, it descends to the low hillocks and flat land, and above all makes choice of meadows for the place of its residence, because it finds the earth there fresher and softer for it to dig through. If the weather continues long dry, it repairs to the borders of ditches, the banks of rivers and streams, and to places contiguous to hedges.

"The mole breeds generally at the beginning of winter, and the months when they are found big with young are January and February. In the month of April a great many of their young may be seen. Among 122 caught in the month of May by my method, there were only four big with young. This animal cannot live without digging; it is obliged to find its nourishment in the bowels of the earth; and on that account is under the necessity of making those long subterranean passages which are found between one mole-hill and another. In general it begins to dig five or six inches under the surface; it scrapes the earth before it on one side until the quantity becomes too great for it to labour with ease; it then works towards the surface; and by pushing with its head, and the assistance of its nervous paws, gradually raises up the earth which inconceives it, and produces those small hills so common in fields. After getting rid of the earth in this manner, it proceeds forwards, and continues its labour as before. The further it goes the more hills are produced. At each period of its labour it throws up four or five.

"In places overgrown with grass and shrubs, the mole is often contented with only forcing a passage through between the roots: and when the earth in gardens has been newly watered, it keeps itself at the depth of scarcely half an inch under the surface. This animal shews an equal aversion to great cold and violent heat; and in order to avoid both, it forces its way, when either prevails, to the greatest depth in the earth.

"It continues its labour at all times, because it is necessary for it to procure nourishment. It is absolutely false that it sleeps throughout the winter, as some naturalists have asserted; for it throws up the earth in the coldest season, as well as during the summer. It is most busily employed towards the end of winter, and at that period forms the greatest number of hills. To this it is impelled by more than one reason. In the first place, it must provide nourishment for itself; secondly, it finds it easiest at that time to dig its way through the earth; and lastly, as the air begins to be milder, the animal then recovers that strength which it has lost during the intense cold. At this season, therefore, it is most proper to pursue means for exterminating this animal, as it can be destroyed with greater ease while employed at its labour.

"The male is much stronger than the female, and the hills thrown up by the former are much larger as well as more numerous. The periods when the mole is most busily employed in digging are in the morning, at sunrise, at noon, and at sunset. In dry weather moles are observed to throw up the earth for the most part only at sunrise, and in winter when the earth has been somewhat heated by the sun's rays.

"A person may easily discover how many moles are contained in a certain space of ground, by coining the fresh raised mole-hills which have no communication with each other. I must remark also, that this animal has very bad sight, being almost totally blind; but its hearing, on the other hand, is so much the more acute.

"I shall now proceed to the method of destroying them. Immediately at day-break it will be necessary to make a tour round the garden or meadow, from which it is wished to extirpate the moles; for at that time they will be all found at work, as may be seen by the hills newly thrown up. If the person is then close to the hill, he must proceed as the gardeners do, and turn up with a stroke of the spade the hill together with the digger. The passage is then cut through before the animal is aware of the attack, and therefore it has no power to escape. If the mole-hill be fresh, even though the animal may not be throwing up earth, the person ought not to lose his time in waiting, but should immediately proceed to the operation above mentioned.

"If you find a fresh hill standing by itself, which seems to shew by its situation that it has no communication with any other, which is always the case when the mole has worked from the surface downwards in endeavouring to procure a more convenient habitation, after the hill has been turned up with the spade, a bucket of water should be poured over the mouth of the passage. By these means the animal, which is at great distance, will be obliged to come forth, and may be easily caught with the hand.
"You may discover also whether a hill has any communication with another, if you apply your ear to it, and then cough or make a loud noise. If it has no communication with the neighbouring hills, you will hear the terrified animal make a noise by its motion. It will then be impossible for it to escape; and you may either pour water into the hole, or turn up the hill with a spade until the mole is found; for in general it never goes deeper into the earth than from fifteen to eighteen inches.

When any of the beds in a garden have been newly watered, the mole, attracted by the coolness and moisture, readily repairs thither, and takes up its residence in them, making a passage at the depth of scarcely an inch below the surface. In that case it may be easily caught. When you see it at work, you need only tread behind the animal with your feet on the passage to prevent its retreat, and then turn up the hill with a spade; by which means you will be sure to catch it.

When you dig after it with a spade, the animal forces its way downwards into the earth in a perpendicular direction, in order that it may better escape the threatened danger. In that case it will not be necessary to dig long, but to pour water over the place, which will soon make the animal return upwards.

People in general are not aware of the great mischief occasioned in fields and gardens by these animals. We are, however, informed by Buffon, that in the year 1740 he planted 15 or 16 acres of land with acorns, and that the greater part of them were in a little time carried away by the moles to their subterranean retreats. In many of these there were found half a bushel, and in others a bushel. Buffon, after this circumstance, caused a great number of iron traps to be constructed, by which in less than three weeks he caught 1350. To this instance of the devastation occasioned by these animals, we may add the following: In the year 1742 they were so numerous in some parts of Holland, that one farmer alone caught between five and six thousand of them. The destruction occasioned by these animals is, however, no new phenomenon. We are informed by history, that the inhabitants of the island of Tenedos, the Trojans, and the Eolians, were infested by them in the earliest ages. For this reason a temple was erected to Apollo Smyrnites, the destroyer of moles.

Insects.—Many insects, in the different states of existence through which they pass, are exceedingly troublesome and destructive. Sometimes they spread their devastations in the state of larva or grub, and sometimes in that of perfect insect.

Of the coleopterous insects, the grub of the cockchafer, which is a brownish or chestnut-colored beetle, commits the greatest ravages. This beetle appears during great part of the summer, the most plentiful in May or June, and hence called the May bug. It flies only in the evening, and lodges during the day under the leaves of trees, in which it devours, and is sometimes in such numbers, as to defoliate whole woods. The beetle deposits its eggs in the earth, and from these are hatched white or bluish grubs, that feed on the roots of grass, corn, and other vegetables, during the whole summer. In the winter they lie deep in the earth; but in the spring, as vegetation advances, they rise to the surface, and renew their work of destruction. In this state they continue for four, five, or six years, before they change to the chrysalis state, in which they remain till the month of May, when the perfect insect appears.

As these insects require so many years to assume the perfect form, they only appear occasionally sufficiently numerous to be extensively destructive to the crops of grain, or vegetables in general. Their numbers, however, have often produced great alarm, and even excited the attention of governments to offer rewards for an effectual method of destroying them.

In the spring season, if the weather prove warm, when the land is ploughed up, these grubs are generally so near the surface as to be turned up with the plough; and being thus exposed, they are picked up and devoured by various birds, which, it is suggested, should not be disturbed or driven away in this salutary labour. When these grubs infest meadow land, it has been proposed to drive them in their holes by over flowing it. But it is supposed that this plan would not be successful, even where it is practicable, unless there is a bed of clay immediately under the soil, to retain the water for a sufficient length of time. A more efficacious way is recommended to prevent the increase of the grubs, by destroying the flies in May or June, before they have deposited their eggs. This may be done by shaking and beating the trees and hedges in the middle of the day; and, as this is a work which may be performed by children, it is a less difficult task than would at first sight be imagined. Domestic fowls are remarkably fond of these beetles, so that a double object is thus gained, the destruction of the beetles and theprocuring of food for the poultry.

Some species of the dermestes, and also of the genus ptinus, are exceedingly destructive in the cabinets of naturalists, and also to furniture. Various methods have been recommended to stop their ravages. We believe the most effectual is spirit of turpentine when it can be properly applied. A solution of corrosive sublimate is sometimes employed, but it should be recollected that it seldom fails in time to produce some chemical change on animal and vegetable matters. Objects of natural history, as birds, animals, &c. are sometimes exposed to the moderate heat of an oven, or before a fire, for several hours; but this method will also be attended with injurious effects, unless practised with great care. Insects which infest furniture have been destroyed by the application of oil, and allowing it to remain for a day or two, before the furniture is rubbed up. Japaned or varnished furniture may be secured from the effects of these insects, by re-coating it, when they are in the larva state, by which they are deprived of air.ailing, and other works out of doors, which are exposed to the weather, are sometimes eaten with insects, and particularly by some of the larva of the genus curculio. The wood thus attacked may be prevented from further ravages, by a fresh coat of paint.

The earwig is a destructive insect in the flower, kitchen, and fruit garden. To prevent these depredations, it has been recommended to take them by the hand, when they come out during the night in search of food. They may be taken also by rolling up a piece of paper, and hanging it up on the plants which they infest; for in these places they take shelter through the day. Another method of destroying them has been mentioned, and that is to watch them. towards morning with the view of discovering the haunts to which they
VERMIN. [ 552 ] VERMIN.

they resist during the day; and this discovery being made, which may perhaps be a melon frame, dunghill, or heap of rubbish, the removing of which will destroy the greater number of those troublesome insects.

The small insect which commits such depredations among turnips, by eating the seeling leaves as soon as they appear, as frequently to destroy whole crops, is supposed to be a small black polished beetle, belonging to the genus Cornutana. It does not seem to be well ascertained whether this small beetle, which is better known by the name of turnip fly, commits its ravages in the larva or in the beetle state. It is said that it prefers the leaves of the common radish to those of the turnip, and it is therefore recommended to sow radishes along with the turnips to prevent the destruction of the latter.

Of the insects belonging to the order hemiptera, there are some which are exceedingly destructive. The cock-roach, a native of the warmer parts of America and the West Indies, is a very troublesome, and a very voracious insect. It has been introduced into this country, and particularly into the seaport towns, in consequence of commercial intercourse. It comes out to feed in the night-time, and eats of almost everything that comes in its way. Cock-roaches are easily taken by the following method. Cover the outside of a deep glass or bason with paper; introduce some bits of bread or sugar into the bason or glass, and set it in a place frequented by the cock-roaches. They creep up by means of the paper on the outside, and drop into the vessel; but in consequence of its smooth polished surface, they cannot effect their escape. In the same way crickets and beetles may be taken and destroyed. It is quite unnecessary to speak of the means of destroying the myriads of locusts which not unfrequently infest eastern countries, and particularly Egypt and Syria; for no means are likely to be devised, which promise to resist the effects of such an host of foes, by whose ravages every green thing is consumed; but the insect itself comes, among the poorer inhabitants of those countries, a partial substitute for the fruits of the earth which it has destroyed. The insects are taken, reduced to powder, and converted into a kind of meal.

The common or the bed-bug is a very troublesome, and a very common inmate in the crowded houses of many large towns in this country. Its usual haunts are the crevices of wood, and particularly those pieces of furniture which are usually kept in the warmest corners of the apartment. Cleanliness will perhaps be found the best preservative against the introduction and increase of these insects; but sometimes even the greatest care and attention are ineffectual in keeping houses entirely free from them. When it can be conveniently done, they are completely destroyed by immersing the furniture in boiling water, or by baking it in an oven; and by filling up the crevices or holes which were their haunts, with glaziers putty, their return and increase will thus be prevented. But a very effectual method of destroying bugs, is to wash the places which they frequent with spirit of turpentine, and then filling up the holes as already mentioned. It is a curious circumstance in the history of these insects, that some persons entirely escape from their attacks, while to others they are exceedingly troublesome and distressing. It is said that lavender-water, sprinkled over the bed clothes, often prevents their approach. How far this is the case, we have had no opportunity of ascertaining.

The small moth, which in the caterpillar state commits such ravages upon woollen cloths, furs, and other animal substances, which remain for any length of time in dark undisturbed places, may be destroyed with the greatest certainty and facility, by exposing the substance on which they are suspected to make their depredations, to the vapour of spirit of turpentine, or brushing them with a brush dipped into the same fluid. This should be done about the months of September or October; but their effects may be prevented by placing the cloths, furs, &c. which are likely to become their residence, in an airy situation, about the months of July and August.

The different kinds of lice are very numerous. Every animal has its peculiar species, and even mankind are not free from this pest. It is often the consequence of indolence and nastiness, and it is observed that the lice which infest any animal increase prodigiously when that animal becomes languid and sickly. We believe that the application of spirits of turpentine, already so often recommended, would also be effectual in this case; but a mercurial preparation is a certain remedy against these insects. For this purpose a very small quantity of what is called mercurial ointment may be employed. At the same time it ought to be recollected, that cleanliness is the best preservative. A singular notion prevails in this country, and even among persons who are by no means in the lowest rank of life, that it is a good sign of health when children's heads are infested with these animals; and on this account they are not very anxious in having them entirely eradicated. A moment's reflection may show the absurdity of such an opinion, so that it would be a waste of time to adduce serious arguments against it.

It is perhaps more difficult for mankind to secure themselves and their habitations from the visits of the common flea. Cleanliness, however, may do much even in effecting this; and in particular it appears to us, that it would be extremely useful, frequently to rub up with a piece of cloth the more inaccessible parts of furniture or apartments, or perhaps it would answer better to employ a small hard brush. By the less accessible places we mean the corners and crevices of rooms and furniture where dust is apt to collect, and especially the canvas part of a bed. We are persuaded that spirits of turpen- tine might also be found useful for the destruction of these very troublesome insects. The Scotch myrtle (myrica gale, Linn.), a plant very common in low and moist marshy places in this country, is said to be an excellent remedy, in consequence of its powerful aromatic odour, against the attacks of these animals. For this purpose, the plant is strewn about the apartment or bed which is infested with fleas.

The following method of destroying or driving away all kinds of noxious vermin from fields and gardens, it said, has been proved by experience to be effectual. It is recommended by M. Socoloff, and the account of it is taken from the Petersburgh Transactions. "As the destructive power of quicklime (says the author), height-eneded by a fixed alkali, which corrodes, dissolves and destroys all the tender parts of animals, has been long known, I thought this mixture would be the best means for accomplishing the object I had in view. I took three
three parts, therefore, of quicklime, newly made, and
two parts of a saturated solution of fixed alkali in water, introduced obtained a somewhat milky liquor sufficiently
castig, highly hostile and poisonous to earthworms and other small animals; and as soon as it touched any part
of their bodies, it occasioned in them violent symptoms of
great uneasiness. If this liquor be poured into those
holes in which the earthworms reside under ground, they
immediately throw themselves out as if driven by some
force; and, after various contortions, either languish or
die. If the leaves of plants or fruit-trees, frequented by
the voracious caterpillars, which are so destructive to
them, be sprinkled over with this liquor, these insects
suddenly contract their bodies and drop to the ground.
For, though nature has defended them tolerably well
by their hairy skins from any thing that might injure
their delicate bodies, yet, as soon as they touch with
their feet or mouths leaves which have been moistened
by this liquor, they become as it were stupefied, instant-
ly contract themselves, and fall down.

"I had not an opportunity of trying a like experi-
ment on locusts; yet we may conclude, and not without
probability, from their nature, and the general de-
structive qualities of the above liquor, that they, in like
manner, may be driven from corn-fields, if it be pos-
sible to sprinkle the corn with the liquor by means of
a machine.

"With regard to plants or corn, these sustain no in-
jury from the liquor, because it has no power over the
productions of the vegetable kingdom, as I have fully
learned from experience; or, if any hurt be sus-
pected, all the danger will be removed by the first
shower that falls. This liquor may be procured in
abundance in every place where lime is burnt. If the
lime be fresh, one part of it infused in about seventy
parts of common water will produce real lime-water.
The want of the fixed alkali may be supplied by boi-
ing wood-ashes in water, and thickening the ley by
evaporation.

"The liquor might be employed also to kill bugs and
other domestic insects which are noxious and trouble-
some; but on account of its strong licentious smell, which
disposes the human body to putridity, I dare not recom-
mand the use of it in houses that are inhabited. Besides,
bugs may be easily got rid of, as I have repeatedly
found by experience, by the oily pickle that remains
in casks in which salted herrings have been packed. To
this liquor they have a strong aversion; and, if they are
moistened with it, they die in a very short time."

For destroying insects and caterpillars, which infest
fruit-trees, the following method is recommended as
having been successfully practised. The author observes
that "The present year, for instance, (1850), offers a
singularity which I have not before perceived. In some
districts the cherry tree has experienced, at the time of
its blossoming, colds and winds which have prevented it
from setting; but another plague, not less disastrous has
attacked the cherry-trees and plum-trees over several
districts in France. Great swarms of little animals re-
ssembling vine-fretters, but which are not so in reality,
established their habitations at the extremity of the
branches of the cherry-trees. As soon as a branch was
attacked, the leaves curled, and the juice was dried up.
On opening the leaf, a considerable number of ants was
discovered, which, jointly with the insect which began
the ravages, sucked the branch, and made it wither."

What I have remarked is, that usually, when the vine-
fruiters attack any tree, the neighbouring tree very
soon experiences the same fate; but the attack of this
year is only partial. In an alley of cherry-trees which
I possess, seven trees have been attacked, but not those
which are next each other. One tree was placed be-
tween two which were very much damaged by these
insects, and yet this one was not hurt.

"On these vermin the smoke of tobacco had no ef-
effect at all; this convinces me that they are different
from the ordinary kind.

Plum-trees, when attacked by the same insect, do
not lose their fruit like the cherry-trees; but the little
animals cover them with more rapidity, so as to extir-
parate the appearance of fruit.

"Having effectually watered a plum-tree, I covered
it with ashes, in the manner we treat beans and call-
bages, and the vermin were destroyed: but this is only
practicable with a tree of low height.

"I made one remark, which I think is essential to
communicate: it is, that plum-trees planted in ground
which is not necessarily watered, are less attacked by
these insects than those which have experienced a hu-
midity communicated by the plants in their neighbour-
hood, to which watering is absolutely necessary. I had
one planted in a bed of artichokes: we know very well
that this plant requires plenty of water; and the tree
was entirely covered with insects. Its leaves withered,
and the fruit fell off; while two other plum-trees, in
ground not watered at all, were much less attacked.
This convinces me that these were not the ordinary ver-
min abundant in dry seasons.

"I was only able to protect my cherries a little, by
cutting off the extremities of the damaged branches.

"Several people had recourse to sulphur; but I did
not follow that method. The smoke of sulphur destroys
the insect, I admit, but it is at least equally dangerous
to the tree; I always prefer an aspersion of the tree with
soap-suds. This very year I experienced the good effects
of it. I saw my plum-trees look green again, and the
insects abandon them. The aspersion is very easily ma-
aged, by means of watering-pots or small garden-engi-
nes. I have also employed a ley of wood-ashes with the
same success as soap and water.

"An observation equally important which I have
made is, the great damage done this season inall orchards
by the caterpillar. As soon as they devoured the young
leaves, they attacked the fruit. In spite of the great
care taken in spring to get rid of them, the number of
these insects is incredible. I have seen them unite on
the large branches, fix their nests to them, and protect
them by means of the downy matter which covers the
buds of the ensuing season. Whatever precaution is
taken, it is almost impossible not to destroy these buds.
It is only necessary to take off these nests and burn
them; and this is the only way of getting rid of the
coves. I employed the same aspersions for my apple-
trees, and by that means got rid of their enemies also.

"The following methods are practised in Germany
for freeing granaries from mites or weevils:

1. Cover completely the walls and rafters, above
and below, of the granaries which are infested by weev-
ils, with quicklime slaked in water in which trefoil,

A

warmwood,
The following method, discovered by M. Catlin, is proposed for destroying earth-flies, bugs, ants, &c.

Take black soap, of the best kind, one pound three quarters, the same quantity of flowers of sulphur, mushrooms two pounds, and sixty measures of river or rain-water. Divide the water into two parts, one of which must be poured into a vessel destined for that purpose: cover the soap to dissolve in it, and add the mushrooms after they have been a little pounded. Boil the other half of the water in a kettle, and tie up the sulphur in a bit of a rag or piece of fine linen, and suspend from it a sufficient weight in order that it may sink in the water. During the time the water is kept boiling, which must be at least 20 minutes, stir it continually with a stick, and press the bag containing the sulphur, that the latter may be forced out into the water, and communicate to it the necessary strength and colour.

When the liquor is taken from the fire, pour it directly into the cask, and stir it round for a considerable time: the process of stirring must be repeated daily till it acquire a fetid smell. Experience has shown that the more fetid the mixture is, its activity is the greater. Each time that the mixture is stirred, the cask must be stopped immediately after. When you wish to use the liquid, nothing is necessary but to sprinkle a little of it on the plants which you desire to preserve, or to dip their branches in it. It will be better, however, to make use of a syringe, having at the end a head, an inch or an inch and a half in diameter, pierced with small holes. This instrument may be used for tender plants; when you apply the liquid to trees, a syringe with larger holes must be employed.

Caterpillars, beetles, earth-flies, bugs, and the tree-llice which infest orange trees, will be destroyed by the first application of the liquid. Insects which reside below the earth, such as wasps, hornets, ants, &c., require that the liquid should be squirted out gently, and without interruption, that it may better penetrate to their nests. Ants nests, according to their size, require from two to three measures of liquid, and in many cases it must be applied for twenty-four hours. When the ants assemble in another place, the process must be repeated. Two ounces of muscomica may be added to the mixture, and boiled along with the sulphur.

The use of elder as a preservative to vegetables against the depredations of insects is detailed in the following observations.

Common elder has appeared to me useful, 1st. For preventing cabbage plants from being devoured or damaged by caterpillars; 2d. To prevent blights, and their effects on fruit and other trees; 3d. To preserve corn from yellow flies and other insects; 4th. To secure turnips from the ravages of flies, &c.

1st. The strong and fetid odour of a bunch of elder leaves induced me to think that different kinds of butterflies might be incommode by it in proportion to their delicacy. I therefore took some young twigs of elder, at the period when butterflies began to appear, and whipped well with them some cabbage plants, but in such a manner as not to damage them. Since that time, during two summers, though the butterflies hovered round the plants, I never saw one of them settle on them; and I do not think that a single butterfly was hatched on the cabbages treated in this manner, though a neighbouring board was dirtied by them in the usual manner.

2d. After a short reflection on the effects here mentioned, and on blights, which, in my opinion, are chiefly occasioned by small flies and small insects, whose egges are still more delicate than those of the former, I was induced to whip in the same manner with elder twigs, as high as I could reach, the branches of a plum-tree which grew in an espalier. The whipped leaves remained green and in a good condition, while from at least six inches above to the top of the tree the rest of the leaves were blighted, wrinkled, and full of worms. It is here to be observed that the tree was in full flower when I whipped it, therefore much too late for this operation, which ought to have been performed once or twice before flowering. But I am of opinion, that if trees were besprinkled with a strong infusion of elder every eight or 15 days, the success would be certain, and that there would be no danger of injuring either the flowers or the fruit.

3d. What the farmers call the yellows in corn, and which they consider as a kind of blight, is the effect, as every one knows, of a small yellow fly with blue wings, nearly of the size of a gnat. It lays its eggs in the ear of wheat, and produces a worm almost invisible to the naked eye, but which, when seen by a magnifying glass, is a large yellow larva, having the shining colour of amber. This fly is so productive, that I have counted upwards of forty worms in the shaft of one ear of wheat, which was a number sufficient to destroy it entirely. I therefore proposed to make my experiment as soon as possible; but the heat and drought of the season having advanced the wheat more than usual, it was in flower before I could attempt it. Next morning, however, at break of day, two servants having drawn bundles of elder over the ears of wheat on each side of the furrow, backwards and forwards, in places where the wheat was not so far advanced, I hoped that the fetid effluvia of the elder would prevent the flies from remaining on the ears that were covered with them: and, indeed, I was not entirely disappointed: for, on examining my wheat some time after, I found that the part which had been beaten with elder was much less damaged than that which had not been treated in the same manner. I have no doubt, that, had I employed this precaution sooner, the corn would have been completely preserved. Should this be the case, the process is simple; and I flatter myself that fine crops of corn may be saved by these means from this small insect, which is so destructive to them. One of these yellow flies laid on my thumb at least eight or ten eggs, of an oblong form, in the small interval of time which I employed in walking over two or three furrows, holding it by the wings, and which I could not observe without the assistance of a magnifying glass.

4th. It often happens that whole crops of turnips are destroyed while young, in consequence of being pricked by certain insects. I have great reason to think that this evil may be prevented in an effectual manner, by causing a person to draw a bunch of elder, sufficiently large to cover about the breadth of a foot, over the young turnips, going backwards and forwards. What confirms me in this idea is, that, having drawn a bunch of elder over a bed of young cauliflowers which had begun to be pricked, they afterwards remained untouched by these insects.

Another
Another fact which tends to support this idea is that when my neighbourhood, about eight or nine years ago, was so infested with caterpillars that they devoured all the vegetables, leaving scarcely a green leaf untouched, they spared the elder trees amidst this general devastation, and never molested them. In reflecting on these circumstances, I am of opinion that the elder might be introduced, with advantage in our gardens, as the means of preserving fruit-trees and various plants from the ravages of insects.

The dwarf elder appears to me to exude a much more fetid smell than the common elder, and therefore ought to be preferred in making experiments on this subject.

Vermont, one of the states of the North American republic. It is entirely an inland state, and has New Hampshire on the east, Massachusetts on the south, New York on the west, and Canada on the north. Its area is 10,237 square miles; and the inhabitants in 1810 amounted to 217,856. The country is traversed by the Green mountains, from which the state takes its name; but though hilly and uneven, it is generally fertile. The whole surface in its natural state is thickly wooded. The snow lies from the middle of December to the middle of March. The extreme summer heat is about 94° F.; the extreme winter cold 27° below zero; the mean heat 43°. Lake Champlain forms the western boundary of this state for three fourths of its length, and Connecticut river the eastern boundary through its whole extent. There are several small streams besides these, but no other considerable rivers in the state.

There are rich mines of iron in Vermont, and mines of lead and copper of less importance. Marble and slate are also found in it. Its natural forests furnish timber of large size, and a great variety of kinds. Of quadrupeds, there are the bear, wolf, wild cat, fox, ermine, raccoon, beaver and musk rat. The lakes and rivers furnish a great variety of fish.

The inhabitants have a more florid complexion than those of the middle and southern states. They are temperate and industrious, and with a few exceptions are engaged in agriculture.

The legislature consists of a general assembly chosen annually by ballot, by the male taxable citizens of twenty-one years of age; and the executive power is invested in a governor, lieutenant-governor, and twelve counsellors chosen along with the representatives. A peculiar feature in the constitution, is the council of censors, thirteen in number, chosen every seven years by the people, to examine and report upon the proceedings of the executive and the representatives, and with power to call a convention of the people to amend the constitution. The judges are chosen annually by the council and assembly. A portion of land out of each township is set apart for the support of the clergyman of any denomination that is first settled. The prevailing sect are the Congregationalists, the next in number the Baptists. Tracts of land have been set apart also for the support of schools. There are two colleges, at Burlington and Middlebury.

The value of houses and lands in this state in 1790 was 167,232,873 dollars, and in 1814 it was 32,747,295, and the average value of lands at the latter period was 6 dollars 40 cents per acre. The manufactures of this state in 1810 were valued at 4,325,824 dollars; and Vermont the exports in 1817 amounted to 913,201 dollars.

VERNACULAR, a word applied to something that is peculiar to any one country.

VERNAL, something belonging to the spring-season.

Vernier's method is derived from the following principle. If two equal right lines, or circular arcs, A, B, are so divided, that the number of equal divisions in B is one less than the number of equal divisions of A, then will the excess of one division of B above one division of A be compounded of the ratios of one of A to B, and of one of B to B.

For let A contain 11 parts, then one of A to B is as 11 to 10, or $\frac{1}{\frac{11}{10}}$. Let B contain 10 parts, then one of B to A is as 10 to 11, or $\frac{10}{11}$.

Now $\frac{1}{\frac{11}{10}} \times \frac{10}{11} = \frac{10}{11} \times \frac{11}{10} = 1$.

Or if B contains n parts, and A contains $n + 1$ parts; then $\frac{1}{n+1}$ is one part of B, and $\frac{1}{n}$ is one part of A.

And $\frac{1}{n+1} \times \frac{n}{n+1} = \frac{n}{n+1}$.

The most commodious divisions, and their aliquot parts, into which the degrees on the circular limb of an instrument may be supposed to be divided, depend on the radius of that instrument.

Let R be the radius of a circle in inches; and a degree to be divided into n parts, each being $\frac{1}{n}$ part of an inch.

Now the circumference of a circle, in parts of its diameter 2R inches, is $3,141.5926 \times 2R = 3,141.5926 \times \frac{360}{2R}$ inches.

Or, $0.01745329 \times 2R$ is the length of one degree in inches.

Or, $0.01745329 \times 2R \times 10 = 0.5236 \times 10$ is the length of 10 parts of an inch.

But as every degree contains n times such parts, therefore $n = 0.01745329 \times 2R \times 10$.

The most commodious perceptible division is $\frac{1}{8}$ or $\frac{1}{8}$ of an inch.

Example. Suppose an instrument of 30 inches radius, into how many convenient parts may each degree be divided? how many of these parts are to go to the breadth of the vernier, and to what parts of a degree may an observation be made by that instrument?

Now $0.01745 \times 30 = 0.5236$ inches, the length of each degree; and if p be supposed about $\frac{1}{8}$ of an inch for one division; then $0.5236 \times p = 0.188$ shows the number of such parts in a degree. But as this number must be an integer, let it be 4, each being $1.5^\circ$; and let the breadth of the vernier contain $3^1$ of those parts, or $72^\circ$, and be divided into 30 parts.
Here \( n = \frac{1}{2} \); \( m = \frac{1}{3} \); then \( \frac{1}{5} \times 3 = \frac{3}{5} = 60 \) of a degree, or 30, which is the least part of a degree that an instrument can show.

If \( n = \frac{1}{2} \) and \( m = \frac{1}{3} \); then \( \frac{1}{5} \times 3 = 60 \) of a minute, or 20-

The following table, taken as examples in the instruments commonly made from 3 inches to 8 feet radius, shows the divisions of the limb to nearest tenths of inches, so as to be an aliquot of 60's, and what parts of a degree may be estimated by the vernier, it being divided into such equal parts, and containing such degrees as their columns show:

By altering the number of divisions, either in the degrees or in the vernier, or in both, an angle can be observed to a different degree of accuracy. Thus, to a radius of 30 inches, if a degree be divided into 12 parts, each being five minutes, and the breadth of the vernier be 21 such parts, or 1 3/4, and divided into 20 parts, then \( \frac{1}{12} \times \frac{1}{20} = \frac{1}{240} = 15'' \); or taking the breadth of the vernier 2 3/4, and divided into 30 parts; then \( \frac{1}{12} \times \frac{3}{30} = \frac{1}{60} = 6'' \); where the breadth of the vernier is 45''.

VERONA, a city of Italy, capital of the Veronese, and in the territory of Venice, now subject to Austria; situated on the river Adige, in E. Long. 11° 24'. N. Lat. 45° 26'. It is seven miles in compass; and is strongly fortified. It contains 57,400 inhabitants.

VERONESE, a district of Italy, in the Austro-Venetian territories; bounded on the north by the Treviso, on the east by the Vicentino and Paduano, on the south by the Mantuan, and on the west by the Bresciano. It is about 50 miles in length, and 27 in breadth; and fertile in corn, wine, fruits, and cattle.

VERONESE. See CAGLIARI.

VERONICA, a genus of plants of the class of dianthia; and in the natural system arranged under the 40th order. Personata. See BOTANY INDEX.

VERSAILLES, a town of France, in the depart-ment of Seine and Oise, 10 miles west-south-west of Pa- ris. It contained 26,000 inhabitants in 1817, and since the Revolution has been created a bishop's see. In the Vexin reign of Louis XIII. it was only a small village. This prince built here a hunting-hut in 1630, which Basme-pierre calls "the paltry chateau of Versailles." Although the situation was low and very unfavourable, Louis XIV. built a magnificent palace here, which was the usual residence of the kings of France till the 6th of October 1789, when the late unfortunate Louis XVI. and his family were removed from it to the Tuileries. By the palace and gardens are adorned with a vast number of statues, done by the greatest masters, and the water-works are all worthy of admiration. The great gallery is thought to be as curious a piece of workmanship of that kind as any in the world; nor is the chapel less to be admired for its fine architecture and ornaments. The gardens, with the park, are five miles in circumference, and surrounded by walls. There are three fine avenues to Versailles; one of which is the common road to Paris, the other comes from Nantes, and the third from St. Cloud. E. Long. 2° 12'. N. Lat. 49° 48.'

VERSE, in Poetry, a line consisting of a number of long and short syllables, which run with an agreeable cadence. Verse is also used for a part of a chapter, section, &c.

VERSION, the act or manner of making verse; also the tune and cadence of a verse. See POETRY, Part III.

VERTEBRAE. See ANATOMY, No. 30.

VERTEX, in Anatomy, denotes the crown of the head. Hence vertex is also used figuratively for the top of other things: thus we say, the vertex of a cone, pyramid, &c.

VERTEX, is also used in Astronomy for the point of the heaven directly over our heads, properly called the zenith.

VERTICILLATE, the name of a class in Ray's and Boerhaave's Methods, consisting of herbaceous vegetables. It is also the name of the 42d order in Lin- neaus's Fragments of a Natural Method.

VERTICILLUS, a mode of flowering, in which the flowers are produced in rings at each joint of the stem, with very short foot-stalks. The term is exemplified in mint, horsemint, and the other plants of the natural order described above.

VERTICITY, is that property of the leadsome whereby it turns or directs itself to one particular point.

VERTIGO, in Medicine. See there, No. 82.

VERTUMNUS, in Mythology, a god who presided over gardens and orchards, honoured among the Europeans, from whom the worship of this deity was trans- mitted to the Romans.

Vertumnus had a temple near the market-place at Rome, being represented as one of the tutelary deities of the merchants. The commentators on Ovid say, that.
Vertumnaus that he was an ancient king of Hetruria, who, by his diligent and successful cultivation of fruit and garden, obtained the honour of being ranked among the gods.

VERUMONTANUM, in Anatomy, a small eminence near the passages where the semen is discharged into the urethra.

VERVAIN. See Verbenae, Botany Index.

VERTOT d'AUBOEF, René Aubert de, a celebrated historian, who descended from a noble and ancient family in Normandy, and born in 1655. At 16 years of age he became a Franciscan friar; afterwards he entered into the order of the Premonstratensians, in which he had several benefices: and at length was a secular ecclesiastic. He became secretary to the duchess of Orleans, member of the Academy of Inscriptions, and historiographer of Malta. He died at Paris in 1735. His principal works are: 1. The History of the Revolutions of Sweden. 2. The Revolutions of Portugal. 3. The Revolutions of the Romans. 4. The History of Malta. These works are written in elegant French, and translated into most of the languages of Europe.

VERULAM. See Bacon.

VESALIUS, ANDREAS, a celebrated physician and anatomist, was born at Brussels about the year 1512. He studied physic at Paris under James Sylvius; but applied himself chiefly to anatomy, which was then very little known, dissections being esteemed unlawful and impious: and it appears from his work De Humani Corporis Fabrica, that he perfected himself in this useful knowledge very early. About the year 1537, the republic of Venice made him professor in the university of Padua, where he taught anatomy for seven years; Charles V. called him to be his physician, as he was also to Philip II. king of Spain. Vesalius was now at the height of his glory, when all of a sudden he formed the design of taking a journey to Palestine; concerning which journey we are told the following story. A young Spanish nobleman he attended, being believed to be dead, Vesalius obtained leave to open him to explore the true cause of his illness; but when he opened the breast, he perceived symptoms of life, and saw the heart beat. The parents, not satisfied with prosecuting him for murder, accused him of impiety to the inquisition, in hopes that tribunal would punish him with greater vigour: but the king interposing, saved him on condition of his making a pilgrimage to the Holy Land. He was shipwrecked on his return, and thrown upon the island of Zante, where he perished, in 1564. He was the author of several works, the principal of which is De Humani Corporis Fabrica.

VESICATORIUM, a Blister; an application of an acrid nature made to any part of the body, in order to draw a flux of humours to that part, and thus elevate the scarfskin into a blister.

VESPA, the Wasp; a genus of insects belonging to the order of hymenoptera. See Entomology Index.

VESPAESIAN, the 10th emperor of Rome; remarkable for his clemency and other virtues. See Rome, No. 332-339.

VESPERIS, in the church of Rome, denote the afternoon service; answering in some measure to the evening prayers of the church of England.

VESPERTILIO, the Bat; a genus of quadrupeds, belonging to the order of primates. See Mammalia Vesperilidae.

VESSEL, a general name given to the different sorts of ships which are navigated on the ocean, or in canals and rivers. It is, however, more particularly applied to those of the smaller kind, furnished with one or two masts. See Ship.

VESTA, in pagan worship, the same with Cybele. See Cybele.

VESTA the Younger, in pagan worship, the goddess of fire, was the daughter of Saturn and Cybele, and the sister of Ceres. She was so much in love with chastity, that on Jupiter's ascending the throne and offering to grant whatever she asked, she only desired the preservation of her virginity, which she obtained.—Vesta was not represented in her temple by any image.

VESTAS, one of the later discovered planets, of which the elements have been determined by Dr. Gauss in a communication to the Royal Society of Gottingen.

Elements of Vesta.

Epoch of the longitude, meridian of Seeberg 108° 19' 34.7".

Diurnal tropical motion 77° 8' 85.49°.

Annual Aphelion, 1806 78 9 23.

Annual motion 326 37 59.

Annual motion 44 2 1.2.

Ascending node, 1806 80 53 23.

Inclination of the orbit, 1806 10 37 34.

Annual diminution 0.4.

Eccentricity, 1806 0.0783486.

Annual diminution 0.000000038.

Log. of the greater semiaxis 0.44270287.

Elements of Ceres by the same.

Epoch of the mean longitude at Bremen, March 20, 1807, at 12 o'clock, mean time 193° 8' 46.20°.

Longitude of its perihelion 209 7 41.

— aphelion 69 57 52.

— ascending node on the ecliptic 103° 8' 36'.

Inclination of its orbit 7.5 49.5°. + ibid.

Diurnal tropical motion 16 18.91 7° 34'.

Logarithm of the mean distance 0.3723428.

Eccentricity 0.0970305.

Greatest distance from the sun 25 625.

Least 21 514.

Period of its revolution 1321 days, 12 hours.

VESTALIA, in Roman antiquity, a festival celebrated in honour of the goddess Vesta, on the 5th of the ides of June; that is, on the 9th of the month.

VESTALS, among the ancient Romans, were priestesses of the goddess Vesta, and had the perpetual fire committed to their charge; they were at first only four in number, but afterwards increased to six; and it does not appear that their number ever exceeded six, among whom was one superior to the rest, and called vestalis maxima.

The vestals were chosen from six to ten years of age, and obliged to strict continency for 30 years; the first of which were employed in learning the ceremonies of religion, the next 10 in the performance of them, and the 10 last in teaching them to the younger vestals.
The habit of the vestals consisted of a head-dress, called *infusa*, which sat close to the head, and from whose hung certain laces called *vittae*; a kind of sur- plice made of white linen, and over it a purple mantle with a long train to it.

**VESTIBLE** or **VESTIBULUM**, in *Architecture*, a kind of entrance into a large building; being an open place before the hall, or at the bottom of the staircase.

**VESTRY**, a place adjoining to a church, where the vestments of the minister are kept; and also a meeting patchplace, consisting of the minister, church-warden, and chief men of most parishes, who make a parish vestry or meeting. By custom there are select vestries, being a number of persons chosen to have the government of the parish, make rates, and take the accounts of church-wardens, &c.

**VESUVIAN**, a mineral substance. See Mineralogy Index.

**VESUVIUS**, a celebrated volcano of Italy, five miles from the city of Naples. This mountain has two tops; one of which only goes by the name of Vesuvius, the other being now called Somma; but Sir William Hamilton is of opinion, that the latter is what the ancients called Vesuvio. The perpendicular height of Vesuvius is only 3700 feet, though the ascent from the foot to the top is three Italian miles. One side of the mountain is well cultivated and fertile, producing a great plenty of vines; but the south and west sides are entirely covered with cinders and ashes; while a sulphureous smoke constantly issues from the top, sometimes attended with the most violent expansions of stones, the emission of great streams of lava, and all the other attendant of a most formidable volcano. The first of these eruptions recorded in history took place in the year 79; at which time the two cities of Pompeii and Herculaneum were entirely buried under the stones and ashes thrown out. Incredible mischief was also done to the neighbouring country, and numbers of people lost their lives, among whom was Pliny the Elder.

It is the opinion of the best judges, however, that this eruption was by no means the first that had ever happened. The very streets of those cities which were at that time overflowed are said to be partly paved with lava. Since that time 39 different eruptions have been recorded, some of which have been extremely violent. In the year 1538, a mountain, three miles in circumference, and a quarter of a mile in perpendicular height, was thrown up in the course of one night.

The first great eruption taken notice of by Sir William Hamilton was that of 1767, which, though very violent, was mild in comparison with that of 1758.

From this time (1767) Vesuvius never ceased for ten years to send forth smoke, nor were there many months in which it did not throw out stones, scoria, and cinders; which, increasing to a certain degree, were usually followed by lava; so that from the year 1767 to 1779 there were nine eruptions, some of them very considerable. In the month of August that year, however, an eruption took place, which, for its extraordinary and terrible appearance, may be reckoned among the most remarkable of any recorded concerning this or any other volcano.

During the whole month of July the mountain continued in a state of fermentation. Subterraneous explo-
 Vesuvius. hing subterranean noise was heard in the neighbourhood of the volcano; the usual throws of red-hot stones and scoriae began and increased every instant. The crater, viewed through a telescope, seemed much enlarged by the violence of last night’s explosions, and the little mountain on the top was entirely gone. About nine o’clock a most violent report was heard at Portici and its neighbourhood, which shook the houses to such a degree as made the inhabitants run out into the streets. Many windows were broken, and walls cracked by the concussion of the air on this occasion, though the noise was but faintly heard at Naples. In an instant a fountain of liquid transparent fire began to rise, and gradually increasing, arrived last at the amazing height of ten thousand feet and upwards. Puffs of smoke, as black as can possibly be imagined, succeeded one another hastily, and accompanied the red-hot, transparent, and liquid lava, interrupting its splendid brightness here and there by patches of the darkest hue. Within these puffs of smoke, at the very moment of emission, a bright but pale electrical fire was observed playing briskly about in zig-zag lines. The wind was south-west, and, though gentle, was sufficient to carry these puffs of smoke out of the column of fire; and a collection of them by degrees formed a black and extensive curtain behind it; in other parts of the sky it was perfectly clear, and the stars bright. The fiery fountain, of such immense magnitude, on the dark ground just mentioned, made the finest contrast imaginable; and the blaze of it reflected from the surface of the sea, which was at that time perfectly smooth, added greatly to this sublime view. The lava, mixed with stones and scoriae, having risen to the amazing height already mentioned, was partly directed by the wind towards Ottaviano, and partly falling, still red hot and liquid, upon the top of Vesuvius, covered its whole cone, part of that of the summit of Somma, and the valley between them. The falling matter, being nearly as inflammation and vivid as that which was continually issuing fresh from the crater, formed with it one complete body of fire, which could not be less than two miles and a half in breadth, and of the extraordinary height above mentioned, and casta heast to the distance of at least six miles round. The brushwood on the mountain of Somma was soon in a blaze, and the flame of it being of a different colour from the deep red of the matter thrown out by the volcano, and from the silvery blue of the electrical fire, still added to the contrast of this most extraordinary scene. The black cloud, increasing greatly, once bent towards Naples, and threatened the city with speedy destruction; for it was charged with electrical fire, which kept constantly darting about in bright zig-zag lines. This fire, however, rarely quitted the cloud, but usually returned to the great column of fire whence it proceeded; though once or twice it was seen to fall on the top of Somma, and set fire to some dry grass and bushes. Fortunately the wind carried back the cloud just as it reached the city, and had begun to occasion great alarm. The column of fire, however, still continued, and diffused such a strong light, that the most minute objects could be discerned at the distance of ten miles or more from the mountain. Mr Morris informed our author, that at Sorrento, which is 12 miles distant from Vesuvius, he read the title-page of a book by that volcanic light.

All this time the miserable inhabitants of Ottaviano were involved in the utmost distress and danger by the showers of stones which fell upon them, and which, had the eruption continued for a longer time, would most certainly have reduced their town to the same situation with Herculanum and Pompeii. The mountain of Somma, at the foot of which the town of Ottaviano is situated, hides Vesuvius from the view of its inhabitants; so that till the eruption became considerable it was not visible to them. On Sunday night, when the noise increased, and the fire began to appear above the mountain of Somma, many of the inhabitants flew to the churches, and others were preparing to quit the town, when a sudden and violent report was heard; soon after which they found themselves involved in a thick cloud of smoke and ashes; a horrid crashing noise was heard in the air, and presently fell a vast shower of stones and large pieces of scoriae, some of which were of the diameter of seven or eight feet, which must have weighed more than 1,000 pounds before they were broken, as some of the fragments which Sir William Hamilton found in the streets still weighed upwards of 20 pounds. When these large vitrified masses either struck against one another in the air, or fell on the ground, they broke in many pieces, and covered a large space of ground with vivid sparks of fire, which communicated their heat to every thing that was combustible. The fragments of these masses were formed of the liquid lava; the exterior parts of which were become black and porous by cooling in their fall through such a vast space; whilst the interior parts, less exposed, retained an extreme heat, and were perfectly red.

In an instant the town and country about it was on fire in many parts, for there were several straw huts in the vineyards, which had been erected for the watchmen of the grapes; all of which were burnt. A great magazine of wood in the heart of the town was all in a blaze; and had there been much wind, the flames must have spread universally, and all the inhabitants would have been burnt in their houses; for it was impossible for them to stir out. Some, who attempted it with pillows, tables, chairs, the tops of wine casks, &c. on their heads, were either knocked down or soon driven back to their close quarters under arches and in the cellars of their houses. Many were wounded, but only two persons died of their wounds.

To add to the horror of the scene, incessant volcanic lightning was whisking about the black cloud that surrounded them, and the sulphurous smell and heat would scarcely allow them to draw their breath. In this dreadful situation they remained about 25 minutes, when the volcanic storm ceased all at once, and Vesuvius remained sullen and silent.

Some time after the eruption had ceased, the air con- Vast quan-tined greatly impregnated with electrical matter. The city of Cetotofo, armed with a pointed wire, out at his window at Naples, it soon became considerably charged. But whilst the eruption was in force, its appearances was too alarming to allow one to think of such experiments.

—He was informed also by the prince of Monte Mileto, that
Vesuvius, that his son, the duke of Popoli, who was at Monte
Mileo the 8th of August, had been alarmed by the
shower of cinders that fell there; some of which he had
sent to Naples weighing two ounces; and that stones of
an ounce weight had fallen upon an estate of his ten
miles farther off. Monte Mileo is about 30 miles
from the volcano. The abbé Cugliani also related, that
his sister, a nun in a convent at Manfredonia, had writ-
ten to inquire after him, imagining that Naples must
have been destroyed, when they, at so great a distance,
were alarm by a shower of ashes which fell on the
city at 11 o'clock at night, so much as to open all the
churches, and go to prayers. As the great eruption
happened at nine o'clock, these ashes must have travel-
el 100 miles in the space of two hours.

Nothing could be more dismal than the appearance
of Otranto after this eruption. The houses were un-
roofed, half buried under the black scoriæ and ashes;
all the windows towards the mountain were broken,
and some of the houses themselves burnt; the streets
choked up with ashes, in some narrow places not less
than four feet thick; and a few of the inhabitants who
had just returned, were employed in clearing them
away, and piling them up in hillocks, to get at their
ruined houses. The palace of the prince of Otranto is
situated on an eminence above the town, and nearer the
mountain. The steps leading up to it were deeply co-
vered with volcanic matter; the roof was totally de-
stroyed, and the windows broken, but the house itself,
being strongly built, had not suffered much.

An incredible number of fragments of lava were
thrown out during the eruption, some of which were of
immense magnitude. The largest measured by Sir Wil-
liam Hamilton was 108 feet in circumference and 17
in height. This was thrown at least a quarter of a mile
clear of the mouth of the volcano. Another, 66 feet
in circumference and 19 in height, being nearly of a
spherical figure, was thrown out at the same time, and
lay near the former. This last had the marks of being
rounded, nay almost polished, by continual rolling in
torrents or on the sea-shore. Our author conjectures
that it might be a spherical volcanic salt, such as that
of 45 feet in circumference mentioned by M. de St.
Fond, in his Treatise of Extinguished Volcanoes.
A third of 16 feet in height and 92 in circumference
was thrown much farther, and lay in the valley between
Vesuvius and the Hermitage. It appeared also, from
the large fragments that surrounded this mass, that it
had been much larger while in the air.

Vesuvius continued to emit smoke for a considerable
time after this great eruption, so that our author was
apprehensive that another would soon ensue; but from
that time nothing comparable to the above has taken
place. From the time of this great eruption to the
year 1784 our author kept an exact diary of the opera-
tions of Vesuvius, with drawings, showing, by the
quantity of smoke, the degree of fermentation within
the volcano. The operations of the subterranean fire,
however, appear to be very capricious and uncertain.
One day there is the appearance of a violent fer-
melation, and the next ev'ry thing is tranquil; but
whenever there has been a considerable ejection of scoriæ
and cinders, it has been a constant observation, that the
lava soon made its appearance, either by boiling over the

crater, or forcing its way through the crevices in the con-
ical part of the mountain. An eruption took place in 1764,
but without any remarkable circumstance, and another in
1794 which destroyed 5000 acres of cultivated land.

Vetch. See Vicia, Botany Index.

Veteran, among the ancient Romans, an appel-
lion given to a soldier grown old in the service, or
who had made a certain number of campaigns.

Veterinary Art. See Farriery.

Vexillum, in Botany; the upper petal of a pes-
bloom, or butterfly-shaped flower, which is generally
larger than any of the others.

Viales, in mythology, a name given among the
Romans to the gods who had the care and guard of the
roads and highways.

Viatricum, in Roman antiquity, an appellation
given in common to all officers of any of the magis-
trates; as Victors, occens, scribes,criers.

Vibex, is sometimes used by physicians, for a black
and blue spot in the skin occasioned by an effusion or
extravasation of blood.

Vibration, in Mechanics, a regular, reciprocal
motion of a body, as a pendulum.

Viburnum, a genus of plants of the class pen-
tandra; and in the natural system arranged under the 436
order, Dumaæa. See Botany Index.

vicar, a person appointed as deputy to another, to
perform his functions in his absence, and under his
authority.

Vicar, in the canon-law, denotes a priest of a parish,
the prelatical tithes whereof are appropriated or appropri-
ated; that is, belong either to a chapter, religious
house, &c. or to a layman who receives them, and only
allows the vicar the small tithes, or a convenient salary.
See the article Parson and Vicar.

Vice, in ethics, is ordinarily defined an elective
habit, denoting either an excess or defect from the just
medium wherein virtue is placed.

Vice, in smeltery and other arts conversant in me-
tals, a machine or instrument serving to hold fast any
thing they are at work upon, whether it is to be beaten,
filed, or rivetted.

Vice is also used in the composition of divers words
to denote the relation of something that comes instead
or in the place of another; as vice admiral, vice-cham-
cellor, &c. are officers who take place in the absence
of admirals, &c.

Viceroy, a governor of a kingdom, who com-
mands in the name and instead of a king, with full and
sovereign authority.

Vicia, a genus of plants of the class dialephus;
and in the natural system arranged under the 326 order,
Papilionaceæ. See Botany Index.

Vicissitude, the regular succession of one thing
after another; as the vicissitude of day and night, of
the seasons, &c.

Victim, denotes a sacrifice offered to some deity,
of a living creature, as a man or beast, which is slain
to appease his wrath, or to obtain some favour.

Victor, Sextus Aurelius, a Roman historian,
who flourished under the emperors Constantius and Ju-
lian; as we learn from many passages in his own writ-
ings, and also from Ammianus Marcellinus. This his-
torian relates, that Constantius made him consul, and
These magnificent suburbs, and the town together, are said to contain above 320,000 inhabitants; yet the former are not near so populous, in proportion to their size, as the town; because many houses in the suburbs have extensive gardens belonging to them, and many families, who live during the winter within the fortifications, spend the summer in the suburbs. The cathedral is built of free-stone, is 114 yards long, and 48 broad, and the steeple is 447 feet high. The university had several thousand students, who, when this city was besieged, mounted guard. Beside this, there is the academy of Lower Austria; and the archdotal library is much frequented by foreigners, as it contains above 100,000 printed books, and 10,000 manuscripts. The academy of painting is remarkable for the fine pictures it produces. The archdotal treasury, and a cabinet of curiosities of the house of Austria, are great rarities. The inhabitants, in general, live in a splendid manner; and people of distinction have all sorts of wines at their tables, which they are very free with to foreigners.

There is a sort of harbour on the Danube, where there are magazines of naval stores, and ships have been fitted out to serve on that river against the Turks. Vienna is an archdotal’s see. It is seated at the place where the river Vienna or Wein, falls into the Danube, 30 miles west of Presburgh, 330 north-north-east of Rome, 520 south-east by south of Amsterdam, 555 east of Paris, and 680 east-south-east of London. E. Long. 16. 15. N. Lat. 48. 15.

VIENNE, a department in the west of France, forming part of the ancient Poitou. It derives its name from the river Vienne which runs through it, and falls into the Loire. There are extensive tracts of heath in this department; but the soil in other parts yields in abundance, grain, hemp, flax, fruits, and vines. Cattle, sheep, game, and poultry, are plentiful. There are extensive forests and mines of coal, antimony, and iron. The manufactures, which consist of coarse woollens, linen, leather, and paper, are trifling. The extent of this department is 689,883 hectares, and in 1817 it contained 253,048 inhabitants. Poitiers is the chief town.

VIENNE, Upper, a department of France, lying south of the Loire, on the upper branches of the river Vienne. The surface of the country is in general hilly, and the soil poor. It produces little wheat, but considerable quantities of rye and barley, and raises great numbers of cattle, horses, and mules. The hills are generally covered with wood, among which chestnuts abound. There are mines of iron, lead, copper, antimony, and coal. The manufactures consist of metals, coarse woollens and linens, handkerchiefs, pottery, &c. The extent of this department is 570,793 hectares, and the population in 1817 was 243,105. Limoges is the chief town.

VIGIL, in church history, is the eve or next day before any solemn feast; because then Christians were wont to watch, fast, and pray, in their churches.

Vigils of Plants, a term under which botanists comprehend the precise time of the day in which the flowers of different plants open, expand, and shut. As all plants do not flower in the same season, or month; in like manner, those which flower the same day, in the same place, do not open and shut precisely at the same hour. Some open in the morning, as the lip flowers, and compound flowers with flat spreading petals;
VIL [ 562 ]

petals; others at noon, as the mallows; and a third set in the evening, or after sunset, as some geraniums and opuntias; the hour of shutting is equally determined. Of those which open in the morning, some shut soon after, while others remain expanded till night.

The hours of opening, like the time of flowering, seem to vary, according to the species of the plant, the temperature of the climate, and that of the season. Flowers, whose extreme delicacy would be hurt by the strong impressions of an ardent sun, do not open till night; those which require a moderate degree of heat to elevate their juices, in other words, whose juices do not rise but in the morning or evening, do not expand till then; whilst those which need a more lively heat for the same purpose, expand at noon when the sun is in his meridian strength. Hence it is, that the heat of the air being greater betwixt the tropics than elsewhere, plants which are transported from those climates into the cold or temperate climates of Europe, expand their flowers much later than in their native soil. Thus, a flower which opens in summer at six o'clock in the morning at Senegal, will not open at the same season in France and England till eight or nine, nor in Sweden till ten.

Linnaeus distinguishes by the general name of soler (flores solares) all those flowers which observe a determinate time in opening and shutting. These flowers are again divided, from certain circumstances, into three species, or kinds:

Equinocial flowers (flores equinociales) are such as open and shut at all seasons, at a certain fixed or determinate hour.

Tropical flowers (flores tropicales) are such whose hour of opening is not fixed at all seasons, but accelerated or retarded according as the length of the day is increased or diminished.

Meteorous flowers (flores meteorici) are such whose hour of expansion depends upon the dry or humid state of the air, and the greater or less pressure of the atmosphere. Of this kind is the Siberian sow-thistle, which shuts at night if the ensuing day is to be clear and serene, and opens if it is to be cloudy and rainy. In like manner the African marigold, which in dry serene weather opens at six or seven in the morning, and shuts at four o'clock in the afternoon, is a sure indication that rain will fall during the course of the day, when it continues shut after seven.

VIGO, a sea-port town of Galicia in Spain, with an old castle and a fort. It is seated in a fertile country by the sea-side. It was rendered famous by a sea-fight between the confederate fleet commanded by Sir George Rooke, and a squadron of French men of war, in which the English took four galleons and five large men of war, and the Dutch five galleons and one man of war. W. Long. 8. 43. N. Lat. 42. 14.

VILLA FRANCA, the name of several towns; one in Piedmont, three miles east of Nice; another at Catalonia, 18 miles west of Barcelona; a third, the capital of St Michael, one of the Azores; and a fourth, a town of Estremadura in Spain, 57 miles south-east of Salamanca.

VILLAGED, an assemblage of houses inhabited chiefly by peasants and farmers, and having no market where by it is distinguished from a town. The word is French, formed of vif or vilis, "low, mean, contemptible," or rather, from the Latin villa, a country-house or farm.

VILAIN, or VILLEIN, in our ancient customs, Villeine, genotes a man of servile or base condition, viz. a bond man or servant.

VILLESAGE, in Lat. The folk-land or estate held in villegage, was a species of tenure neither strictly feudal, Norman, or Saxon; but mixed and compounded of them all; and which also, on account of the hostilities that usually attend it, may seem to have somewhat Danish in its composition. Under the Saxon government there were, as Sir William Temple speaks, a sort of people in a condition of downright servitude, used and employed in the most servile works, and belonging, both they, their children, and effects, to the lord of the soil, like the rest of the cattle or stock upon it. These seem to have been those who held what was called the folk-land, from which they were removable at the lord's pleasure. On the arrival of the Normans here, it seems not improbable, that they who were strangers to any other than a feudal state, might give some sparks of enfranchisement to such wretched persons as fell to their share, by admitting them, as well as others, to the oath of fealty; which conferred a right of protection, and raised the tenant to a kind of estate superior to downright slavery, but inferior to every other condition. This they called villegage, and the tenants villeins.

These villeins, belonging principally to lords or officers, were either villeins regardants, that is, annexed to the manor or land, or else they were in gross, or at large, that is, annexed to the person of the lord, and transferable by deed from one owner to another. They could not leave their lord without his permission; but if they ran away, or were parolled from him, might be claimed and recovered by action, like beasts or other chattels. They held indeed small portions of land by way of sustaining themselves and families: but it was at the mere will of the lord, who might dispossess them whenever he pleased; and it was upon villein service, that is, to carry out dung, to hedge and ditch the lord's demesnes, and any other the meanest offices; and their services were not only base, but uncertain both as to their time and quantity.

A villein could acquire no property either in lands or goods; if he purchased either, the lord might seize them to his own use; unless he contrived to dispose of them again before the lord had seized them, for the lord had then lost his opportunity.

In many places a fine was also payable to the lord, if the villein presumed to marry his daughter to any one without leave from the lord: and by the common law, the lord might also bring an action against the husband for damages in pursuance of his property. For the children of villeins were also in the same state of bondage with their parents; unless they were called in Latin natiuni, which gave rise to the female appellative of a villein, who was called a neije. In case of a marriage between a freeman and a neife, or a villein and a free woman, the issue followed the condition of the father, being free if he was free, and a villein if he was villein, contrary to the maxim of the civil law, that portus sequitur ventrem. But no bastard could be born a villein, because by another maxim of our law he is nullius filius; and as a he can gain nothing by inheritance, it was hard that he should lose his natural freedom by it. The law, however, protected the persons of villeins against atrocious injuries of the lord: for he might not kill or
Villainage, or main his villain; though he might beat him with impunity.

Villains might be enfranchised by manumission. In process of time they gained considerable ground on their lords; and in particular strengthened the tenure of their estates to that degree, that they came to have in them an interest in many places full as good, in others better than their lords'. For the good nature and benevolence of many lords of manors having, time out of mind, permitted their villains and their children to enjoy their possessions without interruption, in a regular course of descent, the common law, of which custom is the life, now gave them title to prescribe against their lords; and, on performance of the same services, to hold their lands in spite of any determination of the lord's will. For though in general they are still said to hold their estates at the will of the lord, yet it is such a will as is agreeable to the custom of the manor; which customs are preserved and evidenced by the rolls of the several courts, in which they are entered, or kept on foot by the constant immemorial usage of the several manors in which the lands lie. And as such tenants had nothing to show for their estates but these customs, and admissions in pursuance of them, entered on these rolls, or the copies of such entries witnessed by the steward, they now began to be called tenants by copy of court roll, and their tenure itself a copyhold.

Privileged Villainage, a species of tenure otherwise called villain socage. See Tenure.

Ancient demesne consists of those lands or manors which, though now perhaps granted out to private subjects, were actually in the hands of the crown in the time of Edward the Confessor, or William the Conqueror; and so appear to have been, by the great survey in the exchequer, called the doomsday-book. The tenants of these lands, under the crown, were not all of the same order or degree. Some of them, as Britton testifies, continued for a long time pure and absolute villains, dependent on the will of the lord; and common copyholders in only a few points. Others were in a great measure enfranchised by the royal favour; being only bound in respect of their lands to perform some of the better sort of villain-services, but those determinate and certain; as, to plough the king's land for so many days, to supply his court with such a quantity of provisions, and the like; all of which are now changed into pecuniary rents: and in consideration hereof they had many immunities and privileges granted to them; as to try the right of their property in a peculiar court of their own, called a court of ancient demesne, by a peculiar process denominated a writ of right close; not to pay toll or taxes; not to contribute to the expenses of knights of the shire; not to be put on juries, and the like.

These tenants, therefore, though their tenure be absolutely copyhold, yet have an interest equivalent to a freehold: for though their services were of a base and villainous original, yet the tenants were esteemed in all other respects to be highly privileged villains; and especially for that their services were fixed and determinate, and that they could not be compelled (like pure villains) to relinquish those tenements at the lord's will, or to hold them against their own: et idem (says Bracton) dicuntur liberti.

Lands holding by this tenure are therefore a species of copyhold, and as such preserved and exempted from the operation of the statute of Charles II. Yet they differ from common copyholders, principally in the privileges before mentioned: as also they differ from freeholders by one especial mark and tincture of villainage, noted by Bracton, and remaining to this day; viz. that they cannot be conveyed from man to man by the general common-law conveyances of 17744. 17745. and the rest; but must pass by surrender to the lord or his successor, in the manner of common copyholders: yet with the difference, that, in the surrender of these lands in ancient demesne, it is not used to say, "to hold at the will of their lord," in their copies; but only, "to hold according to the custom of the manor."

Villi, among botanists, a kind of down like short hair, with which some trees abound.

Villoose, or Villous, something abounding with villi or fibres like short hair; such is one of the coats of the stomach.

VINCA, a genus of plants of the class pentandria; and in the natural system arranged under the 30th order, Contortae. See Botany Index.

St. VINCENT, one of the windward Caribbe islands, which received its name from being discovered on the 3rd of January, the feast of that saint. It is inhabited by a race of people, of whom Dr Robertson gives this account: "There is a great distinction in character between the Caribbees and the inhabitants of the larger islands. The former appear manifestly to be a separate race. Their language is totally different from that of their neighbours in the large islands. They themselves have a tradition that their ancestors came originally from some part of the continent, and having conquered and exterminated the ancient inhabitants, took possession of their lands and of their women. Hence they call themselves Baniaree, which signifies a man come from beyond sea. Accordingly, the Caribbees still use two distinct languages, one peculiar to the men, and the other to the women. The language of the men has nothing common with that spoken in the large islands. The dialect of the women considerably resembles it. This strongly confirms the tradition which I have mentioned. The Caribbees themselves imagine that they were a colony from the Galibis, a powerful nation of Guiana in South America. But as their fierce manners approach nearer to those of the people in the northern continent, than to those of the natives of South America, and as their language has likewise some affinity to that spoken in Florida, their origin should be deduced rather from the former than from the latter. In their wars they still preserve their ancient practice of destroying all the males, and preserving the women either for servitude or for breeding."

It remained a long time after it was discovered inhabited by these people, and by another race improperly styled Black Caribs, who are in reality negroes descended, as is generally believed, from some who escaped out of a Guinea ship wrecked upon the coast, and gradually augmented by such as from time to time fled thither from Barbadoes. These nations were often at war; but when their quarrels were composed, they had a strength sufficient to prevent strangers from settling by force. The French, about half a century ago, at the request of the Caribs, made a descent from Martinico and attacked the negroes, but were repulsed with loss; and found it their interest to conciliate a friendship with both nations.
St. Vincent, by means of presents, and furnishing them with arms and ammunition.

St. Vincent was long a neutral island; but at the peace of 1763, the French agreed that the right to it should be vested in the English; who, in the sequel, at the instance of some rapacious planters, engaged in an unjust war against the Caribbees, who inhabited the windward side of the island, and who were obliged to consent to a peace, by which they ceded a very large tract of valuable land to the crown. The consequence of this was that in the next war, in 1779, they greatly contributed to the reduction of this island by the French, who, however, restored it by the peace of 1783. Since that time it has continued in the possession of Great Britain. During the French revolutionary war, the Caribee revolted; and, assisted by the French, spread desolation over the whole island; but by the exertions of the governor and the British forces in the West Indies, the revolt was quelled.

St. Vincent is in length about 23 miles, and about 18 in breadth. The climate is very warm. The country is in general hilly, in some places mountainous; but interspersed with a variety of pleasant valleys, and some luxuriant plains, the soil being everywhere very fertile, and the high grounds are at least in general easy of ascent. Few islands are so well watered with rivers and springs. The inhabitants raise all kinds of ground provisions in plenty. The rivers supply them with variety of fish. W. Long. 61°. N. Lat. 13°.

VINCI, LEONARDO DA, an illustrious Italian painter, descended from a noble Tuscan family, was born in the castle of Vinci, near Florence in 1450. He was placed under Andrea Verocchia, a celebrated painter in that city; but soon surpassed him and all his predecessors so much as to be reposed the master of the third or golden age of modern painting. But his studies were far from terminating here; for man's genius was more universal: he applied himself to arts, to literature, and to the accomplishments of the body; and he excelled in every thing which he attempted. Lewis Sforza duke of Milan prevailed on him to be director of the academy for architecture he had just established; where Leonardo soon banished all the Gothic fusions, and reduced every thing to the happy simplicity of the Greek and Roman style. By the duke's order he constructed the famous aqueduct that supplies the city of Milan with water: this canal, given by the name of Mortesana, being above 200 miles in length, and conducts the water of the river Adda quite to the walls of the city. In 1497, he was desired to construct some new device for the entertainment of Louis XII. of France, who was then to make his entrance into Milan. Leonardo accordingly made a very curious automaton in the form of a lion, which marched out to meet the king, reared up on its hind legs before him, and opening its breast, displayed an image in them, with fleurs-de-lis quartered on it. The doors of Lombardy, with the misfortunes of his patrons the Sforza, obliging Leonardo to quit Milan, he retired to Florence, where he flourished under the Medici: there he raised the envy of Michael Angelo, who was his contemporary; and Raphael, from the study of his works, acquired his best manner of design. At length, on the invitation of Francis I., he came to France when above 70 years of age; where the journey and change of climate threw him into his last sickness.
Virgil of Andes, near Mantua, where he was born, 70 years B.C. He studied first at Mantua; then at Cremona, Milan, and Naples; whence going to Rome, he acquired the esteem of the greatest wits and most illustrious persons of his time; and among others of the emperor Augustus, Maccenas, and Pollio. He was well skilled not only in polite literature and poetry, but also in philosophy, the mathematics, geography, medicine, and natural history. Though one of the greatest geniuses of his age, and the admiration of the Romans, he always preserved a singular modesty, and lived chaste at a time when the manners of the people were extremely corrupt. He carried Latin poetry to such a high perfection, that he was justly esteemed the prince of Latin poets. He first turned himself to pastoral; and being captivated with the beauty and sweetness of Theocritus, was ambitious to introduce this new species of poetry among the Romans. His first performance in this way is supposed to have been written U. C. 709, the year before the death of Julius Caesar, in which the poet was in 27th year; it is called "Poeten,": it is a close imitation of the fourth and fifth Idylls of Theocritus. Mr. Wharton places "Silentium in" which is said to have been publicly recited on the stage by Cytheris, a celebrated comedian. Virgil's fifth eclogue is composed in allusion to the death and deification of Caesar. The battle of Philippi in 712 having put an end to the Roman liberty, the veteran soldiers began to demand for their pay; and Augustus, to reward them, distributed among them the lands of Mantua and Cremona. Virgil was invited to this common calamity; and applied to Varus and Pollio, who warmly recommended him to Augustus, and procured for him his patrimony again. Full of gratitude to Augustus, he composed the "Tityrus," in which he introduces two shepherds; one of them complaining of the distraction of the times, and of the hawks the soldiers made among the Mantuan farmers; the other rejoicing for the recovery of his estate, and promising to honour as a god the person who restored it to him. But our poet's joy was not of long continuance; for we are told, that when he returned to his province of his farm, he was violently assaulted by the intruder, and would certainly have been killed by him if he had not escaped by swimming hastily over the Minio. Upon this unexpected disappointment, he returned to Rome to renew his petition; and during his journey seems to have composed his ninth eclogue. The celebrated eclogue, intitled "Pison," was composed U. C. 714, upon the following occasion: The consul Pollio on the part of Antony, and Maccenas on the part of Cesar, had made up the differences between them; by agreeing, that Octavia, half-sister to Cesar, should be given in marriage to Antony. This agreement caused universal joy; and Virgil, in his eclogue, testified his. Octavia was with child by her late husband Marcellus at the time of this marriage; and whereas the Sibylline oracles had foretold, that a child was to be born about this time, who should rule the world, and establish perpetual peace, the poet ingeniously supposes the child in Octavia's womb to be the glorious infant, under whose reign mankind was to be happy, the golden age to return from heaven, and fraud and violence to be no more. In this celebrated poem, the author, with great delicacy at the same time, pays his court to both the chiefs, to his patron Pollio, to Octavia, and to the unborn infant. In 715, Cn. Pollio was sent against the Parthians, a people of Illyricum; and during this expedition, Virgil addressed to him a beautiful eclogue, called "Pharsalia." His tenth and last eclogue was addressed to Gallus.

In his 34th year, he retired to Naples, and laid the plan of his Georgics, which he undertook at the instigations of Maccenas, to whom he dedicated them. This wise and able minister resolved, if possible, to revive the decayed spirit of husbandry; to introduce a taste for agriculture, even among the great; and could not think of a better method to effect this, than to recommend it by the insinuating charms of poetry. Virgil fully answered the expectations of his patron by his Georgics. They are divided into four books. Corn and ploughing are the subject of the first, vines of the second, cattle of the third, and bees of the fourth.

He is supposed to have been in his 45th year when he began to write the Æneid, the design of which was to reconcile the Romans to the government of Augustus. Augustus was eager to pursue this poem before it was finished; and intreated him by letters to communicate it. Macrobius has preserved to us part of one of Virgil's answers to the emperor, in which the poet excuses himself: who, however, at length complied, and read himself the sixth book to the emperor; when Octavia, who had just lost her son Marcellus, the darling of Rome, and adopted son of Augustus, made one of the audience. Virgil had artfully invented that beautiful lamentation for the death of young Marcellus, beginning with, "Oh, forget not, O marcellus, me quae me curae tur-

In the Æneid, Virgil brought to a conclusion, but not to the perfection our author intended to give it, he resolved to travel into Greece, to correct and polish it at leisure. It was probably on this occasion that Horace addressed that affective ode to him, &c. to Dioct 

Mantua me genuit: Calabri repueru, tenet nunc Parthenopae: cecini Pauca, Rura, Dupae.

His bones were carried to Naples, according to his earnest request; and a monument was erected at a small distance from the city.

Virgil was of a swarthy complexion, tall, of a sickly constitution, and afflicted with frequent headaches, and spitting of blood. He was so very bashful, that he often ran into the shops to prevent being gazed at in the streets;
VIR [ 566 ] VIR

VIRIL, Virginia.

streets); yet was so honoured by the Roman people, that once coming into the theatre, the whole audience rose up out of respect to him. He was of a thoughtful and melancholy temper; he spoke little, and loved retirement and contemplation. His fortune was affluent; he had a fine house and well furnished library near Meccenas’s gardens, on the Esquiline mount at Rome, and also a delightful villa in Sicily. He was so benevolent and inoffensive, that most of his contemporary poets, though they envied each other, agreed in loving and esteeming him. He revised his verses with prodigious severity; and used to compare himself to a she bear, which licked her cubs into shape.

The best edition of Virgil’s works are those of Moxiues, with the notes of Servius, printed at Lewarden in 1717, two vols 4to; and that of Burman, at Amsterdam, 1746, in four vols 4to. There are several English translations, which are well known.

Virgil, Polydore, an English historian, born at Urbino in Italy, was sent in the beginning of the 16th century by Pope Alexander VI. as sub-collector of the Papal tax, called Peter-pence, in this kingdom. He had not been long in England before he obtained preferment in the church; for in 1503 he was presented to the rectory of Church-Langton in the archdeaconry of Leicester. In 1507 he was collated to the prebend of Scablesmy in the church of Lincoln; and in the same year was made archdeacon of Wells, and prebendary of Hereford. In 1513, he resigned his prebend of Lincoln, and was collated to that of Oxgate in St Faliis, London. We are told, that on his preferment to the archdeaconry of Wells, he resigned the office of sub-collector to the pope, and determined to spend the remainder of his life in England, the History of which kingdom he began in the year 1505, at the command of Henry VII. That work cost him 12 years labour. In 1526, he finished his treatise on Prodigies. Polydore continued in England during the whole reign of Henry VIII; and part of that of Edward VI. whence it is concluded that he was a moderate Papist. In 1550, being now an old man, he requested leave to revisit his native country. He was accordingly dismissed with a present of 300 crowns, together with the privilege of holding his preferment to the end of his life. He died at Urbino in the year 1555. As an historian, he is accused by some as a malignant slanderer of the English nation; yet Jovius remarks, that the French and Scotch accuse him of having flattered that nation too much: (See his Elog. cap. 135. p. 179.). Besides the above, he wrote, 1. De Rerum Inventoribus; of which an English translation was published by Langley in 1663. It was also translated into French and Spanish. 2. De Prodigiosis et Sordibus. 3. Episcoporum Angliciae Catalogus. Manuscript. 4. De Vita Perfecta, Basil, 1546. 1553. Svo. 5. Epitomae Erudite, and some other works.

Virginia, one of the United States of the North American republic. It is bounded by the sea and the bay of Chesapeake on the east, by Maryland and Pennsylvania on the north, by Ohio and Kentucky on the west, and by North Carolina on the south. Its greatest length east and west is 330 miles; its breadth 220; and its area is about 56,000 square miles. About one-third of the surface of this state is occupied by the different ridges of the Alleghany chain, which traverse it in the direction of north-east and south-west. These ridges rise to the height of about 3000 feet, and are generally covered with natural wood. That part of the country which lies immediately along the shores of the ocean and the Chesapeake bay is generally flat, sandy, and so poor as to admit of cultivation only on the banks of the rivers. This tract extends about 60 or 80 miles inward. Beyond it, as far as the foot of the Blue ridge or eastern chain of the Alleghanies, the soil is greatly superior, and bears excellent crops of wheat, maize, barley, tobacco, hemp, &c. The soil of the broad valleys between the Alleghany ridges is similar, and that on the western slope of the mountains reaching to the banks of the Ohio, is believed to be the richest of the whole.

In point of climate, this state is probably one of the most agreeable in North America. The extremes of heat and cold, at Mr. Jefferson’s seat of Monticello, are 98° above, and 68° below zero. The mean annual temperature at Williamsburg is 57°; and the average annual quantity of rain 47 inches.

It is remarkable that, proceeding on the same parallel of latitude westwardly, the climate becomes colder in like manner as you proceed northwardly. This continues to be the case till you attain the summit of the Alleghany, which is the highest land between the ocean and the Mississippi. From thence, descending in the same latitude towards the Mississippi, the change reverses; and, if we may believe travellers, it becomes warmer there than it is in the same latitude on the sea-side.

The principal rivers of this state are, James’s river, which falls into the Chesapeake bay after a course of 270 miles, through the greater part of which it admits of boat navigation; York river; Rappahannock; the Patowmac, which separates Virginia from Maryland; the Shenandoah, which falls into the Patowmac; the Monongahela; the Ohio; and the Kenhawa. These rivers afford a great extent of inland navigation, and have contributed much to the improvement of the state.

Iron and lead ores are found and worked in several places. Native copper, manganese, and antimony, have also been discovered. Lime is abundant on the west side, and coal is found on both sides of the mountains. Salt is also extracted in great quantities from springs on the banks of some of the branches of the Ohio.

The wild animals are now scarce on the east side of the Alleghanies, but the bear, wolf, deer, racoon, oppossum, are still numerous in the western parts. There are rattlesnakes and serpents of a large size, but they are rarely met with. The remains of the mammoth have been found also in this state. There are various species of wild fowl, of which the most esteemed are the turkeys. The rivers and bays contain a great variety of fish; with which the towns on the coast are generally well supplied.

This state was first settled in 1607 when the whole inhabitants amounted only to 40 persons. In 1703 they amounted to 63,000; in 1790 to 1,475,610; and in 1810 to 2,374,572, including 392,518 slaves. The inhabitants of the upper country are generally much above the average stature of Europeans, and strong and active in proportion. On the coast, where the climate is rather unhealthy, the inhabitants are not so tall or athletic. The Virginians are polite, frank, liberal,
The legislature consists of a senate and house of delegates; the former composed of 24 members chosen for four years; the latter of two freeholders for each county, and one for each city, chosen annually by the persons possessing land. The executive power is vested in the governor, assisted by a council of eight members chosen annually by both houses of the legislature. The judges are appointed by the legislature, and hold their offices during good behaviour. The clergy are supported by voluntary contributions. The Presbyterians are the most numerous sect.

There are two colleges in this state: That of William and Mary, founded in 1692, is under the direction of 20 governors, who appoint the president and professors, and frame regulations. There are five professorships, viz. law, medicine, mathematics, philosophy, and modern languages. Hampden and Sydney college in Prince Edward county has been lately established. There are academies in all the considerable towns. Hitherto there has been a want of the means of elementary education in this state; but in 1816 the legislature set apart one million of dollars for the support of schools.

The produce of this state consists of tobacco, which is cultivated to a great extent eastward of the Alleghany mountains; maize, or Indian corn, which yields from 12 to 50 bushels an acre; wheat, which yields on an average 15 bushels an acre, being generally raised from land that has been exhausted by crops of tobacco; rice on the borders of the swamps; buck wheat, oats, hemp, and cotton; the last not to a great extent. Potatoes are in general use. Among the fruits are plums, almonds, pomegranates, figs, peaches, and melons. The breed of cattle and horses are much inferior in general to those of Pennsylvania. Mules and oxen are much employed in agricultural labour. Merino sheep have been introduced, and are extending through the state. Great numbers of hogs are fed on acorns in the woods.

The manufactures of this state are inconsiderable. They consist chiefly of spirits, brewed liquors, salt, cabinet ware, leather, and linen for domestic use. The whole value of manufactures in 1810 was estimated at $2,263,473 dollars.

The exports consist chiefly of tobacco, wheat, maize, lumber, tar, turpentine, beef, pork, peltries, &c. The imports are manufactured articles of all kinds, and West India produce. In 1817 the exports amounted to $5,921,442 dollars, of which 60,264 dollars were for foreign produce, and the rest for articles of domestic growth. In 1815 the shipping belonging to this state amounted to 71,492 tons. The principal trading port is Northfolk; the next in importance is Richmond the capital.

Virginia, like the other states, has advanced rapidly since the revolution; and having still vast tracts of uncleared land, she has yet a great progress to make. The baneful influence of slavery, however, will undoubtedly throw her behind the northern and middle states, and the restrictions on the elective franchise have also a tendency to prevent the industrious classes from settling here. The value of lands and houses in Virginia in 1799 was estimated in the official returns of $71,225,127, and in 1815 at $165,608,193 dollars. But including slaves the value in 1815 was $263,737,999 dollars. Virginia has had the honour of giving four presidents to the republic; Washington, Jefferson, Madison, and Monroe. The two first, as well as several other citizens of this state, have been ranked among the most distinguished men whom America has produced.

VIRGO, in Astronomy, one of the signs or constellations of the zodiac.

VIRGULA DIVINATORIA, divining rod. See Mine.

VIRTUOUS, or Potential; something that has a power or virtue of acting or doing. The term is chiefly understood of something that acts by a secret invisible cause, in opposition to actual and sensible.

VIRTUE, a term used in various significations. In the general it denotes power, or the perfection of anything, whether natural or supernatural, animate or inanimate, essential or accidental. But, in its more proper or restrained sense, virtue signifies a habit, which improves and perfects the possessor and his actions. See Moral Philosophy, No 84.

VIRTUOSO, an Italian term lately introduced into the English, signifying a man of curiosity and learning, or one who loves and promotes the arts and sciences. But among us the term seems to be appropriated to those who apply themselves to some curious and quaint rather than immediately useful art or study; as antiquaries, collectors of rarities of any kind, microscopical observers, &c.

VIRULENT, a term applied to anything that yields a virus; that is, a contagious or malignant pus.

VISCERA, in Anatomy, a term signifying the same with entrails; including the heart, liver, lungs, spleen, intestines, and other inward parts of the body.

VISCIDITY, or Viscosity, the quality of something that is viscid or viscous; that is, glutinous and sticky like bird-lime, which the Latins call by the name of viscum.

VISCOUNT (Vice Count), was anciently an officer under an earl, to whom, during his attendance at court, he acted as deputy to look after the affairs of the country. But the name was afterwards made use of as an arbitrary title of honour, without any shadow of office pertaining to it, by Henry VI.: when in the 18th year of his reign, he created John Beaumont a peer by the name of Viscount Beaumont; which was the first instance of the kind.

A viscount is created by a patent as an earl is; his title is Right Honourable; his mantle is two doublings and a half of plain fur; and his coronet has only a row of pearls close to the circle.

VISCUM, a genus of plants of the class dicocia, and in the natural system arranged under the 48th order, Aggregate. See Botany Index.

VISHNOU, that person in the triad of the Bramins who is considered as the preserver of the universe. Brahma is the creator, and Siva the destroyer; and these two, with Vishnu, united in some inexplicable manner, constitute Brahma, or the supreme name of the Hindoos. See Polytheism, No 36.

VISIBLE, something that is an object of sight or vision; or something whereby the eye is affected so as to produce this sensation.

VISIER, an officer or dignitary in the Ottoman empire.
UKRAINE

The Turks Visir-ascen, that is, "grand vizier," is the prime minister of state in the whole empire. He commands the army in chief, and presides in the divan or great council. Next to him are six other subordinate visiers, called visiers of the bench; who officiate as his councillors or assessors in the divan.

VISION, in Optics, the act of seeing or perceiving external objects by means of the organs of sight, the eye. See ANATOMY, No. 142, and METAPHYSICS, No. 49.

VISTULA, or WEISSEL, a large river of Poland, which taking its rise in the mountains south of Silesia, visits Cracow, Warsaw, &c., and continuing its course northward, falls into the Baltic sea beyond Daubitz.

VISUAL, in general, something belonging to vision.

VITAL, in Physiology, an appellation given to whatever ministers principally to the constituting or maintaining life in the bodies of animals: thus the heart, lungs, and brain, are called vital parts; and the operations of these parts by which the life of animals is maintained are called vital functions.

VITELLIUS, the yolk of an egg.

FITIS, or VINE, a genus of the class pantendria, and in the natural system arranged under the 45th order, Heteraceae. See BOTANY Index; and for its culture, see GARDENING.

VITREOUS HUMOUR OF THE EYE. See ANATOMY, No. 142.

VITRIFICATION, in Chemistry, the conversion of a body into glass by means of fire. See GLASS.

VITRIOL, a compound salt, formed by the union of iron, copper, or zinc, with sulphuric acid; hence called from the colours white, blue, and green, according to the metal. See CHEMISTRY.

VITRIOLATED, among chemists, something impregnated, or supposed to be so, with vitriol or its acid.

VITRIOLIC ACID. See Sulphuric Acid and CHEMISTRY Index.

VITRUVIUS POLLIO, Marcus, a very celebrated Roman architect, was, according to the common opinion, born at Verona, and lived in the reign of Augustus, to whom he dedicated his excellent treatises on architecture, divided into ten books. William Philander's edition of this celebrated work is esteemed. Claudius Perrault has given an excellent translation of it in French, with learned notes. There are also several English translations of Vitruvius.

VITUS'S DANCE. See MEDICINE, No. 284.

VIVERIA, the WEASEL; a genus of quadrupeds belonging to the order of ferae. See MAMMALIA Index.

VIVES. See FARRIERS.

VIVIPAROUS, in Natural History, an epithet applied to such animals as bring forth their young alive and perfect; in contradistinction to those that lay eggs, which are called oviparous animals.

UKRAINE, a large country of Europe, lying on the borders of Turkey in Europe, Poland, Russia, and Little Tartary. Its name properly signifies a frontier.

By a treaty between Russia and Poland in 1663, the latter remained in possession of all that part of the Ukraine lying on the west side of the river Dnieper, which is but indifferent cultivated; while the country on the east side, inhabited by the Cossacks, is in much better condition. The Russian part is comprised in the government of Kief; and the empress of Russia having obtained the Polish palatinate of Kief, by the treaty of partition in 1793, the whole of the Ukraine, on both sides of the Dnieper, belongs now to that ambitious and formidable power. The principal town is Kief.

ULCER, in Surgery. See SURGERY Index.

ULCER, in Farriery. See FARRIERY.

ULEX, a genus of plants of the class diadelphus, and in the natural system arranged under the 32d order, Papilionaceae. See BOTANY Index.

ULITEA, one of the Society islands in the South sea. This island is about 21 leagues in circuit. Its productions are plantains, cocoa-nuts, yams, hops, and fowl; the two latter of which are scarce. The soil on the top of one of the hills was found to be a kind of stone marble; on the sides were found some scattered flints, and a few small pieces of a cavernous or spongy stone lava, of a whitish colour, which seemed to contain some remains of iron, so that it may possibly be here lodged in the mountains in a great quantity. Nothing was seen on this island to distinguish either its inhabitants, or their manners, from the other neighbouring islands. The first Europeans who landed on this shore were Mr. (now Sir Joseph) Banks and Dr. Solander; they were received by the natives in the most conciliatory manner, reports concerning them having been seen by the barbarians from Otahite. Everybody seemed to fear and respect them, placing in them at the same time the utmost confidence: behaving, as if conscious that their visitors possessed the power of doing them mischief without a disposition to make use of it.

ULIGINOUS, in Agriculture an appellation given to a moist, morish, and fenny soil.

ULLAGE, in gauging, is so much of a cask or other vessel as it wants of being full.

ULM, formerly a free and imperial city of Germany, but now belonging to Bavaria. It is a pretty large place, defended by fortifications; and the inhabitants, who are chiefly Protestants, amounted to 14,000 in 1820. The town is seated on the Danube, a little above the confluence of that river and the Ille, and carries on a considerable trade. It has many handsome buildings. The principal church is a magnificent Gothic edifice, and is said to surpass all the cathedrals in Germany in height. The Roman Catholics have but two churches, all the rest belonging to the Protestants.

E. Long. 9. 59. N. Lat. 48. 25.

ULMUS, a genus of plants belonging to the class of pentandria; and in the natural system arranged under the 53d order, Scabrieae. See BOTANY Index.

ULSTER, the most northerly province of Ireland. In Latin it is called Ultima, in Irish Ceth Gaill; and gives the title of earl to the dukes of York of the royal family. It is bounded by the Atlantic ocean on the west, St. George's channel and the Irish sea on the east, the Desecladian ocean on the north, and on the south and south-west the provinces of Leinster and Connaught. Its greatest length is near 120 miles, its breadth about 100; and its circumference, including the windings and turnings, 460; containing 9 counties, 58 market-towns and boroughs, 1 archbishopric, 6 bishoprics, and 214 parishes. Ulster abounds in lakes and rivers, which supply it with variety of fine fish, especially salmon, besides what it has from the sea, with which a great part of it is bounded. The southern parts of it are rich, fertile,
Tournefort's methods, consisting of plants whose flowers Umbellate grow in umbels, with five petals that are often unequal, and two naked seeds that are joined at top and separated below.

The same plants constitute the 4th order of Linnaeus's Fragments of a Natural Method. See Botany.

UMBELLIFEROUS PLANTS, are such as have their tops branched and spread out like an umbrella.

UMBRE, or Umbræ, a fossil brown or blackish substance, used in painting. See Mineralogy Index.

UMBILICAL, among anatomists, something relating to the umbilicus or navel.

UMBRELLA, a movable canopy, made of silk or other cloth spread out upon ribs of whale-bone, and supported by a staff, to protect a person from rain, or the scorching beams of the sun.

UMPRIE, a third person chosen to decide a controversy left to arbitration.

UNCIA, in general, a Latin term, denoting the twelfth part of any thing; particularly the twelfth part of a pound, called in English an ounce; or the twelfth part of a foot, called an inch.

UNCTION, the act of anointing or rubbing with oil or other fatty matter.

UNCTION, in matters of religion, is used for the character conferred on sacred things by anointing them with oil. Anointings are very frequent among the Hebrews. They anointed both their kings and high-priests at the ceremony of their inauguration. They also anointed the sacred vessels of the tabernacle and temple, to sanctify and consecrate them to the service of God. The unction of kings is supposed to be a ceremony introduced very late among the Christian princes. It is said that none of the emperors were ever anointed before Justinian or Justin. The emperors of Germany took the practice from those of the eastern empire: King Pepin of France was the first who received the unction. In the ancient Christian church, unction always accompanied the ceremonies of baptism and confirmation. Extreme unction, or the anointing persons in the article of death, was also practised by the ancient Christians, in compliance with the precepts of St James, chap. v. 14th and 15th verses; and this extreme unction the Romish church has advanced to the dignity of a sacrament. It is administered to none but such as are affected with some mortal disease, or in a decrepit age. It is refused to impenitent persons, as also to criminals. The parts to be anointed are the eyes, the ears, the nostrils, the mouth, the hands, the feet, and the reins. The laity are anointed in the palms of the hands, but priests on the back of it; because the palms of their hands have already been consecrated by ordination.

The oil with which the sick person is anointed represents the grace of God, which is poured down into the soul, and the prayers used at the time of anointing expresses the remission of sins thereby granted to the sick person; for the prayer is this: "By this holy unction, and his own most pious mercy, may the Almighty God forgive thee whatever sins thou hast committed by the sight," when the eyes are anointed; by the hearing, when the ears are anointed; and of the other senses.

UNDECAGON, is a regular polygon of 11 sides.

UNDECEMVIR, a magistrate among the ancient Athenians, who had 10 other colleagues or associates joined.
UNION

UNION joined with him in the same commission. The functions of the union were much the same with those of the late premier de marche-houses in France. They took care of the apprehending of criminals; secured them in the hands of justice; and when they were condemned, took them again into custody, that the sentence might be executed on them. They were chosen by the tribes, each tribe naming its own; and as the number of the tribes after Calisthenes was but 10, which made 10 members, a scribe or notary was added, which made the number 11.

UNDERSTANDING. See Metaphysics and Logic.

UNDERWALDEN, a canton of Switzerland, and the sixth in rank. It is bounded on the north by the canton of Lucerne and by the lake of the Four Cantons, on the east by the high mountains which separate it from the canton of Bern, and on the west by the canton of Bern. The religion of this canton is the Roman Catholic.

UNDULATION, in Physics, a kind of tremulous motion or vibration observable in a liquid, by which it alternately rises and falls like the waves of the sea.

UNGUENT, or Ointment, in Medicine and Surgery, a tropical remedy or composition, chiefly used in the dressing of wounds or ulcers. See Materia Medica.

UNICORN, an animal famous among the ancients, and thought to be the same with the rhinoceros. Sawaiu informs us, that the figure of the unicorn described by the ancients has been found delineated by the Snese Hottentots on the plain surface of a rock in Cafriaria; and therefore conjectures, that such an animal either does exist at present in the interior parts of Africa, or at least once did so. Father Lobo affirms that he has seen it. Mr Barrow, in his Travels in Southern Africa, affords additional reason to believe in the existence of this curious animal.

UNICORN-Fish. See Monodon, Cetology Index.

UNIFORM, denotes a thing to be similar, or consistent either with another thing, or with itself, in respect of figure, structure, proportion, or the like; in which sense it stands opposed to deform.

UNIFORMITY, regularity, a similitude or resemblance between the parts of a whole. Such is that we meet with in figures of many sides, and angles respective equal, and answerable to each other. A late ingenious author makes beauty to consist in uniformity, joined or combined with variety. Where the uniformity is equal in two objects, the beauty, he contends, is as the variety; and where the variety is equal, the beauty is as the uniformity.

UNIVERSITY, is particularly used for one and the same form of public prayers, and administration of sacraments, and other rites, &c. of the church of England, prescribed by the famous statutes Eliz. and 13 and 14 Car. II. cap. 4, called the Act of Uniformity. See Liturgy.

UNION, a junction, coalition, or assemblage of two or more different things in one.

Union, or The Union, by way of eminence, is more particularly used to express the act by which the two separate kingdoms of England and Scotland were incorporated into one, under the title of The kingdom of Great Britain. This union, in vain attempted by King James I., was at length effected in the year 1707, 6 Anne, when 25 articles were agreed to by the parliament of both nations; the purport of the most considerable being as follows:

1. That on the first of May 1707, and for ever after the kingdoms of England and Scotland shall be united into one kingdom, by the name of Great Britain.

2. The succession to the monarchy of Great Britain shall be the same as was before settled with regard to that of England.

3. The united kingdom shall be represented by one parliament.

4. There shall be a communication of all rights and privileges between the subjects of both kingdoms, except where it is otherwise agreed.

5. When England raises 2,000,000l. by a land tax, Scotland shall raise 48,000l.

16, 17. The standards of the coin, of weights, and of measures, shall be reduced to those of England throughout the united kingdoms.

18. The laws relating to trade, customs, and the excise, shall be the same in Scotland as in England. But all the other laws of Scotland shall remain in force; but alterable by the parliament of Great Britain. Yet with this caution, that laws relating to public police, not alterable at the discretion of the parliament, laws relating to private right are not to be altered but for the evident utility of the people of Scotland.

22. Sixteen peers are to be chosen to represent the peerage of Scotland, in parliament, and 45 members to sit in the house of commons.

23. The 16 peers of Scotland shall have all privileges of parliament; and all peers of Scotland shall be peers of Great Britain, and rank next after those of the same degree at the time of the union, and shall have all privileges of peers, except sitting in the house of lords, and voting on the trial of a peer.

These are the principal of the 25 articles of union, which are ratified and confirmed by statute 5 Ann. c. 8, in which statute there are also two acts of parliament recited: the one of Scotland, whereby the church of Scotland, and also the four universities of that kingdom, are established for ever, and all succeeding sovereigns are to take an oath inviolably to maintain the same; the other of England, 5 Ann., c. 6, whereby the acts of uniformity of 13 Eliz. and 13 Car. II. (except as the same had been altered by parliament at that time), and all other acts then in force for the preservation of the church of England, are declared perpetual; and it is stipulated, that every subsequent king and queen shall take an oath inviolably to maintain the same within England, Ireland, Wales, and the town of Berwick-upon-Tweed. And it is enacted, that these two acts "shall for ever be observed as fundamental and essential conditions for the union."

Upon these articles and act of union, it is to be observed, 1. That the two kingdoms are so inseparably united, that nothing can ever disunite them; except the mutual consent of both, or the successful resistance of either, upon apprehending an infringement of those points which, when they were separate and independent nations, it was mutually stipulated should be "fundamental and essential conditions of the union." 2. That whatever else may be deemed "fundamental and essential conditions," the preservation of the two churches, of England and Scotland, in the same state that they were in at the time of the union, and the maintenance of
A bishop of the United Brethren can discharge no office but by the appointment of the synod, or of the elders conference. Indeed their deacons can perform every office of the bishops, except ordination, and appear to confirm young persons when they first become candidates for the communion. Even female deacons are employed for the purpose of privately admonishing their own sex, and visiting them in cases of sickness. There are also lay elders, whose business it is to watch over the observance of the laws of the country in which sessions are established, and to guard the privileges conferred on the brethren by the government under which they live.

On Sunday, besides the public prayers, one or two sermons are preached in every church, and after the morning service, an exhortation is given to the children. Previous to the holy communion, which is administered on some Sunday once a month, and on Maunday Thursday, each person, before he communicates, must converse on the state of his soul with one of the elders. Love feasts are frequent, and on Maunday Thursday the society have a solemn footwashing.

Our limits will not permit us to give a systematic view of the doctrinal tenets of the Brethren. Though they acknowledge no other standard of truth than the sacred scriptures, they adhere to the Augsburg confession, and speak respectfully of the 39 articles of the church of England. They profess to believe that the kingdom of Christ is not confined to any particular party, community, or church; and they consider themselves as spiritually joined in the bond of Christian love to all who are taught of God, and belong to the universal church of Christ, however much they may differ in forms, which they deem non-essentials. For a fuller account of this society, see Crantz's Ancient and Modern History of the Protestant Church of the United Brethren, London 1785, and An Exposition of Christian Doctrine, as taught in the Protestant Church of the United Brethren, London 1784.

**United Brethren, or Unitas Fratrum, a society of Christians, whose chief residence is at Herrnhut in Saxony. They are commonly called Moravians from their original country, and Herrnhuters, from their chief place of residence. Some account of this society has already been given under Herrnhut; but as that account may, by some, not be deemed sufficiently full, we shall here add a summary of their institutes, derived from a communication by one of their own clergy.**

Though the church of the United Brethren is episcopal, their bishops possess no elevation of rank or preeminent authority, their church being governed by synods or consistories from all the congregations, and by subordinate bodies, called conferences. The synods are generally held once in seven years. In the first sitting a president is chosen; and the elders appointed by the former synod to superintend the unity, lay down their office, though they still form a part of the assembly, as well as the bishops, the lay elders, and those ministers who have the inspection of several congregations in one province.

Questions of importance, or of which the consequences cannot be foreseen, are decided by lot, though this is never used till after mature deliberation and fervent prayer. In the synods, the state of the unity, and the concerns of the congregations and missions, are taken into consideration.

Towards the conclusion of every synod, a kind of executive board is appointed, called the elders conference of the unity, consisting of 15 elders, and divided into four committees or departments, one for superintending missions into heathen countries; a second for watching over the conduct of congregations; a third for managing the economical concerns of the unity, and a fourth for maintaining the discipline of the society. These conferences, however, are amenable to a higher committee, called the elders conference, the powers of which are very extensive. It appoints and removes every servant in the unity, authorizes the bishops to ordain presbyters or deacons, and to consecrate other bishops, and in short, possesses the supreme executive power over the whole society.

VII. Groningen. | 640 | 114,555 | GRONINGEN, Winchoten.

A great part of these provinces is composed of islands formed by the mouths of the large rivers which here disembogue their waters into the German ocean. The principal islands are Walcheren, Joostland, South and North Beveland, and Wouterwyk, composing West Zealand; Schouwen, Duiveland, Friesland, and St. Philipsland, forming East Zealand; Goeree in South Holland, the Texel, Vlieland, and Ameland, to the west and north of Friesland.

The Dutch have formerly considerable colonial territory; but this is now reduced to Java, Sumatra, and the Molucca islands, with some other settlements in the East Indies; some principal factories on the Guinea coast; St. Eustatius and part of Surinam in South America.

The face of the country is, in general, extremely uniform, consisting of large tracts of marshy pastures, and sandy heaths, interspersed with several large rivers, and numerous canals. There are a few hills in the eastern districts, but the coasts are so low, that, but for the dykes or sea walls, they would be inundated by the sea. The soil consists almost entirely of alluvial earth and vegetable mould, and is very productive. The climate is moist, uniform, and peculiarly salubrious to strangers; intermittent fevers and similar diseases, the attendants on a marshy and watery soil, being extremely frequent. The winters are colder and the summers hotter than in Britain.

The principal rivers of the United Provinces are the Rhine, the Maas or Meuse, and the Escaut or Scheldt, which separates them from French Flanders. There are few lakes of any note, except the sea of Haerlem, near the Zuyder Zee.

There is little interesting in the natural history of Holland; the animals and plants resembling those of the adjacent countries of France and Germany and its minerals being extremely few. Its chief artificial products are flax, tobacco, madder and flower roots, butter and cheese. The state of agriculture is but little advanced; as almost the whole country is under grass, and the corn produced is not nearly sufficient for home consumption.

The changes which the coasts of the Dutch provinces have undergone, in consequence of the shifting of the beds of rivers, the encroachments or retiring of the sea, and tempests from the German ocean, render their progressive geography an interesting object. We find that in the latter periods of the Roman empire, the river Rhine divided itself into two great branches at Burghsium, the modern Schenck, about five miles north-west of Colonisa Trajana, near the present Cleves. The southern branch joined the Meuse at the town of Moes or Mooy, while the northern branch passed by Durenstadt, Utrecht, and Leyden, to the ocean. The northern branch of the Rhine was joined to the Yssel by the canal of Drusus (see Batavorum Insula), while this latter river flowed into a considerable lake called Fleva, now a southern portion of the Zuyder Zee. When the canal of Drusus was

(A) See each of these articles in the general alphabet.
was neglected, the waters of the Rhine poured into the Yssel with such violence as to increase the lake of Flevo to a greater expanse of water, so that instead of a river which once ran from that lake to the sea for nearly 50 Roman miles, there was opened the wide gulf which now forms the entrance. In the mean time, the northern branch of the Rhine became much diminished, and the channel of Drusus gradually disappeared. The estuaries of the Meuse and the Scheldt being open to great inroads from the sea, have also materially changed their figure and position; and the latter, in particular, which once formed merely a triangular island, divided into four or five smaller branches, which are now extensive creeks, dividing the islands of Zealand and South Holland. In the beginning of the 15th century, the estuary of the Meuse suddenly formed a vast lake to the south-east of Dort, overwhelming 72 villages, and 100,000 inhabitants. By a subsequent change, the Rhine was again subdivided, the northern branch falling into the Leek, while the southern formed the modern Waal.

The early history of these provinces, from their subjection by the Romans, till they fell under the dominion of the Spanish monarchy, has been already given under the article NETHERLANDS, so that we have here to relate only those transactions which have taken place since the accession of Philip II. to the crown of Spain [a].

At the death of Charles V. the Dutch provinces were in a very flourishing condition. In this small tract were then reckoned not fewer than 350 large walled cities, and 6,500 considerable towns or large villages, all become rich by their application to arts and commerce. The same application had diffused a spirit of independence among the inhabitants, who were jealous of every invasion of their rights and privileges. The reformed religion had made considerable progress among all ranks, and the doctrines of Calvin had been embraced by a great majority of the people. Hence, nothing could be more impolitic than the measures taken by Philip to advance the cause of popery, and to enforce obedience to the tyrannical acts of his deputies. The establishment of a court of inquisition, the increase of the number of bishoprics, the appointment of Cardinal Granvelle to be chief counsellor to the duchess of Parma, then regent of the Netherlands, and the enormous taxes levied to support the Spanish forces, were no trifling grievances, and created such a spirit of disaffection, that when the duchess assumed the reins of government, in the year 1565, the murmurs of the people could no longer be suppressed.

A deputation of the malcontents, at the head of whom were William prince of Orange, and his brother Louis of Nassau, with the counts of Egmont and Horn, waited on the duchess at Brussels, and insisted either on the dismissal of Cardinal Granvelle, or the calling of an assembly of the states-general. The duchess thought proper to comply with the former of these requests, but as that minister was succeeded by two of his creatures, who trod exactly in his footsteps, and in particular increased the religious persecutions, and the power of the inquisition, the popular ferment became greater than ever. The patriots sent Count Egmont to Madrid, to lay their grievances before the king; but that monarch with his accustomed insincerity, returned a favourable answer to their remonstrances, without changing any of the odious measures of the government at Brussels. In the mean time the diabolical combination that had been formed between Charles IX. of France and Isabella of Spain, for the massacre of the protestants, which soon after took place, had been whispered in the Low Countries, and consequently a general association was formed for the purpose of abolishing the court of inquisition. This association, headed by Henry de Broeckendrode, a descendant of the earls of Holland, waited on the regent in such a formidable body, that she was obliged to promise the exertion of her utmost influence towards obtaining their demands. It is said, however, that she could obtain no better terms from the bigotted Philip than that heretics should in future be hanged instead of burnt.

As the people found that their dutiful remonstrances could obtain no redress, they determined to take into their own hands the necessary reformation. In several towns in Flanders, the people assembled, destroyed churches, pulled down images, and committed other acts of violence. The principal inhabitants, however, while they were preparing to resist the oppressive acts of the government, behaved with more temperance and moderation; a new oath of allegiance had been exacted, and this the counts of Egmont and Horn, probably with a view to temporise, were induced to take, but the prince of Orange steadily refused, and retired into Germany, whither he was followed by great numbers of all ranks and conditions; so that within a few days 100,000 families had left the Low Countries. This emigration so much alarmed the duchess of Parma, that she resigned the regency.

The duchess was succeeded by the duke of Alva, Duke of who had been sent into the Netherlands with an army appointed by the Emperor of Germany to enforce obedience to the civil power. We have already drawn the character of this bloody man (see Alva), and have shown how well he was calculated to execute the orders of a tyrannical and bigotted master. He no sooner entered on his government than the whole country was filled with terror; Counts Egmont and Horn were ignominiously executed, and the estates of the prince of Orange were confiscated.

This prince and his brother had been labouring to support the cause of their injured countrymen among the German patriots.

[a] There is no part of the history of nations more interesting in itself, or more replete with useful lessons to rulers and to subjects, than that which records the struggles of a brave people to preserve or regain their liberties and independence. Hence the glorious contest which the Dutch provinces maintained against the power of Spain, and by which they finally triumphed over tyranny and oppression, might well deserve a much fuller detail than our confined limits will enable us to afford. In the copious view which we have here given of these transactions, we have endeavoured to catch the more prominent features, and thus in some measure preserve the spirit of the picture. We may refer our readers for a minute account of these events to The Modern Universal History, vol. xxxi. and Watson's History of the Reigns of Philip II. and Philip III.
German princes, and had raised a detachment of Germans, by which they were enabled to make head against the regent. The prince of Orange, who had been always a favourite with the people, was now rendered more popular in consequence of his sufferings in their cause, and was invited to take the command of the armed bodies which were preparing to resist the duke of Alva.

13 Commencement of hostilities.
Au. 1569.

The prince first penetrated into Brabant, and attempted to surprise Huremond, but was defeated by a detachment of the Spanish army; but his brother soon after overpowered a body of Spaniards, and killed 600. In a subsequent engagement, however, with the main body of Alva's army, Prince Louis was entirely defeated, and all his infantry cut in pieces. The prince of Orange finding that he could not at present keep the field against so formidable an enemy, and that his soldiers deserted in consequence of his ill success and want of pay, was, in 1569, obliged to disband his army, and return to Germany.

14 Cruelty of the duke of Alva.

The duke of Alva did not fail to make the most of his success. All the prisoners taken in the last campaign were put to death, and the 100th part of every man's estate, with a tenth of all merchandise, were exacted as an annual payment from the inhabitants, under the penalty of military execution. The states offered to pay an annual subsidy of 2,000,000 florins, in place of these taxes; but these offers were rejected with disdain.

15 A fleet fitted out by the patriots.
Au. 1571.

The people thus driven to despair, were resolved to strain every nerve to resist these oppressive acts. The tradesmen in the towns shut their shops, and the peasants refused to bring provisions to the markets. In the mean time a squadron of ships, which is known by the name of "gueses," had been fitted out by the prince of Orange, and the command given to Lumey. The trifling success of this squadron, which had captured Briel, in the island of Voorn, and repulsed a force sent against it by the duke of Alva, induced the Zealanders to collect all their ships, and oppose the enemy at sea. A considerable advantage was gained by this fleet, against a Spanish squadron commanded by the duke of Medina Celi. The duke was entirely defeated, many of his ships were taken, and the Zealanders carried off a booty of nearly 1,000,000 of livres.

16 Successes of the Orange party.

To increase his army, the governor had draughted men from the garrisons of most of the fortified towns, and thus exposed these to the attacks of the patriots. Accordingly, Lewis of Nassau surprised Mons, the county of Bergues gained possession of several towns in Overssel, Gelderland, and Friesland; while another party of the malcontents made themselves masters of North Holland. The duke of Alva now began to feel that he had gone too far, and attempted, when too late, to conciliate the good opinion of the people. He published an edict consenting to remit the most oppressive taxes, if the state could suggest any other method of raising the necessary supplies, and he convoked the states-general of the Provinces to assemble at the Hague. His promises and his threats were, however, now disregarded; and the states who, in contempt of his authority had assembled at Dordrecht, openly espoused the cause of their country, declared the prince of Orange commander of the national forces, and raised a considerable sum for the payment of his troops.

The prince's forces now amounted to 15,000 foot and 7000 horse, with which he advanced into Brabant, and took Huremond by assault. He then possessed himself of Mechlin, Oudenarde, and Dendermonde, and having levied contributions on those inhabitants who adhered to the government, he marched towards Mons then besieged by the duke of Alva, with an intention to raise the siege, by bringing the duke to a general action. This, however, Alva declined, and Mons was obliged to capitulate.

In the midst of these successes, a dam was thrown down over the arbour of the patriots, by the news of the horrible massacre of St. Bartholomew, and in the same degree the spirit of the Spaniards revived. The prince of Orange found himself obliged to retire to the province of Holland, leaving the cities which he had taken at the mercy of the army. Mechlin opened its gates, and was pillaged without mercy, while the other towns were evacuated by the garrison, and loaded with heavy impositions. In a short time nothing remained to the patriots, but the provinces of Holland and Zeeland; but these stood firm in the cause of liberty, and soon became the seat of a sanguinary warfare. Frederick de Toledo was detached by the duke of Alva to reduce the insurgents in these quarters. He quickly reduced Waarden, where his soldiers committed the most horrid acts of barbarity. The capture of this place was followed by that of Haerlem after an obstinate resistance.

To balance this ill success by land, however, the Zealanders obtained many important advantages by sea. They attacked the harbour of Antwerp, and carried off the possessions of several ships; and when the governor equipped a squadron to oppose them, it was thrice encountered by Wetz, the Zeeland admiral, and totally defeated. In the mean time the Spanish forces, under Frederick of Toledo, consisted of 15,000 veterans, set down before Alkmaar, the chief town of the capital of Holland, a town without regular fortifications, and defended only by 300 burghers and 800 soldiers, in great want of provisions, and without any prospect of speedy relief; yet this place, though attacked with great vigour, by a battery of 20 pieces of heavy cannon, which effected a breach in one of the walls, held out against every attempt, and the Spanish soldiers who attempted to storm the place by the breach, were repulsed with great slaughter, and Frederick was at length compelled to raise the siege.

Notwithstanding these partial successes, the affairs of the patriots were still in a precarious situation. Don Louis de Requesenes, who had succeeded the duke of Alva in the government, was directed to carry on the war with the utmost vigour. The prince of Orange had, after a long siege, made himself master of Middelburg, but had sustained a great loss by the defeat and death of his brother Louis. The patriotic cause derived some advantage, however, from a mutiny which took place in the Spanish army, but this advantage was of a transient nature.

In the commencement of the year 1575, an attempt of the States of Brabant at negotiation took place between the contending parties; but they could not come to terms of accommodation, and the war was continued with great virulence. Though much distressed in his finances, Philip made extraordinary efforts to crush the patriots, and succeeded so far, that they almost despaired of ultimate success. In this dilemma they sent a deputation to Queen Elizabeth of England, offering to become her subjects, if she would
would afford them her protection; but from political reasons she declined the offer. The distresses which Philip now experienced, and the death of his deputy Requesens, did more for the cause of the patriots than all their own exertions.

Profiting by those events, in the latter end of this year they attacked and carried the citadel of Ghent, while the inhabitants of Antwerp, in revenge for having been pillaged by the Spanish garrison that held the citadel, united in the common cause, by what was called the pacification of Ghent.

A second application to Queen Elizabeth met with more success, and she advanced them the sum of 20,000l. sterling, on condition that they would not invite the French into their territories, that they would listen to any reasonable terms of accommodation, and repay the loan in the course of the ensuing year. Agreeably to these conditions, a cessation of hostilities was granted to the states by Don John of Austria, the present governor, and a treaty was entered into with him for disbanding the foreign troops. The weak state of the government required some concessions, and Don John acceded to the pacification of Ghent, by which most of the demands of the patriots were granted. The provinces of Holland and Zealand, however, conceiving that by this treaty the other provinces had conceded too much, refused their concurrence, and hostilities soon recommenced.

The king of Spain dissatisfied with the concessions of Don John, recalled that governor, and appointed the archduke Matthias in his room, while he made additional preparations for a vigorous prosecution of the war. The states-general in their turn made another application to Queen Elizabeth, and obtained from her, not only a promise of 100,000l. sterling, but of a body of forces consisting of 5000 foot and 1000 horse; in return for which, the states agreed to put into her possession certain fortified towns, and to transport and pay the forces. These supplies, however, Elizabeth afterwards declined sending, though she professed all possible good will towards the provinces and their cause. A change of measures which about this time took place in the states of Guelderland and Groningen, in favour of the protestant interest, contributed not a little to the general cause of the patriots, though several of the provinces were still torn by intestine dissensions and jarring interests. At last the prince of Orange, perceiving that little confidence was to be placed in the unanimity of provincials rent by faction, different in religion, and divided by ambition, political maxims, and private interest, formed the scheme of more closely uniting the provinces of which he was governor, and cementing them with those more contiguous, in which the protestant interest prevailed. Such an alliance was subject to fewer difficulties than attended the more general one of uniting all the provinces; it was in fact the only measure that could be proposed with safety, and it was prosecuted with that alacrity and address for which William was deservedly celebrated.

On the 23rd of January 1579, deputies from the provinces of Holland, Zealand, Utrecht, Friesland, Groningen, Overysel, and Guelderland, met at Utrecht, and signed the alliance ever since known by the name of the Union of Utrecht, the basis of that commonwealth so renowned by the appellation of the United Provinces. This treaty of alliance was founded on the infraction of the pacification of Ghent solemnly acceded to by Philip, and the late invasion of certain towns in Guelderland.

It was not hereby intended to divide the seven provinces from the other ten, or to renounce the pacification of Ghent; its object was to preserve the liberty stipulated in that pacification, by more vigorous operations, and united councils. The chief articles of this union were the following:

That the seven provinces shall unite themselves in interest as one province, never to be separated or divided by testament, donation, exchange, sale, or agreement; reserving to each particular province and city all its privileges, rights, customs, and statutes. In all disputes arising between either of the provinces, the rest shall interpose only as mediators. They shall assist each other with life and fortune against every foreign attempt upon any particular province, whether to establish sovereignty, the Catholic religion, arbitrary measures, or whatever else may appear inconsistent with the liberties of the province, and the intention of the alliance. All frontier towns belonging to the United Provinces shall, if old, be fortified at the expense of the provinces; if new, at the joint expense of the union. That the public imposts and duties shall be farmed for three months to the highest bidder, and employed with the king's taxes in the public service. No province, city, or member of the union, shall contract an alliance with any foreign prince or power, without the concurrence of all the other members. That foreign powers shall be admitted into the alliance, only by consent of all the contracting parties. As to religion, the provinces of Holland and Zealand shall act in that particular as they think advisable: the rest shall adhere to the purport of the edict published by the archduke Matthias, which prescribed, that no man should be oppressed on account of conscience. All the inhabitants from the age of 18 to 60, shall be trained and disciplined to war. That peace and war shall be declared by the unanimous voice of all the provinces; other matters that concern the internal policy shall be regulated by a majority. That the states shall be held in the usual constitutional manner, and coinage shall be deferred to future determination. Finally, the parties agree, that the interpretation of these articles shall remain in the states-general; but in case of their failing to decide, in the stadholder.

Soon after the union of Utrecht, King Philip did all his power to detach the prince of Orange from the union, and to establish a new confederation. He offered to restore him to all his estates, to indemnify him for all his losses, and give him the first place in his esteem and favour; but William was too wise to rely on the promises of a prince who had already shown himself perfidious, and too generous to abandon a cause in which he had embarked from no interested motives. He determined to share the fate of the United Provinces, and not to disappoint the hopes which they had conceived of his conduct.

In the mean time the duke of Parma was doing his utmost to disconcert the projects of the prince of Orange, and to reduce the provinces to their obedience. He invested Maastricht, and carried it after a siege of four months, and reduced the republican general La Noue to such straits, that he was glad to retreat under the cannon of Antwerp. At length the Provinces, by the advice of the prince of Orange, resolved to solicit the assistance
United
Provinces.

assistance and protection of the duke of Anjou, to whom they had formerly applied in vain, and to offer him the sovereignty of their territories. Accordingly, in 1580, they solemnly renounced their allegiance to Philip, and acknowledged as their sovereign, Francis Hercules de Vallois, duke of Alençon and Anjou; and in the following year they published an edict, entitled the abdication of Philip king of Spain, for ever excluding that monarch from any right or authority over the Netherlands.

In the beginning of the year 1582, the duke of Anjou, who had already taken an active part in favour of his new subjects, and had opposed the duke of Parma with some success, arrived in Holland from England; and in the month of February he was solemnly installed at Antwerp as duke of Brabant. It appears, however, that the prince of Orange, though he had been the great promoter of this measure, and even placed the ducal coronet on the head of the new sovereign, still possessed the greatest influence and authority in the United Provinces.

When Philip of Spain found that he could not bribe the prince of Orange to his interest, he resolved to use every method to rid himself of so dangerous an opponent. Soon after the signing of the union of Utrecht, Philip had prescribed the prince, and offered a reward of 25,000 crowns to any person that should bring him dead or alive to Madrid. The greatness of the reward, and a bigoted regard for the interests of the Catholic religion, promptly induced several to attempt murdering the prince of Orange. He narrowly escaped assassination in 1582; but, two years after he met his unmerited fate at Delft, by the hands of one Guin, or, as he is commonly called, Balhazarr Gerrard. About the same time the duke of Anjou died in France; and the provinces of Holland and Zealand appointed Maurice, son of the late prince of Orange, to be their stadtholder and captain general. For an account of the actions of this great man, see the article Maurice of Nassau.

Philip II. died in 1598, and Philip III. prosecuted the war with the United Provinces with as much rancour as his predecessors, but with much worse success. The great defeat sustained by the archduke Albert in 1602, and many subsequent disasters, induced the court of Madrid at length to listen to terms of accommodation. In 1607 a suspension of hostilities took place, and the year following a treaty on terms favourable to the Provinces was concluded for 12 years.

At the expiration of the truce, both parties prepared for a renewal of hostilities; but now the Spaniards fought with considerable disadvantage: From a strange policy, which they have since frequently practised, in their contests with the powers of Europe, the Dutch contrived to advance their commercial interests at the expense of their enemy. A very lucrative trade took place between the principal Dutch ports and those of Spain, by which the Spaniards were supplied by their enemies even with ammunition and warlike stores. At the same time the Dutch enriched themselves by numerous prizes taken from the Spaniards, and, in particular, gave a severe blow to the resources of the court of Madrid, by capturing the flota from Mexico, a prize valued at 15,000,000 of livres.

These repeated losses of the Spaniards proved the impotency of their continuing the war against a people so de-
The Dutch compléted the sieges of the fortified towns, and the French marched on the banks of the Rhine and the Meuse, with the French generals and ministers who had opposed the elector of Brandenburg and the German general Montecuccoli, who had joined their forces, and were about to pass the Rhine. For three whole months were the elector and Montecuccoli employed in abortive attempts to effect a passage at Mentz, Coblenz, Strasbourg, and other places. This answered the purpose of making a powerful diversion in favour of the Dutch, though they could not accomplish their design of joining the prince of Orange. After repeated disappointments, the imperial army directed its march to Westphalia; and Turenne followed, in order to the bishop of Munster steady to his engagements. For half the campaign he with a body of 16,000 men, baffled every stratagem of the elector and Montecuccoli, the latter the most renowned general of the empire, at the head of an army near triple his strength. He obliged them to go into winter quarters, in a country harassed and exhausted; and confirmed the bishop of Munster in the alliance of France, at the time he was on terms with the emperor. He obliges the elector of Brandenburg, who took the chief command during Montecuccoli's illness, to abandon the siege of Warle, took Umer Kamen, Altena, Berkhem, and several other towns and fortresses. By continuing his operations, he forced the elector out of his winter quarters again into the field, chased him from post to post, until he obliged him to quit Westphalia, repass the Weser, and retire with precipitation into the bishopric of Hildesheim. After taking possession of the elector's towns in Westphalia, he pursued him into the bishopric of Hildesheim, and at length, by mere dint of superior genius, forced him to seek shelter in his hereditary dominions. All this was effected after Louvois had appointed the marshall's army quartered in Alsace and Lorraine, amidst the rigours of a severe winter, opposed by a superior enemy, by the artifices of Louvois, and seconded only by his own prudence, and the affection of his troops, which he maintained in defiance of all the difficulties, hardships, and dangers, they encountered. It was indeed supposed, that Montecuccoli, was prevented from giving Turenne battle by the remonstrances of Prince Lobkowitz, the emperor's ambassador, influenced by the gold of Louis. Certain indeed it is, that Montecuccoli's illness arose from his chagrin at seeing all his projects frustrated by the unsteady dilatory conduct of the court of Vienna. Louis's negotiations disturbed Europe no less than his arms. His tools and creatures swarmed in every court. Leopold could not be prevented from declaring in favour of Holland; but his ministers were bought off from considering the emperor's intentions. The whole English nation exclaimed against the alliance of their kingdom with France; but Charles stood in need of French gold to supply his extravagance and profligacy. The elector of Bavaria had indeed been compelled by Louis to retire to his capital; but it was by dint of intrigue that he was forced from his alliance with Holland, and constrained to make a peace with France.

While the French generals were thus carrying all before them, the combined fleets of France and England...
were scarcely less unsuccessful against the maritime power of the Dutch. The English squadron under the duke of York, uniting to that of France under D'Estrees, thrice engaged the Dutch fleet commanded by De Ruyter; and though neither party could boast of much advantage, the check sustained by the Dutch admirals was of essential service to the cause of the allies.

At length the tide of fortune began to turn in favour of the United Provinces. The court of Spain, jealous of the growing power of France, embraced the cause of the Dutch; and sent an army of 10,000 men to the assistance of the prince of Orange, while the mercenary king of England was compelled by his parliament to withdraw from his unnatural alliance with the French king; and the late ill success among the allied troops of France and Germany cooled the elector of Cologne and the bishop of Munster, in their friendship towards Louis. Thus that monarch, forsaken by his allies, was compelled to maintain singly a war against the empire, Spain, and the United Provinces. The accession of the prince of Orange to the throne of England, in 1688, gave an additional blow to the French power, by bringing on an intimate connection between England and Holland.

At length Louis was compelled to negotiate for peace, which was concluded in 1697, by a treaty extremely favourable to the United Provinces.

An. 1697.

Summary of the Dutch affairs from the end of the 17th to the beginning of the 18th century.

After the death of William III. the same plan of humbling the French king, was, in conjunction with the states-general, pursued by his successor Queen Anne; and the numerous and important victories of the duke of Marlborough and Prince Eugene, led to the famous treaty of Utrecht, in 1713. See BRITAIN, No. 340—371. In 1747, the office of stadtholder was declared hereditary in the princes of Orange. In the war that took place in 1756, between France and England, a French party was formed in Holland, in opposition to the stadtholder, who favoured the alliance with France. Hence arose a jealousy between the two allies, which, during the American war, increased to an open rupture. See BRITAIN, No. 427, and No. 598, et seq. In 1787, some disputes took place between the stadtholder and the states-general, which induced the former to require the assistance of the king of Prussia. That monarch accordingly sent an army of 18,000 Prussians to Amsterdam, under the duke of Brunswick, who, in 1788, brought the whole country into subjection, and reinstated the stadtholder in his authority. See PRUSIA, No. 75. In 1794 the republican armies of France having overrun the greater part of Flanders, took possession of the Dutch provinces, which they converted into the Batavian republic. The stadtholder found refuge in England, and the allied armies of Germany and Prussia retreated into Germany. See FRANCE, No. 409, et seq. In the summer of 1799, a considerable British force landed in the Texel island, made themselves masters of the Dutch fleet, and, in conjunction with a body of Russians, gained some advantages on the continent. Being opposed, however, by a superior French force, the army was obliged to reembark, and return to England. See BRITAIN, No. 1069. By the treaty of Amiens, concluded in March 1802, all the colonies taken by the British were restored to Holland, except the island of Ceylon. On the renewal of hostilities in 1803, the Batavian republic was again compelled to take an active part against Britain, and in consequence again lost the Cape of Good Hope, and several other colonies, besides having her trade entirely ruined. Soon after the imperial decision of France was contested on Napoleon Bonaparte, his brother, Louis, was appointed king of Holland. Louis, however, proved to be a man not calculated to serve his brother's purposes. He was considerate and humane, paid great attention to the complaints of his subjects, employed none but Dutchmen in his government, and continually exerted his influence to soften the harsh measures of which he was compelled to be the instrument. The nation was sensible of his good services, and Louis was highly popular. But in the same proportion as he gained the confidence of the nation, he lost that of Napoleon; who at length determined on setting him aside. Louis learned what was intended, and escaped the humiliation of being deposed, by resigning the crown to his infant son on the first of July 1813. On the 9th July, Napoleon issued a decree, annulling the United Provinces to the French empire. From this period Holland followed the fortunes of France, till the battle of Leipsic shattered the French power. On the 15th November, 1813, one month after the battle of Leipsic, a simultaneous rising took place in all the most considerable towns. The French garrisons were feeble and soon mastered; and on the 21st November, a deputation arrived in London to invite the prince of Orange to return, who accordingly arrived there on the 30th, and obtained immediate possession of the government. By the treaty of Paris, 30th May 1814, the ten provinces of the Netherlands were united to Holland, and the prince of Orange took the title of king of the Netherlands. This plan of union was not favourably received on either side, there being an ancient grudge between the two countries, which was strengthened by commercial jealousy, and by difference of religion, the Dutch being chiefly of the reformed church, and the Belgians catholics. The population of both countries in 1818 was 5,266,000.

According to the statistical table given in No. 2, the population of the United Provinces in the year 1799 appears to amount to 1,880,469 individuals; but that enumeration being made while the French had possession of the country, was believed to be under the truth. By returns made to the government in 1818, the population amounted to 2,010,159.

In the late republic of Holland, previous to the Crisis of the French revolution, the states-general formed the greatest and council of the nation. That assembly was formed by popular deputies from the provincial states, and was invested with the supreme legislative power. It could not, however, make peace or war, form new alliances, or levy taxes, without the consent of the provincial states, nor could these determine any point of importance, without the consent of each of the cities that had a voice in their assembly. The stadtholder exercised a considerable part of the executive power, though in later times his power became very limited. The grand sejm was properly a minister of the prince; and though he possessed great influence, being a perpetual member of the states-general, and of the secret committee, he was considered as inferior to rank to all the deputies.

The revenues of the United Provinces arose principally from taxes imposed on each province and city, according
cording to their ability. These consisted chiefly of a general excise, a land-tax, a poll-tax, and heavy money; and are supposed to have amounted to 3,000,000l. sterling.

Before the French revolution, the Dutch maintained a peace establishment of 30,000 men, which in war was augmented to above 50,000, chiefly by mercenary troops from Germany. Their naval establishment was highly respectable; and at the end of the 17th century it exceeded that of any other maritime power in Europe. Before the late war they could muster 40 sail of the line, 40 frigates, and 10 cutters. Since the celebrated engagement off the Dogger Bank during the American war, the Dutch have been scarcely able to cope with the English at sea; and the victory off Camperdown in October 1797, with the subsequent loss of the Texel fleet in 1798, proved the death-blow to the naval power of Holland.

Before the late change of government, the established religion of Holland was Presbyterianism, according to the doctrines of Calvin; though all sects of Christians were tolerated. The church was governed by consistories, classes, and synods, from which there was an appeal to one great national synod, subject to the control of the states-general.

The Dutch language is a dialect of the German, and in many respects bears a considerable resemblance to the Old English and Lowland Scotch. The literature of the United Provinces has long been respectable; and the universities of Leyden, Utrecht, Groningen, Harderwyck, and Franeker, have produced many eminent and celebrated men in almost every department of science. Grotius, Erasmus, Boerhaave, Leuwenhoek, Swammerdam, Gravius, Burman, Hoogewegen, &c. are names mentioned with admiration and respect in the annals of literature.

The Dutch manufactures consist principally of fine linens, earthen ware, chiefly manufactured at Delft, especially white and painted tyles, tobacco-pipes, borax, oil, starch, paper, leather, woolen and cotton cloths, snuff, tobacco, and gin.

The commerce of the Dutch was formerly more extensive than that of any other country in Europe. They carried on a trade with every quarter of the globe, and in particular their East India Company was perhaps the richest society of merchants in the world. Holland was almost the exclusive centre of the spice trade; and the extensive fisheries on the coast of Greenland and in the North sea, supplied the greater part of Europe with whale oil and herring. Besides this external commerce, they carried on a considerable inland traffic with the interior of Germany, from which they brought immense quantities of timber. Vast rafts of trees, many hundred feet in length, set out annually from the forests of Andernach, and other places on the Rhine, and proceeding down the river under the direction of a great body of labourers, that formed a village of huts on the surface of the raft, sailed down the Rhine and the Waal to Dort, where the timber was disposed of, and where one raft has been sold for 30,000l. sterling. All the foreign trade of Holland may now be considered as annihilated, but the inland traffic in wood and spirit is still continued.

The inland commerce of the United Provinces is greatly promoted by the facility of conveyance from one part of the country to another, by means of the numerous canals.

The Dutch are, by constitution, a cool, or rather Character phlegmatic people, laborious, patient, obstinate, and of the persevering. When stimulated by any predominant passion, as avarice, or formerly love of liberty, they are capable of great exertions. Economy and order in the management of their pecuniary concerns are common among all classes, with whom it is an established maxim to spend less than their income. Interest and love of money regulate all their actions, and appear to supplant in their breasts every noble and generous feeling. These prominent features in the national character are, of course, modified by the rank or situation of the different orders in society. The higher ranks value themselves much on their distinctions, are reserved to strangers, but affable and obliging to those with whom they have had an opportunity of becoming acquainted; friendly, candid, and sincere. The mercantile men and traders are, in general, fair and honest in their transactions; though their natural thirst of gain sometimes tempts them to deceive and overreach their customers. The lower ranks are ignorant, dull, and slow of apprehension, but open to conviction, and patient of fatigue and labour.

Dress, among the Dutch, is regulated less by fashion, Manners then by an attention to climate and season. The moisture and inconstancy of these require a greater quantity of clothing than is found necessary in other countries under the same latitude; and, among the ordinary classes, broad hats, large breeches, and thick boots and shoes, are still almost universal. Most of the women wear hats with low crowns and very broad rims, with jerkins and short petticoats; and, what appears exceedingly ridiculous to strangers, the boys and girls wear the same dress as the men and women.

A close attention to regularity and neatness in the streets and the interior of the houses prevails throughout the United Provinces, but is most conspicuous in North Holland. This was at first rendered necessary by the nature of the climate, to prevent rust and mouldiness from destroying their utensils and furniture, and has since become a habit, conducive at once to comfort and to health. The manner of living in Holland was, till of late, not a little gross. Their diet consisted much of high-seasoned and salted meats, butter, cheese, and spirituous liquors. In no country was gormandizing reduced more to a system. Convivial entertainments were extremely frequent; and the interval between the more substantial meals of dinner, tea, and supper, were filled up with cakes, fruits, jellies, and other light things; not to mention smoking and drinking, which supplanted the place of conversation (c). If we may rely on the report of a late writer on the statistics of Holland*, the style of living is now much changed, though not much improved.

---

(c) We must admit, that, in so moist and cold a climate, a full and generous diet may be safe if not necessary; but the Dutch, like many of our own countrymen, absurdly carried the same system into their tropical colonies.
The account given by a late traveller (see Barrow's *Voyage to Cochin-China*) of the luxurious mode of living at Batavia, affords a melancholy, but accurate picture of Dutch gluttony.
VOETIUS or VOET, GISSBERT, an eminent divine of the 16th century, was professor of divinity and the Oriental tongues at Utrecht, where he was also minister. He assisted at the synod of Dort; and died in 1676, aged 87. He wrote a great number of works, and was the declared enemy of Des Cartes and his philosophy. His followers are called Voetians. Voetius had two sons, Daniel and Paul, both authors. John Voetius, the son of Paul, was doctor and professor of law at Hertborn, and wrote a commentary on the Pandects.

VOICE, a sound produced in the throat and mouth of an animal, by peculiar organs.

Voices are either articulate or inarticulate. Articulate voices are those whereof several conspire together to form some assemblage or little system of sounds: such are the voices expressing the letters of an alphabet, numbers of which joined together form words. Inarticulate voices are such as are not organized, or assembled into words: such is the barking of dogs, the braying of asses, the hissing of serpents, the singing of birds, &c.

For a description of the organs of the voice, see Anatomy; see also Physiology Index.

Voice, in Grammar, a circumstance in verbs, whereby they come to be considered as either active or passive, i.e., either expressing an action impressed on another subject, as I beat; or receiving it from another, as, I am beaten. See Grammar.

Voice, in matters of election, denotes a vote or suffrage.

Voice, in Oratory. See Declamation; Reading, No. 5; and Oratory, No. 120—131.

VOLANT, in Heraldry, is when a bird, in a coat of arms, is drawn flying, or having its wings spread out.

VOLATILE, in Physics, something that is easily dissipated by fire or heat. VOLATILE Alkali. See Ammonia, Chemistry Index.

VOLATILISATION, the art of rendering fixed bodies volatile, or of resolving them by fire into a vapour.

VOLCANO, a name given to burning mountains, or to vents for subterraneous fires. See Geology Index, AEThNA, HECLA, &c.

VOLERY, a bird-cage, of such a size that the birds have room to fly up and down in it.

VOLGA, the largest river in Europe, derives its origin from two small lakes in the forest of Volkonski about 80 miles from Tver, a town in Russia. It is navigable a few miles above that town. This noble river waters some of the finest provinces in the Russian empire, and at last falls into the Caspian sea by several mouths, below Astrakan.

The Volga is subject to annual inundations. In the year 1774, the inundations exceeded the lowest water-mark by nearly 40 feet, since which period they have been rather on the decline; for in 1775, they rose only to 39 feet 2 inches above that mark; in 1782, they rose to 26 feet; in 1785, to 25 feet 2 inches; and in the year 1791, their height was the same. Pallas is of opinion that this phenomenon may have originated from the diminished quantity of snow and rain which had fallen in the higher countries; from the greater evaporation of the Caspian sea, and the gradual extension of the different mouths of the river, or perhaps from the joint operation of all these causes.

VOLITION,
VOLITION, an act of willing. See Metaphysics.

Volley, a military salute, made by discharging a great number of fire arms at the same time.

Volones, in Roman antiquity, slaves who in the Punic war voluntarily offered their service to the state, which is the reason of the appellation; upon which they were admitted to citizenship, as none but freemen could be soldiers.

Voll, in the manege, a round or circular treadmill, and, by the phrase to make volle, is understood a gate of two treades, made by a horse going sideways round a centre, in such a manner that these two treades make parallel tracks; one larger, made by the fore-feet, and another smaller, made by the hind-feet; the group approaching towards the centre, and the shoulders bearing out.

Voltaire, Francis Arouet de, a celebrated French author, was born at Paris, February 20, 1694. His father, Francis Arouet, was ancien notaire au Châtelet, and treasurer of the chamber of accounts; his mother, Mary-Margaret Draumart. At the birth of this extraordinary man, who lived to the age of 85 years and some months, there was little probability of his being reared, and for a considerable time he continued remarkably feeble. In his earliest years he displayed a ready wit and a sprightly imagination; and, as he said of himself, made verses before he was out of his cradle. He was educated under Father Poré, in the college of Louis the Great; and such was his proficiency, that many of his essays are now existing, which, though written when he was between 12 and 14, show no marks of infancy. The famous Ninon de l'Enclos, to whom this ingenious boy was introduced, left him a legacy of 2,000 livres to buy him a library. Having been sent to the equity schools on his quitting college, he was so disgusted with the dryness of the law, that he devoted himself entirely to the muses. He was admitted into the company of the alibi Chaslieu, the marquis de la Fare, the duc de Sully, the grand prior of Vendome, Marshal Villars, and the chevalier du Boulonn; and caught from them all the easy style and delicate humour which distinguished the court of Louis XIV. Voltaire had early imbibed a turn for satire; and, for some philippics against the government, was imprisoned almost a year in the Bastille. He had before this period produced the tragedy of Oedipus, which was represented in 1718 with great success; and the duke of Orleans happening to see it performed, was so delighted, that he obtained his release from prison. The poet waiting on the duke to return thanks, "Be wise," said the duke, "and I will take care of you." "I am infinitely obliged (replied the young man); but I intreat your royal highness not to trouble yourself any farther about my lodging or board."

He began his Henriade before he was 18. Having one day read several cantos of this poem when on a visit to his intimate friend, the young president de Maisons, he was so teased with objections, that he lost patience, and threw his manuscript into the fire. The president Henaut with difficulty rescued it. "Remember (said Mr. Henaut to him, in one of his letters) it was I that saved the Henriade, and that it cost me a handsome pair of tongs." Some years after, several copies of this poem having got abroad, while it was only a sketch, an edition of it was published, with many false names, under the title of The League. Instead of fame and friends, the author gained only enemies and mortification, by this first edition. The bishop took fire at it, and the poet was considered as highly criminal for praising Admiral Coligny and Queen Elizabeth. Endeavours were even used to get the piece suppressed; but this strange design proved abortive. His chagrin, on this occasion first inspired him with the thought of visiting England, in order to finish the work, and publish it in a land of liberty. He was right; for King George I. and more particularly the princess of Wales, afterwards queen of England, raised an immense subscription for him. Their liberality laid the foundation of his fortune; for on his return to France in 1728, he put his money into a lottery established by M. Desfores, comptroller-general of the finances. The adventurer received a rent charge on the Hotel-de-Ville for their tickets; and the prizes were paid in ready money, so that if a society had taken all the tickets, it would have gained a million of livres. He joined with a numerous company of adventurers, and was fortunate.

His Lettres Philosophiques, abounding in bold expressions and indecent vitriolisms against religion, having been burnt by a decree of the parliment of Paris, and a warrant being issued for apprehending the author in 1735, Voltaire prudently withdrew, and was sheltered by the marchioness du Chatelet, in her castle of Cirey, on the borders of Champagne and Lorraine, who entered with him on the study of the system of Leibnitz, and the Principia of Newton. A gallery was built, in which Voltaire formed a good collection of natural history, and made an infinite number of experiments on light and electricity. He laboured in the mean time on his Elements of the Newtonian Philosophy, then totally unknown in France, and which the numerous admirers of Des Cartes were little desirous to be known. In the midst of these philosophic pursuits he produced the tragedy of Alcina. He was now in the meridian of his age and genius, as was evident from the tragedy of Medea; first acted in 1744; but it was represented to the procureur general as a performance offensive to religion; and the author, by order of Cardinal Fleury, withdrew it from the stage. Medea, played two years after, 1745, gave an idea of a species of tragedy, of which few models had existed. It was at the representation of this tragedy, that the pit and boxes were clamorous for a sight of the author; yet it was severely censured when it came from the press. He now became a favorite at court, through the interest of Madame d'Etiole, afterwards marchioness of Pompadour. He was appointed a gentleman of the bed-chamber in ordinary, and historian of France. He had frequently attempted to gain admittance into the Academy of Sciences, but could not obtain his wish till 1746, when he was the first who broke through the absurd custom of filling an inaugural speech with the fulsome adulation of Richelieu; an example soon followed by other academicians. From the satires occasioned by this innovation he felt so much uneasiness, that he was glad to retire with the marchioness du Chatelet to Luneville, in the neighbourhood of King Stanislaus. The marchioness dying in 1749, Voltaire returned to Paris, where his stay was but short. The king of Prussia now gave Voltaire an invitation to live with him, which he accepted towards the end of August.
VOLTAIRE. On his arrival at Berlin, he was immediately presented with the Order of Merit, the key of chamberlain, and a pension of 20,000 livres. From the particular respect that was paid to him, his time was now spent in the most agreeable manner; his apartments were under those of the king, whom he was allowed to visit at stated hours, to read with him the best works of either ancient or modern authors, and to assist his majesty in the literary productions by which he relieved the cares of government. But a dispute which arose between him and Maupertuis soon brought on his disgrace. Maupertuis was at some pains to have it reported at court, that one day while General Mannstein happened to be in the apartments of M. de Voltaire, who was then translating into French the Memoirs of Russia, composed by that officer, the king, in his usual manner sent a copy of verses to be examined, when Voltaire said to Mannstein, "Let us leave off for the present, my friend; you see the king has sent me his dirty linen to wash, I will wash yours another time." A single word is sometimes sufficient to ruin a man at court; Maupertuis imputed such a word to Voltaire, and succeeded. It was about this very time that Maupertuis published his very strange Philosophical Letters; and M. de Voltaire did not fail to heighten, with his utmost powers of raillery, every thing which he found, or could make ridiculous, in the projects of M. Maupertuis, who was careful to unite his own cause with that of the king; Voltaire was considered as having failed in respect to his majesty; and therefore, in the most respectful manner, he returned to the king his chamberlain's key, and the cross of his Order of Merit; accompanied with four lines of verse, in which he, with great delicacy, compares his situation to that of a jealous lover, who sends back the picture of his mistress. The king returned the key and the ribbon; but they were not followed by an immediate reconciliation. Voltaire set out to pay a visit to her highness the duchess of Gotha, whom he honoured with his friendship as long as she lived. While he remained at Gotha, Maupertuis employed all his batteries against him: Voltaire was arrested by the king's orders, but afterwards released.

He now settled near Geneva; but after being obliged to quit that republic, he purchased the castle of Ferney in France, about a league from the lake of Geneva. It was here that he undertook the defence of the celebrated family of Calas, and it was not long before he had a second opportunity of vindicating the innocence of another condemned family of the name of Sirven. It is somewhat remarkable, that in the year 1774, he had the third time a singular opportunity of employing that same zeal which he had the good fortune to display in the fatal catastrophe of the families of Calas and Sirven.

In this retreat M. Voltaire continued long to enjoy the pleasures of a rural life, accompanied with the admiration of a vast number of wits and philosophers throughout all Europe. Near him in length, however, with his situation, or yielding to the importunities of friends, he came to Paris about the beginning of the year 1778, where he wrote a new tragedy called Irene. By this time his understanding seems to have been impaired, either through the infirmities of age, or continued intoxication by the flattery of others; and he ridiculously suffered himself to be crowned in public with laurel, in testimony of his great poetical merit. He did not long survive this farce: for having overeasted himself with receiving visits, and exhausted his spirits by supplying a perpetual fund of conversation, he was first seized with a spitting of blood; and at last becoming restless in the night-time, he was obliged to use a soporific medicine. Of this he unluckily one night took so large a dose, that he slept 36 hours, and expired a very short time after awakening from it.

VOLUME, in matters of literature, a book or writing of a just bulk to be bound by itself. The name is derived from the Latin volvere, "to roll up," the ancient manner of making up books being in rolls of bark or parchment. See BOOK.

VOLUNTARY, in Music, a piece played by a musician extemopore, according to his fancy. This is often used before he begins to set himself to play any particular composition to try the instrument, and to lead him into the key of the piece he intends to perform.

VOLUNTEERS, persons who, of their own accord, for the service of the prince or state, serve in the army without being enlisted, to gain honour and preferment.

VOLVOX, a genus of animals belonging to the vermes infusoria. See HELMINTHOLOGY Index.

VOLUSENUS. See WILSON.

VOLUTA, a genus of shell-fish. See CONCHOLOGY Index.

VOLUTE, in Architecture, a kind of spiral scroll used in Ionic and Composite capitals, whereof it makes the principal characteristic and ornament.

VOMICA, in Medicine, an abscess of the lungs. See MEDICINE, No 186.

Nux VOMICA, in Pharmacy. See MATERIA MEDICA Index.

VOMIT. See EMETIC, MATERIA MEDICA Index.

VOMITING, a retrograde spasmodic motion of the muscular fibres of the esophagus, stomach and intestines, attended with strong convulsions of the muscles of the abdomen and diaphragm; which when gentle create a nausea, when violent a vomiting.

VOORN, one of the islands of Holland, lying at the mouth of the Maese, opposite to Rotterdam.

VORTEX, in Meteorology, a whirlwind, or sudden, rapid, and violent motion of the air in circles; or that motion of the water called an eddy or whirlpool.

Vortex, in the Cartesian philosophy, is a system of collection of particles of matter moving in the same way, and round the same axis.

VOHITICELLA, an animalcule. See MICROSCOPE.

VOGES, a department in the east of France, forming part of the ancient Lorraine. It takes its name from Mount Vosges, which forms its eastern boundary. It is traversed by the upper branches of the Moselle. The soil of this department is poor in the hilly parts, but tolerably fertile in the plains. It produces vines, though not to a great extent. There are mines of iron, copper, lead, and silver, and quarries of marble. The manufactures are trifling. The extent of the department is 587,955 hectares, and the population in 1817 was 334,160. Epinal is the chief town.

VOSSIUS, JOHN GERARD, a most learned and laborious writer of the 17th century, was a considerable family in the Netherlands; and was born in 1577, in the palatinate, near Heidelberg, at a place where his father John Vossius was minister. He was made direc-
UR

UR. Vote of the college of Dort, and afterwards professor of eloquence and chronology at Leyden, from whence he was called in 1633 to Amsterdam, to fill the chair of professor of history. He died in 1649.

VOTE, the suffrage or resolve of each of the members of an assembly, where any affair is to be carried by a majority; but more particularly used for the resolves of the members of either house of parliament.

VOTIVE MEDALS, those on which are expressed the vows of the people for the emperors. See MEDAL. VOW, a solemn religious promise or oath. See OATH.

The use of vows is found in most religions. They make up a considerable part of the Pagan worship, being made either in consequence of some deliverance, under some pressing necessity, or for the success of some enterprise. Among the Jews, all vows were to be voluntary, and made by persons wholly in their own power; and if such person made a vow in any thing lawful and possible, he was obliged to fulfill it. If he appointed no particular time for accomplishing his vow, he was bound to do it in-tantely, lest by delay he should prove less able, or be unwilling, to execute his promise. Among the Romanists, a person is constituted a religious by taking three vows; that of poverty, chastity, and obedience.

VOWS, among the Romans, signified sacrifices, offerings, presents, and prayers made for the Caesars, and emperors, particularly for their prosperity and the continuance of their empire. These were at first made every five years, then every 15, and afterwards every 20, and were called quinquennalia, decennalia, and vigintennalia.

VOWEL, in Grammar, a letter which affords a complete sound of itself, or a letter so simple as only to need a bare opening of the mouth to make it heard, and to form a distinct voice. The vowels are six in number, viz. A, E, I, O, U, Y.

VOWEL. John. See HOOKER.

UPHOLSTER, UPHOLSTERER, or Upholder, a tradesman that makes beds, and all sorts of furniture thereunto belonging, &c.

UPLAND, denotes high ground, or, as some call it, terra firma, by which it stands opposed to such as is moorish, marshy, or low.

Upland, a province of Sweden, bounded on the north-east by the Baltic sea, on the south by the sea of Sudermania, and on the west by Westmania and Gesticia, from which it is separated by the river Dela. It is about 72 miles in length and 45 in breadth, and contains mines of iron and lead. Stockholm is the capital.

Uppsala, a rich and considerable city of Sweden, in Upland, with a famous university, and an archbishop's see. The town is pretty large, and as straight as a line; but most of the houses are of wood, covered with birch bark, with turf on the top. On aeminence, to the south of the town, is a ruined castle. It was formerly the residence of the kings, and is now the usual place where they are crowned. It is seated on the river Salja. It is 26 miles north-west of Stockholm. E. Long. 17° 48'. N. Lat. 59° 52'.

UPUPA, a genus of birds belonging to the order of Picea. See Ornithology Index.

UR, in Ancient Geography, a citadel of Mesopotamia, situated between the Tigris and Nisibis; taken by some for Ur of the Chaldees, the residence of Abraham. What seems to confirm this is that from Ur to Haran, the other residence of the patriarch, the road lies directly for Palestine. And it is no objection that Ur is said to be in Mesopotamia; because the parts next the Tigris were occupied by the Chaldeans, as seems to be confirmed from Acts vii. 2, 4. It is called Orche, in Strabo; Orche, in Ptolemy.

URALIAN CHAIN, a range of mountains which form part of the boundaries of Asia; anciently known by the name of Riphaï Monste. See Riphaï Monste, and GEOLOGY Index.

URANIA, in fabulous history, one of the nine Muses, was supposed to preside over astronomy. She is commonly represented in an azure robe, crowned with stars, and supporting a large globe with both hands.

URANIUM, one of the lately discovered metals. See CHEMISTRY and Mineralogy Index.

URANOSCOPUS, a genus of fishes belonging to the order of jugulares. See Ichthyology Index.

Raphael d'URBINO. See Raphael.

URCHIN, or Hedgehog. See Erinaceus, Mammalia Index.

See Urchin. See Echinus, Helminthology Index.

UREA. See CHEMISTRY.

URETERS. See Anatomy, No. 101.

URETHRA. See Anatomy, No. 107.

Uric Acid. See Chemistry Index.

URIM and THUMMIM, among the ancient Hebrews, a certain oracular manner of consulting God, which was done by the high-priest dressed in his robes, and having on his pectoral or breast-plate.

Various have been the sentiments of commentators concerning the urim and thummim. Josephus, and several others, maintain, that it meant the precious stones set in the high-priest's breast-plate, which by extraordinary lustre made known the will of God to those who consulted him. Spencer believes that the urim and thummim were two little golden figures shot up in the pectoral as in a purse, which gave responses with an articulate voice. In short, there are as many opinions concerning the urim and thummim as there are particular authors that wrote about them. The safest opinion, according to Broughton, seems to be, that the words urim and thummim signify some divine virtue and power annexed to the breast-plate of the high-priest, by which an oracular answer was obtained from God when he was consulted by the high-priest; and that this was called urim and thummim, to express the clearness and perfection which these oracular answers always carried with them; for urim signifies "light," and thummim "perfection!" these answers not being imperfect and ambiguous, like the heathen oracles, but clear and evident. The use made of the urim and thummim was to consult God in difficult cases relating to the whole state of Israel; and sometimes in cases relating to the king, the sanhedrim, the general of the army, or some other great personage.

URINAL, in Medicine, a vessel fit to receive and hold urine, and used accordingly for the convenience of sick persons. It is usually of glass, but sometimes of metal.

URINE, a fluid, separated from the blood, and carried by the emunctory arteries to the kidneys, from whence it descends to the bladder by the ureters, and is from time to time emitted thence by the canal of the urethra. See Anatomy, No. 107. For the properties of urine, see Chemistry Index.

URN,
URN, a kind of vase, of a roundish form, but biggest in the middle, like the common pitchers; now seldom used but in the way of ornament over chimney-pieces, in buffets, &c. The great use of urns among the ancients, was to preserve the ashes of the dead after they were burnt; for which reason they were called cineraria, and urnae cinerariae, and were placed sometimes under the tombstone whereon the epitaph was cut; and sometimes in vaults in their own houses. Urns were also used at their sacrifices to put liquid things in.

UROGALLUS. See TETRAX, ORNITHOLOGICAL INDEX.

URSA, in Astronomy, the name of two constellations in the northern hemisphere

URSULINES, in church history, an order of nuns, founded originally by St. Angela of Brescia, in the year 1537; and so called from St. Ursula, to whom they were dedicated.

URSUS, the Bear, a genus of quadrupeds belonging to the order of Ferae. See MAMMALIA INDEX.

URTICA, a genus of plants of the class of Monocot; and in the natural system classed under the 53d order, Scabridae. See BOTANY INDEX.

URTICA Marina. See ANIMAL-FLORA.

USANCE, in Commerce, is a determined time fixed for the payment of bills of exchange, reckoned either from the day of the bills being accepted, or from the day of their date; and thus called because regulated by the usage and custom of the places whereon they are drawn.

USE, in Law, the profit or benefit of lands and tenements; or a trust and confidence reposed on a person for the holding of lands, &c. that he to whose use the trust is made shall receive the profits.

USHANT, an island of France, 15 miles west of the coast of Brittany, at the entrance of the British channel.

USHER, an officer or servant who has the care and direction of the door of a court, hall, chamber, or the like.

USHIRE of the Black Rod, the eldest of the gentlemen ushers, daily waiters at court, whose duty is to bear the rod before the king at the feast of St. George, and other solemnities.

USK, a river of Wales, which rises on the west of Brecknockshire, and runs south-east through that county and Monmouthshire, falling into the mouth of the Severn.

USQUEBAUGH, a strong compound liquor, chiefly taken by way of dram.

There are several different methods of making this liquor; but the following is esteemd one of the best:

To two gallons of brandy, or other spirits, put a pound of Spanish liquorice, half a pound of raisins of the sun, four ounces of currants, and three of sliced dates; the tops of baum, mint, savory, thyme, and the tops of the flowers of rosemary, of each two ounces; cinnamon and mace well bruised, nutmegs, aniseeds, and coriander needs, bruised likewise, of each four ounces; of citron or lemon, and orange-peel, scraped, of each an ounce: let all these infuse 48 hours in a warm place, often shaking them together; then let them stand in a cool place for a week: after which the clear liquor is to be decanted off, and to it is to be added equal quantity of neat white port, and a gallon of canary, after which it is to be sweetened with a sufficient quantity of double refined sugar.

Vol. XX. Part II.
VULGATE, a very ancient Latin translation of the Bible, and the only one acknowledged by the church of Rome to be authentic. See Bible.

VULNERARY, in Medicine, an epithet formerly given to remedies supposed to possess virtues for the cure of wounds and ulcers.

VULTUR, a genus of birds belonging to the order of Accipitres. See Ornithology Index.

VULVA. See Anatomy, No. 132.

UVULA. See Anatomy, No. 102.

UZ, or UZZ, the country and place of residence of Job. In the genealogy of the patriarchs there are three persons called Uz, either of which might give this district its name. The first was the grandson of Sem, by his son Aram (Gen. xxii. 23.), who, according to Josephus, occupied the Trachonitis, and Damascus, to the north of Palestine: but Job was among the sons of the East. Another Uz was the son of Nahor, Abraham's brother (Gen. xxi.), who appears to have removed, after passing the Eufrates, from Haran of Mesopotamia to Arabia Deserta. The third Uz was a Horite, from Mount Seir (Gen. xxxvi. 28.), and thus not of Eber's posterity. Now the question is, from which of these Job's country, Uz, took its name: Not from the first, as is already shown; nor from the second, because his country is always called Seir, or Edom, never Uz; and then called a south, not an east, country in Scripture. It therefore remains, that we look for the country and place of residence of Job in Arabia Deserta; for which there were very probable reasons. The plunders of Job are called Chaldeans and Sabaeans, next neighbours to him. These Sabaeans came not from Arabia Felix, but from a nearer Sabe in Arabia Deserta (Ptolemy); and his friends, except Elipzax the Tamarite, were of Arabia Deserta.

UZBECK TARTAR. See Tartar.

W.

W, or w, is the 21st letter of our alphabet; and is composed, as its name implies, of two v's. It was not in use among the Hebrews, Greeks, or Romans; but chiefly peculiar to the northern nations, the Teutones, Saxons, Britons, &c. But still it is not used by the French, Italians, Spaniards, or Portuguese, except in proper names, and other terms borrowed from languages in which it is originally used, and even then it is sounded like the single v. This letter is of an ambiguous nature; being a consonant at the beginning of words, and a vowel at the end. It may stand before all the vowels except e; as water, wedge, water, wonder: it may also follow the vowels a, e, o, and unite with them into a kind of double vowel, or diphthong; as in saw, few, row, &c. It also goes before r, and follows s and th; as in south, suer, thous: it goes before a, also, though in reality it is sounded after it; as in sober, what, &c. In some words it is obscure, as in shadow, widow, &c.

WAAG, a river of Hungary, which rises in the Carpathian mountains, and falls into the Danube opposite to the island of Schut.

WAAL, a river of the United Netherlands, being one of the branches of the Rhine, which runs from east to west, through Guelderland; passing by Nimegen, Tiel, Bommel, and Gocem; and, uniting with the Maes, falls into the German sea below the Briel.

WACHENDORFIA, a genus of plants of the class of
W A I [ 587 ]

WACHENDORDIA and arranged in the natural method under the 6th order, Enastae. See Botany Index.

WADD, or WADDING, is a stopple of paper, hay, straw, or the like, forced into a gun upon the powder, to keep it close in the chamber, or to put up close to the shot, to keep it from rolling out.

WADSET, in Scots Law. See Law, No. clxix. r.

WAFFERS, or Sealing WAFFERS, are made thus: Take very fine flour, mix it with glair of eggs, isinglass, and a little yeast; mingle the materials; beat them well together; spread the batter, being made thin with gum-water, on even tin plates, and dry them in a stove; then eat them out for use.

You may make them of what colour you please, by tinting the paste with brasil or vermilion for red; indigo or verditer, &c. for blue; saffron, turmeric, or gamboge, &c. for yellow.

WAGER of Law. See (Wager of) Law.

Wager of Battle. See (Wager of) Battle.

WAGGON, a wheel-carriage, of which there are various forms, accommodated to the different uses they are intended for. The common waggons consist of the shafts or rods, being the two pieces which the hind horse bears up; the wheels; the slots, or cross pieces, which hold the shafts together; the bolster, being that part on which the fore-wheels and the axle-tree turn in wheeling the waggons across the road; the chest or body of the waggons, having the staves or rails fixed thereon; the bales, or hoops which compose the top; the tilit, the place covered with cloth, at the end of the waggons. See Mechanics, Sect. iv.

WAGTAIL. See Motacilla, Ornithology Index.

WAIF, Bona VAVIATA, are goods stolen, and waived or thrown away by the thief in his flight, for fear of being apprehended. These are given to the king by the law, as a punishment upon the owner for not himself pursuing the felon, and taking away his goods from him. And therefore if the party robbed do his diligence immediately to follow and apprehend the thief (which is called making fresh suit), or do convict him afterwards, or procure evidence to convict him, he shall have his goods again. Waived goods do also not belong to the king till seized by somebody for his use; for if the party robbed can seize them first, though at the distance of 20 years, the king shall never have them. If the goods are hid by the thief, or left anywhere by him, so that he had them not about him when he fled, and therefore did not throw them away in his flight; these also are not bona usurciata, but the owner may have them again when he pleases. The goods of a foreign merchant, though stolen and thrown away in flight, shall never be waifs: the reason whereof may be, not only for the encouragement of trade, but also because there is no wilful default in the foreign merchant's not pursuing the thief, he being generally a stranger to our laws, our usages, and our language.

WAIGATS STRAITS, situated between Nova Zembla and Russia, through which the Dutch sailed to the north, as high as 75°, in order to discover a north-east passage to China and the East Indies.

WAUNSCOT, in building, the timber-work that serves to line the walls of a room, being usually made in panels, and painted, to serve instead of hangings.

WAIVE, in Law, a woman that is put out of the protection of the law. She is called waive, as being forsaken of the law; and not an outlaw as a man is; by reason women cannot be of the decennas, and are not sworn in leets to the king, nor to the law, as men are, who are therefore within the law; whereas women are not, and so cannot be outlawed, since they never were within it.

WAKE, the print or track impressed by the course of a ship on the surface of the water. It is formed by the re-union of the body of water which was separated by the ship's bottom whilst moving through it; and may be seen to a considerable distance behind the stern, as smoother than the rest of the sea. Hence it is usually observed by the compass, to discover the angle of lee-way.

A ship is said to be in the wake of another when she follows her on the same track, or a line supposed to be formed on the continuation of her keel.

Two distant objects observed at sea are called in the wake of each other, when the view of the farthest is intercepted by the nearest so that the observer's eye and the two objects are all placed upon the same right line.

WAKA is the eye feast of the dedication of churches, which is kept with feasting and rural diversions.

Mr Whitaker, in his History of Manchester, has given a particular account of the origin of wakes and fairs. He observes, that every church at its consecration received the name of some particular saint; this custom was practised among the Roman Britons, and continued among the Saxons; and in the council of Caerleith, in 816, the name of the denomiating saint was expressly required to be inscribed on the altars, and also on the walls of the church, or a tablet within it. The feast of this saint became of course the festival of the church. Thus Christian festivals were substituted in the room of the idolatrous anniversaries of heathenism: accordingly, at the first introduction of Christianity among the Jutes of Kent, Pope Gregory the Great advised, what had been previously done among the Britons, viz. Christian festivals to be instituted in the room of the idolatrous, and the suffering day of the martyr whose relics were reposed in the church, or the day on which the building was actually dedicated, to be the established feast of the parish. Both were appointed and observed; and they were clearly distinguished at first among the Saxons, as appears from the laws of the Confessor, where the dies dedicationis, or dedicatio, is repeatedly discriminated from the propriis festivitatis sancti, or celebratio sancti. They remained equally distinct to the Reformation; the dedication-day in 1536 being ordered for the future to be kept on the first Sunday in October, and the festival of the patron saint to be celebrated no longer. The latter was, by way of pre-eminence, denominated the church's holiday, or its peculiar festival; and while this remains in many parishes at present, the other is so utterly annihilated in all, that Bishop Kennet (says Mr Whitaker) knew nothing of its distinct existence, and has attributed to the day of dedication what is true only concerning the saint's day. Thus instituted at first, the day of the treetal saint was observed, most probably by the Britons, and certainly by the Saxons, with great devotion. And the evening before every saint's day, in the Saxon Jewish method of reckoning the hours, being an actual hour of the day, and
and therefore like that appropriated to the duties of public religion, as they reckoned Sunday from the first to commence at the sunset of Saturday; the evening preceding the church's holiday would be observed with all the devotion of the festival. The people actually repaired to the church, and joined in the services of it; and they thus spent the evening of their greater festivities in the monasteries of the North, as early as the conclusion of the seventh century.

These services were naturally denominated from their late hours decon or dookres, and vigils or eve. That of the anniversary at Rippon, as early as the commencement of the eighth century, is expressly denominated the vigili. But that of the church's holiday was named cytry decon, or church-wake, the church-vigil, or church eve. And it was this commencement of both with a wake, which has now caused the days to be generally preceded with vigils, and the church-holiday particularly to be denominated the church-wake. So religiously was the eve and festival of the patron saint observed for many ages by the Saxons, even as late as the reign of Edgar, the former being spent in the church, and employed in prayer. And the wakes, and all the other holidays in the year, were put upon the same footing with the Octaves of Christmas, Easter, and of Pentecost. When Gregory recommended the festival of the patron saint, he advised the people to erect booths of branches about the church on the day of the festival, and to feast and be merry in them with innocence. Accordingly, in every parish, on the returning anniversary of the saint, little pavilions were constructed of boughs, and the people indulged in them to hospitality and mirth. The feasting of the saint's day, however, was soon abused; and even in the body of the church, when the people were assembled for devotion, they began to mind diversions, and to introduce drinking. The growing intemperance gradually stained the service of the vigil, till the festivity of it was converted, as it now is, into the rigour of a fast. At length they too justly scandalized the Puritans of the last century, and numbers of the wakes were disused entirely, especially in the east and some western parts of England; but they are commonly observed in the north, and in the midland counties.

This custom of celebrity in the neighbourhood of the church, on the days of particular saints, was introduced into England from the continent, and must have been familiar equally to the Britons and Saxons; being observed among the churches of Asia in the sixth century, and by those of the west of Europe in the seventh. And equally in Asia and Europe, on the continent and in the islands, those celebrities were the causes of those commercial marts which we denominate fairs. The people resorted in crowds to the festival, and a considerable provision would be wanted for their entertainment. The prospect of interest invited the little traders of the country to come and offer their wares; and thus, among the many pavilions for hospitality in the neighbourhood of the church, various booths were erected for the sale of different commodities. In larger towns, surrounded with populous districts, the resort of the people to the wakes would be great, and the attendance of traders numerous; and this resort and attendance constitute a fair. — Basilea expressly mentions the numerous appearance of traders at these festivals in Asia, and Gregory notes the same custom to be common in Europe. And as the Waked festival was observed on a saria or holyday, it naturally assumed to itself, and as naturally communicated to the mart, the appellation of saria or fair. Indeed several of our most ancient fairs appear to have been usually held, and have been continued to our time, on the original church-holydays of the places; besides, it is observable, that fairs were generally kept in church-wards, and even in the churches, and also on Sundays, till the indecency and scandal were so great as to need reformation.

Wake Robin. See Arum, Botany Index.

Walachia, a province of Turkey in Europe, bounded on the north by Moldavia and Transylvania; on the east and south by the river Danube, and on the west by Transylvania. It is 225 miles in length, and 125 in breadth; and was ceded to the Turks by the treaty of Belgrade, in 1739. It abounds in good horses and cattle; and there are mines of several kinds. The soil is so fertile, that it is capable of producing anything; and there are good pastures, with wine, oil, and all manner of European fruits. The inhabitants are chiefly of the Greek church.

Walachern, an island of the Low Countries, and one of the principal of those of Zealand; separated from the county of Flanders by the mouth of the Scheldt. It is about nine miles in length, and eight in breadth; and though it lies low, has good arable and pasture land. The chief town of this island and the whole province is Middleburgh. But the principal sea-port is Flushing, which is strongly fortified. Walcheren was taken by the British forces in August 1809; but it soon after was abandoned, the troops having suffered severely by sickness.

Walden, a town of Essex, commonly called Soff from Walden, with a market on Saturdays, and two fairs on Mid-June Saturday for horses, and November for cows. It is remarkable for the plenty of garden fruit that grows about it. This town was incorporated by Edward VI, and is governed by a mayor and 24 aldermen. It is 27 miles north-west-by-north of Chelmsford, and 43 north-east of London. E. Long. 0. 20. N. Lat. 52. 4.

Waldenses. See Waldon.

Waldo, a merchant of Lyons in the former part of the 12th century, who applied himself to the study of the Scriptures, and finding no warrant there for several of the Romish doctrines, particularly that of transubstantiation, publicly opposed them. His followers, who from him were called Waldenses, being chased from Lyons, spread over Dauphine and Provence; upon which Philip IL is said to have razed 300 gentlemen's seats, and destroyed several walled towns to stop their growth: but this, instead of suppressing, spread them over a great part of Europe. The articles of their faith, which they drew up and dedicated to the king of France, agreed in most points with those of the present Protestants. In the year 1200, those of them who dwelt in the province of Albigois in Languedoc, from whence they were called Albigenses, stood upon their defence; upon which Philip drove them into Bohemia, Savoy, and England. The crusade against them is said to have consisted of 500,000 men, who wore their crosses on their breasts, to distinguish themselves from those who went to the Holy Land, and wore them on their shoulders.

Wales, a country situated in the south-west part of
Wales, into which the ancient Britons retired from the persecution of the Saxons. Anciently it was of greater extent than it is at present, and comprehended all the country beyond the Severn; that is, besides the 24 counties included in it at present, those of Herefordshire and Monmouthshire, which now are reckoned a part of England, were then inhabited by three different tribes of the Britons, namely the Silures, the Dimetae, and the Ordovices. The Romans were never able to subdue them, till the reign of Vespasian, when they were reduced by Julius Frontinus, who placed garrisons in their country to keep them in awe. Though the Saxons made themselves masters of all England, they never could get possession of Wales, except the counties of Monmouthshire and Herefordshire, formerly a part of Wales. About the year 970, Roderic king of Wales divided it among his three sons; and the names of these divisions were, Demetia, or South-Wales; Povetia, or Powis-Land; and Venedotia, or North Wales. Another division is mentioned afterwards in the records, viz. North Wales, South Wales, and West Wales; the last comprehending the counties of Monmouth and Hereford. The country derived the name of Wales, and the inhabitants that of Welsh, from the Saxons, who by those terms denote a country and people to which they are strangers; for the Welsh, in their own language, call their country Cymry, and their language Cymraeg. They continued under their own princes and laws from the above-mentioned period, and were never entirely subjected to the crown of England till the reign of Edward I. when Llewellyn ap Gryfthin, prince of Wales, lost both his life and dominions. Edward, the better to secure his conquest, and to reconcile the Welsh to a foreign yoke, sent his queen to lie in at Caernarvon, where she was delivered of a prince; to whom the Welsh, on that account, the more readily submitted. Ever since that time, the eldest sons of the kings of England have commonly been created princes of Wales, and as such enjoy certain revenues from that country.

As to the character of the Welsh, they are said to be a brave hospitable people; and though very jealous of affronts, passionate, and hasty, yet are easily reconciled. The common people look with a suspicious eye on strangers, and bear a hereditary grudge to the English nation, by whom their ancestors were expelled from the finest parts of the island. The gentlemen are apt to value themselves upon the antiquity of their families; and with some reason, as they can generally trace them much higher than the inhabitants of most other countries.

All the better sort, both in town and country, can speak English, especially in the counties bordering upon England. The common people, in general, only speak their own language, which is the ancient British; and not only differs entirely from the English, but has very little affinity with any of the western tongues, unless we should except the Gaelic, Ese, or Irish. It is said to be a dialect of the ancient Celtic, and in many respects resemble the Hebrew. Most of the clergy are natives of the country, and understand English so well, that they could exercise their functions in any part of Britain. The public worship, however, is as often performed in Welsh as in English, excepting in the towns, where the latter is the prevailing language. According to the returns in 1811, the population of Wales was 61,778.

The country, though mountainous, especially in North Wales, is far from being barren or unfruitful; the hills, besides the metals and minerals they contain, feeding vast herds of small black cattle, deer, sheep, and goats, and their valleys abounding in corn, as their seas and rivers do in fish. Here are also wood, coal, and turf, for fuel, in abundance.

Wales is bounded on all sides by the sea and the Severn; except on the east, where it joins to the counties of Chester, Salop, Hereford, and Monmouth. Its length, from the southernmost part of Glamorganshire to the extremity of Flintshire north, is computed at about 123 miles; and its greatest breadth, from the river Wye east to St. David's in Pembrokeshire west, is nearly of the same dimensions, being about 90 miles.

After the conquest of Wales by Edward I. very material alterations were made in their laws, so as to reduce them nearer to the English standard, especially in the forms of their judicial proceedings: but they still retained very much of their original polity, particularly their rule of inheritance, viz. that their lands were divided equally among all the issue male, and did not descend to the eldest son alone. By other subsequent statutes their provincial immunities were still farther abridged: but the finishing stroke to their dependency was given by the statute 27 Hen. VIII. c. 26, which at the same time gave them utmost advancement to their civil prosperity, by admitting them to a thorough communication of laws with the subjects of England. Thus were these brave people gradually conquered into the enjoyment of true liberty; being insensibly put upon the same footing, and made fellow-citizens, with their conquerors.

It is enacted by the 27 Hen. VIII. 1. That the dominions of Wales shall be forever united to the kingdom of England. 2. That all Welshmen born shall have the same liberties as other king's subjects. 3. That lands in Wales shall be inheritable according to the English tenures and rules of descent. 4. That the laws of England, and no other, shall be used in Wales; besides many other regulations of the police of this principality. And the 34 and 35 Hen. VIII. c. 26 confirms the same, adds farther regulations, divides it into 12 shires, and in short, reduces it to the same order in which it stands at this day; differing from the kingdom of England is only a few particulars, and those too of the nature of privileges (such as having courts within itself, independent of the process of Westminster-hall), and some other material peculiarities, hardly noticeable than are to be found in many counties of England itself.

WALL, in Architecture, the principal part of a building, as serving both to enclose it, and to support the roof, floors, &c. —Walls are distinguished into various kinds, from the matter whereof they consist; as plaster or mud walls, brick walls, stone walls, flint or boulder walls, and boarded walls. See Architecture.

Cob or Mud Wall. In those parts of England where stone is scarce, it is usual to make walls and houses of mud.
mud, or, as it is called in Devonshire, cob; which is a composition of earth and straw, wet up somewhat like mortar, but well beat and trod together. When a wall is making, after being raised to a certain height, it is allowed time to pitch or settle before the work is resumed. Some value themselves on their skill in building with this composition; the price, when materials are found, is generally in Devonshire 3s. per perch of 16 feet; but a stone foundation costs more. Houses built with this, being covered with thatch, are very dry and warm; a cob wall, if in a good situation, will last 50 or 60 years or more. When pulled down, they are used as manure, and new earth employed to rebuild with.

WALLACE, SIR WILLIAM, a gallant general of the Scots, who endeavoured to rescue his country from the English yoke; but being taken prisoner, he was unjustly tried by the English laws, condemned, and executed as a traitor to Edward L in 1304. See Scotland, No 103, et seq.

WALLACHIA. See Wallachia.

WALLER, EDMUND, a celebrated English poet, was the son of Robert Waller, Esq. of Agmonesham in Buckinghamshire, by Anne, the sister of the great Hampden who distinguished himself so much in the beginning of the civil wars. He was born in 1603; and his father dying when he was very young, the care of his education fell to his mother, who sent him to Eton. He was afterwards sent to King's college in Cambridge, where he must have been very assiduous in his studies, since, at sixteen or seventeen years of age, he was chosen into the last parliament of King James L, and served as burgess for Agmonesham. He began to exercise his political talent so early as the year 1623; as appears from his verses "upon the danger his majesty (being prince) escaped in the road of St. Andero;" for there Prince Charles returning from Spain that year, had like to have been cast away. It was not, however, Mr Waller's wit, his fine parts, or his poetry, that so much occasioned him to be first publicly known, as his carrying off the daughter and sole heiress of a rich citizen, against a rival whose interest was espoused by the court. It is not known at what time he married his first lady; but he was a widower before he was 25, when he began to have a passion for Sacharissa, which was a fictitious name for the lady Dorothy Sidney, daughter to the earl of Leicester, and afterwards wife to the earl of Sunderland. He was now known at court, caressed by all who had any relish for wit and polite literature; and was one of the famous club of which Lord Falkland, Mr Chillingworth, and other eminent men, were members. He was returned burgess for Agmonesham in the parliament which met in April 1640. An intermission of parliaments having disgusted the nation, and raised jealousies against the designs of the court, which would be sure to discover themselves whenever the king came to ask for a supply, Mr Waller was one of the first who condemned the preceding measures. He showed himself in opposition to the court, and made a speech in the house on this occasion; from which we may gather some notion of his general principles in government; wherein, however, he afterwards proved very variable and inconsistent. He opposed the court also in the long parliament which met in November following, and was chosen to impeach Judge Crawley, which he did in a warm and eloquent speech, July 16th 1641.

This speech was so highly applauded, that 20,000 copies of it were sold in one day. In 1642, he was one of the commissioners appointed by the parliament to present their propositions of peace to the king at Oxford. In 1643, he was deeply engaged in a design to reduce the city of London and the Tower to the service of the king; for which he was tried and condemned, together with Mr Tomkins his brother-in-law, and Mr Challoner. The two latter suffered death; but Mr Waller obtained a reprieve; he was, however, sentenced to suffer a year's imprisonment, and to pay a fine of 10,000l. After this, he became particularly attached to Oliver Cromwell, upon whom he wrote a very handsome panegyric. He also wrote a noble poem on the death of that great man.

At the Restoration, he was treated with great civility by Charles II. who always made him one of the party in his diversions at the duke of Buckingham's and other places. He wrote a panegyric upon his majesty's return; which being thought to fall much short of that he had before written on Oliver Cromwell, the king one day asked him in raillery, "How is it, Waller, that you wrote a better encomium on Cromwell than on me?" "May it please your majesty," answered he, "we poets generally succeed best in fiction." He sat in several parliaments after the Restoration, and continued in the full vigour of his genius to the end of his life, his natural vivacity bearing him up, and making his company agreeable to the last. He died a droppy in 1687, and was interred in the churchyard of Beaconsfield, where a monument is erected to his memory. Mr Waller has been honoured as the most elegant and harmonious versifier of his time, and a great refiner of the English language. The best edition of his works, containing poems, speeches, letters, &c. is that published in quarto by Mr Fenton, to 1730.

WALLIS, DR JOHN, a celebrated mathematician, was educated at Cambridge; where he became fellow of Queen's college, and continued so till, by his marriage, he vacated his fellowship. In 1642, he received holy orders, and became chaplain to the lady Vere. While he lived in this family, he cultivated the art of deciphering; and it is said that the elector of Brandeburgh, for whom he explained several letters written in ciphers, sent him a gold chain and medal. In 1643 he published, "Truth tried; or Animadversions on the Lord Brooke's treatise, called The Nature of Truth, &c." The next year he was chosen one of the scribes or secretaries to the assembly of divines at Westminster. Dr Peter Turner, Savilian professor of geometry in Oxford, being ejected by the parliament-visiters in 1649, Mr Wallis was appointed to succeed him in that place. In 1653 he published at Oxford a Grammar of the English Tongue in Latin. In 1655 he entered the lists with Mr Hobbes; and their controversy lasted a considerable time. In 1657 the Doctor published his Mathematical Works. Upon the death of Dr Langbaine, he was chosen custos archivorum of the university. After the Restoration he met with great respect, the king himself entertaining a favourable opinion of him on account of some services he had done both to his royal father and himself. He was therefore confirmed in his places, admitted one of the king's chaplains in ordinary, and appointed one of the divines empowered to review the book of common prayer. He complied with the
WALPOLE, the eminent service he was thought to have done the crown, by the vigorous prosecution of those ministers who were deemed the chief instruments of the peace, was soon rewarded by the extraordinary promotions to the offices of first commissioner of the treasury, and chancellor and under treasurer of the exchequer.

In two years time he resigned all his offices, on account of a misunderstanding which took place between him and the rest of the ministry about certain supplies demanded for the support of his majesty’s German dominions. On the day of his resignation he brought in the famous sinking-fund bill, which he presented as a country gentleman, saying, that he hoped it would not fare the worse for having two fathers; and that his successor Mr Stanhope would bring it to perfection. His calling himself the father of a project, which hath since been so often employed to other purposes than were at first declared, gave his enemies frequent opportunity for satire and ridicule; and it hath been sarcastically observed, that the father of this fund appeared in a very bad light when viewed in the capacity of a nurse.

In the next session of parliament, Walpole opposed the ministry in every thing; and even Wyndham or Shippen did not exceed him in patriotism. Upon a motion in the house for continuing the army, he made a speech of above an hour long, and displayed the danger of a standing army in a free country, with all the powers of eloquence. Early in 1720 the rigor of the patriot began to soften, and the compliance of the courtiers to appear; and he was again appointed paymaster of the forces, and several of his friends were found soon after in the list of promotions. No doubt now remained of his entire conversion to court measures; for before the end of the year, we find him pleading as strongly for the forces required by the war-office as he had before declaimed against them, even though at this time the same pretences for keeping them on foot did not exist.

It was not long before he acquired full ministerial power, being appointed first lord commissioner of the treasury, and chancellor of the exchequer; and, when the king went abroad in 1723, he was nominated one of the lords justices for the administration of government, and was sworn sole secretary of state. About this time he received another distinguished mark of the royal favour; his eldest son then on his travels being created a peer, by the title of Baron Walpole of Walpole. In 1725 he was made knight of the Bath, and the year after knight of the Garter. The measures of his administration, during the long time he remained prime or rather sole minister, have been often canvassed with all the severity of critical inquiry. It is difficult to discern the truth through the exaggerations and misrepresentations of party. He has indeed been accused of employing the sinking fund for the purposes of corruption, of which it was long the fashion to call him the father; but the man who reflects on the transactions of Charles II. and his infamous cabal, will acquit him of the latter part of this charge. He was an enemy to war, and the friend of commerce; and because he did not resent some petty insults of the court of Spain so suddenly as the fiery part of the nation thought he should have done, a formidable opposition was formed against him in the house, which had influence enough to
WALPOLE. to employ in its cause almost all the wit of the nation. Pelley and Pitt were the great leaders of the party in the house of commons; while Bolingbroke and Pope and Johnson, and almost every man of genius, exerted themselves without doors to enlighten, by pamphlets in prose and verse, the minds of the people, and show the necessity of a Spanish war. This strenuously opposed, because he knew that the foreign settlements of that power were very remote, and in a climate destructive to Englishmen; and that such of them as we might be able to take, we could not possibly retain. The opposition however prevailed. The nation was induced in a war, of which it surely had no cause to boast of the success; and it is now universally known, that the greater part of those who with honest intentions had, either in parliament or out of it, been engaged to run down the minister, lived to repent of their conduct, and do justice to the man whom they had so perniciously vilified.

In order to encourage commerce and improve the revenue, Sir Robert projected a scheme for an extension of the excise, as the only means of putting a stop to the frauds of merchants and illicit traders. This was another ground of clamour to the orators within, and the wits without, doors; and while the opposition represented it as a measure big with public mischief, Swift and Pope occasionally alluded to it as an oppression calculated to deprive private life of all its comforts. The minister was therefore obliged to abandon the scheme; but in a succeeding administration it was partly carried into execution, at the express solicitation of the principal persons concerned in that article of trade which it was suggested would be most affected by it; and afterwards the most popular minister that ever directed the councils of this country declared in full senate, that if a time should ever arrive which was likely to render the project feasible, he would himself recommend an extension of the excise laws as a measure of the greatest advantage to commerce, to the revenue, and to the general interests of the kingdom.

In 1742 the opposition prevailed; and Sir Robert being no longer able to carry a majority in the house of commons, resigned all his places, and fled for shelter behind the throne. He was soon afterwards created earl of Orford; and the king, in consideration of his long and faithful services, granted him a pension of 4000l. per annum. The remainder of his life he spent in tranquility and retirement, and died, in 1745, in the 71st year of his age.

He has been severely, and not unjustly, censured for that system of corruption by which he almost avowed that he governed the nation; but the objects which he had in view are now acknowledged to have been in a high degree praise-worthy. Johnson, who in the earlier part of his life had joined the other wits in writing against his measures, afterwards honoured his memory for the pliability of his temper, and for keeping his country in peace for so many years; and Mr Burke has declared, that his only defect as a minister was the want of sufficient firmness to treat with contempt that popular clamour, which, by his yielding to it, hurried the nation into an expensive and unjust war. But his rancorous prosecution of Atterbury bishop of Rochester (see ATTERBURY), by a bill of pains and penalties, may be considered as something worse than a de-
by this means he happily retarded this formidable invasion for a whole year. In short, he spent his whole time and faculties in the service of Queen Elizabeth; on which account her majesty was heard to say, "That in diligence and sagacity he exceeded her expectations." However, after all his eminent services to his country, this man gave a remarkable proof at his death, which happened on the 6th of April 1590, how far he preferred the public interest to his own; he being so poor that excepting his library, which was a very fine one, he had scarcely effects enough to defray the expense of his funeral. His principal works are, 1. Memoirs and Instructions for the use of Ambassadors, with his Letters and Negociations. 2. Political Memoirs.

WALDERHIA, a genus of plants in the class monadelphias, and in the natural system arranged under the 37th order, Columniferae. See BOTANY INDEX.

WALTON, BRYAN, bishop of Chester, a learned English divine, who gained great reputation by his edition of the Polyglot bible, with his Prolegomena in the beginning; which is more exact, says Father Simon, than any other which had been published on that subject. He died in 1661.

WAMPUM, the money used by the North American Indians. It is much used in all their treaties as a symbol of friendship. It is made of a shell of a particular species of VENUS.

WAPENTAKE, is the same with what is called a hundred; especially used in the north counties beyond the river Trent. The word seems to be of Danish original, and to be so called for this reason: What first this kingdom, or part thereof, was divided into wapentakes, who was the chief of the wapentake or hundred, and who is now called a high constable, as soon as he entered upon his office, appeared in a field on a certain day on horseback with a pike in his hand, and all the chief men of the hundred met him there with their lances, and touched his pike; which was a sign that they were firmly united to each other by the touching their weapons. But Sir Thomas Smith says, that anciently musters were made of the armour and weapons of the several inhabitants of every wapentake; and from those that could not find sufficient pledges for their good abating, their weapons were taken away and given to others; from whence he derives the word.

INTRODUCTION.

IN treating the subject of war, we may consider it first in a political and moral point of view, as one of those powerful engines employed by civil governments, to bring about some ends which they deem beneficial to the community over which they preside; and secondly, in a theoretical and practical point of view, as a science or an art, which the necessities or the fancies of mankind have rendered an important object of consideration, not only to certain individuals, but in some measure to society at large.

Vol. XX. Part II.
preserve that due and equitable balance of power among neighbouring states, which has of late been considered as an essential point in the political economy of civilized nations. We say that these are usually the ostensible objects of war; for though it will scarcely be denied that ambition, avarice, religious bigotry, a desire of dominion, and a thirst of military fame, have been the real causes of many of those long and bloody wars which have desolated the face of nature, and heaped misery and wretchedness on millions of human beings, we believe few heroes and conquerors, either of ancient or modern times, have had the honesty or effrontery to avow these as the real motives of their military expeditions. Yet, if we examine the pages of history, we shall scarcely find a war, from the Battle of the Kings recorded by the sacred historian, to the present contest which has for 17 years involved all Europe in confusion and bloodshed, and reduced many of its fairest states and provinces under the subjection of a single monarch, in which one or other of these latter motives has not, at least to one party, been a principal inducement.

Among the political objects of war, we must not omit to mention one which, though perhaps less openly avowed than any other, has, in monarchial and aristocratical governments, always formed a material part of the state policy—we mean the object of preventing tumults and commotions among the people, by engaging them in a foreign war. It was long ago observed by a good judge of human nature, "that no body can be healthful without exercise, neither natural body nor politic;" and that "to a kingdom or a state, a just and honourable war is the true exercise." That politicians have often acted on these principles, is certain. On the justice of the principles themselves, we presume not to decide, though we may safely express a doubt whether the remedy be not worse than the disease, and whether these popular commotions might not be prevented with equal ease, and with more advantage to the nation, by employing the populace in such works of improvement as may advance the manufactures, commerce, or internal comforts of the state.

Embracant population regarded as a primary cause of war.

An able and ingenious writer considers a redundance of population as one of the chief primary causes of war. "One of its first causes and most powerful impulses, was undoubtedly an insufficiency of room and food; and, greatly as the circumstances of mankind have changed since it first began, the same cause still continues to operate, and to produce, though in a smaller degree, the same effects. The ambition of princes would want instruments of destruction, if the distresses of the lower classes did not drive them under their standards. A recruiting sergeant always prays for a bad harvest, and a want of employment, or, in other words, a redundant population." This redundance he proposes to oblivate, and thus to counteract one of the principal causes of war, by throwing obstacles in the way of marriage. Without calling in question the justness of his position, we do not see the necessity of the remedy which he proposes. We must acknowledge ourselves much friends to the increase of population as to think that every encouragement ought to be given to it, instead of throwing obstacles in its way. There are few countries so populous, or so completely cultivated, as to render it necessary to plunge them into wars in order to diminish the number of inhabitants, which might be abundantly supported, were agriculture encouraged, and glutanny repressed.

Whatever may be the objects for which a nation goes to war; whatever the causes which have induced her to have recourse to such an expedient, we may venture from history and experience, to affirm that she will gain little solid advantage by the contest. She may drive an invading enemy from her dominions, and pursue him to his own; she may acquire plunder and territory, and may raise her name among the neighbouring states by her victories and prowess; but all these, except the first, will scarcely compensate for the blood and treasure which she has expended, and for the check given to her agriculture, manufactures and commerce, by drawing of many of the labouring part of the community to supply the fleets and armies of the state. These are the inevitable consequences even of a successful war; and should it prove otherwise, the calamities and distresses of the vanquished may readily be conceived. Even to the established government of a state, war, while it appears to strengthen their hands and increase their influence, is fraught with difficulty and danger. No situation affairs is so well calculated to show the abilities or insufficiency of a cabinet as this, and melancholy is the lot of that nation whose administration has been conducted by a weak, inexperienced, or profligate ministry; but be they ever so able or so upright, still the want of success, or a reverse of fortune, will lower them in the opinion of the people, and will compel them at last to conclude a disadvantageous, perhaps a dishonourable peace, or quit their posts and leave the task to a more popular or successful administration.

The evils of war do not terminate on the return of peace. Many of the burdens which it had imposed on the people must still continue, to discharge the debt contracted by the state; while the sudden disbanding of the fleets and armies pours into the community numbers of idle and dissipated men, adverse to labour, and accustomed to scenes of confusion, slaughter and rapine. At no time are robberies, murders, seditions, so frequent as on the termination of a long protracted war; at no time are the internal peace and quiet of a nation in so much danger.

On the moral evils of war we surely need not enlarge. In itself, when undertaken without necessity, it is an act of the most criminal and atrocious nature; and the aggressors are accountable for all the horrid consequences which may attend it. "The pomp and circumstancs of glorious war" may form a desirable subject for the poet and the historian; but the Christian and the philosopher must regard it with horror and detestation, as the greatest evil with which providence has been pleased to arm the hands of its ministers to punish and affect mankind. A late available and learned prelate has laboured to prove that "the frequency, duration, by innumerable and cruelty of wars (in Christendom) are less now than they have been in ancient times;" but we think that neither his reason, his examples nor his hypotheses are capable of establishing the first part of this position. If we take the last 120 years, and compare it with an equal period of ancient history; if we recollect the crusades, the almost continual struggles between France and Britain, the civil dissensions in both these mighty empires, the wars between the Russians and their neighbours, the Turks, the Poles, and the Swedes; if we advert to the reigns of Edward
Edward III. of England, Charles V. and Philip II. of Spain, Louis XIV. of France, Gustavus Adolphus and Charles XII. of Sweden, Frederick II. of Prussia, and Catherine II. of Russia; and lastly, if we turn our attention to the long and ruinous contests which distinguish our own times, we shall find little cause to boast of having profited by the specific lessons of our Saviour, whose great object was to promote "peace on earth," and good will and brotherly love among the children of men.

There is indeed one consolatory circumstance with respect to the modern system of warfare, that our wars are less sanguinary than those of ancient times. The immense slaughter which attended some of the battles in the Greek and Roman wars, where the greater part of the vanquished army was frequently put to the sword, is familiar to our classical readers; but in modern warfare, even of the large armies that have appeared in the field on the continent of Europe, we seldom find so many as 30,000 killed and wounded on both sides, a number vastly inferior to what fell of the Romans at Cannae, and by no means equal to the loss of the Carthaginians at the battle of Zama. This diminished slaughter is attributed, and we believe with justice, to the use of fire-arms; and it is computed that in this mode of fighting not one than one musket ball in 400 proves fatal. The introduction of these weapons, therefore, however it may be declaimed against by theorists, must be considered as a real improvement in the art of war; and it is sincerely to be regretted that the use of them should be laid aside. If, however, the present practice of deciding battles by the bayonet and the saber be continued, it is to be feared that we shall soon rival the ancients as much in the sanguineous nature of our wars as in their frequency.

After what we have said on the impolicy of war, and the moral evils which attend it, it will scarcely be expected that we should allow it to be justifiable, except in cases of necessity. Indeed we think that war can be justified only on the principles of self-defence. When a nation is invaded, or attacked in relation to her undoubted rights and principles, it is then, and then only, that she has a pretence for war. We will not, indeed, go so far as to assert, that she ought to await the attack. Whilst she takes the best methods for defending her territories at home, it is doubtless proper, especially for a maritime state, to meet the enemy half-way, and by a timely and spirited resistance, endeavour to avert those greater evils which would attend a system of pusillanimity and neglect.

In the present state of human nature, war must be regarded as a necessary evil, and as it is sometimes unavoidable, the principles and practice of it must be studied by those who are to superintend or to conduct its operations. It is this necessity that has given occasion to the art of war, the practice of which is to form the subject of the present article.

Before we enter on the immediate object of this essay, however, it may not be improper to enumerate those branches of knowledge which constitute the principles of the military art, and of which no officer who expects to have a principal command in military operations should be ignorant. We shall first mention those sciences which should form a part of the education of every command
count of the progressive improvements that have been
made in the art of war. Indeed this would be to repeat
much of what has already been detailed under the prin-
cipal historical articles of this work; for the history of
nations, as it is commonly treated, is little more than a
history of their wars. We might, no doubt, bring for-
wards much curious information respecting the offensive
and defensive weapons of different ages and countries,
and the character and organization of their armies; but
for those and other matters of a similar nature, we may
refer our readers to the following respectable authorities:
Vegetius De re militari; Polybius's History, with the
Commentaries of Foulard; Salmasius De re militari Ro-
manorum; Tacitus's Vita Agricola; Rollin's Ancient
History; Potter's Grecian Antiquities; Kennet's and
Adam's Roman Antiquities; Goguet's Origin of Laws,
Arts, &c.; Daniel Histoire de la Milice Françoise;
Gough's Sepulchral Monuments; Ascham's Toxophilus,
and Grove's History of the English Army, and Essay
on Ancient Armour.

At a period like the present, when the two greatest
powers of Europe are struggling for glory and domi-
nation, it will not be thought wanting, or irrelevant
to the subject of the present article, if we offer a com-
parative statement of the present military and naval es-
cablishments of these two mighty empires, with a sketch
of the military character of their armies; and with these
we shall conclude our preliminary observations.

According to a statement made to the French go-
vernment at the commencement of 1805, the grand to-
tal of the French armies consisted of 570,964 men; viz.
infantry of the line, 341,475; light infantry, 100,139;
cavalry, 77,488; artillery, 46,489; engineers, 5445.
Since that time, more than 100,000 have been added,
and, according to the best authority, the present total
does not fall short of 700,000 men. This vast body
is divided into companies for both cavalry and in-
fantry; a certain number of companies forming a batta-
illion of infantry, or a squadron of cavalry. The de-
nomination of regiment is appropriated to the cavalry and
artillery, while, in a similar body of infantry, is called a
half brigade. The commanding officer of a regiment
is called colonel, but the commander of a large body of
infantry is called chief of brigade. Those general
officers who in other armies are called major-generals,
are, in the French service, denominations of general of
brigade, and lieutenant-generals are there generals of di-
vision.
The corps of engineers has for its officers 8 inspec-
tors general, 34 directors, 124 captains of the first class,
117 captains of the second class, 33 lieutenants
of the first class, 21 of the second class, and 20 pupils
under the lieutenants. Attached to this corps are 6 com-
panies of miners, commanded by a chief of battalions.
Each company is officered by a captain-command-
ant, a second captain, first and second lieutenant.
Twelve battalions of miners; each battalion, containing
3 companies, forming in all 106 men, including
officers. The battalion staff is composed of a chief
of battalion, an adjutant major, and an adjutant.
Each company is officered by a captain, a lieuten-
ant, and a sub-lieutenant.

To raise and recruit this great military force, the
French government has, since the year 1796, had re-
course to one of the most tyrannical measures which was
ever adopted by a despotic monarchy, we mean that of
conscription, by which every man within a certain age,
is made liable, under circumstances of the greatest ri-
gour, to serve in the armies of the state. This system
of conscription is exceedingly complex; but we are en-
abled, from a respectable periodical publication, to pre-
sent such a summary of it as will be readily under-
stood. France is divided into about 30 military govern-
ment, subject to a general division and his staff, to which
communipalities are attached as executive officers. The
civil division consists of 122 departments; 24 of which
have been acquired since the overthrow of the na-
archy, exclusive of Tuscany, not included in any part
of this statement. The departments are divided into di-
stricts or arrondissements, from three to five in number;
the arrondissements into cantons, and the cantons into
municipalities, amounting to about 55,000. Each de-
partment is governed by a prefect and his council, com-
pounded of a commissary of police, a mayor, and certain
inspectors, denominated conservateurs of préfectures; the
district or arrondissement, by a subprefect and his con-
cil, of a similar formation. The cantons and municipali-
ties are under the supervision of an administration, com-
pounded of the civil authorities, with a president at their
head. A mayor, a commissary of police, and two offi-
cers of the government, styled adjoint, are allotted to
each division having a population above 5000 souls.
These several authorities are in strict subordination to
each other, and, at the command of the prefects and sub-
prefects, are charged with a weighty and inflexible responsibil-
ity as to the military levies.

By the code de la conscription, all Frenchmen, be-
tween the ages of 20 and 25, are liable to serve. They
are divided into five classes, from which the municipal
administration draws up the lists for the ballot. They
are transmitted to the prefects, by whom they are sent
to the war ministry, and, when properly adjusted, the
subprefect proceeds to the drawing of the quota imposed
on each district. The conscripts drawn are formed into
three divisions, the first called conscrits for actual ser-
vice, the second the reserve, and the third supplemen-
tary conscrits. They are marshalled in companies of 50
men, to the places which are established as depots
where they are furnished with their arms and clothes.
After this they are trained, and exercised, so as to be
fitted to answer the requisitions of the service.

What gives peculiar energy to the French military
system, is the circumstance that their officers rise by meri-
d and experience, and not by interest. By a law of
the directory, no person (with the exception of engi-
neers), could become officer who had not served three
years in a subordinate capacity. The revolution natu-
ally opened the way to merit; and, seconded by this
admirable policy, has filled all the posts of their army
with men, who unite in themselves the qualities of the
soldier, with the excellencies that qualify for command.
It is not hazarding too much to assert, that nine-tenths
of the present French officers have sprung from the
ranks. Educated in distant camps, they know no other
country, and, habituated by long devotion to the trade
of war, it has become their element and their passion.
Their whole fortune is staked on the sword; and their
attachment is therefore necessarily secured, under the
auspices.
The Progressive advance of our navy will appear by attending to the following recital of its tonnage at different periods, from the reign of Henry VIII. to the present time.

- **At the death of Henry VIII.**
  - Edward VI. 1547 2,400
  - Mary 1553 11,000
  - Elizabeth 1559 7,000
  - James I. 1625 19,000

- **Rebellion, At the death of Charles I.**
  - 1641 22,400
  - At the Restoration, 1660 57,460
  - At the death of Charles II. 1685 203,559
  - Abdication of James II. 1688 101,920

Since the passing of Mr. Wincham's act, this number is somewhat diminished, though one military force is now probably more effective. At the end of 1808 it stood as follows. Two regiments of life-guards, one regiment of royal horse guards, 7 of dragoon guards, 25 of dragoons, 3 battalions of rillemen, 7 battalions of foot-guards, 5 of light infantry, 176 battalions of infantry, a corps of royal horse artillery, a regiment of royal foot artillery, a corps of royal engineers, a brigade of artillery drivers, and a waggon train. The dragoons, independent of the royal life and horse guards, amounted to 15,200; the battalions of rillemen and light infantry to 800; the infantry of the line to 149,000; the king's German legion to about 20,000; exclusive of about 90,000 regular militia, 250,000 local militia, and about 50,000 volunteers; making an effective force of about 580,000 men.

Each regiment of not more than 500 men is officered by a colonel, a lieutenant-colonel, a major, 10 captains, 10 lieutenants, 3 ensigns, an adjutant, quartermaster, paymaster, a surgeon and assistant surgeon; a sergeant-major, a quartermaster-sergeant, with 30 ordinary sergeants, 30 corporals, a drum-major and 20 drummers. If the regiment amount to 750 men, it has usually an addition of second lieutenant-colonel, a second major, 10 sergeants, and 10 corporals.

The gradation of rank among the officers of the British army is as follows. Under the king, who commands the whole as captain-general, is the commander in chief, then follow the field-marshals, generals, lieutenant generals, major-generals, brigadier-generals, colonels, lieutenants-colonels, majors, captains, and subalterns. The different departments of the army are under the superintendence of an adjutant-general, a quartermaster-general, a bursar-master-general, a commissary-general, a paymaster-general, a board of ordnance, and a medical board. See ADJUTANT, QUARTERMASTER, &c.
WAR.

It appears, however, that notwithstanding the vast increase of our navy, not a single dockyard has been added to it since the reign of William III. about 100 years ago, at which time the tonnage of the naval force of this kingdom amounted to nearly 160,000 tons; it is now nearly 800,000 tons, or about five times as large.

In sketching the military character of the French and British armies at the commencement of the 19th century, we shall avail ourselves of the observations of an anonymous, but able and apparently impartial publication, which appeared soon after the peace of Amiens, entitled The Military Character of the European Armies at the Peace of Amiens.

The astonishing success which has attended the French arms on the continent of Europe, is to be attributed partly to the regular organization and severe discipline established by the Code de la Conscription, but it is still more to be ascribed to the skill, experience, and activity of their officers. The French generals early discovered the advantages resulting from dispatch. The alertness of the soldiers, the lightness of their baggage, and their inattention to regularity in time of action, enabled them to execute their movements with a celerity which has frequently ensured success. In an open country, lines could not be preserved without difficulty. The French armies were therefore formed in columns. Brigade succeeded brigade, and when one division was repulsed, and fell back on the columns in the rear, those in their turn attacked the enemy, or sustained his shock, and fresh troops perpetually came forward, to supply the place of those which had been defeated.

The French battalions have no field-pieces attached to them; but this want is amply compensated by their flaying artillery, which is composed of the flower of the French soldiers, and by its boldness and rapidity of movement, supplies the place of that large train of artillery with which the other European armies are usually burdened. It is a constant maxim in the French armies to have a body of reserve, composed of their best troops, and under the command of an able general. If the main body should be beaten, the reserve covers their retreat, and on more than one occasion it has snatched the victory from the hands of the enemy.

The French generals, like rich and bold gamblers, are incessantly tempting fortune. They look upon their losses as nothing, provided they succeed in the end. The little value at which they estimate their men, the certainty of being able to replace them, the personal ambition of their chief, and the customary superiority of their numbers, afford them an advantage which cannot be counteracted but by great skill, conduct and activity.

The soldiers of Britain are as intrepid by land as her sailors by sea. Their want of success on the continent cannot be ascribed to their want of bravery, but rather to the organization of the British armies, their inferiority of numbers, or the inexperience of the officers by whom they are commanded. Most of their commanding officers, instead of conforming to general regulations, follow their own particular plans and ideas, according to their several genius, acquirements, and prejudices. In a nation, which, from the spirit of its constitution and the habits of its people, is formed rather for naval than military operations, a ministry, however enlightened, scarcely possesses that authority which is necessary to give uniformity to the different departments of the army, to constitute a regular and corresponding whole, and to surmount those obstacles which are thrown in the way of all uniformity of military system, by the distance and distribution of the troops. The small numbers in which British troops are generally compelled to act on the continent, and their mixture with those of other nations, to which they are sometimes even subservient, are circumstances extremely disadvantageous.

In a military life, good faith, honour, and courage, are the principal qualifications, and these are easily conspicuous in the British army. Their military ardour is greater than what is seen in any other service, but this is in a great measure damped among the officers by the difficulty of promotion. Interest with ministers, and the necessity of raising money to defray the expenses of the different departments of the state, though far from being the most equitable, are here unhappily among the first means of military promotion.

The soldiers of the British army are possessed of elements to enable them, under a commander of abilities and officers of experience, to be the best troops in the world. They require neither brandy nor self-confidence to make them brave; their courage is innate; it is a national instinct. Their officers too usually possess much greater information on general topics than those of all other European nations, as education is more cultivated in Britain than elsewhere. They are attached to their profession, and follow it rather from generous motives and military spirit, than like mercenaries from a view of interest and profit.

On the political and moral principles of war, see Cicero De Officiis, Gratius De Jure Belli et Bardi, Puffendorf's Law of Nature and Nations, and Machiavel's Discorsi; and on the principles of war considered as a science, see a memoir by Mazierey, in the 4th volume of Histoire de l'Acaudemie des Inscriptions et Belles Lettres, and Folard's Commentaries on Polybius.

PART I. MILITARY TACTICS.

Some writers on the military art distinguish tactics from what they call strategy; understanding by the latter the science of military movements when not in sight of the enemy, or at least out of the range of their shot; while they describe the former to be the science of military movements in sight of an enemy, or within the range.
range of cannon shot. We do not see the necessity of this distinction; and under the head of military tactics, we shall consider whatever relates to military operations on land.

It is not possible for us, within the very scanty limits to which we are now reduced, to give any thing like a regular treatise on the military art. We shall therefore endeavour to select the most useful and interesting topics, and supply the place of disquisition by numerous plates with appropriate explanations.

The science of military tactics comprehends the disposition and arrangement of troops, whether on marches, in camps, or in line of battle; the attack and defence of posts; the construction and superintendence of the works by which they are to be defended; the conducting of sieges; and the defence of besieged places. These are the principal operations of a soldier, and these we shall briefly consider nearly in the order in which we have enumerated them,

To direct the march of an army is not one of the least difficult parts of a general's duty. To do this with ability, he must be well acquainted with the nature of the country through which his troops are to pass, with the obstacles which are likely to oppose them in their progress, and with the disposition of the inhabitants. Our business here is only with the first of these considerations. There are three descriptions of countries which may become the theatre of war; an open country intersected by rivers, a mountainous, and a woody country. The march of an army through the first, as far as respects the face of the country alone, is seldom difficult, except in the passage of rivers, which we shall consider by and bye; and the last description of country is now so uncommon in Europe, that we need not dwell on it.

A mountainous country, however, presents numerous difficulties to call forth the abilities and experience of a commander, as in such a country, not only are the roads winding and difficult of access, but the unevenness of the ground, and the intervals between the hills, render it very easy for an enemy, with a small force, to oppose and distress a numerous army.

The plan in Plate DXLIV is intended to illustrate the march of an army through a mountainous country. At A is shown the position of the army previous to its march, with the artillery and baggage, drawn up under their proper escort, in front of the camp. At B are parties of hussars constituting the advanced guard of the army on its march; and at C are parties of infantry forming the advanced guard of the columns in which the army is disposed. D represents the infantry forming the head of the columns; E the park of artillery and wagons attached to it; F, battalions of artillery, G the cavalry, H the baggage of the army, and I their escort. At K are parties of hussars and at L parties of dragon. M represents the infantry of the reserve forming the rear guard, and N Platoons of infantry sent forward upon the heights, to cover the flanks of the principal columns. At O are villages in front of the position where the army is to encamp, and which have been taken possession of by the light infantry.

The number of columns into which the marching army is to be divided, will depend on the number of roads or accessible approaches that lead to the position which it is to take up. In the present case there are only two principal roads, each leading across the river, and winding through the valleys to the principal heights, so that the army must march in two divisions. The usual disposition of the columns is as follows. Four or five brigades of infantry, according to the numbers which compose the army, should be placed at the head of each column; the same partition should be made with regard to the artillery, which must follow the infantry; the cavalry must march next, and the baggage of each column, well escorted by infantry, must follow the cavalry, then the rest of the corps of light horse which are not detached; and the dragons are placed the last, in order to dismount, and sustain the rear-guard in case it shall be attacked.

An army seldom proceeds far without encountering on the pass a river in its march, and as it commonly happens in a sage of a country which has become the seat of war, that the bridges are destroyed or rendered impassable, the army must cross the river, either by swimming, at some ford, or by temporary bridges thrown over for the purpose. It is most advantageous to cross a river at some part where the stream is divided by small islands, unless the river be so shallow that it may be easily forded. If it be necessary to construct a bridge, this is best done by means of boats or pontoons, and all the necessary apparatus should be ready at the place of crossing at an appointed hour, and every measure should be taken to avoid confusion, and to be prepared for the enemy, who will probably dispute the passage. The two heads of the bridge when constructed should be entrenched, and well furnished with troops, and, if possible, the islands in the neighbourhood should be fortified by proper works, to prevent the enemy from destroying the bridge, or incommoding the labourers employed in its construction.

If the river be narrow, it is best to cross at some place where it makes an angle, especially if, as commonly happens, one of its banks be higher than the opposite bank, so that the higher ground may be defended by a battery. If the river be fordable by infantry, care should be taken beforehand to clear the bed at the ford, and render the banks easy of access.

The lower figure of Plate DXLV illustrates the passage of a river. AAA represent bridges of boats; B, redoubts by which the bridges are protected; C, a battery, under cover of which the infantry work at the construction of the redoubts; D, a battery, to prevent the enemy from annoying the army on its march; E, the march of the army; F, the artillery distributed among the brigades of infantry; G, infantry forming in columns to open on the opposite side through the intervals of the redoubts; H, march of the columns in the front of the redoubts, where they halt to give time for a part of the cavalry to form upon its flanks; I, a battery erected to facilitate the forming of the cavalry; K, cavalry, which in gaining the opposite shore, forms in order of battle, and posts itself upon the flanks of the infantry; L, eight battalions in column upon the right wing of the army, to go and examine the village and attack the enemy in it, in case he should be possessed of it; M, hussars and dragoons, who have taken possession of the height which is on the left wing of the army; N, a brigade of infantry posted next the height, covering the left wing of the cavalry; O, the disposition of the army marching up to the enemy.

It is in general a very difficult task to defend the passage.
sage of a river against an army that is determined on crossing it. Indeed, if the river be of such a nature as to prevent several points by which an enemy can cross, and if the defending army be not of such strength as to meet their opponents in the field, such a defence will be almost impracticable. Where it can be attempted, however, and where sufficient notice can be procured of the enemy's approach, all the boats and barks found on the river should be removed or destroyed, to prevent the enemy from using them in constructing his bridges. Both banks of the river should be carefully reconnoitred, that the fords and other accessible points of passage may be sufficiently obstructed; and the ground which might protect the enemy's passage, should in particular be attended to. Roads sufficiently wide to admit of many columns, should be made along the side of the river to be defended, that a great number of troops may be advantageously disposed. It must be confessed, however, that if the accessible points extend along the considerable tract of country, and if the bank of the river next the enemy overhang that on the opposite side, a defence will be nearly impossible.

Fig. 1. The upper figure of Plate DXLVI. shews the manner of disposing the troops to defend the passage of the river. A, the march of the main army in three parts to defend the river; B, the camp of the light horse, infantry, and dragoons, on the wings of the army; C, castle and village, guarded by light infantry; D, a town occupied by the infantry belonging to the army; E, bridge broken down; F, islands occupied by infantry; G, posts of infantry distributed along the side of the river; H, batteries established along the side of the river; I, posts of cavalry, to keep the communication between the camps; K, bridges constructed to preserve the communication of the islands; L, bridges for the communication of the camps.

Modern warfare is distinguished from that of the ancients, not more with respect to the arms which it employs, than the multitude of stores, ammunition, and provisions necessary for a campaign. The number of horses now employed for drawing the artillery, and the ammunition wagons, as well as to mount the great increase of cavalry, considerably adds to the quantity of military stores required by the troops. This has produced the necessity for magazines, established in such number, and at such distances from each other, as may most expeditiously dispose of the operations of the campaign; and these magazines require not only to be fortified themselves, but to be strengthened by forts or redoubts in their vicinity. To these magazines modern writers on the art of war have appropriated the term of basis of military operations, and the roads by which an army receives its subsistence from the magazines, are called lines of operation. The situation of the principal magazine, and the length and direction of the lines of operation, are considered as of the highest importance. With respect to the first and second of these, we must refer to Templeton's History of the Seven Years War, where the question is considered with great minuteness and scientific accuracy. The direction of a line of operations may be illustrated by the first seven figures of Plate DXLVI. Fig. 1 represents a line of operation forming the segment of a circle, having a line of posts ACB towards the enemy's country, and two principal fortresses DE within the segment. As this circular segment is supposed to surround a part of the enemy's territory, and is strengthened by the two fortresses AB, at the extremities of the basis, it is esteemed the most advantageous form. On the other hand, if the segment had its circumference directed towards the enemy, as in fig. 2, it would form the worst possible direction for a basis; for here the fortresses CD, placed in the circumference, are very much exposed, and might be easily taken by detachments from the columns E and F. The only way of preventing this would be to detach troops from A and B laterally, to incommode the columns E and F, and to take up a strong position either at G or H. The more the segment approaches to the elliptical form, as in fig. 3, it is the less susceptible of defence, as it is evident from the relative position of the three fortresses A, C, and B.

The line of operation represented by fig. 4, consisting of salient and obtuse angles, such as A c E, B d G, constitutes an excellent form, as it resembles the outworks of a fortress, and it is as impracticable for an enemy to enter into the interior of this basis, as to carry a curtain between two flanks. The two fortresses C and D are not nearly so much exposed as C in fig. 3; as if one of them were attacked, it would be easy to make a diversion from the other into the enemy's country. If the points which terminate the basis advance as in fig. 5, it will be a favourable circumstance, especially if the most advanced post were bounded by the sea, or by a large river.

The basis which we have been considering consists of curved or angular lines. Now, let us suppose two bases, the one A B, fig. 6. forming merely a straight line; the other c e d g, having two of its lines c e and d g, advanced towards the enemy. This latter is the more advantageous, as it exposes so much more of the enemy's country. In general, it is a good rule to construct fortresses opposite to those of the enemy, as here the fortress g, if moderately strong, is capable of protecting the whole line from c to d, against the three opposite forts A B. It is a great fault for any part of a basis to recede, as c d from the line of the enemy AB, fig. 7. It is as to form an angle with it, as here all the country between A and c is exposed to the hostile attacks of A and B; but, if the line were parallel to that of the enemy, as d c, it would be a good position.

Next to the establishing of magazines, and providing for their security, and that of the lines by which they are connected, it is of the highest importance for a general when he takes the field, to select the proper positions where he may encamp his army, so as to be readily defended against the attacks of a superior enemy, and have an easy communication with his own posts. In selecting such a situation he must be guided partly by the nature of the country, and partly by the situation of the enemy; but if possible, he should choose a position which is rather elevated, and which may be protected on the flanks or rear, either by the natural situation of the ground, or by works thrown up for that purpose. It should not be too near the bank of a river, though it may be of advantage to have such an object in front. The encampment of an army in such a situation is pointed out by Plate DXLVII.; where A is the camp of the main body of the army; B, an advanced camp composed of dragoons and horsemen, in order to cover the right of the army, to guard the passes by which the enemy might make incursions upon the flanks and rear of the army, molest the convoys, and cut off the communications
Military Tactics

Part I.

A.R.

into Stemmern. M, a small wood, cut down in order to have a full view in front of Stemmern. N, a thick wood which covers some high mountains by which the left wing is supported. O, an abattis which is made across the wood for greater security. P, infantry pickets. Q, a redoubt on a small eminence, constructed for the purpose of covering the opening behind the left wing of the camp. B, a line of communication from the last redoubt to the left of the intrenchment. S, several passages 30 feet broad and closed in by chevaux-de-frise, to afford an opportunity for the cavalry to advance, should the enemy be foiled in his attack against any part of the works. T, the infantry and cavalry encamped behind the recontrements; the infantry in the first line, and the cavalry in the second. U, X, Y, Z, four roads behind the camp to facilitate the retreat of the army, should it be pressed.

Fig. 2. and 3. represent an intrenched camp with inundations in front. Fig. 1. a & b, two dykes 40 paces long, 5 broad, and as many high. CD two rows of stakes from 4 to 5 inches thick. E, the coffined with means of stakes filled up. It is eight feet broad. F, the adjacent country, inundated by the rivulet being forced out of its current by the last dyke and by a and b. G and H, the outlets which the rivulet seeks, to continue its course. I, small creeks or ends of ditches dug about the ground. Fig. 3. represents the current of a rivulet, with a dyke to occasion inundations. Camp, with several dykes in front, which are calculated to produce inundations. The spaces between these dykes are called coffins, viz. 1, 2, 3, 4, 5.

We have mentioned the works by which the field posts are fortified, and which are usually called redoubts. As some other advantages of the construction of redoubts is generally a work of the moment, and falls within the province of the commanding officer of a detachment, it is proper that we should here describe the most useful and expeditious methods of raising such works. These methods are illustrated by the plans in the upper part of Plate DL.

Plate DL.

Plate DXXLIX. are shown other methods of intrenching a camp in the neighbourhood of a town or village, and in situations where the camp can be protected by inundations. Fig. 1. represents an intrenched camp in the neighbourhood of a town. A, a deep marshy valley, with an unflooded rivulet across it. B, a redoubt constructed on a mountain, by which the right wing is appuyed. C, a small wood in front of the mountain. D, a line which connects two flocks together at the foot of the mountain, where the village of Weilheim is situated. E, a rivulet, over which are thrown bridges of communication, to facilitate an intercourse between the camp and the redoubt on the hill. F, an eminence with a gentle declivity, at the foot of which is the village of Mansfield, surrounded by defiles and hollow roads. G, defiles and hollow roads. H, lines which run along the circumference of the heights about Weilheim, forming a retranchment. I, close works. J, a redoubt which masks the entrance

Vol. XX. Part II.
War.

The lines being finished, fascines or faggots of brushwood are to be laid between the two innermost squares, as a foundation to support the earth of the banquet; a second range is laid on the lines AB, GH, to support the inside of the parapet, and a third on the square O, P, Q, R, to strengthen the outside of the parapet, leaving a space through all the fascines to the ditch, on the side least exposed to the enemy, as at B, for an entrance. It is sometimes convenient to make this entrance take a winding direction, as is shown at T, fig. 2.

Fig. 3. exhibits a section of these works, where AB is the breadth of the ditch at the top; MN its breadth at the bottom; FN its slope, on a line with the outside of the parapet, called the scarp, and GM its slope towards the open country, called the counterscarp. AL and ID represent the fascines forming the outer and inner slopes of the parapet, the interval between them being filled with earth trodden down hard. At E is the banquet, DC is the thickness of the parapet below, and IL its thickness above, which forms a slope for the more convenient firing of musketry.

In this square redoubt it is evident that the men must fire straight forward in lines perpendicular to the sides of the squares, as in fig. 4. As it is often of great consequence that the directions of firing should cross each other, the better to flank the enemy, the banquet is sometimes formed with angles, as in fig. 5, so that the men may stand two together in little redans. As, however, such a construction takes up too much time and labour for ordinary occasions, M. Le Coite prefers a circular redoubt, such as is represented at fig. 6, where the men may fire from every part of the circumference.

The construction of such a redoubt is extremely simple, and differs only in its first step, viz. describing the concentric circles, which is done with a cord fastened at one end by a picket at a central point C.

The strength of the redoubt will be much increased, if the ditch can be filled with water, as by turning into it the stream of a rivulet. See Q, fig. 7. If the ground be uneven, so that the water will not run equally into every part of the ditch, dams must be raised, as C, to keep up the water in the higher parts, whence it may run to the lower, after the former are full.

Fig. 7. represents a plan of the square redoubt, with a wet ditch, when completed. A, the inner ground of the redoubt; B, the bottom of the ditch; CDE, the dam of earth; F, a dam of boards, planks or fascines; G the upper part of the redoubt, made with fascines or with earth thrown out of the ditch; H, the lower part of the redoubt cut into the earth; I, the berme or space left at the outer bottom of the parapet, to keep up the earth; L, the entrance of the redoubt; M, the inside of the parapet; N, the outside of the parapet; O, the banquet; P, the glacis; Q, the river introduced to fill the ditch with water.

The attack and defence of posts are among the most important departments of what the French call la petite-guerre, and in a country where fortified towns are rare, constitute a considerable part of field operations. We shall consider them rather more at large than we have the preceding parts of military tactics.

When an officer is detached either to attack or to guard a post, he should provide himself with a cord regularly divided, for the purpose of describing lines, and raising temporary works, and should procure a skilled and confidential guide, from whom he may derive the requisite information respecting the nature of the country, and the breadth and goodness of the roads. He should dispose his party in such a manner that an advanced guard of cavalry, as A, fig. 8, Plate DL, should set out first, preceded by a small detachment of about six horsemen, headed by a corporal, as B, C, C; two horse- men in the middle, and two on each side. While the main body is moving along the principal road, as from H to F, a detachment of about 8 or 12 horsemen, according to the strength of the corps, should be sent about 50 paces on each side, by way of wings, as DD; and from each of these wings 2 men should keep 50 paces further out, as at EE, by which means the country will be properly examined, and surprises from the enemy prevented. On coming near a wood, as at NN, the cavalry should spread, the better to scour the outskirts and the wood itself. When the corps is numerous, the cavalry should be formed into squadrons, as G, G, G, and the infantry into platoons, as F, F, F, marching alternately along the road.

If, on the march, the advanced guard come to a cross road, or the entrance of a hollow way, as at L, where it is likely they may be met by a party of the enemy, they should immediately prepare for an attack; and if the commander of the main body observes his advanced guard in action, he should immediately draw off his platoons of infantry, and form them on the side of the road, as at L, L, or, if some some neighboring height, as at M, M, that they may be out of the way of the enemy's cavalry, and ready to engage if occasion should require it.

On the march the party should carefully avoid villages, and rather halt or refresh his men in a wood, or some other concealed spot.

The commander of a detached party must take the safest and most effectual methods to reconnoitre the country through which he is to pass, without being observed or suspected by the enemy. The method of doing this recommended by M. Jeney will frequently succeed, and is as follows: He supposes himself with his party at Soest in Westphalia A, Plate DLJ, and the enemy posted at Berwick B, two leagues from him. To know the situation of this place without stirring from Soest, he takes the map of the country; and from Soest as the centre, he draws a circle, whose circumference passes half a league beyond Berwick. He draws a circle of the same size upon a leaf of paper, to make his plan, as in fig. 2, and then places Soest in the centre A, and marks all the villages which he finds in the map near the circumference upon his plan, with the distances and bearings as they are represented in the map, making use of a pencil to mark the places DDD, so as to correct the errors more easily which the map may have led him to make.

Having thus formed his plan, with a scale of two leagues, he goes to the burgomaster of the town of Soest, where he causes some of the most intelligent inhabitants to come, and speaking to them freely and openly, induces them to communicate all the information for which he has occasion.

The better to conceal his designs, he begins his reconnoitring by Brockhausen, a village distant from the enemy. He asks the distance from Soest to Brockhe-

must be swept away by dragging trees with their leaves and branches over the ground (A).

In attacking posts of considerable magnitude, such as villages, it is best to divide the attack, and to make a feint on those parts which seem best defended, while the true attacks are reserved for those situations which seem most difficult of access, and where consequently, the enemy is least upon his guard. As soon as part of the village has been carried, some divisions of the detachment should hasten to strengthen their guards, by possessing themselves of some church, or high ground, from which they annoy the enemy.

When a post is once occupied, if it be thought of sufficient consequence to retain it, the best methods should immediately be taken to protect it against an attack of the enemy. The infantry to remain under arms in the middle of the place, the cavalry to patrol without, while the commanding officer, escorted by a dozen horsemen, goes to examine the environs to make his arrangements; having sent several small detachments before, to cover him in time of reconnoitring.

Having remarked the places proper for his guard, defence, and retreat, as well as the dangerous ones by which the enemy can make approaches secretly to surprise him, he should choose the most convenient in the front of his post to fix his grand guard D, (fig. 1. Plate DLI,) which must face the enemy. He must mark the heights for this guard to place their vedette E E E, and regulate the number according to the exigencies of the situation. In a covered country you must not be sparing of them, and must reinforce every guard. At 50 paces from the front of the grand guard a non-commissioned officer with eight horsemen should be always ready to set out at K, to go and reconnoitre, when the vedettes have observed any party.

If the post to be defended be merely a redoubt, it will be proper to keep in readiness a number of trees cut down with their branches, to stop up any breaches made by the enemy's shot. The men employed in the defence should stand in three ranks, the front and centre ranks with fixed bayonets, and the third rank provided with long pikes, so as to project as far as the bayonets of the front rank. On the enemy's approach, the men should reserve their fire till the enemy come up to the glacis, and the rear rank should be furnished with hand grenades, or lighted faggots, to throw among the enemy, when they attempt to scale the parapet.

In the defence of a village or small town, guards should be posted at the entrance of the principal streets; trenches should be cut across the streets, and cannon planted behind them, while a detachment of cavalry should occupy the market-place, or broadest street, to attack the enemy, if they force an entrance. If the advanced guards are driven in, they should retire with coolness and deliberation, defending their posts from house to house, till proper support can be given them from the body of the detachment.

If there be any dangerous place capable of covering the approaches of the enemy in the environs of the post, and

(A) The principal engines employed in the attack of posts, are represented in Plate DLV, to which we shall presently refer.

WAR.

Part I.

and out of the circuit of the patrols, there should be a guard placed there, more or less strong according to the importance of the place, and care should be taken to preserve the communication. The guards and pickets being placed, the detachment that was sent out on the roads must be called in, and then go to work to lodge the party in the gardens that open upon the country, and the commanding officer's quarters; beating down hedges, filling up ditches, and levelling a piece of ground large enough to draw up the whole corps. The horses to be put under cover in barns, contiguous to the gardens; but in case there are no barns, they may substitute sheds open on one side, that the horses may go out together in case of an alarm. The officers should occupy the houses in the neighborhood of the sheds, and one or each company remain day and night with the company, to prevent any of the men from entering the village without leave, upon any pretence. The commanding officer must acquaint the officers of his having chosen the place M for the rendezvous in case of a retreat; which ought to be at some distance from the village, and on the side he judges most convenient for retiring to the army. At sunset the grand guard are to return to the post and join the picket, the half of each to mount alternately till daybreak, and then the grand guard to return to the place which they possessed the day before. The sentries and vedettes should be doubled, and all the passages shut up with wagons placed in two rows, except one for sallying out at in case of a retreat, made wide enough for the passage of the patrols or the whole cavalry.

The corporals of the ordinary guard should lead the relief of the vedettes every hour, setting off together; but when they come to the passage of the post A, they must separate into two parties, the one to the right to relieve the vedettes B B B B, the other to the left for the vedettes C C C; then each of them, with the parties they have relieved, should go on at their head a quarter of a league by the two routes pointed out in the plan, to examine the environs, supposing an hour to each. Besides this reconnoitering, the captain of the grand guard should send two patrols in the night. To fill up the intervals, they should set about one half an hour after the corporals, and make the same round.

In defensive operations in an open country, the fortifying of a village or a church-yard may often prove of immense service; such posts well defended may obstruct the movements of the enemy, and give time for a sufficient force to collect to meet them in the field. We shall therefore describe the most approved mode of strengthening these positions.

When it is proposed to fortify a village, inquiry should first be made respecting the surrounding country, whether there are woods, hills, or rivers near the village, whether the roads be accessible, whether provisions can be easily obtained, &c. If the village is to be occupied as a post of defence merely, the woods, rivers, ravines, or heights, may afford advantageous outposts or situations for batteries or ambuscades; but if it is to be possessed as an advanced post on the eve of a battle, the woods next the army should be cut down, the hollows filled up, and every thing removed which may obstruct the free communication between the village and the main army; while on the side of the enemy, every obstruction by works, trees, &c. should be thrown in the way of his approach. The roads should be broken up or intersected with deep ditches.

If there be good hedges or deep roads parallel to the village, or in such a situation as to form the enemy, these will serve as breastworks, and for shelter. The hedges should be cut down to within four feet of the bottom, their tops sloping towards the country, and deep ditches should be dug in front. If the roads are deep, banquets or steps must be thrown up next the hedge to raise the men to the proper height for firing. For want of such natural means of defence, it will be necessary to throw up intrenchments on the side next the enemy and on the flanks.

Fig. 1. Plate D L I I. will explain the method of doing this in a village, under ordinary circumstances. The village stands in a plain, and in front of the army, which is distant from it about 600 paces. a. The front of the intrenchment consists of three fleches or arrows, b, c, d, joined together by lines. There are well holes before the works that cover the left flank e; the line f, which crosses some narrow grounds, is broken in several places g; and the grove of wood h, is cut down, to prevent the enemy from approaching under cover of it. As the right flank, consisting of a level plain, is more exposed than any other quarter, in addition to the works made of earth, which are thrown up at m, trees are collected, and heaped up in the form of an abattis. These are defended by a discharge of musketry from the intrenchments, whose lines are raised as high as possible behind the growing hedges i, which inclose the gardens. It has however been judged necessary to throw the works up in a forward position p, and to have an interval between them and the hedges, lest the house should be set on fire by the enemy, and the troops be exposed to it. Everything is left clear and open at the back of the village, in order to secure a free intercourse with head-quarters.

Other measures, however, must be adopted in the fortifying of villages which lie at so great a distance from the camp, that the enemy might surprise and take possession of them before any succour could be sent; for in that case, intrenchments must be thrown up throughout the whole of their circumference. If, on the contrary, one of the wings of the army should be supported by such a post, it would be more judicious to put the flank in a state of defence, and to lengthen the works in that quarter, to prevent the enemy from turning it.

If it should be judged expedient, under the circumstances of the army being cantonned, to fortify a village which lies in a plain, other means must be used; for in that case there would not be troops enough to defend it. Should there be a sufficiency of men, intrenchments must be thrown up in the manner we have described, and fleches must be adopted to cover them behind, with lines to connect the vacant intervals, but if there be a scarcity of soldiers, nothing but what is absolutely necessary must be done; for it is highly improper to attempt more than can be easily defended. Under these circumstances you must be satisfied with erecting small works, or using barricades to mask the entrances, and there likewise fleches must be constructed, whose communication will be kept up by the garden and hedgerows. If the village should stand on an eminence, it may
may be fortified with more facility, and many things may be omitted, as the natural situation is itself a respectable post.

Should there be a very great disproportion between the extent of the village, and the number of men intended for its defence; and the latter should be too small, a part only must be fortified, and the remainder of the houses must be secured by lines. Sometimes indeed it is found necessary to burn or destroy them, to prevent the enemy from approaching the fortified parts, under cover of the buildings.

But if the garrison should not be sufficiently strong even to defend a part of the village, you must be contented with fortifying the church and church-yard, or the castle if there be one. If any of these posts be thought defensible, troops must occupy them on the first alarm; but this must be done in perfect safety, and without the soldiers being exposed to be cut off on their march. This precaution is above all others necessary where villages are so long and open that the cavalry may enter them at every opening. On this account the ordinary roads and avenues must not only be obstructed, but the garden hedges must be repaired, and every opening must be closed, which may be easily done by driving stakes into the earth, and nailing boards across them, which will prevent any sudden irruption of the cavalry, from which alone any danger is to be apprehended on occasions of this sort; for the infantry would scarcely advance, except by surprise, before the garrison could occupy its station. If any apprehensions are formed of an attack, the soldiers must not be absent from their post, either in the dusk of the evening, or at night; they must, on the contrary, be assembled in the intrenchments during that period, to be ready in the neighbouring houses, always clothed and accoutred.

A church and church-yard afford an admirable post of defence, especially if, as usually happens, they are seated on an elevation. In fortifying such a post, we should first block up every road and by way leading to it, by means of wagons or carts, with their wheels taken off and loaded with dung or earth; trees laid across, or chevaux de frize. The narrow paths may be barricaded with rails, with their points standing upwards, and a little outwards, having behind them thick branches of trees, or logs of wood, with a ditch in front. These previous precautions being taken, the doors of the church should be pierced in several places, about eight feet from the bottom, with holes large enough to admit the muzzle of the musket, and platforms should be raised with steps within for the men to fire from. Other loop holes should be made at the bottom of the doors just above the level of the ground, and a ditch must be dug within, about three feet deep, so as to admit of men fixing from thence through these lower loop-holes. See fig. 2. The doors must also be secured by barricades, consisting of pallasades driven several feet into the ground, and set extremely thick, some being deeper than others, so as to leave spaces between them and the top for loop-holes. See a, a, fig. 3. This barricade is technically called tambour. The walls of the church must also be pierced in various places as directed for the doors, see fig. 3. and ditches must be dug within them, and scaffolding erected as before.

Again, on the outside of the church, a ditch is to be dug as close to the walls as is consistent with safety to the foundation, about 12 feet in breadth at the top, and four in depth; and from the farther side of this ditch the ground should be gradually sloped towards the open country. Through the main door of the church an opening should be made about two feet above the ground, sufficiently large to admit of one man passing through without much difficulty, so that when the church-yard becomes untenable, the garrison may retreat into the church.

It must not be forgotten to secure the means of a cross fire. If the church be built in the form of a cross, cross firings may easily procured through the proper loop-holes; but when this is not the case, loop-holes should be made through every salient angle of the building, or tambours, such as represented in fig. 3, must be formed wherever it can be conveniently done.

Men must be distributed in the upper part of the building. These men will take out the tiles or slates in different places, in order to observe the approaches of the enemy, and to fire upon him when he comes within musket-shot. The lower windows of the tower or steeple must likewise be barricaded, and have loop-holes made in them. The pavement of the church must be taken up, and the stones or bricks carried to the top of the building, to enable the besieged to let them drop upon the enemy, when he gets sufficiently near.

In order to render the defence as practicable as possible, you must also collect some large barrels or tubs, and keep them constantly at hand filled with water, for the purpose of extinguishing any fire which might break out in the church, or be effected by the enemy's shells.

Fig. 4. shows a plan of the church and church-yard Fig. 4. thus fortified. a, a, a, a, the wall of the church-yard; b, c, tambour work in the front of the entrances; d, the church; e, f, tambour work constructed opposite the doors; g, the sacristy or vestry.

Connected with the attack and defence of posts is the subject of ambuscades, which we must now briefly consider.

Ambuscades may be formed in any place where a part may lie concealed, to surprise the enemy in passing. They are easily carried into execution in woods, hollow places, and large deserted buildings; but the placing of an ambuscade in any situation requires previous accurate information with respect to the movements of the enemy. When the commander of a party has been directed to form an ambuscade, to surprise a convoy of artillery, baggage, or provisions, or a body of recruits going to reinforce the enemy, he should first make every necessary inquiry respecting the route which the enemy is to take; the situation of the places near which he is to pass, and the post to which he is about to march. He must also inquire with seeming anxiety about the roads which lead in an opposite direction, on which he should seem more intent than on his own object. Having concerted his plan, he should set out at the head of his detachment if possible, and leaving his post on the side opposite to his true route, the better to conceal his design. If the place where he intends to plant his ambuscade be not far distant, he should come into his true route about half way, and there place half his infantry in ambush to favour his retreat. But when the country where he proposes going is distant, and the march
march requires at least two nights, he must conduct his party by meandering from wood to wood, if there be any. He must not forget to provide necessary refreshments for the day, which must be passed in some concealed place where he may not be perceived, and must cause three rations of oats to be carried for each horse.

Proper precautions having been taken to guard any cross road or bridge that may lie near the place of ambush, the commanding officer should take care to be at least two hours before the enemy, and to place the ambush on that side, by which, if worsted, he may retire with the greatest safety.

Plate DLIII. fig. 2. will illustrate the proper method of laying an ambush. A represents the infantry of the surprising party, which ought to be placed at least 500 paces behind B, the cavalry, so that, if pursued, they may both fall back to A, and make good their retreat to the guard at the bridge or cross road; or the another party of infantry placed in ambush half way. If the ambush be placed in a wood, an intelligent non-commissioned officer should be chosen to get upon a high tree C, from which he can see the march of the enemy, and give notice of the most essential circumstances. The first of these is the seeing the advanced guard; the second is the approach of the corps, and the third is the time when their front is advanced as far as the ambush B; for which the commanding officer should instruct the observer what signals he is to make from the top of the tree, to communicate the necessary information without speaking, which may be done by means of a small cord D, of a brown or green colour, so as to be least perceptible. Let this cord be placed in the plan, so that no branch intercept it, with one end in the hand of the observer, and the other in the commanding officer's hand in the ambush B.

As soon as the advanced guard appears, the observer must pull the cord, and the commanding officer cause the party to mount and remain in deep silence. If by a stratagem, which is practised for particular reasons, the advanced guard is immediately followed by the corps, which may be easily known by their being more numerous than ordinary, and not followed by any other corps, that the commander may not be deceived by the enemy, the cord should be drawn a second time, and a third time when their front is advanced as high as the ambush. At that instant the party must rush out, and furiously attack the flanks of their centre in the following manner.

If the advanced guard E is formed only of an ordinary number, they should be allowed to pass; and at the approach of the principal part or convoy F, the chief to be informed by the second pulling of the cord. At the moment the head of the convoy shall be advanced as high as B, the cord must be pulled the third and last time; and at this signal the party must rush out without being perceived, and suddenly attack the centre on the flank, engaging only with their swords, and making such a noise as to prevent the enemy from hearing the orders of their officers. They must disarm all whom their bravery shall throw in their way, taking care not to scatter or pursue too far, unless it be certain that they are so far from their army or parties, on account of which they cannot be affected; for in either of these cases they will not fail to run at the noise, and disturb the retreat.

In all secret expeditions, great circumspection should be used, that the party be not seen or betrayed; as if they be discovered by the advanced guard before the blow be struck, the enterprise must be immediately abandoned, and the party retire. When the guide, or any one of the party deserts, and cannot be caught, a retreat must immediately be thought of; or the ambush must be placed somewhere else; but to prevent such a misfortune, the officers should be charged to examine frequently whether they have all their men.

An ambush should never be formed for cutting off the enemy's retreat, as this will drive him to despair, and make him rally and attack the party with desparate resolution. There may be an exception to this, when it is pretty certain that the whole party of the enemy may be cut off or taken prisoners, either from the smallness of their number, or from the peculiar situation of the place of ambush.

Several ambuscades should not be formed at once, except for the purpose of seizing foragers, in which case they should be disposed so that the sentinels may see from one to another. Then the first guard which sees the foragers, should commence the attack, and can soon be assisted by the rest of the party.

In all ambuscades, no sentries should be placed but officers or non-commissioned officers. On downs, behind mountains, or in gullies, the sentries should lie with their bellies on the ground, and their feet towards the ambush, the body covered with a grey or green cloak, according to the colour of the ground, their heads a little raised and wrapped in a handkerchief of straw green, or white in time of snow, so as not to be easily perceived. The numbers of sentinels cannot be determined, but they should be disposed so as to watch on all sides of the ambush, and stop every one who may inadvertently approach too near. The sentinels should give notice of what they discover by gestures, in which all the officers should be very attentive. In counties where there are no woods, vineyards, or heaths, an ambush may be placed in a field of hemp or corn, or some sort of grain, provided it be high enough to cover the men, at least with the help of an arm. Then the stalk of the corn is not high enough, some of the infantry must be set to work with spades and pickaxes, which they must have brought along with them, for the purpose of digging holes in the field deep enough to make up for the defective height of the corn.

An ambush often forms part of a stratagem for bringing on an action with a party of the enemy which would be superior, were it not for some advantage of this kind, as in the following case. See Plate DLIII. fig. 1. Suppose the whole party to set out from a fortress marching under the conduct of a trusty guide by covered ways at a distance from the enemy. Being come to the place C, which ought to be in the environs, and as high as the field of battle, the infantry should be concealed out of the road far from the sight of passers. This must be the centre of correspondence with the army, the rendezvous of the booty, and support the retreat of all the cavalry, of which there should be as many detachments as there are attacks proposed to be made. We shall suppose six of 100 men each, and they...
must go secretly by particular routes to their respective posts, E, D, F, G, H, I. Neither trouble nor expense should be spared to procure good guides. Each detachment should lie in ambush half a league, if necessary, from the object of the attack BKKKKK.

The noise of the musketry in the armies is to be the signal for their irruption; and then bravery, intrepidity, and courage will give wings to the people. The second detachment D will glance imperceptibly between the villages, and fall like thunder on the camp B; and while 80 attack all whom they meet, the other 20 should light their torches at the fires that are to be found everywhere, and spread the flames rapidly to the straw of the tents. As they cannot fail to have the picquet of the camp soon at their heels, they must strike their blow with all possible expedition, without stopping to plunder, being content with the glory of having excited a general alarm, capable of confounding the whole army, and contributing to the gaining of a battle.

At the same time that the detachment D attacks the camp B, the others, E, F, G, H, must with equal violence attack the villages K, K, K, which they have in front, doing the same the first did in camp, except that they may seize as plunder every thing which they can conveniently carry off, with which these villages are commonly filled, seizing the best horses, hamstringing others with the stroke of a sword, and setting fire to all the places which contain the enemy’s baggage. Each detachment should cause some horsemen to advance beyond the village, to observe the motion of the troops, who will not fail to run to their assistance. As soon as they perceive them, they must make their retreat as fast as possible by the routes which the commanding officer has preconcerted, and which are represented in the plate by the coarse lines. The sixth detachment, in ambush on the side of the road leading from the camp, should remain there, to seize all the enemy who think of saving themselves by flight.

When the commander of a detachment finds himself obliged to abandon a post, or that it is not worth defending, it becomes necessary for him to prepare for his retreat. This is often a difficult and dangerous affair, and requires much prudence, as well as bravery on the part both of officers and men. If possible, he should retreat on that side which forms a communication with the general basis or line of posts occupied by his party. The following observations on lines of retreat, connected with the lines of operation described in No. 22, will be found of importance.

A retreat on a single line is a fault of the utmost magnitude, for it is evident that if the army C (Fig. 8) Plate DXXVII) retire from it towards B, along the line AB, the enemy may send besides, two corps a, d, against the flanks of this army, which would separate it at the point B, and in this case it would be surrounded. Nor is this the only disadvantage, for all the country situated to the right and left of the line AB, would fall into the hands of the enemy; while, in a retreat, it is always a rule to cover as much of the country as possible.

A concentric retreat is of such a nature, that in an extensive position they fall back to one more confined, so that the two lines of operation at the extremities AB, (Fig. 9) unite at the object of retreat C, forming an acute angle, or as at Fig. 10, an obtuse angle; such a retreat would have no better issue than the former. The same disadvantages which result from retreats on a single line would likewise attend this. There is one circumstance which might induce a general to retreat in this manner, and that is, with the view of covering any important place, a capital, for example, by taking an advantageous position, which is indicated by C, in the figures; the important place required to be covered would probably be at D. But nevertheless this measure would be ineffectual if the enemy were at all versant in the art of war, and operated on the flanks of the army they were pursuing. The best method of covering a country, which is in our rear, is to proceed against the flanks of the enemy which is advancing; and by this intrepid and bold movement, to change our defensive operations into those of an attack.

A retreat conducted in parallel lines, as the basis AB, Fig. 11, in four corps, 1, 2, 3, 4, or the lines AC, EG, FH, BD, is doubtless better than the concentric retreats which we have just considered. In the first place, the country is better covered by means of the parallel lines; secondly, the enemy cannot so easily insult the flanks of the retreating army, provided this is in a condition to perform the same manoeuvre with regard to them, and obtrude their progress; lastly, they would be afraid of advancing with too much precipitation, from the moment their attention is divided by the attempt which may be made against them. But there might be something still better attending it, viz. to retire in an eccentric direction, as we shall show presently.

The excellence of parallel retreats is maintained from the idea that they cover a country better, and likewise stop the progress of an enemy, when opposed in a direct line. Certainly this appears evident to the eye; but the sight is often the medium only of error. It is the ignis fatuus which leads us into the mire, and the present instance is a proof of it. This opinion was not indeed well founded among our predecessors, and still less is it so among the moderns. We do not now arrest the progress of the enemy, by presenting ourselves to their strongest part, viz. their front; but, on the contrary, by intercepting their flanks, which are the weakest parts; by harassing their rear; by menacing their provisions and their communication with the sources of their vigour and power. It follows from hence, that eccentric retreats are the best. An army (Fig. 12.) who retire from a, b, c, d, e, towards f, g, h, i, k, runs no risk of seeing the enemy advance in the segment f, k; for he would, by such a movement, be in danger of being surrounded.

We may lay it down as a rule, that it is essentially necessary, in all retreats, to divide into different columns, in order to divert the attention of the enemy; and it is fully demonstrated that there is not in war a more important maxim. We might show that this method of attracting the attention of the enemy to many different points at once is, properly speaking, exciting a degree of apprehension with regard to his flanks and rear. But it naturally results from all that has been said relative to the inutility of diverting offensive operations, as well as those which are directed by a single line, or by an acute angle, that eccentric retreats are of all others the most preferable. Since concentric operations are the most advantageous in attacking, eccentric ones must necessarily possess the same advantages in defence; every thing
thing should be in opposition, in two different kinds of warfare, which are in their nature and interests contradictory.

In conducting a retreat, as in all other field operations, an army should assume, as the principal object, its own magazines, and the safety of its lines of convoy, rather than the army of the enemy; and it should never take a position opposite the enemy, but rather on one side of him.

We have hitherto considered military operations in the field, as they are subservient, or preparatory to, that most important consequence of war, a battle. We must now examine what are the causes which should induce a general to hazard or avoid a battle; and if he determine on a general action, what are the best methods of disposing the troops under his command.

At present, actions in the field are distinguished into two kinds, according as they are more or less general. When the whole of the adverse armies are engaged, it is called a battle; but where only a part of each is concerned, a combat. The latter of these, however desperate, does not in general involve such important consequences as the former; but as in a general engagement, the vanquished party usually lose the greater part of their artillerie and baggage, and are compelled to retire and leave the country behind them at the mercy of the victors, a prudent general never hazards such losses without important reasons.

When an army is superior to its opponents in number or discipline; when discord prevails among the chiefs of the adverse army; when a neglect of the ordinary precautions in marching, encamping, or other obvious duties, demonstrate their incapacity; when it is necessary to relieve a considerable town or post that is besieged by the enemy; when it is apprehended that the army will be dispersed or ruined, without a general engagement; when intelligence has been received that reinforcements are approaching to the enemy, which will render him superior; when the enemy has received, in some preceding action, a considerable check which he has not yet recovered, or when the army whose general is thus canvassing the advantages and disadvantages of a battle, is in such a state, that every thing ought to be hazarded for its relief, the commander is warranted in giving battle to the enemy.

On the contrary, when less is to be hoped for from a victory than feared from a defeat; when the army is inferior either in number, courage, or discipline, to the enemy; when it is in expectation of being reinforced by a strong detachment of fresh troops; when the enemy is so advantageously posted that it would be impossible to bring him to an engagement on equal terms, or to force his entrenchments; or when there is a prospect, by temporising and declining battle, of ruining the army of the enemy by disease, famine, or desertion, it would be wrong to place the fortune of the campaign on the issue of a battle.

When a general engagement has been resolved on, the general is to devise the means of carrying it into execution, so as to have the strongest presumption of success. He is to arrange, with the officers of his staff, the manner in which the troops are to be divided and disposed, or what is called the order of battle; he should assign to his several officers their respective posts, and see that copies of the order of battle be given to those that have a separate command. The proper officers should take care that the troops under their command be properly armed and equipped, and that they are allowed time to rest and refresh themselves before the engagement. The heavy baggage, and every thing that might encumber the operations of the troops, should be removed, and placed at a distance under a proper guard. A reserve should be formed near the park of artillery, consisting of some of the bravest and best disciplined troops, headed by the most experienced officers.

In time of action, the commander in chief should be so situated as to be able to issue his orders with the least difficulty, and to observe as far as possible the operations of his troops, and more especially the effects of the firing of attack. Every other general officer must keep his own station, to direct the charge of the troops, or to rally and re-form those which have been routed and dispersed. When the action becomes general, and is obstinately contested, the commander-in-chief should direct the principal efforts of his troops against that part of the enemy's line which makes the greatest resistance, and should himself hasten to this spot, to animate his men to greater activity and exertion by his presence and exhortations.

The artillery of the army should accompany the first line, and the remainder of the troops should follow the movements of those before them, so as to preserve the proper distance between the lines, and march with the least possible disorder and confusion. If the first line give way, the second should march up to its relief, and either charge the enemy, or keep him employed till the first line has time to rally and re-form. If, however, as often happens, the other lines are struck with a panic on observing the repulse of their predecessors, the reserve should be brought up, and it is probable that their courage and resolution will reanimate the scattered troops, and turn the fortune of the day.

In forming the order of battle, regard must be paid to the nature and situation of the place where the battle is to be fought; to the number and quality of the troops engaged, and to the mode of fighting which it is most likely to take place during the action, or, to decide the victory. There are two principal methods of forming troops in order of battle, the column and the line. The latter of these was most in use among the ancients, has been greatly recommended by Folard in his commentaries on Polybius, and practised with the most brilliant success by the French armies since their portentous revolution. This order of battle is adapted chiefly to cases where the activity of the troops can be relied on, and where much firing with musketry or artillery, is not expected to take place, and where of course the affair is to be decided principally by the pike or the bayonet. It is also well calculated for a body of infantry who are to resist the attack of cavalry. It is obvious that from the close arrangement of troops in column, this disposition must expose them to the fire of a line, and must endanger their being flanked or surrounded by an enemy whose front is more extended. The relative advantages and disadvantages of the column and the line, will be more readily perceived by attending to the following principles.

From the order of battle as a basis are deduced many instructive
Part I.

Military Tactics.

There are as many lines of marching and lines of firing, which constitute a considerable part of the elements of modern tactics.

Principles of marching and firing, deduced from the order of battle.

Let us suppose two lines of troops, A and B, fig. 13.

Plate DXLVI. fig. 13.

Again, the line AB (fig. 14) being attacked by the line c d, the flank B cannot extend itself parallel to c d, if this line advances always front towards A. The line attacked is surrounded, and even so pressed upon that they must all take flight towards A. If any troops by chance should endeavour to form upon the line e f, they would not be attacked by the enemy's fire, they could never resist such an attack. The cavalry would experience the same disadvantages in a similar case. Horsemen attacked to the right, to the left, and in front, could not defend themselves; the celerity of the horses, no doubt, would enable them to deploy quicker than the infantry; but, by the same reasoning, the enemy's cavalry, which is always ready to make the most of its advantages in its own provisions and in its country, could not defend itself against the enemy's cavalry. Thus it would be equally difficult to form the line e f; every thing would be overthrown, and they must retire in the greatest disorder towards A. It is hence clear that every effort should be made by an army in line of battle to turn the enemy's flanks with its front.

Concentric lines of marching and firing well executed, are exceedingly important. Hence it is that a fortress must yield when it is besieged, as the fire from the fortress is eccentric, while that of the besiegers is concentric. Hence, too, sorties from a garrison rarely succeed, because they are eccentric operations.

When an army is much weaker than its opponent, if the former be compelled to an action, it should throw itself on the enemies flanks; and to do this with effect, the enemy's front should be kept occupied, so as to draw off his attention from his flanks. If the line were long, he would have time to convey all that part opposite to the side attacked, as A (fig. 15) into the line e f; before the attacking army could extricate itself and throw and repulse the flank B, which would be the object of their efforts. In this case, things would again be equal; for an engagement in front would take place, the issue of which is always doubtful. If, however, they occupy the line AB, by corps sent for that purpose, as g and h, while, with a greater force, they attack in flank, then it would be impossible for any part of AB to throw themselves into the line e f, before having beaten g h; and the time would probably be too short for this operation, if c d pushed in front in a vigorous manner. From this it follows that the army AB, though the stronger, can do nothing better at this time than quit the field of battle, as it will otherwise be surrounded. Now, the attacking army have nothing to do but to affect an eccentric retreat; namely, to fall back with the left wing upon i k, and with the right upon l m, provided CD do not obstruct the passage; for in that case, the retreat of the right wing, or of that part of the army nearest the flank B, would be on n, in order to create in the enemy c a some solicitude for his left flank d. It is by such eccentric retreats that the pursuit of the enemy is prevented. They dare not venture it, if they do not wish to be taken in the flank by themselves, and to become in their turn exposed to an escalade and a concentric fire, and consequently a terrible havoc. Eccentric retreats in tactics are equally as advantageous as in strategy. The latter kind alarm the enemy with regard to his lines of operation, and consequently prevent him from advancing; the former make him afraid of exposing his flanks and rear, and hinder him from pursuing.

From these considerations it appears that it is no great misfortune for an army to be attacked in its centre, and divided. If the army be divided in two at the centre, it will retire eccentrically on e and f (fig. 16).

By this movement it will throw an obstacle in the way of all farther progress on the part of the enemy, who has divided in the middle the dotted line AB. It is impossible for the enemy c d to advance in front between e and f; they would take him in flank on both sides; he must therefore advance in front towards e and f, both at the same time. In this position e and f might detach forces to the rear of c d, and operate at once or at the same time. In this case, c d would have no resources to operate on part of the flanks e and f, which are opposite to the points A, B, to compel e f to retreat, and replace its front in the direction of A, B.

It does not require a great body of men to occupy the front of the enemy, while the rest of the army attack the flanks. It is best done by means of a scattered troop, or what the French call tirailleurs, consisting of light infantry, which are usually instructed in the following manner. The troop, formed into two ranks, divides in such a manner that there may be a space between the two, as indicated in fig. 17. The second rank, placed behind the intervals left by the first, secures its flanks. When they attack, the second rank, CD, passing through the intervals of the first AB, advances to the line EF, and fires. The great advantage arising from this, is that of forming a more extensive front than when they are wedged in elbow to elbow; secondly, they keep up a more fatal fire with their musketry, because each soldier, being unmolested by the one next to him, aims better, and continues his firing without interruption; thirdly, a less number of men is lost, because...

Part I.

Military Tactics.

bavonets, it would be sufficient for a division of the line AB to make a conversion on the flank of the échelon c d; while they are fighting in front, and overthrow it before c f; 300 paces distant, or even the second line of the échelon, could come up to afford it any assistance. Thus, according to all appearances, the line AB would conquer all the échelons successively, and this the more easily as they would be taken in flank as soon as c d is obliged to fly.

The most useful, and in fact the only process for reinforcing an attack, is to have a second line of cavalry behind a first line of infantry; in case of bad success they secure and cover their retreat, and complete the disorder of the enemy's infantry, if they come to an engagement.

When the infantry is ranged en échiquier, a first line when beaten, may retreat by files through the lines in the rear, without creating any disorder in the second, on account of the extensive spaces; but it is not the same with the long phalanx in open order. The cavalry, placed immediately behind the infantry, protects an attack much better than if there were between them a second line of infantry; for in the first instance, there would be no hindrance to their hastening to the succour of the runaways, and receiving them in their bosom. Hence there should be only two lines, one of infantry, and one of cavalry; and this is the more necessary, because the two lines of infantry cannot be useful, except in as far as they are beyond the shot of the cannon; it is evident, therefore, that they should be considered rather as a reserve of fresh troops than as a second line of combatants. Hence, the superadded strength which is supposed to be given to the échelons, by double lines of infantry, is quite illusory.

Cannons which fire concentrically, assist greatly the efficacy of an attack; but this measure may be employed as well for right lines as for the échelons; in an attack of the latter kind, the batteries should not be placed before the division c d, but before c f, to enfilade that part of the line AB, which should attempt to fall back to make a conversion, in case it were attacked in flank by c d.

It is impossible to take the enemy in flank by the diagonal or side-step, executed during the march; if, previous to commencing their march, they are not already considerably by their wings; for they would completely frustrate that scheme, if they made directly with their flanks a movement to the side. During the same time they would pass over a more considerable extent of ground than with an oblique step, because they move in a direct line, and before, and obliquely, both at the same time, which would considerably shorten their distance; and likewise because they march on one of the sides and you on the hypothenusse, which is longer. It is therefore impossible to succeed in stretching beyond the wings of the enemy, while they are advancing in front in the order of battle, if they know how to conduct themselves.

There is, however, one advantage to be noticed, which the échelons possess over the uninterrupted oblique front, which is, not exposing the flank to the enemy advancing in front. The échelons naturally possess this advantage, while the oblique front cannot obtain it without being much more extensive than the enemy's front; for the oblique line, formed into échelons, changes into a number of parallel lines by a conversion (fig. 3s.), and they may, by this movement, defend their flanks against the enemy. But still the best way is to attack him in his own flanks, whilst his front is amused with detached corps, and the columns should be prepared for the principal attack out of sight of the enemy, in the same manner as an admiral adopts at a considerable distance, his measures for gaining the windward of the enemy. No manœuvre within cannon-shot can possibly be attended with success, if the enemy be skilful.

Much useful military instruction may be derived from perusing the accounts of the most celebrated battles, detailed by writers of ancient and modern history; and we could here enumerate a long list of these engagements, many of which have been described in the historical articles of this work. A few, however, must suffice. Of ancient battles we may notice those of Marathon * in 490 B. C.; Platea, 479; Léuctra, * 362; Salamine, 387; the Granicus *, 334; Ar BELA *, 321; the Persians, 522; Thermopylae, 480; Cannae *, 216; ZAMA *, 202; Magnesia, 192; Nefeleph, 147; Pharsalia *, 48; and Philippi *, 42. Of modern battles, the most important are those of Hastings *, A. D. 1066; the Battle of Indus, 1582; reception the, 1584; Crewe *, 1568; Poictiers *, 1356; Almanzor *, 1194; Bosworth *, 1485; Flodden *, 1513; Pavia, 1525; Nara *, 1700; Blenheim *, 1704; Ramillies *, 1706; Pavia *, 1708; Zaa *, 1709; Malplaquet *, 1709; Fontenoy *, 1745; and City of London, 1757; Liass or Lee *, 1757; Minden, 1759; Freiburg, 1754; Field-mappe, 1792; Triermont, 1793; Fleurus, 1794; Hill *, 1796; Zurch, 1799; Ulm, 1800; Marengo, 1800; Austerlitz, 1805; and Wagram, 1809.

By way of illustrating the modern French tactics, and more fully explaining what has been said on the order of battle, we shall here give a detail of the battle of Jemappes, in which Dumberor entirely defeated General Clairfait, by enticing him from a situation where he was impregnable.

In the beginning of November 1702, when Dumberir arrived with his army in the vicinity of Mons, he found the Austrian general Clairfait occupying a strong position on the heights near the village of Jemappes, where he had entrenched himself, and was defended by nearly 100 pieces of cannon. The position of the Austrians was extremely formidable. Their right extended to the village of Jemappes, and formed a square with their front and left, which stretched to the causeway of Valenciennes. They were posted on a woody mountain, where they had erected, in an amphitheatre, three tiers of redoubts. Their whole force amounted to about 16,000 infantry, and 3000 cavalry.

The army of Dumberir was much more numerous than that of Clairfait, but not so well supplied with artillery. The elevation of the Austrian batteries, however, gave them such an advantage, that the French cannon could produce but little effect.

On the 4th of November, Dumberir had fully reconnoitred the Austrian camp, and, by way of feint, made an attack with his infantry on the village of Carrignon, while he kept up a brisk cannonade on their left. Towards evening the French army encamped opposite to Jemappes, with its left wing extending to Hoorne, and its right to Frenery. As Dumberir resolved
Part I.

W A R.

solved to make a decisive attack on the height of Jemappes the next morning, he ordered his troops to abandon the village of Carrignan which was commanded by the enemy's cannon.

On the morning of the 6th, he ordered his artillery to be advanced and disposed along the front of the line. It was soon found, however, that little was to be done with artillery, and that the great object was, to entice the Austrian general from his strong position, and draw him to the plain. For this purpose, at noon of the 6th, the French infantry formed in columns, and advanced with the greatest spirit and rapidity to the Austrian intrenchments. The lower tier of redoubts was instantly carried; but, as the centre of the French became endangered, and the Austrian cavalry appeared descending from the heights, and preparing to enter the plain, with an evident intention of flanking the French columns, Dumourier despatched the duke of Orleans to lead those columns against the second tier of redoubts, while a detachment of chasseurs and hussars flew to check the progress of the Austrian cavalry. Some smart skirmishing between the cavalry on both sides now ensued, and while this diversion was taking place, the left division of the French army possessed themselves of the village of Jemappes, while its centre obtained entire possession of the second tier of redoubts. In the mean time the whole of the Austrian cavalry had quieted the heights, and engaged the French on the plain below Jemappes. This was the point to which Dumourier had wished to bring them, and now the superior numbers and activity of the French quickly decided the fortune of the day. The Austrians were routed at every point, and forced to abandon the field of battle, leaving 5000 dead, while the French gained their artillery. The loss of the French, however, was considerably greater, and is, on good authority, estimated at 14,000; but this loss appeared trifling to Dumourier, as by this victory he acquired possession of the whole of the Austrian Netherlands.

The positions of the French and Austrian forces in this battle are represented in Plate DLIV. 1. The centre of the Austrian army, commanded by Clairfayt. 2. A part of this army commanded by General Lilien. 3. Another part under the command of General Beauville. 4. Redoubt on the heights of Jemappes. 5. Austrian intrenchments. 6. French columns advancing to attack the intrenchments. 7. A battery. 8. Columns of cavalry. 9. Columns attacking the eminences above Mons. 10. Battery on the height of Frenery. 11. The wood of Frensey. 12. The plain on which the French and Austrian cavalry were engaged. 13. Austrian detachment.

The columns No. 9. were first engaged; and No. 6. having obtained some advantage, Dumourier ordered the battery, No. 7. to be erected, by which the redoubts, No. 5. were silenced. In the mean time the French advanced against the intrenchments, and attacked in front. From the left of the French army, as far as the centre, the cavalry fought hand to hand, in the plain, 12. with the Austrian horse, which was dreadfully cut up in the wood of Du Frensey. 11. The right of the Austrians, being totally routed, gave way and fell back on Mons. The superiority of the French in numbers is evident from inspecting the columns in the plan.

After having dwelt so long on that part of military tactics which relates to operations in the field, we must be extremely brief with respect to the attack and defence of fortified towns. Indeed our principal object in this part will be to explain the nature of a siege, and the various circumstances that may occur, both on the part of the besiegers, and on that of the besieged, rather than to lay down a system of instructions for either party. With this view, we shall first enumerate the principal instruments and engines employed in the attack, or defence of a fortress, and explain the nature and construction of the works constructed by the besiegers, either for the purpose of making their approaches to the place, or for undermining its walls or outer works.

In Plate DLIV. are represented the principal instru-instruments employed in sieges. Fig. 1. is a fascine for the construction of redoubts or temporary defence of a detachment. Figs. 2. 3. and 4. exhibit various views of what are called gabions, or cylindrical cases of wicker work, open at both ends, for sticking into the ground, as seen at fig. 4. when they are filled with earth, and fascines, &c. laid on them. Fig. 2. is a section of the gabion; fig. 3. shews its hollow inside, and fig. 4. its elevation. Fig. 5. and 6. represent bags for holding sand, the former empty, the latter full; and fig. 7. represents the manner in which they are usually disposed for the protection of the men. Fig. 8. is a saucisson, or very long close sagger, for laying over gabions. Fig. 9. is the outline of a blind, which is stuck into the earth by the sharp stakes at its extremity, and hides the workmen from the besieged. Fig. 10. represents what is called a chandelier, and fig. 11. two of these with fascines piled up across them. Fig. 12. is a cheval de frize; fig. 13. 14. 15. exhibit various views of a mantlet, or movable blind placed on both to protect and conceal the workmen of the besiegers.

Fig. 13. is a plan of the mantlet; fig. 14. a side view of it, and fig. 15. a view of its front next the enemy. Fig. 16. is a madrier or screen with two leaves, moveable on wheels; and fig. 17. represents a gate with organs or lattice work on one side, and a portcullis on the other. Fig. 18. is a hook, and fig. 19. a fork used in sapping. Fig. 20. represents three caltops or crowns feet, used to scatter over the ground, to prevent the approach of cavalry, by laming their horses feet. For a fuller explanation of these instruments, see the several articles in the general alphabet.

When a town is about to be besieged, it is first invested; that is, a considerable body of troops, usually cavalry, encamp in its neighbourhood, and take possession of all the avenues till the army arrive, which is to carry on the regular operations of the siege.

When the army has sat down before the place, its first object is, to ascertain the lines or direction of the circumval lion. These are called lines of circumval lion, and their direction is to be determined by the plan of the fortification about to be besieged. After ascertaining, in the manner explained under Fortification, the number of sides of which the polygon of the place consists, and the length of each, as well as the radius of a circle to be drawn round the place, concentric with its works, the polygon of the circumval lion is easily described. This being traced, the engineer takes on each of the extremities of its sides the lines BD and BE, fig. 21. each of 15 fathoms, and from the points D and E,
taken for the centre and distance of 2½ fathoms, he describes two arcs cutting each other at F, whence are drawn the lines FD, FE, for the faces of the 8-dans of the line of circumvallation; thus are formed the salient parts EFD of this line, which serve to flank it. The same operation is performed on every side of the circumvallation, and then the principal line is traced. The parapet within must be six or eight feet deep, and without is made a ditch parallel to all its parts, three or four fathoms in breadth. The parapet of the circumvallation will be 7½ feet high, and the depth of the ditch equal to the height of the parapet.

To make the profile of the circumvallation, let AB, fig. 22, be a line level with the country, and CD the scale of the profile. Let A be the side of the town, and B that of the country; take AE of six feet; from the point E, raise the perpendicular EF, of three feet, and draw the line AF, which will be the talus or slope of the baquette.

Draw FG parallel to AB, three feet from F to G, and the line FG will be the breadth of the baquette. On the point G raise the perpendicular GH, on the line FG, 4½ feet. Draw from the point H, HK parallel to AB; make HK 7½ feet, HI, ½ foot; draw GI, which will be the inside of the parapet of circumvallation.

From the point K, let fall on the line AB the perpendicular KM, take KL ½ foot, and draw IL, which will be the upper part of the parapet of the line of circumvallation. Take MN equal to five feet, and from the point N draw the perpendicular NO, and set off 7½ feet from N to O. Draw OR parallel to AB, making the distance equal to 18 feet from O to R; draw LN, and produce it to P, and LP will be the scarp. From the point R raise RS, perpendicular to OR, or parallel to ON. Make OR = OP, and draw QS, which produce beyond S; three feet to V; then take SX equal to six feet, and draw VX, and the profile of the circumvallation is completed; VQ being the countercarp, and VX the glacis.

At A and A (fig. 21) are small half moons before the gates of the circumvallation in the middle of the curtains.

Plate DLVI. In Plate DLVI, at fig. 1. is represented the manner in which the lines of circumvallation were drawn at the siege of Philipensburg in 1734. In these lines regular bastions were constructed, as seen in fig. 2. The same plate represent another line of circumvallation drawn around the city of Arras, when it was besieged by the Spaniards in 1654. Before the circumvallation were dug a great number of holes, two feet in diameter, and ½ foot deep, in which were fastened stakes for obstructing the approach of cavalry. While the lines of circumvallation, which are intended to protect the besiegers from the enemy without, are constructed, all materials necessary for the trenches are got ready, and the figure and direction of these are determined. If the place be regularly fortified, and stand on level ground, it is indifferent on which side the besiegers commence their attack. Suppose C, fig. 2, two bastions to be attacked. The besiegers begin with these two bastions; in like manner the capital of the half moon opposite the curtain between these two bastions is produced. Eight hundred fathoms are set off from the salient angles D and E of the covert-way of F and G. This done, the lines DH and DI are drawn, each equal to 300 fathoms, and about the centre C with the radius CH or CI, is described an arch produced beyond H and I, and on this arch HI constructed the first parallel. Then on the same lines DF, EG, etc., taken the points M and N, each 150 fathoms distant from H and I; and through these points M and N, about the centre C, is described another arch, on which is constructed the second parallel. This second arch will cut the produced capital of the half-moon in the point L, which is to be observed, in order to begin from hence a trench which may extend to the salient angle of the covert-way before this half-moon. Lastly, through the points O and P, the distance of 20 or 25 fathoms from the angles D and E, a third arch is described from the centre C, on which the third parallel is constructed. The first parallel is terminated by producing the faces of the bastions A, B, of the half-moons 1 and 2, collateral to the bastions A and B; but the parallel is extended 15 or 20 fathoms beyond the intersection of this prolongation. The second parallel will be less extended than the first, by about 30 fathoms on each side, and the third less than the second by the same distance.

The trenches or approaches are now to be traced. For this purpose, the engineer takes a long ruler, and lays it on the point G, so that it may make with the produced capital EG of the bastion B, an angle EGS, whose side GS being produced, shall meet no part of the covert-way, and shall be distant about 10 or 12 fathoms from the angles to which it approaches nearest. GS is taken of any extent, and the ruler is put on the point S; so that it shall make with GS such an angle GST, as that the side ST produced shall not fall on any part of the covert-way, but be 10 or 12 fathoms distant from the most salient parts. This side is terminated in T; and now the angle STI is made, whose side TI should terminate at the point I, where it meets the first parallel. The same operation being performed on FH, the outline of the trenches is completed as far as the first parallel.

Fig. 1 of this plate illustrates the method of constructing what are called lines of counter-vallation. These are drawn nearer the town than the lines of circumvallation, but are constructed on the same principles. They are employed chiefly when the garrison of the place is so strong as to disturb the operations of the besieging army by sallies.

In sieges where the garrison is strong, it is often necessary to cut parts of trenches, as WV (fig. 2) between the second and third parallels, so as to communicate with the main trench. These parts of parallels are denominated half parallels, or places of atom, and are constructed in the following manner. Let ABCDFMQ (fig. 1. Plate DLVIII.) be a part of the trenches, and let AB be one of the sides opposite to the enemy; produce AB, so that BE shall be five or six fathoms, and in EG take also five or six fathoms from I to L, which will give the ends of the trench BFLI, the use of which is to cover the boyage or branch IOMG, whereby the enemy will not know the place where it falls into the trench AB, and to make room for withdrawing those who are in this part of the trench.
Part I. Military Tactics.  

War.

es, and that the passage may be free at all the angles. In like manner produce the side GM from M to N, and the side IC from O to P, and this will give the end of the trench MINOP, which will cover the branch DCQ. The same is to be done at all the angles of the trench. The parapet of the trench being made to cover it, ought to change sides alternately. If, for instance, AE, in the preceding figure, be towards the place, it is evident that the side GN will be towards it also, and likewise the side CD; and therefore the parapet of the trench is successively constructed from the right side to the left, and from the left to the right.

Figs. 2, 3, 4, of this plate represent profiles of the regular trenches and the places of arms, and require no particular explanation.

In tracing the trenches, it is of the greatest consequence to ascertain the distance of the extremity of the line of direction to the top of the salient angle of the covert-way. The following simple method of doing this is given by Vauban. Let A (fig. 5.) be the vertex of the salient angle of the covert-way, and AB the line of direction of the trench whose length is required. At the point B, draw BC perpendicular to AB, to which give any other name. From P draw PE perpendicular to BC. In CD take any point E, and in the line of direction between it and the angle A place a picquet G in the line BC. Measure GC and CE, and say as GC : BG :: CE : AB.

When in carrying on the trenches towards the town, the workmen begin to be much annoyed by the fire of the besieged, recourse is had to what is called sapping, which may be thus explained. Let ABC be the part of the trenches advanced to A (fig. 6. Plate DLI. VIII.), so near the town as to render it impossible, without evident danger, to work any longer at the approaches unless the men have some cover against the fire of the place; and let the branch AD be traced by the engineer, not with a cord, as at the opening of the trenches, but with some pickets, which he has taken care to place in the direction this branch ought to have, to serve as a guide to the workmen. A cut is made in the parapet BA of the trenches, and then the men designed to work by sap, who are therefore called sappers, will move forward through the opening A successively, eight in number. Fig. 7. of Plate DLI. VIII. and fig. 1. of Plate DLI. IX. will illustrate the mode of operation. The first sapper rolls a mantlet before him, and places a gabion on the line AD, fig. 6. He then makes a small excavation about six inches from the gabion, of about one foot and a half in depth, and as much in breadth, emptying the earth which he digs up into the gabion. He then pushes forward his mantlet, fixes another gabion, and continues his trench as long as he is able. He is followed by a second, who widens the trench six inches in breadth away from the gabion, and six in depth. The rest follow this second, till the trench is made three feet wide, and as many deep, and as soon as the gabions are filled with earth, fascines or palissades are placed on their top, and the superfluous earth is thrown over them, and on the opposite side, by way of parapet.

Cannon are made use of at a siege for two different purposes; the first to drive away the enemy from their defences, and the second to dismount their guns. To produce these two effects, the batteries should not be above the mean reach of cannon shot from the place; that is, above 300 fathoms. Therefore there is no possibility of constructing them till the first parallel be formed; and as the distance of this first parallel from the place is generally 300 fathoms, the batteries must be on this line, or beyond it, nearer the town. They must always be placed, when the ground will permit, on the produced faces of the works attacked. Let Z be the centre of the place attacked (fig. 3. Plate DLI. IX.), and the trenches as well as the parallels completed. To find a proper position for erecting batteries, produce the faces AD, AC, BE, BF, of the two bastions attacked, till their prolongation cuts the first parallel. Produce also the two faces OM and OL of the half-moons Mol of the front attacked, and the faces HG and IK of the two collateral half-moons 1 and 2, to the first parallel, and erect batteries on those produced faces, as is seen in P, Q, R, S, T, U, X, and Y. They are advanced beyond the first parallel 40 or 50 fathoms; and are parted from the trenches, that they may be used with greater ease and convenience, and less trouble to the workmen.

When the works of the besiegers approach the glacis, or terrace, they are continued in a zig-zag direction, by short angular trenches, but from the foot of the glacis they are continued in the following manner. Two sets of sappers, protected by their mantlets, make a sap on each side of the ridge of the glacis, with a deeper ditch than usual, and a parapet on each side. This is called a double sap, and has across it traverses or banks three fathoms thick (see Plate DLI. IX. fig. 1.), with small passages on one side (see fig. 4.) to preserve the communication. These traverses are constructed so near to each other, as to be a sufficient cover, by their elevation and distance, against the fire of the place. In order to guard against the effect of grenades, on coming within their reach, or within 14 or 15 fathoms of the covert-way, care must be taken to cover this trench with blinds, or to cover the upper part of it. Figs. 1. and 2. of Plate DLI. IX. show this direct trench. The first exhibits the plan, and the second the profile, which passes over one of the traverses. This being done, and the third parallel finished in the manner supposed, they advance from this parallel on the glacis to each of the salient angles of the covert-way of the front attacked, and begin with making two or three short turnings, as marked on Plate DLI. IX. fig. 6. along the ridge of the glacis, so as to occupy about one-third of it. These are to be made as deep as is necessary, to be a shelter against the fire of the covert-way; afterwards they may proceed directly along the ridge of the glacis by a deep ditch, to the salient angle of the covert-way. M. Vauban observes, that if we follow directly the ridge of the glacis, this trench is made without much danger; for the palisade which is placed at the salient angle of the covert-way, and the other two next it, do not press directly to the ridge, but only opposite to the faces, where at most there is only room for one or two fusillers to see the head of the trenches, and who are easily silenced by the fire of the third parallel, which ought to be well served, and likewise by that of the ricochet. On coming to the middle, or two-thirds of the glacis, two new saps are made, b, b, ibid, which embrace both sides of the covert-way, to which they are almost parallel. Their length is 18 or 20 fathoms, and about five breadth.
broad. They are covered at the end with crochets and winding traverses, which prevent the fire of the covert-way from enslaving them easily.

In this way, is gradually effect a lodgment on the covert-way, as is represented in fig. 5, where AAAA, is the trench, with BBBB its traverses.

Plate DLXI. fig. 5. represents a profile of these works, with three banquettes next the trench, by which the parapet is raised, so that the soldiers may fire over into the covert-way. This work is called by Vauban, the cavalier of the trench.

When the besieged are entirely driven out of the covert-way, the next thing to be done is the erecting of batteries, in order to ruin the defences of the place, and to make a breach. As it is necessary for the besiegers to make themselves masters of the half-moon C, (Plate DLX. fig. 6.) before they can come to the body of the place, which is defended by part of the faces of the bastions A and B opposite to its ditch, they must begin with erecting batteries on the covert-way opposite to these parts. They are marked on the plan e e. Batteries must also be erected to make a breach on the half-moon. But, before they are erected, it will be proper to consider what part of the face of the half-moon is to be attacked, or what part of the half-moon is to be entered. It must not be at its flanked angle, because an opening towards the point would not afford a sufficient space to make a lodgment able to withstand the enemy, and the troops would be seen in their passage by the two faces of the bastions by which its flanked angle is defended. The most favourable passage is towards the third part of its face, reckoning from its flanked angle, because by battering at the same time the two faces near this part, the whole point of the half-moon may be destroyed, and a large opening made there easier than anywhere else. Thus the batteries for making a breach in the half-moon C will be placed in d and e, and will occupy almost one-third of each of the faces of the half-moon from its flanked angle. These batteries are each to consist of four or five pieces of cannon. When the faces of the bastions A and B are well enfiladed by rocchet batteries, there will be no farther occasion for the batteries e e, and when the half-moon is taken, the faces of the bastions A and B may be destroyed, by using the batteries d d, placing them in the situation of e e. Batteries must also be erected to destroy the flanks of the bastions in the front of the attack; and it is evident that they can be placed nowhere but at i, i, on the covert-way. Besides these batteries, others are erected in the re-entering places of arms of the covert-way, as in k k; and in k, k they serve to batter the tenaille when there is one, the curtain, and the faces of the bastions. Sometimes they are of mortars for throwing stones.

While the workmen are employed in erecting batteries on the covert-way, preparations are made for passing the ditch of the half-moon. This is often a difficult and dangerous undertaking, as this ditch is commonly very deep, is well defended, and either filled with water, or in general capable of being so filled. The descent into the ditch is commonly effected by subterraneous passages or galleries, made like those of miners, and erected in such a manner, that its opening into the ditch may be opposite to the breach where it is intended to make the assault. These galleries are sloping, and in general there are several for the same passage. The passage is made on each side of the faces of the half-moon. See m m, fig. 6. Plate DLXI.

As the business of forming these galleries is liable to be obstructed by mines from the besieged, the workmen are protected by a guard of grenadiers. At fig. 1. Plate DLXI. is seen a plan of the descent under ground, and of its opening into the dry ditch; and fig. 2. gives a profile of the same passage; fig. 3. gives a perspective view of the opening of this descent, seen from the bottom of the glacis, and fig. 4. a similar view of the opening of the same descent, seen from the top of the breach.

At Plate DLXII. fig. 1. is seen the plan of the passage over a wet ditch in the open air; that is to say, the gallery of which is an open sap. A is the opening of it; at B, towards its opening, are seen the blinds laid on its upper part, to support the fascines with which it is covered. On these blinds, at first, is laid a bed of fascines, ranged according to the length of the gallery; over this first bed a second is laid, whereon the fascines are ranged according to the breadth of the gallery, as seen at B and C. D is the epanoulement of fascines, which covers the passage against the fire of the place by which it is flanked. E is part of the bridge of fascines; and F is an elevation also of fascines, intended to cover the head of the work, and to secure it from the immediate fire of the place. Fig. 2. represents the profile of this descent into the ditch. Fig. 3. gives its opening seen in perspective from the country; and fig. 4. its opening into the ditch, also in perspective, as it appears from the top of the breach.

The following references will explain fig. 5. of Plate DLXII. a, cavaliers of the trenches. b, batteries of stone mortars. c, batteries to breach the half-moon before the hornwork. d, batteries against the defence of this half-moon. e, passages over the ditch before this half-moon. f, lodgment in it. g, batteries against the flanks of the hornwork. h, batteries to breach the half bastions of the hornwork. i, batteries against its curtain. l, lodgments in the half bastions, and in the hornwork. m, passages over the ditch before these retrenchments in the hornwork. n, lodgments in these retrenchments. o, batteries against the defences of the collateral half-moon. p, batteries to breach those half-moons. q, passages over the ditch before these works. r, lodgments in the same. s, batteries to breach the redoubts of the half-moon. t, passages over the ditch before these redoubts. u, lodgments in the redoubt. x, bridge of fascines. y, batteries against the defences of the bastion A. z, batteries to breach this bastion. B, passages over its ditch. C, lodgments in the bastion A. D, lodgments on the border of the ditch before the retrenchment of the bastion A. E, passages over the ditch before this retrenchment.

There are places which, without any foss-ditch, have lunettes opposite to the salient and re-entering angles of the glacis, which are also enveloped by a second covert-way; sometimes they are vaulted and bomb-proof, as at Luxemburg; and sometimes they have only a ditch, a parapet, and covert-way. Those which are vaulted and bomb-proof are not easily taken, because the rocchet firing and the bombs can do them no mischief. In that case they must either be turned, or be taken by mines. A work is said to be turned, when the batter-
Part II. NAVAL TACTICS.

BY naval tactics is understood the art of arranging fleets or squadrons in such an order or disposition as may be most convenient for attacking the enemy, defending themselves, or of retreating with the greatest advantage. Naval tactics are founded on those principles which time and experience have enabled us to deduce...
from the improved state of modern naval warfare, which has occasioned, not only a difference in the mode of constructing and working ships, but even in the total disposition and regulation of fleets and squadrons.

In the present part we propose to lay down the general principles of naval tactics, and to describe as briefly as is consistent with perspicuity, the most improved systems which are now adopted in the French and British navy. As we have elsewhere (see Navigation and Seamanship) detailed the methods of working single ships, as they are unconnected with military operations, we shall presume that our readers are already acquainted with these ordinary movements.

Fleets are generally divided into three squadrons, the van, centre, and rear, each under the command of a flag officer. The admiral of the fleet, or chief in command, leads the centre division, while the van is usually commanded by a vice-admiral, and the rear by a rear-admiral. Each squadron is distinguished by the position of the colours in the ships of which it is composed. Thus, the ships of the centre squadron carry their pendents at the main-top-gallant mast-head; while those of the van division have their pendents at the fore-top-gallant mast-head, and those of the rear at the mizen-top-mast head. Each squadron, as far as possible, consists of the same number of ships, and as nearly as may be of the same force. In large fleets, the squadrons are sometimes again divided in a similar manner; the van and rear of the squadron being headed by rear-admirals, or senior captains, called commodores. In the usual mode of forming the lines, each commanding admiral arranges his ship in the centre of his own squadron, and thus the admiral of the fleet is in the centre of the line. When no enemy is in sight, the sloops, store-ships, fire-ships, and other small vessels, are dispersed to windward of the fleet, that they may be more easily supported, and more readily answer signals. The frigates lie to windward of the van and rear of the convoy, thus keeping a good look-out, and keeping the small vessels in their proper station. When sailing in three columns, the centre still keeps in the middle, while the van and rear form the starboard or the larboard column, according to circumstances. These arrangements are called orders of sailing; and will be better understood from the following definitions.

The starboard line of bearing, is that line on which the arranged ships of a fleet bear from each other, on a close-hauled line, whatever course they may be steering, so that when the ships haul their wind, or tack together, they may be on a line close hauled upon the starboard tack. The larboard line of bearing, is that line on which the ships when hauling their wind, or tacking together, may be formed on a line close hauled on the larboard tack. These ships are said to be on a line abreast, when their keels are parallel to each other, and their mainmasts lie in the same straight line. Ships are said to lie in a line on the bow or quarter, when they are arranged in a straight line, cutting their keels obliquely in the same angle, so that reckoning from any intermediate ship, the ships towards one extremity of the line will be on the bow of that ship, while those towards the other extremity will be on her quarter.

When several ships in the same line steer the same course, while that course is different from the line of sailing, they are said to sail chequeredwise.

When the ships of a fleet arranged in any of the orders of sailing, and on the same line, perform successively the same manoeuvre, as each gets into the wake of the ship that leads the van of the line or squadron, tacking or veering, bearing away or coming to the wind in the same point of the wake of the leading ship, they are said to manoeuvre in succession.

There are usually reckoned five orders of sailing, exclusive of the line of battle, the order of retreat, fig. 6, of the fleet.

In the first order (see Plate DLXIV. fig. 1 and 2) when the fleet is arranged on the starboard or larboard line of bearing, all the ships steer the same course. In these cases the fleet, by hauling the wind when in the starboard line, as in fig. 1, will be ready to form the line on the starboard tack; and when ranged on the larboard line of bearing, as in fig. 2, it will, by tacking, be ready to form the line on the larboard tack.

N.B. The arrows annexed to the diagrams on the plates, mark the direction of the wind, as in ordinary charts.

This first order of sailing is now seldom employed, except in passing through a narrow strait. In the second order of sailing, the fleet steering any proper course, is ranged in a line perpendicular to the direction of the wind, as in fig. 3. This second order, besides being equally defective with the former, is subject to the additional disadvantage of rendering it extremely difficult for the ships to tack, without each ship falling on board that next astern.

In the third order of sailing, the whole fleet is close hauled, and ranged on the two lines of bearing, so as to form an angle of 12 points, having the admiral's ship (A fig. 4) in the angular point, and the whole fleet steering the same course. Thus, supposing as in the plate, the wind at north, the starboard division of the fleet will bear W. N. W. of the admiral, and the larboard E. E. N. This order in small fleets or squadrons, is superior to either of the former; but when the fleet is numerous, the line will be too much extended.

In the fourth order, the fleet is divided into six or more columns, and is thus more concentrated. The commanders, ranged on the two lines of bearing, have their squadrons a stern of them on two lines parallel to the direction of the wind; the first ships of each column being, with respect to the commander of the squadron, the one on his starboard, and the other on his larboard quarter. The distance between the columns should be such that the fleet may readily be reduced to the third order of sailing, and from that to the order of battle. This order is adapted for fleets or convoys crossing the ocean, and is represented in fig. 5. But as it requires much time to reduce a fleet from this order to that of battle, it is defective when in presence of an enemy.

In the fifth order, the fleet, close hauled, is arranged in three columns parallel to each other; the van commonly forming the weather, and the rear the lee column. See fig. 6. Fig. 7 represents the same order; except that each column is here subdivided into two, with the ship bearing the commander of each squadron in the centre of each subdivision.

In forming the order or line of battle, the ships of the fleet are drawn up in a line nearly close hauled, thus standing...
Part II. W A R.

60 Order of retreat.

When a fleet is compelled to retreat before a superior force, it is usually arranged in an order, the reverse of the third order of sailing; the divisions of the fleet being ranged in the two lines of bearing, so as to form an angle of 135° or 120 points, the admiral's ship being in the angular point, and the frigates, transports, &c. included within the wings to leeward. See fig. 9. where the fleet is sailing right before the wind. Though any other direction may be taken, the two lines still form the same angle.

The order of convoy is that in which the ships are all in each others wake, steering in the same point of the compass, and forming a right line. If the fleet is numerous, it may be divided into three columns, which are to be ranged parallel to each other, that of the admiral occupying the centre, and all steering the same course.

Having thus described the ordinary positions of a fleet, we must explain the manœuvres by which they are produced, and we shall begin with the orders of sailing.

61 Method of forming the first order of sailing.

To form a fleet in the first order of sailing, suppose the ships to be in no particular order, that ship which is to lead on the proposed line of bearing for the order of sailing, runs to leeward of the greater part of the fleet, and then hauls her wind under an easy sail. Each of the other ships then proceeds to take the proper station, by chasing the ship, which is to be a-head of her, and when in the wake of the leading ship, adjusts her quantity of canvas so as to preserve the proper distance. The ships thus arranged astern of each other, are in the line of battle, and from this the first order of sailing is formed, by each ship bearing away at the same time, and all steering the proposed course.

62 Second order of sailing.

In forming the second order of sailing, the leading ship runs to leeward of so many of the fleet as that each ship may readily fetch her wake, and then steers a course eight points from the wind, under an easy sail. The line is formed by each ship in the same manner as in the first order, except that before bearing away, the line is perpendicular to the direction of the wind, or each ship has the wind on her beam.

63 Third order.

As, in the third order of sailing, the admiral's ship is in the centre; to produce this position, the fleet being formed in a line on one of the lines of bearing, and the ships steering in each others wake, ten points from the wind, the leading or leeward most ship first hauls her wind. The second ship does the same as soon as she gets into the wake of the former, and this is done by each ship till the admiral's ships haul their wind, when they reach the wake of the leading ship. At the same time that the admiral's ship hauls her wind, the sternmost half of the fleet does the same. The ships are now in the third order of sailing, from which the fleet can be formed in the line of battle on either tack.

To form the fourth order of sailing (see No. 58), the commanding admirals range themselves on the two lines of bearing, at a proper distance from each other, steering the proposed course, and the ships of the several columns take each their respective places, parallel to each other, and forming lines in the direction of the wind.

64 To form the fifth order, the three leading ships of fifth order take their posts abreast and to leeward of each other, keeping their wind under an easy sail; then the ships of each squadron make sail, and take their respective stations at the proper distance astern of their leaders, while the commanders of each division, and the corresponding ships of each, keep mutually abreast of each other.

In forming from the first order of sailing, if the ships are running large on the tack that answers to the line of bearing on which they sail, and if the line is to be formed on the same tack, all the ships haul their wind at once, or as quickly as possible after the next to windward; but if they be on the other tack, with respect to the line of bearing, they all haul their wind and tack or veer together. If the line of battle is to be formed on the other line of bearing, the ship most to leeward veers or tacks, and hauls her wind, while the rest of the fleet veer or tack at the same time, and steer Fig. 10, with the wind four points free, and each ship hauls her wind as soon as she gets within the wake of the leader. See fig. 10. Plate DLXIV. and fig. 1. Plate DLXV.

Suppose the fleet running before the wind in the second order of sailing; to form the line from this position, all the ships haul up together on the proper tack, presenting their heads eight points from the wind at the line on which they are arranged; the leading ship then hauls her wind, immediately making sail, or shortening sail, so as to close or open the order, and the same is done successively by all the rest (see fig. 2).

In a fleet running large in the third order, the line of battle is formed by the wing which is in the line of bearing corresponding to the tack on which the line is to be formed, and the ship at the angle, hauling their wind together, while the ships of the other wing haul up together eight points from the wind. Each ship moving in this direction, till she reach the wake of the other wing, when she hauls close up (see fig. 3).

In forming the line of battle on the same tack from the fifth order of sailing (as the fourth is not calculated for forming a line of battle), the centre brings to, so as only to keep steerage way; the weather column bears away two points, and when it gets a-head of the centre, hauls its wind, while the ships of the lee column tack together, and crowd sail to gain the wake of the centre, when they retack together, and complete the line (see fig. 4); or, the weather column brings to, while the centre and lee tack together, and bear away two points free. When the ships of the centre column have gained the wake of the van, they retack together, and bring to; and when those of the lee have gained the rear line, they retack together, and all stand on; or, lastly, the lee column brings to, the centre runs under easy sail two points free, to get a-head of the rear squadron, while the rear bears away under a press of sail two points free, to get a-head of the centre division.

2. Suppose the weather and centre columns to inter-change. To form the line under these circumstances the centre stands on, while the weather column bears away 8

Plate

DLXV.

fig. 1.
points, and having reached the wake of the centre, which
now forms the van, hauls up; the ships of the lee column
tack to, and run under a press of sail, within two
points free, as just to gain the rear of the line when
they retack together (see fig. 5), or the lee column
brings to, while the centre squadron bears away three
points under easy sail; and having reached the wake of
the van, hauls up, to form the centre division.

3. Suppose the centre and lee columns to interchange.
The lee column stands on close hauled under an easy
sail, the weather column bears away to points under a
press of sail, till it reach the head of the line, when it
hauls up, and the centre bears away eight points, and
when in the wake of the lee, now the centre, hauls its
wind. (See fig. 6.)

4. If the weather and lee columns interchange; the
lee column stands on under a press of sail close hauled,
while the centre, under easy sail, bears away two points,
and when it reaches the wake of the now van squadron,
hauls its wind, and the weather column bears away
eight points, hauling up when in the wake of the centre.
(See fig. 7.)

5. Suppose the centre column to form the van, and
the weather the rear division. Here the lee column
brings to, while the centre bears away two points,
forming the line a-head of the former, now the centre,
and the weather column veers away seven points on the
other tack, forming the rear squadron. (See fig. 1.)

6. To form the line so that the lee column may form
the van, and the centre the rear. The lee column is to
stand on under a press of sail, while the weather bears
away three points under easy sail, and the centre bears
away eight points, the ships of each column hauling
their wind, when in the wake of the now van division.
(See fig. 2.)

7. If the line of battle is to be formed on the other
tack, so that the weather shall form the van division, as
in the first case, the ships of the weather column first
tack successively, while those of the centre and lee
stand on, the former under easy sail, and the latter
shortening sail, the leading ships tacking when in the
wake of the now van, taking great care that the ships
of the centre and lee draw not too near to the sternmost
ships of the van, or to each other. (See fig. 3.)

8. To form the line on the other tack, when the
centre and weather columns interchange. The weather
column brings to, while the centre column stands on, till
the leading ship be fully able to clear the weather
column, when the ships of the centre tack successively as
they reach the wake of the van. The lee column
stands on, tacking successively, as the ships get into the
wake of the van, under moderate sail. (See fig. 4.)

9. In forming the line on the other tack, when the
centre and lee interchange. The centre brings to,
and the ships of the weather tack under shortened sail,
ship having gained the wake of the line, tacks, and is
followed in succession by her division. The centre
column fills and stands on, when the first ship of that
column, and the last of the lee, bear from each other in
a direction perpendicular to that of the wind. (See
fig. 5.)

10. To form on this same tack, so that the weather
and lee may interchange. The weather and centre
bring to, while the lee crowds sail, till it can pass a head
of the weather column, when the ships tack in suc-
cession. As soon as the leading ship of the centre, and the
last of the lee bear from each other in a line perpendic-
ular to the wind, the centre fills, and tacks in succession
when in the wake of the now van, and the ships of the
weather column do the same when their leading ship
and the last of the centre are under similar circum-
stances. (See fig. 6.)

11. Suppose the centre is to form the van, and the
weather the rear, in forming the line on the other tack.
The weather brings to, while the other columns make
sail, till they can pass a-head of the former on the other
tack, when they tack successively. The weather col-
umn, when the others have passed it, fills, and tacks
to form the rear. (See fig. 7.)

12. Suppose now the lee column is to form the van.
The weather and centre bring to, while the lee crowds
sail, and tacks when it can pass a-head of the weather
column. When the last ship of the new van has passed
windward of the former weather column, the van
shortens sail, to give time for the other columns to form,
and the weather and centre fill at the same time, to
gain the wake of the van, when they tack in suc-
cession. (See fig. 8.)

We must now show how a fleet may be disposed in
the principal orders of sailing from the line of battle
and here, as before, we have several varieties.

1. To form the first order of sailing from the line of
battle on the same tack. All the ships are to bear
away together as many points as the admiral may direct,
keeping in the line of bearing for the proper tack. The
stemmost first bears away, and the others follow in
quick succession to prevent running foul of each other.

2. If they are to form on the other tack; the lead-
ing ship bears away four points to leeward, and the rest
follow in succession. The sternmost ship having borne
away, the whole haul up, and will be in bearing for the
line on the other tack. (See fig. 9.)

3. To form the second order of sailing from the line
of battle; the whole fleet is to bear away together 10
points, so that when the headmost ship, which first
presses sail, shall come abreast of the second ship, the second
ship adapts her sail to keep in this bearing, and so in
succession, each taking care to keep the preceding ship
in a line with herself, perpendicular to the direction of
the wind. The whole fleet will now be before the
wind. (See fig. 10.)

4. To form the third order, the whole fleet is to bear
away together ten points, the headmost half, including
the centre ship, carrying a degree of sail to preserve
their line of bearing, while each of the remaining ships
is successively to shorten sail, so as to form the other
line of bearing with respect to that on which they were
before arranged. (See fig. 1.)

5. To change from the line of battle to the fifth or-
der on the same tack. Of this evolution there are sev-
eral varieties, but we shall mention only two; first,
when the van is to form the weather, and the rear the
lee column, and the fleet to keep as much as possible to
windward. — In this case the van and centre tack to-
gether, and run close hauled in bow and quarter line,
while the rear proceeds in its former course under easy
sail. When each ship of the centre is abreast of the
corresponding ship of the rear, the centre retacks,
while
Part II.

while the van stands on, till the centre and rear come up, when it also retacks, and all the columns regulate their distance. (See fig. 2.) Secondly, when the van is to form the lee, and the rear the weather column.

Fig. 3.

The van bears away under easy sail, and goes at right angles with the line a-head, while the centre runs two points free, each ship steering for that ship of the van which is to be a-breach of her when in column. The distance must be determined by the leader of the van, who is not to haul up with her division, till she and the sternmost ship of the centre column are in a line at right angles with the wind, when both stand on under easy sail, while the rear crowds sail to pass to windward of both. (See fig. 3.)

6. To form the fifth order of sailing from the line of battle on the other tack—of which there are also several varieties; but we shall confine ourselves to two: First, when the van is to form the weather, and the rear the lee column; the van tacks in succession, while the leading ship of the centre is to tack when the leader of the van passes him exactly to windward, in which she is followed by her division, and the rear manœuvres in the same manner with respect to the centre. (See fig. 4.)

Secondly, when the rear is to form the weather and the van the lee column; the van tacks in succession, and when about, either shortens sail, or brings to, to allow the other columns time to form. The centre and rear then crowd sail, and tack in succession, the former tacking when its leader has the centre of the lee column in a line at right angles with the wind, or when its centre passes a-stern of the lee column. When the centre has tacked, it regulates its rate of sailing by the lee, and both wait for the rear to pass to windward. The rear tacks when the leader has the first ship of the lee in a line at right angles with the wind, or when its centre passes a-stern of the centre column. (See fig. 5.)

7. Fig. 6. represents the order of retreat formed from the line of battle, the whole fleet going four points free. This evolution is so seldom required in a British fleet, that we need not dwell on it.

There are various evolutions or manœuvres performed by a fleet when in line of battle, some of which we must here describe.

Sometimes the fleet has to form the line on the other tack, by tacking in succession. To do this, the leading ship of the fleet tacks first, after making more sail, or after the second has shortened sail, to increase the interval between them. When the first ship is about, either the second makes more sail, or the third shortens sail, and as soon as the second gets into the wake of the leader, she tacks, putting down the helm just as she opens the weather quarter of the first ship, already on the other tack. In the same manner, each of the other ships tacks when in the wake of the leader; and the ships already about must preserve their proper distances, by shortening sail, if necessary, till the whole fleet be on the other tack. If a ship should miss stays, she must immediately fill again on the same tack, and make sail with all possible expedition, taking care not to fall to leeward. Thus she will get a-head, and to windward of the following ships, which will successively perform their evolutions in the wake of the ships that are already on the other tack, standing on rather further than if the ship a-head had not missed stays. (See fig. 7.)

But suppose the ships are not to tack in succession.

To form the line on the other tack, the whole fleet veers together; the rear ship hauls her wind on the other tack, and stands on, while the rest go two points free on the other tack, and haul up as they successively gain the wake of the leading ship. (See fig. 8.)

If the line is to veer in succession, the van ship veers, and stands four points free on the other tack, hauling her wind when clear of the sternmost ship, and the rest follow and haul up in succession. (See fig. 9.)

Sometimes the fleet has to turn to windward while in line of battle. The best way to do this, when there is good sea-room, is for all the ships to tack together, when the fleet will be in a line of battle on the one hand, and in bow and quarter line on the other. If, however, the fleet be turning to windward in a narrow channel, it is best for the ships to tack in succession, as, were they all to tack together, the van would be soon in with the land on one side, while the stern ship, soon after the fleet had retacked, would be too near the land on the other side.

If the van and centre are to interchange; the van is to bear away a little, and then bring to, while the centre passes on to windward, edging a little, to get a-head of the former van on the same line; the rear, coming under an easy sail, edges away likewise, to gain the wake of the now centre squadron. (See fig. 10.)

If the van and rear are to interchange; the van and centre are to bear away a little, and then bring to, so that the van may bear away a little more to the leeward than the centre. The rear stands on to gain the head of the line; and when a-breast of the former van, the centre fills, and both standing on, form a-head of the now rear, by edging down till they are in a line with it. (See fig. 11.)

If the centre and rear are to intercchange; the van stands on under an easy sail, while the centre bears away a little, and brings to, and the rear at the same time carries a press of sail to pass the centre to windward, and get into the wake of the van. The van and centre then edge away to gain the line, with the now rear squadron, which then fills. (See fig. 12.)

Several evolutions are required while a fleet is in the fifth order of sailing, and of these we shall notice some of the more important.

When the columns are to tack in succession, the ships of the lee must tack first, as they have most distance to run, and when the leader of the centre comes a-breast of the leader to leeward, or at right angles with the close-hauled line on the other tack on which the leader of the lee is now moving, she tacks and is followed successively by the ships of her division. The weather column manœuvres in the same manner, paying the same regard to the centre. Here the weather column is still to windward, and should the columns have closed too much, or be too far asunder, the order may be recovered, either by the lee or windward column bearing away, so as to make an angle equal to that proposed between any column, and a line joining the leader of that column, and the sternmost ship of the next. (See fig. 13.)

When all the columns are to tack together; the sternmost ships put in stays together; and when in stays, their seconds a-head put down their helms, and so on through the whole fleet. Each column will then be in bow and quarter line. (See fig. 14.)
When the columns are to veer in succession; the leader of the lee column must steer four points free on the other tack, followed by the ships of that division, and when she is clear of the sternmost ship of that division, she hauls up. The same evolution is performed by the centre and weather ships successively, standing on till they bring the point at which the lee column began to veer to bear in a right line to leeward of them. They likewise successively spring their luffs when the point at which the lee column hauled its wind, bears right to leeward. (See fig. 15.)

Suppose the fleet, when in the fifth order of sailing is to turn to windward; let the ships be so ordered that the leaders and corresponding ships may be in the direction of the wind. The van ships must tack together, which are followed in succession, each by the remaining ships of the division, when they reach the wake of their leaders, or the same point when they tacked; so that there will always be three ships in stays at once, till the whole fleet is on the other tack. The fleet then stands on to any proposed distance, and retacks as before. (See fig. 1; Plate DLXVIII.)

When the weather and centre columns interchange; the weather and lee lie to, or only keep steerage way. The centre column tacks together, and forming a bow and quarter line, goes close hauled to gain the wake of the weather column; it then tacks together, and stands on, while the weather column bears away to its new station in the centre, and the lee column fills. (See fig. 2.)

When the weather and lee columns are to interchange; the centre column must bring to; while the lee stands on under a press of sail; and when its sternmost ship can pass to windward of the van of the centre column, that is, when the centre ship of the lee is in a perpendicular line to the direction of the wind with the van of the centre column, the lee column then tacks together, and stands on close hauled till it comes in a line with the centre column, when it goes large two points to get into the situation which the weather column left; and then veers together, hauling the wind for the other tack. At the beginning of the evolution the weather column bears away together under little sail, and goes large six points on the other tack, to get into the wake of the centre column; then it hauls to the former tack, going two points large, till it comes abreast of the centre column, when it brings to, and waits for the new weather column. (See fig. 3.)

Suppose the weather column is to pass to leeward; the weather column is to stand on under easy sail, while the centre and lee tack together, carrying a press of sail till they reach the wake of the weather column, when they retack, and crowd sail till they come up with it. The weather column, when the others have gained its wake, bears away two points, to gain its station to leeward, when it brings to, till the other columns, now the weather and centre, come up. (See fig. 4.)

Suppose the lee column is to pass to windward. The weather and centre columns bring to, while the lee column carries sail and tacks in succession as soon as the leading ship can weather the headmost ship of the weather column; and when arrived on the line on which the weather column is formed, it retacks in succession, forms on the same line, and either brings to or stands on under easy sail. If it brings to, the other two columns bear away together two points, to put themselves abreast of the column now to windward; but if the now weather column stood on under an easy sail, they may bear away only one point, to gain their proper stations. (See fig. 5.)

It is of the greatest importance that each ship of a fleet or squadron preserve her proper station and distance with respect to the rest. These may be regulated in two ways, either by observation with the quadrant, or by what is called the naval square. This

square is usually constructed in the following manner.

On some convenient place in the middle of the quarter-deck is described the square ABCD, fig. 6, having the sides AD and BC parallel to the keel of the ship. Through the centre G, the line EF is drawn parallel to AD or BC, and the diagonals AC and BD are drawn.

The angles EGD, EGC are bisected by the straight lines GH, GI, and thus the naval square is completed. Now the angles GFD, GFC are equal half a right angle, because the angles EGD, EGC, the complements of these angles, are each equal to half the last angle. Now, if a ship be running close hauled on the starboard tack, in the direction EF, the direction of the wind will be IG, and her close-hauled course on the other tack will be GG; but if she be running close hauled on the larboard tack in the same direction, her direction when close hauled on the starboard tack will be GD.

Now, to apply the naval square to the keeping of ships in their respective stations, suppose the fleet formed on the fifth order of sailing, close hauled, the corresponding ships of the columns coinciding with the direction of the wind, in order to run to windward with greater facility. The corresponding ships in the column must be kept in the direction of GH or GI, according to the direction of the wind and the tack they are on, while all the ships of the same column must be in the direction of EF. (See fig. 7.)

Again, suppose the ships arranged in three columns on one of the lines of bearing, close hauled on the other tack. The ships of each column will be in the direction of one of the diagonals, while the corresponding ships of the other columns will be in the direction of the other diagonal. (See fig. 8.)

Sometimes the line of battle is disorderly on the wind's shifting, and requires to be restored. Of this there are several cases, a few of which we shall notice.

1. When the wind comes forward less than 6 points.

In this case the whole fleet except the leader brings to.

The leading ship, that the same distances between the ships may be preserved on restoring the line, steers a course as ab (fig. 9), so as to be at right angles with the middle point between the former and present direction of the wind. His required course may be known by adding half the number of points the wind has shifted to eight points, and applying this sum to the former close-hauled course. When the leader has arrived at the new close-hauled line with respect to the second ship a-head, this ship immediately fills, and bears away as many points as the leader; and when both these have reached the close-hauled line with respect to the third ship, she also fills, and bears away; and thus with the rest in succession; and when they have got into the close-hauled

D LXVIII.

close-hauled line be with the sternmost ship, they all haul their wind together, and the sternmost ship sings and stands on close hauled. This may be expeditiously performed, if the whole fleet fall off as soon as the wind shifts, the same number of points, and the leader bear away eight points from the middle between the former and present directions of the wind, or when the wind shifts nearly six points, if the leader bear away eight points from the present direction of the wind, and hauls her wind as soon as the sternmost ship bears from her in the close-hauled line, while the second ship bears away when she reaches the wake of the leader, and hauls her wind when she has again gained his wake. The third, fourth, &c. ships bear away, and also haul their wind in succession, till the sternmost and the whole line be formed again. (See fig. 15.)

2. Suppose the wind comes forward less than six points, and the order of battle is to be re-formed on the other tack. In this case all the ships are to veer round till their heads come to the requisite point with respect to their former course, when the rear ship, now become the van, hauls close by the wind, followed successively by the other ships. Should the wind come ahead more than six points, but less than twelve, the fleet is to manoeuvre as before, but if it shift exactly twelve points a-head, the tack must be changed.

3. Lastly, suppose the wind to shift often—if less than two points, the leader hauls her wind, while the fleet stands on as before, each successively hauling her wind as she gains the wake of her leader. If the tack is to be changed, the whole fleet tack together, and the sternmost ship, now the leader, hauls up, while the rest bear down and haul up in succession.

Should the wind change 16 points, all the ships immediately brace about for the other tack, by which means the fleet will be going four points large; then the ships instantly tacking or veering together, the order of battle will be restored or formed again on the same tack as before the wind changed.

It is inconsistent with the nature of our plan to be more minute on the various evolutions of a fleet, when not in action with the enemy. Our nautical readers will find abundant information of this kind in the usual works on naval tactics, especially the Elements and Practice of Rigging, Seamanship, Naval Tactics, &c. of which the latest edition is in 4 vols 8vo.; and The System of Naval Tactics, with coloured figures, both published by Steel.

Having described and illustrated the principal evolutions which are performed by fleets or squadrons under ordinary circumstances, we are prepared to consider the nature and consequences of a naval engagement.

In forming a fleet for battle, it is proper to consider the size and number of the ships of which it is to consist, and the distance at which they are to be placed with respect to each other. In the present system of naval warfare, it is generally deemed of advantage to have the ships that are to form the principal line as large as possible; for though large ships are not so easily and expeditiously worked as those of a smaller size, they are most serviceable during the action, both as carrying a greater weight of metal, and as being less exposed to material injury, either from the enemy's shot, or from the weather. In boarding, too, a large ship must have greatly the superiority of a small one, both from her greater height, and from the number of hands which she contains. With respect to the number of ships, it is of advantage that they be not too numerous, as if the line be too extensive, the signals from the centre are with difficulty observed.

In arranging a fleet in line of battle, it is proper to regulate the distance so that the ships shall be sufficiently near to support each other, but not so close as that a disabled ship may not readily be got out of the line without disturbing the rest of the fleet.

It has long been deemed a point of great consequence advantages with the commander of a fleet to gain the weather gage, or to get to windward of the enemy, before coming to the action. In deciding on the propriety of this, much will depend on the relative strength of each fleet, and on the state of the weather at the time. We shall state the advantages and disadvantages of the weather gage, as they are commonly laid down by writers on naval tactics, though we may observe by the way, that if a fleet be much superior to its opponent, it is seldom of consequence whether it engages to windward or to leeward.

A fleet to windward of the enemy is thought to possess the following advantages. It may approach the leeward fleet at pleasure, and can of course accelerate or delay the beginning of the engagement. If more numerous, it may send down a detachment on the rear of the enemy, and thus throw him into confusion. It may also readily send down fire ships on the enemy's fleet, when thrown into confusion or disabled. It may board at any time, and is scarcely incommoded by the smoke of the enemy. The reverse of these circumstances, of course, act against a leeward fleet.

The disadvantages of being to windward of the enemy respect chiefly the circumstances attending a retreat, which this be necessary. The windward fleet can seldom retire without passing through the enemy's line; and if in attempting to retreat, the windward ships tack together, those of the leeward fleet may do the same, rake the weather ships in stays, and follow them on the other tack, having now the advantage of the wind. In stormy weather, the windward ships can seldom open their lower deck ports, and the lee guns are not easily managed after firing. Again, any disabled ships cannot easily quit the line without disordering the rest of the fleet, and exposing either that or themselves to be raked by the enemy to leeward. A leeward fleet has the advantages of serving their lower deck guns in all weathers; of being able to retreat at pleasure; of drawing off without difficulty their disabled ships; of forming with more readiness the order of retreat; or of continuing the action as long as convenient; of having it in their power, when superior in number, to double the enemy, and of cannonading with great effect the windward ships as they bear down for the attack.

As an engagement between two adverse ships is in some measure an epitome of an engagement between two fleets, we shall first briefly describe the former, as it takes place under ordinary circumstances, and shall then notice the usual manner of conducting a general engagement.

A naval engagement may be divided into three stages, the preparation, the action, and the repair.

When.
When an enemy's ship heaves in sight, and it is thought advisable to bring her to an engagement, orders are first given to clear for action, which is begun by the boatswain and his mates piping up the hammocks, in order to clear the space between decks, for the more easy management of the guns, as well as to afford the men on the quarter-deck, &c. a better protection against the enemy's shot, the hammocks being stowed in the nettings above the gunwale and bulwarks. After this, the boatswain's mates go to work to secure the yards, which is done by fastening them with strong chains or ropes in addition to those by which they are suspended. They likewise get ready such materials as may be necessary for repairing the rigging, if it should be cut away, or otherwise damaged by the enemy's shot. In the mean time the carpenter and his mates prepare shot plugs and mauls, to stop any dangerous shot holes that may be made in the hull near the surface of the water, and provide the necessary iron work for refitting the chain-pumps, if their machinery should be injured during the engagement; while the gunner and his mates, and the quarter gunners, examine the guns, to see that their charges are dry, and provide every thing that may be required for supplying the great guns and small arms with ammunition. The master and master's mates see that the sails are properly trimmed, according to the situation of the ship, and increase or reduce them as may be found necessary; and the lieutenants visit the different decks, to see that all is clear, and to take care that the inferior officers do their duty.

When the hostile ships have approached within a proper distance of each other, the drums beat to arms; the boatswain and his mates pipe all hands to quarters! All the men who are to manage the great guns repair immediately to their respective stations. The crows, hawspikes, rammers, sponges, powder-horns, matches, and train tackles, are placed in order by the side of the guns: the hatches are immediately closed, to prevent sculkers from getting below; the marines are drawn up on the quarter-deck, &c. the lashings of the guns are cast loose, and the topmasts withdrawn. The whole artillery, above and below, is run out at the ports, and levelled to the point-blank range, ready for firing.

When these necessary preparations are completed, and the officers and crew are ready at their respective stations, and when the two ships are sufficiently near each other, in a proper relative situation for the shot to take full effect, the action commences with a vigorous cannonade from the great guns, accompanied by the whole efforts of the swivels and small arms. The firing is seldom performed in volleys, as that would shake the ship too much, but the guns are loaded and fired one after another, with as much dispatch and as little confusion as possible, care being taken to fire only when each gun is properly directed to its object. During the firing, the lieutenants traverse the decks, to see that the battle is prosecuted with vivacity, and that the men do their duty, while the midshipmen second their injunctions, and give the necessary assistance where required, at the guns committed to their charge. The youngest of these inferior officers are generally employed to carry orders from the captain. The gunners are all this time employed in the magazines, filing cartridges, which are carried along the decks in boxes by the boys of the ship. When the action has continued so long, or has produced such an effect, that one of the ships must yield or retreat, if the vanquished ship cannot get off, she acknowledges her inferiority by striking, or hoisting down her colours, when she is, as soon as possible, taken possession of by the victor, the commander of which sends a part of his own crew into the captured ship, and brings away most of her officers and men on board his own ship, as prisoners of war.

The engagement being concluded, they begin to re-repair; the guns are secured by their breechings and tackles, with all convenient expedition. Whatever sails have been rendered unserviceable are bent out, and the wounded masts and yards struck upon deck, to be haled or replaced by others. The standing rigging is knotted, and the running rigging spliced where necessary. Proper sails are bent in the room of those which have been displaced as useless. The carpenter and his mates are employed in repairing the breaches made in the ship's hull, by shot plugs, pieces of plank, and sheet lead. The gunner and his assistants are busy in replenishing the allotted number of charged cartridges, to supply the place of those which have been expended, and in refitting whatever furniture of the guns may have been damaged by the action.

A general engagement between two adverse fleets of engaged ships involves a greater variety of circumstances, and must therefore require greater judgment, and more comprehensive skill in the commanding officer.

When the commander of a fleet has discovered an enemy's ship, his principal object, if he be sufficiently strong, is to bring it to action as soon as possible. Every inferior consideration gives way to this important object, and all necessary preparations are immediately made to prepare for such an event. The state of the wind and situation of the enemy will in general regulate his conduct with regard to the disposition of his ships on that occasion. To facilitate the execution of the admiral's orders, the whole fleet is disposed in three squadrons, and each of these classes into three divisions, under the command of different officers. Before the action begins, the adverse fleets are drawn up in two lines, as formerly described. As soon as the admiral displays the signal for the line of battle, the several divisions separate from the columns in which they were disposed in the usual order in sailing, and every ship crowds sail to get into its station in the wake of the next ahead; and a proper distance from each other is regularly observed from the van to the rear. The admiral, however, occasionally contracts or extends his line, so as to regulate the length of his line by that of his adversary. This is more particularly necessary to prevent his being doubled, by which his van and rear would be thrown into disorder. When the hostile fleets approach each other, the courses are commonly hauled upon the braces, and the lower topsail yards and topgallant sails furled. The movement of each ship is regulated chiefly by the main and fore-top sails and the jib: the mizen-top sail being reserved to haster or retard the course of the ship; and by filling or backing, hoisting or lowering it, to determine her velocity. The signal for a general engagement is usually displayed when the fleets are sufficiently near each other, to be within the range of point-blank shot, so that the guns may be levelled with some certainty of execution. After the battle has commenced, it is carried on much in the same manner as between two ships, except that each
Part II.

W  

A.R.  

62;  

Naval Tactics.  

vessel of the fleet, besides attending to her own movements, has to observe the signals made by the commanding officer, and repeated by the frigates on the van and rear. The other object of the admiral is to keep his line as complete as possible, by ordering ships from those in reserve to supply the place of such as may have been disabled, and to annoy the enemy as much as possible, both by strengthening the feeble parts of his own line, and, if circumstances admit of it, by sending down fire-ships upon that of the enemy. When the engagement draws near a close, either by the defeat of the enemy, or by the disabled state of either fleet, signals are made from the admiral to take possession of such of the enemy's ships as have struck, to tow his own disabled ships into a place of security, and either to chase the remainder of the enemy's squadron, or, if that be impracticable, to draw off his own ships to be refitted.

Such are the general incidents attending an engagement at sea, modified of course by numerous circumstances, of which a general description can convey no idea. There are, however, various movements and evolutions connected with a naval engagement, which it will be necessary for us to notice.

Where the weather-gage is deemed of sufficient importance, it is often an object with two fleets to dispute it with each other. When the enemy is to windward, and it is wished to gain the weather-gage of him, the fleet to leeward should avoid extending itself the length of the enemy's line, in order to oblige them to edge down upon theirs, if they intend to attack them; which will be a mean, if they still persist in doing so, of losing the advantage of the wind. It is impossible for a fleet to leeward to gain to windward, so long as the enemy keep the wind, unless a change happens in their favour; therefore all that a fleet to leeward can do must be to wait with patience for such a change, of which they will undoubtedly avail themselves, as well as of any inadvertency the enemy may commit in the mean time. And as long as the fleet to leeward does not extend its line the length of the enemy's, it will be impossible for the latter to bring them to action without running the hazard, by bearing down, of losing the advantage of the wind, which both fleets will be so desirous of preserving. That an admiral may take advantage of such shifts of wind as occasionally happen, he must endeavour to get his ships into such situations where these shifts most frequently take place. It is well known to experienced naval officers, that particular winds reign most on certain coasts, or off certain headlands. Here, therefore, the admiral should await the approach of the enemy; and though by this plan he may sometimes be unsuccessful, he will more frequently gain a material advantage. The disposition of projecting headlands, and the setting of tides and currents, often contribute materially towards gaining the wind of the enemy. The fleet to windward should keep that to leeward as much as possible abreast of it; and unless the wind changes considerably, they will preserve the advantage they have gained. They should also force them to keep their wind, unless they think it prudent not to engage, in which case it would be better to keep altogether out of sight.

When the enemy appears desirous of avoiding an action, there are various methods of attempting to force him to engage; as first, when he has the weather gage. In such a case the lee fleet, which is desirous of bringing on an engagement, must keep always on the same tack with the enemy to windward, taking care to keep their own ships so exactly abreast of the enemy, as to prevent losing sight of them; and hence be ready to take advantage of the first favourable shift of wind to make the attack. An alteration of the course may be attempted in the night. The lee fleet must have frigates on the look-out, and these must continually give notice by signal of the manœuvres and course of the retreating fleet to windward. Thus the weather fleet is always exposed to pursuit, without being able to get off unseen; hence must sooner or later be compelled to an engagement, unless they can get into some friendly port, or should be favoured by a gale of wind sufficient to disperse both fleets, and thus prevent the possibility of a general engagement.

Secondly, when the enemy is to leeward,—if the lee fleet keep close to the wind in the order of battle, the fleet to windward is to stand on in the same manner till it be abreast of the enemy, ship to ship, and at the same time to bear away, and steer so as to bring their respective opponents on the same point of the compass with themselves. Thus the adverse fleets will be sufficiently near each other to begin the action, by each ship's preventing her bow to the ship abreast of her in the order of sailing, which may be easily changed for the order of battle, by all the ships haul ing together close to the wind, in the moment which precedes the action. If the fleet to leeward appear inclined to engage, it may bring to, to prevent losing time, and after this they will fall as soon as the action commences, because it is of advantage to a lee line to be advancing a head. As the lee fleet fills and stands in close by the wind, the weather line should keep abreast, before it bears away, to come within the requisite distance, that the van ship of the weather fleet may always keep to windward of the leading ship of the lee line, and be guarded against any shift of wind a-head.

If the lee fleet bear away four points to move their order of battle on the other tack, and avoid the action, filing off in succession in the wake of the van ship, the weather line, by bearing away all together eight points, cannot fail, as both fleets are supposed to sail equally, to pass through the middle of their line, and force them to fight with disadvantage, if their extent be double the distance between the two fleets. If the extent of the fleet be less than the above limitation, then the weather fleet will divide the lee fleet more unequally; and if the distance between the fleets be considerable, the weather fleet will be able to break through the line. If the lee fleet bear away four points all together, being of equal extent with the fleet to windward, and their distance from each other equal to that of the length of one of the lines; should the weather fleet bear away at the same time eight points, they will approach very near the sternmost of the retreating fleet; but they will not have it in their power to cut off any part of that fleet, even with an equality of sailing, so that the only advantage gained by this manœuvre will be an ability of attacking the rear, and bringing it to action.

If the van ship and the rest of the weather fleet had a sufficient velocity to keep the centre ship of the lee line on the same point of bearing; in that case, the leading ship may break through the enemy's line about the
middle ship of the centre division; for, supposing the fleets in the order of battle, on the starboard tack, steering east, with the wind at south-south-east, being at two leagues distance from each other, both the lines being four leagues in extent; then the lee line bearing away all together four points, will run north-east; while the fleet to windward, bearing away all together eight points, will steer north; the van ship of which will keep the centre division of the lee line in the point of bearing north-west. As she is supposed to be able to continue in this position, it follows, that the van of the weather line must close the centre of the flying line to leeward, after having run four leagues. 'The time and distance necessary to cut off a retreating fleet may always be known according to the last supposition. If the lee fleet should get on the other tack, and run large, still in the order of battle, they will be sooner forced to action by the weather fleet, who have only to bear away eight or nine points on the same tack, or run right before the wind.

As in forcing a fleet to action, there are two principal cases in which a fleet may avoid an action, where circumstances are not sufficiently favourable; first, when the enemy is to windward, and secondly, when he is to leeward. In the former case the lee fleet should form the order of retreat, if the enemy are in view, and run on the same tack as their leading ship; but if he is still out of sight, and they have received intelligence of his approach, by their frigates on the look-out, they may bear away large, without confining themselves to keep the wind directly off, unless when in the order of retreat. In the second case, it seldom happens that the weather fleet can be forced to an engagement, because it can always stand on that tack which increases its distance from the enemy; that is, by standing on one tack while the enemy is on the other. The windward fleet must of course not keep too near the enemy, and take all possible means of avoiding being abreast of him.

It is often of advantage to double the enemy; that is, to bring a part of the fleet round upon his van or rear so as to place him between two fires. This manoeuvre also resolves itself into two principal cases; first, when the enemy is to windward; secondly, when he is to leeward. In the first case, the lee fleet that attempts to double the enemy, should extend itself abreast of him, so that its van or rear may extend beyond his line, in order to overreach him, by tacking in succession, so that the extended part of the line may get up to windward. If this manoeuvre be properly executed, it will be impossible for the ships of the weather line long to maintain their stations, for no vessel closely attacked by two others of equal force can long resist.

It is of some consequence to determine whether the attempt to double should be made on the van or the rear of the enemy, as on the propriety of adopting the one or the other of these measures, may in a great measure depend the issue of the battle. In the present case, it is easiest to double the van of the enemy, because if they are engaged by the ships abreast of them, those which are advanced ahead will be able, by making all sail, to get in the perpendicular to the direction of the wind with the van of the enemy, and tack in succession to gain the wind of them on the other board, thus keeping them to leeward; and when they are come sufficient-

ly to windward, they are again to go about, in order to keep the two headmost ships of the enemy's line continually under their fire. If there be two or three ships to tack in succession and gain the wind of the enemy, they may edge down on the van of the water line at pleasure, keeping themselves a little to the windward of it; and as that van is already engaged by the other ships abreast on the other side, she must necessarily be soon disabled. If they bear away, they must drop open the line with which they are engaged to leeward, while the ships to windward still continue to cannonade them. If they attempt going about, in order to attack more closely the ships to windward, they will be raked, while in stays, by their opponents to leeward and to windward, who enfilading them with whole broadsides which they cannot return, must complete their disorder. If they make sail, in order to frustrate the design of the ships inclined to double, those with which they are engaged abreast to leeward have only to perform the same manoeuvre, and keep them under their fire; while the others, after having harassed them as much as possible, will do their best to perform the same manoeuvre on the succeeding ships.

If any of the ships in the van of the weather line are disabled in the masts or yards, they will drop astern, and run foul of the next succeeding ship, and these again on the next astern. Thus, the enemy's order of battle will be broken, while on the other hand the lee line is preserved; and those ships which have gained the wind of the enemy will, without engaging more ships than they can manage, contribute to increase the confusion.

When the enemy is to leeward, and the weather fleet attempts to double, the ships of the weather line must extend their van beyond that of the enemy, and then veer in order to bring the headmost ships of the lee line between two fires. It must not, however, be conceived, that it is much more dangerous to the ships engaged in this service to attempt doubling a fleet to leeward, than one to windward, as if disabled, or separated too far from their own fleet, they cannot so easily extricate themselves, and rejoin the fleet.

When one fleet attempts to double another, this latter will of course do all in their power to avoid the impending danger; and this they will the more readily do, according to their number, or their situation. If the fleet thus threatened be to windward, one of the methods proposed to avoid being doubled, is to extend the line towards the point threatened, so as to leave a greater space between the ships; but in doing this, there is a risk of having the line broken by the superior force. Another method suggested is, for the flag ships of the windward fleet to oppose themselves to those of the lee line, which is supposed to render several of the enemy's ships in the intervals of little use; but one great inconvenience of this manoeuvre is, that it leaves the van and rear most exposed to the enemy's fire, and that the rear division in particular is in great danger of being doubled. To remedy these defects, the largest ships should be placed in the van and rear of each division, and the fleet must regulate its sailing in such a manner that its rear shall never be astern of the rear of the enemy.

When the enemy is to leeward, the weather fleet to keep astern of the enemy, so that the van of the weather fleet, may be opposed to, and attack the enemy's centre. Hence the enemy's van will become useless for
Part II.

Naval Tactics.

A. War.

24

Of chasing.

There are several circumstances of importance to be considered in the subject of chasing, i.e. when one ship or fleet pursues another, called the chase, either to bring her or them to action, or to oblige them to surrender.

When a single ship chases another, it is to be presumed in general, that one of them is the better sailor, though this is not always the case, and still by proper manouevring the chasing ship, or chaser, may gain on the chase. In the following observations, however, we shall suppose the chaser to sail faster than the chase.

The manouevres of the chaser will depend on her being to windward or leeward of the chase.

When the chase is to windward, it is evident that as soon as she perceives a strange ship which she takes for an enemy, she will haul her wind, in order to prolong the chase, as otherwise her retreat would soon be cut off.

The chase then stands on also nearly close hauled, till she has the chase on her beam; she then tacks, and stands on close hauled till the chase is again on her beam, and then retacks. In this manner she continues tacking every time she brings the chase perpendicular to her course on either board; and by thus manouevring, it is certain that the chaser will, by the superiority only of her sailing, join the other in the shortest time.

For since the chaser tacks always as soon as the chase is perpendicular to her course, she is then at the shortest distance possible on that board; and since the chaser is supposed to be the fastest sailer, these shortest distances will decrease every time the chaser tacks. It is therefore of advantage to the chase to keep constantly on the same course, without losing her time in going about, as tacking cannot be so favourable to her as to her adversary, whose sailing is superior.

If the captain of the chaser should so little understand his profession as to stand on a long way, and tack in the wake of the chase, the best thing she can do is to heave in stays, and pass to windward of him on the other tack, except she should find herself likely gaining advantage by going large; for if the chaser persists in tacking in the wake of the other ship, the pursuit will be very much prolonged.

When the chase is to leeward, the chaser is to steer that course by which she thinks she will gain most on the chase.

If, after having run a short time, the chase is found to draw more ast, the chaser should then bear away a little more; but if the chase draw a head, the chaser should haul up a little, and thus the course may be so regulated, that the chase may always bear on the same point, and then the chaser will get up with the chase in the shortest time possible; for if any other course were steered, the chaser would be either too far ahead or too far astern, and hence the pursuit would be prolonged.

The chase should run on that course which will carry her directly from the chaser, and should consider which is her best trim with respect to the wind, that she may move with the greatest possible rapidity from the chaser; for some ships have more advantage in going large, others with the wind right aft, and others when close hauled.

Another method has been proposed for chasing a ship to leeward, that is, by constantly steering directly for the chase: in this case, the tract described by the chaser is called the line of curve of pursuit. To illustrate this, let A (fig. 11. Plate DLXVIII.) represent the chaser, and B the chase directly to leeward of her, and running with less velocity than the pursuer, in the direction BC, perpendicular to that of the wind. Now, to construct this curve, let B b be the distance run by the chase in any short interval of time; join A b and make A a equal the distance run by the chaser in the same time.

Again, make b c, c d, d e, f, &c., each equal to B b; join 1 c, and make 1 1 = A a; join 2 d, and make 2 3 equal to 1 1; proceed in like manner till the two distances carried forward meet as at C, and a curve described through the points A, 1, 2, 3, &c., will represent nearly the curve of pursuit; and the less the interval A 1 is taken, the more accurately will the curve be formed. In this particular case, the length of the distance BC may be found as follows, provided the distance AB and the proportional velocities of the two ships be known.

Let the velocity of the chase be denoted by a fraction, that of the chaser being unity. Multiply the given distance AB by this fraction, and divide the product by the complement of the square of the same fraction, and the quotient will be the distance run by the chase BC. Suppose AB, the distance of the chase directly to leeward of the chaser, be taken at 12 miles, and suppose the velocity of the chase three-fourths of that of the chaser; what will be the distance run by the chase before she is overtaken? Now

\[9 \times \frac{3}{4} = 6\text{ miles; and since the velocity of the chaser to that of the chase is as 4 to 3, hence the distance run by the chaser will be } 20 \times \frac{3}{4} = 27\text{ miles.} \]

As the chaser alters her course at every point, and probably sails better with the wind in one direction with respect to her course than when the wind is in another direction, her velocity will be different at different points of the course. Thus, suppose her to sail faster when the wind is on the quarter; her velocity will constantly increase to a certain point, and then diminish. Hence in real practice the curve of pursuit will not be exactly what is laid down in the above problem, and of course the measure of BC will differ a little from what we have there laid down. See Resistance of Fluids and Seamanship.

If the whole fleet is to give chase, the admiral will in the case make the proper signal, and then each ship will instantly make all the sail possible. If the retreating fleet is not much inferior to the other, a few of the fastest sailing vessels only are to be detached from the superior fleet, in order to pick up any stragglers, or those ships which may have fallen astern; and the remaining part of the fleet will keep in the same line or order of sailing as the retreating fleet, so that they may, if possible, force them to action. But if the retreating fleet is much inferior, the admiral of the superior fleet will make the signal.
signal for a general chase, and then each ship will immediately crowd all the sail possible after the retreating fleet; or, if the chase be still less numerous, the admiral will detach one of the squadrons of his fleet, by hoisting the proper signal for that purpose, and he will follow with the remainder of the fleet. The squadron that chases, should be very careful not to engage too far in the chase, for fear of being overpowered; but at the same time to endeavour to satisfy themselves with regard to the object of their chase. They must pay great attention to the admiral's signals at all times; and in order to prevent separation, they should collect themselves before night, especially if there be any appearance of foggy weather coming on, and endeavour to join the fleet again. The ships are diligently to observe when the admiral makes the signal to give over chase; that each regarding the admiral's ship as a fixed point, is to work back into her station, to form the order of line again as quickly as the nature of the chase and the distance will permit.

When a fleet is obliged to run from an enemy who is in sight, it is usual to draw up the ships in that form or order, called the order of retreat; and the admiral, when hard pursued, without any probability of escaping, ought, if practicable, to run his ships ashore, rather than suffer them to be taken afloat, and thereby give additional strength to the enemy. In short, nothing should be neglected that may contribute to the preservation of his fleet, or prevent any part of it from falling into the hands of the conqueror.

We have now gone through the principal evolutions of fleets and squadrons, nearly as they are described in the Elements of rigging, seamanship, and naval tactics, and other approved publications on similar subjects. We have indeed omitted the method of forcing an enemy's line, and of avoiding being forced, because the former will be readily understood from what we have to add on the improved method of tactics of M. Grenier, and Mr Clerk of Eldin.

Defects of the usual line of battle.

Various defects have been observed in the tactics usually employed at sea, especially in a line of battle, and in the mode of bringing an enemy to action. The usual order of battle first introduced by the duke of York, afterwards James II. of England, is defective from its length. Its great extent makes it difficult for the admiral to judge what orders are proper to be issued, to the ships stationed at the extremities, while his signals, however distinctly made, are liable to be mistaken by the commanders of these ships. Besides, the extremities of a long line, especially if it be to leeward, are necessarily defenceless, as the enemy may throw himself with a superior force on the van or rear, and cut either of these off before it can be properly supported by the other squadrons. Viscount de Grenier, who was, we believe, one of the first to notice these defects, proposed to remedy them by introducing a new order of battle.

The leading principles of De Grenier's tactics are founded on the following considerations. It is evident that each ship of a fleet must at all times occupy the centre of a certain horizon. This horizon De Grenier divides into two unequal parts, calling the greater the direct and graduated space, and the less the indirect, crossed, and ungraduated space. The reason of these apppellations is, that on the greater segment of the horizon circle there are 20 different points, which may be marked by degrees from one of the close-hauled lines to the other, and to which a ship may sail from the centre by so many direct courses without tacking; whereas from the other 12 points, including that from which the wind blows, she cannot arrive but by steering crossed courses, which must necessarily delay her progress. Suppose now a fleet to leeward, so disposed that only a part of it can fight with another equally numerous, and ranged to windward in a single line, and let the leeward be ranged on three sides of a lozenge. abcd, ef (fig. 12). The squadron ab, which is most to windward, being drawn up in line of battle, cannot be fought but by an equal number AB, CD, EF. All the rest of that fleet therefore must remain inactive, unless the ships which are not engaged should try to pass to leeward of the fleet ab, cde, ef. But should the ships of the weather fleet, which are placed between B and F, bear away as they appear in the figure between C and F', the ships between A and B, which are fighting to windward, cannot bear away with them. Suppose now that the ships between C and F have passed to leeward, the squadrons cde, ef, which are ranged according to De Grenier's system, and have not yet been engaged, should come to windward and join with their friends ab against that squadron of the enemy AB which is still to windward and engaged; it is almost impossible but that the squadron AB must be destroyed by so great a superiority, before it could receive assistance from the ships to leeward between C and F'.

De Grenier proposes only three orders of sailing, one when a fleet is to pass a strait; a second when it steers in open sea, on the look-out for an enemy, or with a view to avoid him; and a third when on an extensive cruise disposed so that it cannot be easily surprised or broken. Of these three orders, the second and third differ from the usual orders of sailing. The former of these is represented by fig. 1. Plate DLXIX., where the columns ab, cd, ef, are disposed on three sides of a regular lozenge, on the two close-hauled lines. The ships of the two divisions cde, ef, sometimes to windward (as in fig. 2.) and sometimes to leeward (as in fig. 1.) of the third division ab, are to be formed on two parallels of one of the close-hauled lines in the wakes of their respective headmost ships; while the third division ab is to be ranged ahead or astern of others on the other close-hauled line, steering chequerswise the same course as the other divisions.

When ab is to windward of cd and ef (fig. 1), De Grenier calls that the windward primitive order of sailing, and when to leeward (fig. 2), the fleet is said to be in the leeward primitive order of sailing. These are the two principal positions in almost every case, and with very little variety, may become the order of battle of chasing, &c.

His third order is illustrated by fig. 3, where the divisions ab and ef, are supposed at the distance of about six leagues from each other; cd and ef resting on the extremities of the base of a triangle T, while the centre ship of the division ab rests on its summit T; none of the divisions could be cut off by any enemy, however formidable, seen from its centre ship at the distance of six leagues. For if, on the proper signal, the division ab should steer from T toward X, on the course opposite
Naval Tactics.

Part II.

Plate DLXIX.

His order of battle.

Fig. 5.

To form De Grénier's order of battle represented in fig. 4. and 5. it will be sufficient for the ships of the three divisions ranged in the windward primitive order of sailing (see N° 95.) to beave in stays all together, and get on the other tack on the opposite line of bearing (fig. 4.); or for the ships in the leeward primitive order at once to haul the wind on the same tack as they steer; and they will find themselves in order of battle, fig. 5.

When the two columns c and d, are to leeward of the third division a b, ranged in order of battle, this is called the natural order of battle, and when c and d are to windward of a b, this is the inverted order of battle. The former of these is calculated for a fleet combating to leeward, and the latter for a fleet which must fight to windward.

To explain the advantages of these dispositions, let us suppose the line AB, CD, EF, fig. 6. to represent an enemy's fleet to windward in the usual order of battle, on the close-hauled line, and on the starboard tack, and let a b be one of the divisions of a fleet disposed according to the now natural order, on the starboard tack, while the line c d, e f, represent the other two divisions standing on weatherly tack on the same tack, but forms on the opposite close-hauled line. When the enemy comes to attack this latter fleet on a supposition that it is inferior to their own, their divisions AB and EF, in order to attack the ships a or b, must bear away. Now, to prevent the attack, each of the divisions c d, e f, must make the following evolutions according to their respective situations, and the manœuvres of the enemy.

1. The ships of the division a b are to slacken as much as possible their headway, and form a very close line, till the enemy makes a movement to attack the headmost or sternmost ship of that division. 2. The ships of the division c d are to make sail till they come under the second or third ship of the rear of the line of battle a b, when they will take the same sail as the ships of that division, to preserve that position until the hostile ships make their evolution to attack the rear ships of that division. In this situation the ships of the division c d, will be able to observe the manœuvres of the enemy, in order to change tack, and form themselves in order of battle on the opposite board as soon as the hostile ships shall have run over a certain space; because the ships of the division c d, steering afterwards close hauled in the wake of the sternmost ship of the division a b, will be able to cover the rear ships of that division, and get the weather-gage of the hostile divisions which are bearing away; rake their ships; run along side of them, double their rear-guard, and put it between two fires, if those hostile ships are following in the wake of the other; and vice versa, if they bear a way weatherly; or gain to windward, and pot between two fires the enemy's division CD, while engaged with the division a b. 3. The division e f may abandon that post, and run weatherly under a press of sail as soon as the enemy falls a-head of a b; that if the enemy's division AB attempts to fall on e f, or on the van of a b, they may, by going about,

steer in order of battle close hauled on the opposite line, and cover the ship a, double the hostile division CD a-head, or divide AB which is running chequerewise on the opposite tack.

Fig. 7. marks another method of manœuvring by the Fig. 7. divisions c d e f, when the enemy's ships are arranged in a single line not well formed.

Figs. 8. and 9. illustrate De Grénier's method of placing the admiral's ship, and the frigates and transports attached to a fleet. A, fig. 8. is the admiral ranging the placed a-head of the fleet, at a short distance from the admiral's headmost of the second division, and in the same direct. ship, frigates and transports. Figs. 8. and 9. are frigates observing the same rule and position, with respect to the van of the third, and rear of the first division. When the fleet is in order of battle, as in fig. 9. the admiral's ship A is in the centre of the lozenge, and two of the frigates, ff, on the fourth side of the lozenge. The transports and store-ships, when the fleet is in order of sailing or convoy, occupy the space circumscribed by the lozenge, but in order of battle they are disposed in a line opposite to that of the enemy.

We cannot enter on a more minute or satisfactory account of this system; for a full exposition of which we must refer to the original work entitled L'Art de Guerre en Mer, ou Tactique Navale, etc. par M. le Viscounte de Grénier, or the extracts from it contained in the Elements and Practice of Rigging and Seamanship.

We must now turn our attention to the improvements Mr. Clerk's in tactics suggested by our countryman Mr. Clerk; improvements which have received the approbation of several distinguished officers of the British navy, and to hints derived from which we are in a great measure indebted for some of the most signal victories which have heaped additional honour on the naval power of Britain.

Before entering on an explanation of Mr. Clerk's tacti,. Mr. Clerk's tics, we must briefly state his objections to the usual objections to the usual method of bringing ships to action, by the weather ship method of fleet steering directly down upon the enemy. By doing this, the enemy to leeward often has an opportunity of completely disabling the ships making the attack, as the former can use all their guns on one side, while the latter can only use their bow chases. Suppose B, fig. 10. Plate DLXIX. to represent a ship of 80 guns to windward, in sight of an enemy's ship of equal force, F, to leeward. Now, if B bears down directly upon F, the latter, by lying to, as in fig. 11., will present a broadside of 40 guns, all bearing for a considerable time on B, while the latter coming down headwise, can only bring the two light guns of her forecastle to bear on F, not to mention that F, by lying broadside to, will have her masts and rigging little exposed to the enemy's shot, while B standing head on, is exposed to be raked by every shot from F, and in particular her rigging is in the utmost danger.

Instead of this objectionable mode of attack, Mr. Clerk proposes that B having the wind, should run method down astern as in the dotted line at fig. 12. till she gets into the course of F, near her wake, or in such a position as will bring her parallel to F's course, and within a proper distance, when she can run up close along side of F, and engage on equal terms; or, that she should shoot a-head, then veer, and run down on the weather bow of F, as in fig. 13. till she can force the chase to bear...
bear away to leeward, keeping close by her, on equal terms, taking care in both cases not to put it in the power of F to bring her broadside to bear on her without retaliation.

Fig. 14. is employed by Mr. Clerk to illustrate the different procedure of a French and British man of war in firing, the former at the rigging, and the latter at the hull of the enemy, with their effects. Let F represent a large ship desirous of avoiding a close engagement, but lying to, to receive with advantage an enemy's ship B, of equal force. Suppose that F, by firing at the rigging of B, may have carried away some of the principal stays, several of the windward shrouds, a fore-topsail, or other rigging of less consequence, without having wounded a single man; and suppose a second ship consort to E, receiving an enemy's ship like B, but firing only at her hull, so as to kill 30 or 40 men, without damaging her rigging. Now, when F and her consort wish to avoid a close engagement, it is evident that such a ship B, which has lost part of her rigging, is much more disabled from coming to close action than her consort whose rigging is entire, though she may have lost a great number of her men.

By the scheme at fig. 15, it is intended to illustrate the impossibility of one ship being exposed to the fire of many ships at one time. Let I, H, F, E, I, represent five ships in line of battle, about a cable's length, or 240 yards asunder, and suppose the length of each ship to be 40 yards, so that the whole space between the head of one ship and the head of that next adjacent equals 280 yards. Let the perpendicular line FK, extending from the beam of F six cables lengths or 1440 yards, be divided into six equal parts. It is evident that any ship stationed at E in the line FK, 720 yards distant, cannot long be exposed to the fire of more than the centre ship F of this squadron. For if we suppose that H and K a-head and stern of F, can bring their broadsides to bear on E, by putting themselves in positions for that purpose, they will not only disorder their own line, but one will lose her head and the other her stern exposed to a raking fire from the opposite ships BB in the enemy's line. If C can suffer little from the two ships H, I, at the distance of 720 yards, it is evident that she will suffer still less from these ships as she approaches nearer the enemy's line. Again, if instead of a cable's length asunder, we suppose the ships I, F, I, two cables length asunder, to bear on the ship B. It is evident from the figure that in this case B will not be more exposed to the fire of I and I at the distance of 1440 yards than she was to that of H and I at half that distance; and so in similar cases.

In explaining the principles on which we are to judge of the advantages or defects of different modes of bringing ships to action, Mr. Clerk supposes a fleet of 10, 20, 30 guns each, drawn up in line of battle to leeward, as at F, fig. 16, and lying to with an intention to avoid an action; while another fleet, as B, of equal number and force, also drawn up in line of battle, three or four miles to windward, wishes to make an attack, and come to close quarters on equal terms. The fleets being thus disposed, should the fleet at B attempt running down to attack the fleet at F, each ship line, it is to be expected, from what we have already stated, that the attacking ships will be disabled, at least in their rigging, before they can come to close action; but suppose that the commander of the weather fleet, though his ships have been disabled in their rigging during their course as to leeward, fig. 17, has made them bring to at a great distance, but sufficiently near to injure F. This latter fleet, which has been endeavouring to avoid an action, will now bear away with little injury to a new station, as G, and there remain out of the reach of B's shot, and this fleet must repair its rigging before it can make another attack.

Again, suppose that the fleet B, instead of standing head on, were to run down in an angular course, as at fig. 18. It is plain that if any ship in this angular line should be crippled, her defect in sailing will occasion a confusion of several of the other ships in that line. It may be said that the stoppage of one ship a-head will not necessarily produce a stoppage of every ship a-stern of her, because they may run to leeward of the disabled ship; but we must observe that by this time the ship a-head in the van A may be engaged, and consequently not having much head way, are nearly stationary, so that each ship a-stern, in attempting to bear down at D, D, must be confused to a certain course, and must run the risk of being raked in coming down before the wind, and consequently of being disabled before coming up with the enemy.

Thirdly, the van of the fleet B having attained their station at A, a-breast of the van of F, fig. 19, and having begun the action, the van ships of F, with a view to retreat, may throw in a broadside on the van of B, and then bear away in succession, as at H, followed by the rest of the fleet F, which, after exchanging broadsides with the van of B, may draw up in a new line two or three miles to leeward at I, fig. 20.

Suppose again, for further illustration, that B, fig. 1, Plate DLXX. represents a fleet putting before the wind, each ship intending, when brought to at a determined distance at A, to take up her particular antagonist in the line of the enemy F to leeward; and let E be supposed at rest, without any motion a-head. It is easy to conceive that while the alternate ships of F's line, under cover of the smoke, withdraw from battle to GGG, the intermediate ships left behind them in the line will be sufficient to amuse even the whole of B's fleet, till the ships G shall form a new line HII as a support from the leeward. In such case B, after being disabled, and not having foreseen the manoeuvre, will neither be able to prevent the intermediate ships with which he is engaged from bearing away to join their friends, nor, were he able, would it be advisable to follow them, for the same manoeuvre with equal success can again and again be repeated.

To explain the relative motion of these two fleets, let F, fig. 2, represent a fleet of 12 ships in line of battle, each a cable's length asunder, and suppose the length of each ship from the end of the jib-boom to the stern to be 385 fathoms. The whole fleet will occupy a space of two English miles; and if it be supposed to sail in the direction FG, at the rate of four knots an hour, it will in an hour have moved to G, four miles from its former position.

Now, let there be an opposite fleet B, also 12 ships, situated four miles to windward, and let the point A be a quarter of a mile right to windward of the point G. Then, if B by bearing away in the direction BA, gain...
Part II. Naval Tactics.

the point A at the same time that the leeward fleet F has arrived at G, B will have moved nearly at the rate of 33 miles an hour, and the angle contained between the direction of its line of bearing and its present course will be nearly four points.

Secondly, in fig. 3, if F, by carrying more sail, move at the rate of six miles an hour, from F to G, and then B, with a more slanting course, will have more difficulty in keeping the line abreast while coming down to the attack, owing to the additional obstruction which will attend each succeeding ship in such a slanting course.

Again, if the leeward fleet shall lie up one point higher, as FG, fig. 4, the rears of the two fleets will be removed to a much greater distance, and the van A must be sooner up with the enemy's van, and of course so much farther from support, while F bringing up his ships in succession, may disable the van of A, and afterwards bear away at pleasure with little injury, as at H. Now B being supposed disabled, and having his rear D distracted, will be unable to prevent F from escaping.

From these considerations it appears that a fleet to windward, by extending its line of battle with a view to stop and attack the whole line of an enemy's fleet to leeward, must labour under considerable disadvantage, and will scarcely succeed in the attempt.

On these principles Mr. Clerk explains the reason why, before the commencement of the present contest between Britain and France, the French fleets so repeatedly escaped from the British without any serious defeat or loss; viz. by avoiding a general engagement, and disabling the British van as it bore down to attack them. He therefore recommends a different mode of attack from the windward, which we shall proceed to illustrate by proper diagrams.

Let F (fig. 5) represent a fleet in line of battle, under easy sail, willing to avoid an action, but ready to receive an attack in the usual way, from another fleet B, three or four miles to windward, arranged in three columns. How shall B make the attack on F, so as, without aiming at the improbable advantage of taking or destroying the greater part of this fleet, they may secure three or four of the sternmost ships? Mr. Clerk advises, that a sufficient strength be detached to secure these ships, while the admiral keeps aloof with the rest of his fleet, disposed as in the figure, ready to make the necessary observations and give the requisite support to the detached ships. If F continues to avoid an action by standing on in line, the detachment, coming into the position BA, will secure the three ships at I; and if the headmost ships of F were to tack, and be followed by the rest in succession as at fig. 6, not only the three ships at I will be left at the mercy of the ships detached from B, but two more, as G, will be exposed to an attack from another squadron of B at C. If all the three ships of F tack together, as in fig. 7, the delay, and probably the confusion, consequent on this manoeuvre, will still more endanger the sternmost ships, or will bring on a general and close action. Again, if F attempts to haul off, beginning with his sternmost ship G, and then runs to leeward, as at fig. 8, he will expose his ships to a raking fire from B, and still endanger his sternmost ships by getting too far off the wind for their support; or if the headmost ships at H, fig. 9, veer first, to be followed by the rest astern, the danger would be still greater. Thus it appears that in every assignable case, a fleet to leeward, avoiding an attack from an equal or superior windward, as here advised, by preserving the line, will risk the loss of three or more of their sternmost ships.

Now, let us suppose that F, while standing on a line fig. 10. on the larboard tack, when threatened with an attack, on his rear from B, veers and passes on opposite tacks to leeward (see fig. 10.). The consequence of this will be, that his headmost ships will be forced to leeward by B, and compelled to engage under disadvantageous circumstances, and the disadvantage to F will be much the same, whether he again veers and resumes his former position, as at G, fig. 11. or stands on before the wind, as at F, fig. 12.

We have hitherto supposed that the wind has been Fig. 3. fixed in one point; but let us suppose it to shift, and let us inquire what will be the effect of such a circumstance on the two lines F and B. While the fleets are in the former position, F in line, and B in four divisions, B, B, B, A, steering E, with the wind at N, fig. 13. let the wind shift to the west. The only consequence of this will be, that F will be thrown still farther to leeward, to its greater disadvantage. But let the wind shift to E, so as to be a-head, as in figs. 14. and 15. Still if the admiral of B manages properly, and carefully watches the motions of F, this change will produce no advantage to the latter. For B has nothing to do but veer as the wind comes round, so as to bring his ships to windward of the three sternmost ships of F, and to leeward of the rest of his line, so as to cut off the three sternmost ships.

If the wind should be supposed to veer from point to point all round the compass, so that the fleet F, maintaining the weather-gage of B, shall make a circuit round B to leeward; still if B act cautiously, F will lose the three threatened ships.

Lastly, suppose the wind should instantly shift to a point opposite to what it was at the commencement of the attack, as from N. to S. Before it can be ascertained whether such a change will be to the advantage or disadvantage of F, the relative situations of the two fleets must be considered. Suppose that the van and centre be separated at some distance from his rear, and that in consequence this fleet shall have taken such a position as is shown at fig. 16. Though in this case he Fig. 16. will have got to windward, his three ships can never be regained or preserved from the attack of B. The most favourable situation for F would be when the fleets were in the position denoted by fig. 13., as then he could not only support his three ships with advantage, but even threaten, and cut off a part of B's detachment. In attempting this, however, he incurs the risk of coming to a close engagement, which we have supposed him to be sedulously avoiding.

Besides this method of attack from the windward by From the detachments from the main fleet, Mr. Clerk shows how a successful attack may be made by a fleet to leeward, by its breaking the enemy's line, and this either near the rear, near the centre, or not far from the van, of which cases the two former will be most likely to prove successful. The enemy's line can only be cut when the two hostile fleets veer on opposite tacks. The most simple method of effecting this is for the van ship of the attacking squadron, instead of ranging parallel to that of the enemy, and to leeward of him, to pass through the
The first interval that offers, followed by the rest of the line, which is thus led across that of the enemy. In consequence of this manoeuvre, the van of the leeward fleet will be to windward of the enemy’s rear, and thus the attacking squadron will have its line entire, while that of its adversary is divided. Again, the ships of the rear division, having their progress obstructed, will probably crowd on each other, get into confusion, and be driven to leeward. We cannot detail the different cases mentioned by Mr. Clerk; but for these and many other valuable suggestions on the subject of naval tactics, we must refer to his useful and ingenious Essay.

The above is a very faint and meagre outline of Mr. Clerk’s tactics, but it is all which our limits enable us to give. It will afford general readers some idea of the nature of the proposed improvements, and professional men will naturally consult the original essay.

On these or similar principles is founded the method of breaking through the enemy’s line, and thus cutting off a part of his fleet, so successfully adopted by the British admirals in the great naval actions that have distinguished the late and present wars with France. We cannot better illustrate the principles above laid down, than by giving a short detail of the last of these memorable engagements, the Battle of Trafalgar.

With this we shall conclude our sketch of naval tactics, and our practical observations on the art of War.

After having been long blocked up in the harbour of Cadiz, the combined French and Spanish fleet effected their escape, while the British fleet, under the command of Lord Nelson, was at a considerable distance. On the 19th of October 1805, the ships which had been left to watch the motions of the enemy, communicated to the commander in chief the agreeable intelligence, that the combined fleet had put to sea, and was sailing with light winds in a westerly direction. Lord Nelson, concluding that their destination must be the Mediterranean, immediately made all sail with his ships for the entrance of the straits. Here he was informed by Captain Blackwood, that the enemy had not yet passed the straits.

On the 21st of October, at daylight, Cape Trafalgar bearing east by south about seven leagues distant, the combined fleet was discovered about six or seven miles to the eastward. The wind was about west, and very light. As Lord Nelson had long expected to fall in with the enemy’s fleet, he had concerted with his officers the best and most expeditious measures for bringing them to a speedy and decisive action. As soon, therefore, as they hove in sight, he immediately made the signal for the British fleet to bear up in two columns, as they formed in order of sailing. The combined fleet was drawn up in line of battle, with their heads to the northward, and had formed the line with of the line, 18 French, and 15 Spanish, under Admiral Graves, in the Bucentaure, while the Spanish admiral, the Prince of Asturias, led the rear in the Prince of Asturias. The British fleet consisted of 27 ships, including three sixty-fours. Lord Nelson headed the van in the Victory, having under him the Temeraire, Neptune, Conqueror, Leviathan, Ajax, Orion, Agamemnon, Minotaur, Spartiate, Britannia, Africa, with the Euryalus, Sirius, Phoebe, and Naiad frigates, Pickle schooner, and Extravagante cutter; while the rear, consisting of the Royal Sovereign, Mars, Belleisle, Tonnant, Bellisph, Colossus, Achilles, Polyphemus, Revenge, Swiftsure, Defence, Thunderer, Defence, Prince, and Dreadnought, was led by Vice-admiral Collingwood in the Royal Sovereign.

As the mode of attack adopted by the British was unusual, the combined fleet was obliged to draw up their line in a new manner. It formed a crescent, with its convexity to leeward, so that in leading down to their centre, the rear division of the British had both their van and rear abaft the beam. Before the action commenced, every alternate ship was about a cable’s length to windward of her second ahead and astern, thus forming a kind of double line, and appealing, when on their beam, to leave a small interval between them without crowding their ships. The French and Spaniards were not formed in separate divisions, but intermixed without any apparent regard to order of national squadrons. As the British commander had previously communicated to his flag-officers and captains his preconcerted mode of attack, few signals were necessary, and none were made on approaching the enemy, except to direct close order as the lines bore down.

The action commenced at noon, by the leading ships of both columns breaking through the enemy’s line; the Victory about the tenth ship from the van, and the Royal Sovereign about the twelfth from the rear; the succeeding ships breaking through in every part astern of their leaders, and engaging the enemy at the very muzzles of their guns. By this manoeuvre the van of the enemy was unengaged, and thus the inferiority of the British, in point of number, was of less consequence, while the superior skill and bravery of British seamen soon acquired a decided advantage. The conflict was severe, as the enemy’s ships were fought with a gallantry highly honourable to their commander. The British attack, however, was irresistible. About three P.M. many of the enemy’s ships had struck their colours, and their line had given way. Ten ships of the line, and the frigates, under Admiral Graves, made their escape, and stood to leeward towards Cadiz. The five headmost ships of their van tacked, and standing to the southward, to windward of the British line, were brought to action, and the sternmost of them taken. Nineteen ships of the line, with three flag-officers, including the commander in chief, remained in the hands of the British. Never was there a victory more glorious or more decisive; never was the pre-eminence of the British flag more triumphantly conspicuous.

The events subsequent to this memorable battle, and the losses sustained on either side, having little connexion with the subject of the present article, need not be here detailed. They are fresh in the memory of our readers, and Britain still laments the loss of her immortal Nelson.

WARBURTON. a disease of horses. See Farriery Index.

WARBURTON, William, a learned English bishop, was descended from an ancient family in Cheshire, and was the second son of George Warburton, an attorney at Newark in the county of Nottingham, who was born at Newark, December 24, 1698. He was first put to school there under a Mr. Twisles, but had the chief part of his education at Okeham in Rutlandshire, where he continued till the beginning of the year 1714, and soon after he was put out clerk to an eminent attorney of Great Markham in Nottinghamshire, where he continued till the year 1719, when he returned to his family at Newark, but whether he practised there or elsewhere as an attorney, is not known.

He had always expressed a strong inclination to take orders; and the love of letters, which tended to retard, rather than forward, his progress in the profession chosen for him by his friends, growing every day stronger in him, it was deemed expedient to give way to that inclination. He therefore devoted himself to the studies necessary to fit him for the church, and at length in 1723 he was ordained deacon, and priest in 1727.

In 1728 he was presented by Sir Robert Sutton to the rectory of Brand-Troughton, in the diocese of Lincoln, where he spent the greater part of his life, and composed all the great works which will carry his fame down to posterity. In the same year he was put upon the king's list of Masters of Arts, erected on his majesty's visit to the university of Cambridge. He had already published some juvenile performances, which displayed genius and reading, and attracted considerable notice; but it was not till the year 1736 that he may be said to have emerged from the obscurity of a private life into the notice of the world.—The first publication which rendered him afterwards famous now appeared, under the title of "The Alliance between Church and State; or, the Necessity and Equity of an Established Religion and a Test Law; demonstrated from the Essence and End of Civil Society, upon the fundamental Principles of the Law of Nature and Nations." In this treatise, says Bishop Horsley, the author "hath shown the general good policy of an establishment, and the necessity of a Test for its security, upon principles which republicans themselves cannot easily deny. His work is one of the finest specimens that are to be found perhaps in any language, of scientific reasoning applied to a political subject."

At the close of the Alliance was announced the scheme of the Divine Legation of Moses, in which he had then made considerable progress. The first volume of this work was published in January 1737, under the title of "The Divine Legation of Moses demonstrated on the Principles of a religious Deist, from the Omission of the Doctrine of a future State of Rewards and Punishments in the Jewish Dispensation, in six books, by William Warburton, M. A., author of, Vol. XX. Part II."

The Alliance between Church and State," and the Alliance between Church and State; or, the Necessity and Equity of an Established Religion and a Test Law; demonstrated from the Essence and End of Civil Society, upon the fundamental Principles of the Law of Nature and Nations." In this treatise, says Bishop Horsley, the author "hath shown the general good policy of an establishment, and the necessity of a Test for its security, upon principles which republicans themselves cannot easily deny. His work is one of the finest specimens that are to be found perhaps in any language, of scientific reasoning applied to a political subject."

At the close of the Alliance was announced the scheme of the Divine Legation of Moses, in which he had then made considerable progress. The first volume of this work was published in January 1737, under the title of "The Divine Legation of Moses demonstrated on the Principles of a religious Deist, from the Omission of the Doctrine of a future State of Rewards and Punishments in the Jewish Dispensation, in six books, by William Warburton, M. A., author of, Vol. XX. Part II.

the Alliance between Church and State," and met Warburton with a reception which neither the subject, nor the manner in which it was treated, seemed to authorize. It was, as the author afterwards observed, fallen upon in so outrageous and brutal a manner as had been scarce pardonable, had it been "The Divine Legation of Moses."—It produced several answers, and so much abuse from the authors of "The Weekly Miscellany," that in less than two months he was constrained to defend himself, in "A Vindication of the Author of the Divine Legation of Moses, from the Aspersions of the Country Clergyman's Letter in the Weekly Miscellany of February 24, 1737-8, 8vo."

Mr Warburton's extraordinary merit had now attracted the notice of the heir apparent to the crown, in whose immediate service we find him in June 1738, when he published "Faith working by Charity to Christian Edification, a Sermon, preached at the last visitation in the Diocese of Lincoln; with a Preface, showing the Reason of its Publication; and a Postscript, occasioned by some Letters lately published in the Weekly Miscellany; by William Warburton, M. A. Chaplain to his Royal Highness the Prince of Wales."

The "Essay on Man" had now been published some years; and it is universally supposed, that the author had, in the composition of it, adopted the philosophy of Lord Bolingbroke, whom, on this occasion, he had followed as his guide, without understanding the tendency of his principles. In 1738, M. de Crousaz wrote some remarks on it, accusing the author of Spinozism and Naturalism; which falling into Mr Warburton's hands, he published a defence of the first epistle, and soon after of the remaining three, in seven letters; of which six were printed in 1739, and the seventh in June 1740, under the title of "A Vindication of Mr Pope's Essay on Man, by the author of the Divine Legation."

The opinion which Mr Pope conceived of these defences, as well as of their author, will be best seen in his letters. In consequence, a firm friendship was established between them, which continued with undiminished fervour until the death of Mr Pope; who, during the remainder of his life, paid a deference and respect to his friend's judgment and abilities, which will be considered by many as almost bordering on servility.

Towards the end of the year 1739, Mr Warburton published a new and improved edition of the first volume of the Divine Legation; and in 1741, appeared the second part, which completed the argument, though not the entire plan of that work. "A work, says Bishop Hurd," in all views of the most transcendent merit, whether we consider the invention or the execution. A plain simple argument, yet perfectly new, and yet perfectly new, proving the divinity of the Mosaic law, and laying a sure foundation for the support of Christianity, is there drawn out to a great length by a chain of reasoning so elegantly connected, that the reader is carried along it with ease and pleasure; while the matter presented to him is so striking for its own importance, so embellished by a lively fancy, and illustrated from all quarters by exquisite learning and the most ingenious disquisition, that in the whole compass of modern or ancient theology, there is nothing equal or similar to this extraordinary performance."

This is the panegyric of a man reflecting with ten-
Warburton's memory on the memory of his friend and benefactor; but it approaches much nearer to the truth than the censures of those cabalistic critics, who, fastening upon some weak part of the Divine Legation, or perhaps never having looked into it, have ridiculously contended that the author was far from being eminent as a scholar, and that his work is inimical to the cause of Christianity! Putting partiality aside, there is in the Divine Legation of Moses abundant evidence of the malignant folly of this charge, as no man can read and understand that work without being convinced that its author was a Christian, not only sincere but zealous; that he was, what Johnson calls him, "a man of vigorous faculties, of a mind fervent and vehement, supplied, by unlimited and incessant inquiry, with a wonderful extent and variety of knowledge, which had neither depressed his imagination nor clouded his perspicuity; and that to every work, and this work in particular, he brought a memory full fraught, with a fancy fertile of original combinations, exerting at once the powers of the scholar, the reasoner, and the wit." But we think it must be acknowledged, that his learning was too multifarious to be always exact, and his inquiries too eagerly pushed to be always cautious. We have no hesitation, however, to say, that to the divine this great work, with all its imperfections, is, in our opinion, one of the most valuable that was to be found in any language.

In the summer 1741, Mr. Pope and Mr. Warburton, in a country ramble, took Oxford in their way. The university was naturally pleased at the arrival of two such strangers, and seemed desirous of enrolling their names among their graduates. The degree of D. D. was intended for the divine, and that of L.L. D. for the poet: but intrigue and envy defeated this scheme; and the university lost the honour of decorating at the same time the two greatest geniuses of the age, by the fault of one or two of its members. Pope retired with some indignation to Twickenham, where he consoled himself and his friend with this sarcastic reflection—"We shall take our degree together in fame, whatever we do at the university."

The friendship of this eminent poet was of service to Mr. Warburton in more respects than that of increasing his fame. He introduced and warmly recommended him to most of his friends, and among others to Mr. Murray, afterwards Earl of Mansfield, and Ralph Allen, Esq. of Prior-park. In consequence of this introduction, we find Mr. Warburton at Bath 1742; where he printed a sermon which had been preached at the Abbey-church on the 24th of October, for the benefit of Mr. Allen's favourite Charity, the General Hospital or Infirmary. In this year also he printed a Dissertation on the origin of books of chivalry, at the end of Jarvis's Preface to a translation of Don Quixote, which Mr. Pope tells him, he had not got over two paragraphs of, before he cried out, Aut Erasmus, aut Diabolus.

In 1742, Mr. Warburton published "A Critical and Philosophical Commentary on Mr. Pope's Essay on Man, in which is contained a Vindication of the said Essay from the Misrepresentation of M. de Resnial, the French Translator, and of M. de Crousaz, Professor of Philosophy and Mathematics in the Academy of Lausanne, the Commentator." It was at this period, when Mr. Warburton had the entire confidence of Mr. Pope, that he advised him to complete the Dunciad, by changing Walter, the hero, and adding to it a fourth book. This was accordingly executed in 1742, and published early in 1743, with notes by our author; who, in consequence of it, received his share of the abuse which Mr. Cibber liberally bestowed on both Mr. Pope and his annotator. In the latter end of the same year, he published complete editions of "The Essay on Man," and "The Essay on Criticism," and from the specimen which he there exhibited of his abilities, it may be presumed Mr. Pope determined to commit the publication of those works which he should leave to Mr. Warburton's care. At Mr. Pope's desire, he, about this time, revised and corrected the "Essay on Homer," as it now stands in the last edition of that translation.

The publication of "The Dunciad" was the last service which our author rendered Mr. Pope in his life. After a lingering and tedious illness, the event of which had been long foreseen, this great poet died on the 30th of May 1744; and by his will, dated the 12th of the preceding December, bequeathed to Mr. Warburton one half of his library, and the remainder of all such of his works already printed as he had not otherwise disposed of or alienated, and all the profits which should arise from any edition to be printed after his death; but at the same time directed that they should be published without any future alterations.

In 1744, Mr. Warburton turned his attention to the several attacks which had been made on the Divine Legation, and defended himself in a manner which, if it did not prove him to be possessed of much humility or diffidence, at least demonstrated, that he knew how to wield the weapons of controversy with the hand of a master. His first defence now appeared, under the title of "Remarks on several occasional Reflections, in Answer to the Reverend Dr. Middleton, Dr. Pococke, the Master of the Charter-house, Dr. Richard Grey, and others; serving to explain and justify divers Passages in the Divine Legation, objected to by those learned Writers. To which is added, a general Review of the Argument of the Divine Legation, as far as it is yet advanced; wherein is considered the Relation the several Parts bear to each other and the whole. Together with an Appendix, in Answer to a late Pamphlet entitled, An Examination of Mr. W——'s Second Proposition." This was followed next year by "Remarks on several occasional Reflections, in Answer to the Reverend Doctors Stebbing and Sykes; serving to explain and justify the Two Dissertations in the Divine Legation, concerning the command to Abraham to offer up his Son, and the Nature of the Jewish Theocracy, objected to by these learned Writers. Part II. and last." Both these answers are couched in those high terms of confident superiority, which marked almost every performance that fell from his pen during the remainder of his life.

On the 5th of September 1745, the friendship between him and Mr. Allen was more closely cemented by his marriage with Miss Tucker, who survived, and is now, if alive, Mrs. Stafford Smith of Prior-park. As this important crisis our author preached and published that important crisis our author preached and published three sermons: 1. "A Faithful Portrait of Mr. Pope, by which it is seen to be the Remover of Christianity, as it is the Destruction of Morality, Piety, and Civil Liberty." Preached at St. James's, Westminster, October.
WAR [ 635 ]  

WAR

Warburton, October 1745. 2. A Sermon occasioned by the present unnatural Rebellion, &c. Preached in Mr. Allen's Chapel at Prior Park, near Bath, November 1745.

3. "The Nature of National Offences truly stated. Preached on the General Fast-day, Dec. 18. 1745-6." On account of the last of these sermons, he was again involved in a controversy with his former antagonist Dr. Stebbing, which occasioned "An Apologetical Dedication to the Reverend Dr. Henry Stebbing, in Answer to his Censure and Misrepresentations of the Sermon preached on the General Fast, &c."

Notwithstanding his great connections, his acknowledged abilities, and his established reputation, a reputation founded on the durable basis of learning, and upheld by the decent and attentive performance of every duty incident to his station; yet we do not find that he received any addition to the preferences given him in 1728 by Sir Robert Sutton (except the chaplainship to the prince of Wales), until April 1746, when he was unanimously called by the Society of Lincoln's Inn to be their preacher. In November he published "A Sermon preached on the Thanksgiving appointed to be observed the 9th of October, for the Suppression of the late unnatural Rebellion." In 1747 appeared his edition of Shakespeare and his Preface to Clarissa; and in the same year he published, 1. "A Letter from an Author to a Member of Parliament concerning Literary Property." 2. "Preface to Mrs Cockburn's Remarks upon the Principles and Reasons of Dr. Rutherfurd's Essay on the Nature and Obligations of Virtue, &c." 3. "Preface to a Critical Inquiry into the Opinions and Practice of the ancient Philosophers, concerning the Nature of a Future State, and their Method of teaching by double Doctrine," (by Mr Towne) 1747, second edition. In 1748, a third edition of "The Alliance between Church and State, corrected and enlarged."

"In 1749, a very extraordinary attack was made on the moral character of Mr Pope, from a quarter where it could be least expected. An insignificant pamphlet, under the name of A Patriot King, was that year published by Lord Bolingbroke, or by his direction, with a preface to it, reflecting highly on Mr Pope's honour. The provocation was simply this: The manuscript of that trivial declaration had been intrusted to the care of Mr Pope, with the charge (as it was pretended) that only a certain number of copies should be printed. Mr Pope, in his excessive admiration of his guide, philosopher, and friend, took that opportunity, for fear so invaluable a treasure of patriotic eloquence should be lost to the public, to exceed his commission, and to run off more copies, which were found, after his death, in the printer's warehouse. This charge, however frivolous, was aggravated beyond measure; and, notwithstanding the proofs which Lord Bolingbroke, had received of Pope's devotion to him, enamoured with the utmost malignity. Mr Warburton thought it became him to vindicate his deceased friend; and he did it so effectually, as not only to silence his accuser, but to cover him with confusion."

About this time the publication of Dr Middleton's Inquiry concerning the miraculous Powers of the Christian church, gave rise to a controversy, which was managed with great warmth and asperity on both sides, and not much to the credit of either party. On this occa-

Mr Warburton published an excellent performance, Warburton, written with a degree of candour and temper, which, it is to be lamented, he did not always exercise. The title of it was "Julian; or a Discourse concerning the Earthquake and fiery Eruption which defeated that Emperor's attempt to rebuild the Temple at Jerusalem, 1750." A second edition of this discourse, "with Additions," appeared in 1751, in which year he gave the public his edition of Mr Pope's Works, with Notes, in nine volumes 8vo.; and in the same year printed "An Answer to a Letter to Dr Middleton, inserted in a Pamphlet intitled, The Argument of the Divine Legation fairly stated," &c.; and "An Account of the Prophecies of Arie Evans, the Welsh Prophet in the last Century," annexed to the first volume of Dr Jortin's Remarks on Ecclesiastical History, which afterwards subjected him to much trouble.

In 1752, Mr Warburton published the first volume of a course of sermons, preached at Lincoln's Inn, intitled, "The Principles of Natural and Revealed Religion, occasionally opened and explained;" and this was two years afterwards followed by a second. After the public had been some time promised, it may, from the alarm which was taken, be almost said threatened with the appearance of Lord Bolingbroke's Works, they were about this time printed. The known abilities and infidelity of this nobleman had created apprehensions in the minds of many people, of the pernicious effects of his doctrines; and nothing but the appearance of his whole force could have convinced his friends, how little there was to dread from arguments against religion so weakly supported. Many answers were soon published, but none with more acuteness, solidity, and spirit, than "A View of Lord Bolingbroke's Philosophy, in two Letters to a Friend, 1754;" the third and fourth letters were published in 1755, with another edition of the two former; and in the same year a smaller edition of the whole; which, though it came into the world without a name, was universally ascribed to Mr Warburton, and afterwards publicly owned by him. To some copies of this is prefixed an excellent complimentary epistle from the priest Montesquieu, dated May 26. 1754.

At this advanced period of his life, that preferment which his abilities might have claimed, and which had hitherto been withheld, seemed to be approaching towards him. In September 1754, he was appointed one of his majesty's chaplains in ordinary; and in the next year was presented to a prebend in the cathedral of Durham. About this time the degree of Doctor of Divinity was conferred on him by Dr Herring, then archbishop of Canterbury. A new impression of the Divine Legation being now called for, he printed a fourth edition of the first part of it, corrected and enlarged, divided into two volumes, with a dedication to the earl of Hardwicke. The same year appeared "A Sermon preached before his Grace Charles Duke of Marlborough, President, and the Governors of the Hospital for the Smallpox and for Inoculation, at the Parish-church of St Andrew, Holborn, April the 24th, 1755." And in 1756, Natural and Civil Events the Instruments of God's Moral Government; a Sermon, preached on the last public Fast-day, at Lincoln's Inn Chapel."
tract, entitled, *The Natural History of Religion*, filled the margin of the book, as well as some interleaved slips of paper, with many severe and shrewd remarks on the infidelity and naturalism of the author. These he put into the hands of his friend Dr Hurst, who, making a few alterations of the style, added a short introduction and conclusion, and published them in a pamphlet, entitled, "Remarks on Mr David Hume's Natural History of Religion, by a Gentleman of Cambridge, in a Letter to the Reverend Dr Warburton." This lively attack upon Mr Hume gave him so much offence, that he thought proper to vent his spleen on the supposed author, in the posthumous discourse which he called his *Life*; and thus to do greater honour to Dr Hurst than to any other of his numerous antagonists.

Towards the end of the year 1757, Dr Warburton was promoted to the deanship of Bristol; and in the beginning of the year 1765, he was, through Mr Allen's interest with Mr Pitt, afterwards earl of Chatham, advanced to the bishopric of Gloucester. That great minister is known to have declared, "that nothing of a private nature, since he had been in office, had given him so much pleasure as bringing our author on the bench." There was, however, another minister, who dreaded his promotion, and thought he saw a second Atterbury in the new bishop of Gloucester; but Warburton, says Bishop Hurst, had neither talents nor inclination for parliamentary intrigue or parliamentary eloquence: he had other instruments of fame in his hands, and was infinitely above the vanity of being caught

*With the fine notion of a busy man.*

He was consecrated on the 30th of January 1760, and on the 30th of the same month preached before the house of lords. In the next year he printed "A Rational Account of the Nature and End of the Sacrament of the Lord's Supper." In 1762, he published "The Doctrine of Grace; or the Office and Operations of the Holy Spirit vindicated from the Insults of Infidelity and the Abuses of Fanatism," 2 vols 12mo; and in the succeeding year drew upon himself much illiberal abuse from some writers of the popular party, on occasion of his complaint in the house of lords, on the 15th of November 1755, against Mr Wilkes, for putting his name to certain notes on the infamous "Essay on Woman."

In 1765 he published a new edition of the second part of the Divine Legation, in three volumes; and as it had now received his last hand, he presented it to his great friend Lord Mansfield, in a dedication which deserves to be read by every person who esteems the well-being of society as a concern of any importance. It was the appendix to this edition which produced the well-known controversy between him and Dr Lowth, which we have noticed elsewhere (see LOWTH), as doing no great honour, by the mode in which it was conducted, to either party. In the next year he gave a new and much improved edition of the Alliance between the Church and State. This was followed, in 1767, by a third volume of sermons, to which is added, his first *Trinual Charge to the Clergy of the Diocese of Gloucester*; which may be safely pronounced one of the most valuable discourses of the kind that is to be found in our own or any other language. With this publication he closed his literary course; except that he made an effort towards publishing, and actually printed, the ninth and last book of the Divine Legation. This book, with one or two occasional sermons, and some valuable directions for the study of theology, have been given to the world in the splendid edition of his works in seven volumes 4to, by his friend and biographer the present bishop of Worcester. That prelate confesses, that the ninth book of the Divine Legation displays little of that vigour of mind and fertility of invention which appear so conspicuous in the former volumes; but he adds, perhaps truly, that under all the disadvantages with which it appears, it is the noblest effort which has hitherto been made to give a *rationale* of Christianity.

While the bishop of Gloucester was thus exerting his last strength in the cause of religion, he projected a system by which he hoped to render it effectual after his death. He transferred 300 to Lord Mansfield, Sir Eardley Wilmot, and Mr Charles Yorke, upon trust, to found a lecture, in the form of a course of sermons, to prove the truth of revealed religion in general, and of the Christian in particular, from the completion of the prophecies in the Old and New Testament, which relate to the Christian church, especially to the apostasy of Papal Rome. To this foundation we owe the admirable Introductory Lectures of Hurst, and the well adapted Continuation of Halifax and Bagot.

It is a melancholy reflection, that a life spent in the constant pursuit of knowledge, frequently terminated in the loss of those powers, the cultivation and improvement of which are attended with too strict and unabated a degree of arduous. This was the case with Dr Warburton; and it seems probable that this decline of intellectual vigour was aggravated by the loss of his only son, a promising young man, who died of a consumption but a short time before the bishop, who himself resigned to fate in the year 1779, and in the 81st of his age. A neat marble monument was erected to his memory in the cathedral of Gloucester.

WARD, DR SETH, an English prelate, chiefly distinguished for his knowledge in mathematics and astronomy, was born at Huntingford in Hertfordshire, about the year 1617. He was admitted of Sidney college, Cambridge, where he applied with great vigour to his studies, particularly to the mathematics, and was chosen fellow of his college. He was much involved in the consequences of the civil war, but soon after the Restoration obtained the bishopric of Exeter; in 1667, he was translated to Salisbury; and in 1671 was made chancellor of the order of the Garter; he was the first Protestant bishop that enjoyed that honour, and he procured it to be annexed to the see of Salisbury. Bishop Ward was one of those unhappy persons who have the misfortune to survive their senses, which happened in consequence of a fever ill cured; he lived to the Revolution, without knowing any thing of the matter, and died in 1690. He was the author of several Latin works in mathematics and astronomy, which were thought excellent in their day; but their use has been superseded by later discoveries and the Newtonian philosophy.

WARD, is variously used in our old books: a ward in London is a district or division of the city, committed to the special charge of one of the aldermen; and in London there are 26 wards, according to the number of the mayor and aldermen, of which every one has
WAR [ 637 ]

Ward

Warden.

his ward for his proper guard and jurisdiction. A for-
rest is divided into wards; and a prison is called a ward.
Lastly, the heir of the king's tenant, that held in capite,
was termed a ward during his nonsense; but this ward-
ship is taken away by the statute 12 Car. II. c. 24.
WARD-Holding, in Scots Law. See Law, No. clxv.
1. and clxv. 3.
WARD-Hook, or Wadd-hook, in Gunner, a rod or
staff, with an iron end turned serpentwise, or like a
screw, to draw the wadding out of a gun when it is to
be unloaded.
WARDEN, or GUARDIAN, one who has the charge
or keeping of any person, or thing, by office. Such is
the warden of the Fleet, the keeper of the Fleet pris-
son; who has the charge of the prisoners there, especially
such as are committed from the court of chancery
for contempt.
WARDHUYS, a port of Norwegian Lapland, 120
miles south-east of the North Cape. E. Long. 31. 12.
N. Lat. 70. 23.
WARDMOTE, in London, is a court so called,
which is kept in every ward of the city; answering to
the curiata comitia of Rome.
WARDROBE, a closet or little room adjoining to
a bedchamber, serving to dispose and keep a person's
apparel in; or for a servant to lodge in, to be at hand
to wait, &c.
WARDROB, in a prince's court, is an apartment
wherein his robes, wearing apparel, and other necessa-
ries, are preserved under the care and direction of pro-
er officers.

In Britain, the Master or Keeper of the Great Ward-
robe was an officer of great antiquity and dignity.
High privileges and immunities were conferred on him
by King Henry VI. which were confirmed by his suc-
cessors; and King James I. not only enlarged them,
but ordained that this office should be a corporation or
body politic for ever.

It was the duty of this office to provide robes for the
royal coronations, marriages, and funerals of the royal
family; to furnish the court with hangings, cloths of state,
carpets, beds, and other necessaries; to furnish houses
for ambassadors at their first arrival; cloths of state,
and other furniture, for the lord lieutenant of Ireland,
and all his majesty's ambassadors abroad; to provide
all robes for foreign knights of the garter, robes for the
knights of the garter at home; robes and all other fur-
nishings for the officers of the garter; coats for kings,
heralds, and pursuivants at arms; robes for the lords of
the treasury, and chancellor of the exchequer, &c.; li-
very for the lord chamberlain, grooms of his majesty's
privy chamber, officer of his majesty's robes; for the
two chief justices, for all the barons of the exchequer,
and several officers of those courts; all livery for his
majesty's servants, as yeomen of the guard, and war-
dens of the Tower, trumpeters, kettle-drummers, and
fifes; the messengers, and all belonging to the stables,
as coachmen, footmen, liverymen, positions, and groom,
&c. all the king's coaches, chariots, harn-ses, saddles,
bats, bridles, &c. the king's watermen, game-keepers,
&c. also furniture for the royal yachts, and all rich em-
broidered silts, and other furniture for the harges.

Besides the master or keeper of the wardrobe, who
had a salary of 2000l. there was his deputy, who had
150l. and a comptroller and a patent clerk, each of,
whom had a salary of 200l. Besides many other infer-
ior officers and servants, who were all sworn servants
to the king.

There was likewise a removing wardrobe, who had
its own set of officers, and standing wardrobe-keepers at
St James's, Windsor Castle, Hampton Court, Kensing-
ton, and Somerset House; but the whole of the ward-
robe establishment was abolished by act of parliament
in 1789, and the duty of it in future to be done by the
lords chamberlain.

WARDSHIP, in chivalry, one of the incidents of
possession by knighthood. See feudal System, Knight
Service, and TENURE.

Upon the death of a tenant, if the heir was under the
age of 21, being a male, or 14, being a female, the
lord was intitled to the wardship of the heir, and was
called the guardian in chivalry. This wardship con-
sisted in having the custody of the body and lands of
such heir, without any account of the profits, till the
age of 21 in males, and 16 in females. For the law
supposed the heir's male unable to perform knight-service
less 21; but as for the female, she was supposed capable
at 14 to marry, and then her husband might perform
the service. The lord therefore had no wardship, if at
the death of the ancestor the heir's male was of the full
age of 21, or the heir's female of 14: yet if she was then
under 14, and the lord once had her in ward, he might
keep her so till 16, by virtue of the statute of Westmin-
ter, 1. 3 Edw. I. c. 22. the two additional years being
given by the legislature for no other reason but merely
to benefit the lord.

This wardship, so far as it relates to land, though it
was not nor could be part of the law of feudal, so long
as they were arbitrary, temporary, or for life only; yet
when they became hereditary, and did consequently of-
ten descend upon infants, who by reason of their age
could neither perform nor stipulate for the services of
the feud, does not seem upon feudal principles to have
been unreasonable. For the wardship of the land, or
custody of the feud, was retained by the lord, that he
might out of the profits thereof provide a fit person to
supply the infant's services till he should be of age to
perform them himself. And if we consider a feud in its
original import, as a stipend, fee, or reward for actual
service, it could not be thought hard that the lord should
withhold the stipend so long as the service was sus-
pected. Though undoubtedly to our English ancestors,
where such stipendary donation was a mere supposition
or figment, it carried abundance of hardship; and ac-
cordingly it was relieved by the charter of Henry I.
which took this custody from the lord, and ordained
that the custody, both of the land and the children,
should belong to the widow or next of kin. But this
noble immunity did not continue many years.

The wardship of the body was a consequence of the
wardship of the land; for he who enjoyed the infant's
estate was the properest person to educate and maintain
him in his infancy: and also in a political view, the
lord was most concerned to give his tenant a suitable
education, in order to qualify him the better to perform
those services which in his maturity he was bound to
render.

When the male heir arrived at the age of 21, or the
heir female at that of 16, they might sue out their li-
very or ouster lemain; that is the delivery of their lands.
WAR

WARSHIP out of their guardian's hands. For this they were obliged to pay a fine, namely, half-a-year's profits of the land; though this seems expressly contrary to *magna charta*. However, in consideration of their lands having been so long in ward, they were excused all reliefs, and the king's tenants also all primer seisin. In order to ascertain the profits that arose to the crown from these fruits of tenure, and to grant the heir his livery, the itinerant justices, or justices in eyre, had it formerly in charge to make inquisition concerning them by a jury of the county, commonly called an *inquisitio post mortem*; which was instituted to inquire (at the death of any man of fortune) the value of his estate, the tenure by which it was held, and who, and of what age, his heir was; thereby to ascertain the relief and value of the primer seisin, or the wardship and livery accruing to the king thereupon. A manner of proceeding that came in process of time to be greatly abused, and at length an intolerable grievance; it being one of the principal accusations against Empson and Dudley, the wicked engines of Henry VII, that by colour of false inquisitions they compelled many persons to sue out livery from the crown, who by no means were tenants thereunto. And afterwards a court of wards and livings was erected, for conducting the same inquiries in a more solemn and legal manner.

When the heir thus came of full age, provided he held a knight's fee, he was to receive the order of knighthood, and was compelled to take it upon him, or else pay a fine to the king. For in those heroic times no person was qualified for deeds of arms and chivalry who had not received this order, which was conferred with much preparation and solemnity. We may plainly discover the footsteps of a similar custom in what Tacitus relates of the Germans, who, in order to qualify their young men to bear arms, presented them in a full assembly with a shield and lance; which ceremony is supposed to have been the original of the feudal knighthood. This prerogative, of compelling the vassals to be knighted, or to pay a fine, was expressly recognised in parliament by the statute de millibus, 1 Edw. II.; was exerted as an expedient for raising money by many of our best princes, particularly by Edw. VI. and Queen Elizabeth; but this was the occasion of heavy murmurings when exerted by Charles I.; and among whose many misfortunes it was, that neither himself nor his people seemed able to distinguish between the arbitrary stretch and the legal exertion of prerogative. However, among the other concessions made by that unhappy prince before the fatal recourse to arms, he agreed to divest himself of this undoubted flower of the crown; and it was accordingly abolished by statute 16 Car. I. c. 20.

WARE, a town of Hertfordshire, with a market on Tuesdays, and a fair on the last Tuesday in April, and market day, and other cattle. It is a large, well-frequented town, seated on the river Lea, 21 miles north of London, and contained 3369 inhabitants in 1811. It carries on a great trade in malt and corn, which they are continually sending in large quantities to London. E. Long. c. 3. N. Lat. 51. 50.

WARN, in Law, is to summon a person to appear in a court of justice.

WARING of Tenants, in Scots Law. See Law, Warr. No. clxvii. 10.

WARP, in the manufactures, a name for the threads, whether of silk, wool, linen, hemp, &c. that are extended lengthwise on the weaver's loom; and across which the workman, by means of his shuttle, passes the threads of the woof, to form a cloth, ribbed, fustian, or the like.

WARP, a small rope employed occasionally to remove a ship from one place to another, in a port, road, or river. And hence,

To WARP, is to change the situation of a ship, by pulling her from one part of a harbour, &c. to some other, by means of warps, which are attached to buoys, or to anchors sunk in the bottom; or to certain stations upon the shore, as posts, rings, trees, &c. The ship is accordingly drawn forwards to those stations, either by pulling on the warps by hand, or by the application of some purchase, as a tackle, windlass, or capstan, upon her deck.

When this operation is performed by the ship's master, anchors, these machines, together with their warps, are carried out in the boats alternately towards the place where the ship is endeavouring to arrive: so that when she is drawn up close to one anchor, the other is carried out to a competent distance before her, and being sunk, serves to fix the other warp, by which she is farther advanced.

Warping is generally used when the sails are unburst, or when they cannot be successfully employed, which may either arise from the unfavourable state of the wind, the opposition of the tide, or the narrow limits of the channel.

WARRANT, in Scots Law. See Law, No. cxliv. 11.

WARRANT, is a power and charge to a constable or other officer to apprehend a person accused of any crime. It may be issued in extraordinary cases by the privy council, or secretaries of state; but most commonly it is issued by justices of the peace. This they may do in any cases where they have a jurisdiction over the offence, in order to compel the person accused to appear before them; for it would be absurd to give them power to examine an offender, unless they had also power to compel him to attend and submit to such examination. And this extends to all treasons, felony, and breaches of the peace; and also to all such offenders, as they have power to punish by statute. Before the granting of the warrant, it is fitting to examine upon oath the parts requiring it, as well as to ascertain that there is a felony or other crime actually committed, without which no warrant should be granted; as also to prove the cause and probability of suspecting the party against whom the warrant is prayed.

This warrant ought to be under the hand and seal of the justices; should set forth the time and place of making, and the cause for which it is made; and should be directed to the constable or other peace officer, or it may be to any private person by name. A general warrant to apprehend all persons suspected, without naming any particular or describing any person in special, is illegal and void for its uncertainty; for it is the duty of the magistrate, and ought not to be left to the officer, to judge of the ground of suspicion. Also a warrant to apprehend
WAR [ 639 ]
WAR

WARRANT, warrant. All persons guilty of such a crime, is no legal warrant; for the point upon which its authority rests, is a fact to be decided on a subsequent trial; namely, whether the person apprehended thereupon be guilty or not guilty. When a warrant is received by the officer, he is bound to execute it, so far as the jurisdiction of the magistrate and himself extends. A warrant from any of the justices of the court of king's bench extends over all the kingdom, and is sealed or dated Eng. and but a warrant from a justice of the peace in one county, must be backed, that is, signed, by a justice of another county, before it can be executed there. And a warrant for apprehending an English or Scotch offender, may be indorsed in the opposite kingdom, and the offender carried back to that part of the united kingdom in which the offence was committed.

WARRANTY, warrantia, in law, a promise, or covenant by deed, made by the bargainer for himself and his heirs, to warrant and secure the bargains and his heirs, against all actions, for enjoying the things agreed on or granted between them.

WARREN, sir Peter, an admiral, distinguished by his virtue, learning, and undaunted courage, was descended from an ancient family in Ireland, and received a suitable education to qualify him for a command in the royal navy, in which he served for several years with great reputation; but the transaction which placed his great abilities in their full light, was the taking of Louisbourg in the year 1745, when he was appointed commodore of the British squadron sent on that service. He joined the fleet of transports, from Boston in Canada, on the 25th of April, having under his command the Superb of 60, and the Launceston and Eltham of 40 guns; he was afterwards joined by several other men of war sent from England, and took possession of Louisbourg on the 17th of June. The French, exasperated at this loss, were constantly on the watch to retake it; and in 1747 fitted out a large fleet for that purpose, and at the same time another squadron to prosecute their success in the East Indies. These squadrons sailed at the same time; but the views of the French were rendered abortive by the gallant Admiral Anson and Sir Peter Warren, who had been created rear-admiral, who with a large fleet of ships fell in with the French, defeated the whole fleet, and took the greatest part of the men of war. This was the last service Sir Peter rendered to his country as a commander in the British fleet; for a peace being concluded in the succeeding year, the fleet was laid up in the several harbours.

He was now chosen one of the representatives in parliament for Westminster; and in the midst of his popularity he paid a visit to Ireland, his native country, where he died of an inflammatory fever in 1752, sincerely lamented by all ranks of people; and an elegant monument of white marble was erected to his memory in Westminster abbey.

WARREN, is a franchise or place privileged by prescription or grant from the king, for the keeping of beasts and fowls of the warren; which are hares and conies, partridges, pheasants, and some add quails, woodcocks, and water-fowl, &c. These being ferae nature, every one had a natural right to kill as he could: but upon the introduction of the forest laws at the Norman conquest, these animals being looked upon as royal game, and the sole property of our savage monarchs, this franchise of free-warren was invented to protect them, by giving the grantee a sole and exclusive power of killing such game, so far as his warren extended, on condition of his preventing other persons. A man therefore that has the franchise of warren, is in reality no more than a royal game-keeper; but no man, not even a lord of a manor, could by common law justify sporting on another's soil, or even on his own, unless he had the liberty of free-warren. This franchise is almost fallen into disregard since the new statutes for preserving the game; the name being now chiefly preserved in grounds that are set apart for breeding hares and rabbits. There are many instances of keen sportsmen in ancient times, who have sold their estates, and reserved the free-warren, or right of killing game, to themselves: by which means it comes to pass that a man and his heirs have sometimes free-warren over another's ground.

A warren may lie open; and there is no necessity of inclosing it as there is of a park. If any person offend in a free warren, he is punishable by the common law, and by statute 21 Edw. III. And if any one enter wrongly into any warren, and chase, take, or kill, any conies without the consent of the owner, he shall forfeit treble damage, and suffer three months imprisonment, &c. by 22 and 23 Car. II. c. 25. When conies are on the soil of the party, he hath a property in them by reason of the possession, and action lies for killing them; but if they run out of the warren and eat up a neighbour's corn, the owner of the land may kill them, and no action will lie.

WARSAW, a large city, capital of the province of Masovia, and of the ancient, as well as the revived kingdom of Poland. It is built partly in a plain, and partly on a gentle ascent rising from the banks of the Vistula, which is about as broad as the Thames at Westminster, but very shallow in summer. This city and its suburbs occupy a vast extent of ground, and contained in 1797, 70,000 inhabitants, among whom is a great number of foreigners. The whole has a melancholy appearance, exhibiting the strong contrast of wealth and poverty, luxury and distress. The streets are spacious, but ill paved; the churches and public buildings, and the palaces of the nobility are numerous and splendid; but the greatest part of the houses are mean and ill-constructed wooden hovels. — At the final division of Poland in 1795, Warsaw fell to the share of Prussia, but was ceded by her to Bonaparte at the peace of Tilsit in 1807; and on the overthrow of the French power, was assigned to Russia, with the territory named the duchy of Warsaw, which has since taken the name of the kingdom of Poland. E. Long. 21° 6' N. Lat. 52° 14'.

WARWICK, the capital of Warwickshire in England, and from which this county derives its name. It is very ancient, and supposed by Camden to be the place called by the Romans Præsidium, where the Dalmatian horse were posted. It stands on a rock of freestone, of which all the public edifices in the town are built. At the Norman invasion it was a considerable place; and had many burgesses, of whom 12 were obliged by their tenure to accompany the king in his wars. It is supplied with water brought in pipes from springs half a mile from the town, besides what it derives from the wells within it made in the rock: and it is easily kept clean, by being situated upon a declivity. Four streets, from the four cardinal points of the compass, meet in the centre of the town. The principal public buildings are
WAR [640] WAS

Warwick, St Mary's, a very stately edifice, an hospital, a town-house of freestone, three charity schools, and a noble bridge over the Avon. It has had several charters; but is governed at present by a mayor, 12 brethren, 24 burgesses, &c. It contained 6,497 inhabitants in 1811; and gives title of earl to the family of the Grevilles.

Warwickshire, a county of England, 47 miles in length, by 39 in breadth. It is bounded at its northern extremity by a point of Derbshire; on the north-west by Staffordshire; on the north-east by Leicestershire; on the east by Northamptonshire; on the south-west by Gloucestershire, and on the south-east by Oxfordshire. It is situated partly in the diocese of Lichfield and Coventry, and partly in that of Worcester; it contains four hundreds, and one liberty, one city, 12 market towns, 158 parishes; sends six members to parliament, and the population in 1811 amounted to 228,735. The air is mild, pleasant, and healthy. The river Avon divides the north part of it, or the Woodlands, from the south, called the Fledon; and the soil of both is rich and fertile. Its productions are corn, malt, wood, wool, cheese, coal, iron, and limestone. The chief rivers of this county are the Avon, Tame, and Arrow. Warwick is the capital; but Birmingham is far superior in it respect of trade and manufactures, and even to any other town in England.

Birmingham, in this county, of which the account in the order of the alphabet is very deficient, is one of the most remarkable towns in England, or perhaps in Europe for the extent, variety, elegance, and utility of its manufactures. This town was little distinguished previous to the reign of Charles II. but since that period it continued to increase in extent and importance. In the year 1700, the number of streets in Birmingham was only 30; they are now nearly 250. In the year 1779 there were only three houses on a particular spot, which in 1791 contained 833.

Birmingham owes its prosperity and population to its manufactures, which are in a great measure the consequence of its vicinity to coal, aided by the spirited and industrious exertions of a few individuals. It has been stated, and no doubt with great truth, that its prosperity is in no small degree indebted to its exemption from the restrictions of borough and corporate laws. To give some notion of the progress and extent of the manufactures of this place, it may be mentioned that the late Mr Taylor, who introduced gilt buttons, japanned, gilt, and painted snuff-boxes, with various articles of manufacture in enamel, died in 1775, at the age of 64, having amassed a fortune of 200,000l. In painting snuff-boxes at so low a rate as one farthing each, one man could gain 3l. 10s. per week. The weekly produce of Mr Taylor's manufacture of buttons amounted to 800. Beside many other valuable and curious productions.

The manufacture of Messrs Boulton and Watt, which for depth, variety, and importance, stands unrivalled in Europe, has been already noticed under the word Soho. The new coinage of copper, which is so often deservedly admired, and the re-stamped dollars, are the productions of the Soho manufacture. The first coining mill was erected at Soho in 1793. It is now so much improved, that eight machines driven by the steam engine, are going on at the same time. Each of those machines strikes from 70 to 84 pieces of the size of a guinea per minute, and hence the whole eight machines work off in one hour between 35,000 and 40,000 coins. The different processes of the machinery are: 1. Rolling the masses of copper into sheets. 2. Rolling them through cylindrical steel rollers. 3. Clipping the pieces of copper for the dye. 4. Shaking the coin in bags. 5. Striking both sides of the coin, and then milling it; after which it is displaced, and another is introduced, to be subjected to the same operation. But the most extraordinary contrivance of this ingenious machinery is, that a precise account of every coin which passes through it is regularly kept, so that it is impossible to practise fraud.

Beside the branches of industry already mentioned, there are manufactories of guns, bayonets, and swords, of sporting guns, of whips, of japan ware, of numerous works in brass and steel, both for ornament and use, and at one time of leather to a considerable extent.

Birmingham contains a museum of natural and artificial curiosities, a handsome theatre, rebuilt since 1796, several churches belonging to dissenting meeting houses, and a number of charitable establishments. By means of canals Birmingham has the advantage of easy communication with almost every part of the kingdom. See Warwickshire, Supplement.

WASH, among distillers, the fermentable liquor used by malt distillers. See BREWERY.

WASHING, in Painting, is when a design, drawn with a pen or crayon, has some one colour laid over it with a pencil, as Indian ink, bistre, or the like, to make it appear the more natural, by adding the shadow of prominences, apertures, &c. and by imitating the particular matters whereof the thing is supposed to consist. Thus a pale red is employed to imitate brick and tile; a pale Indian blue, to imitate water and slate; green, for trees and meadows; saffron or French berries, for gold or brass; and several colours for marbles.

Washing of Orce, the separation of the ores of metals, by means of water, from earths and stones, which would otherwise render it difficult of fusion. See Ores, Reduction of.

WASHINGTON, a city of North America, and now the metropolis of the United States. It is seated at the junction of the rivers Potomac and the Eastern Branch, extending about four miles up each, including a tract of territory scarcely to be exceeded, in point of convenience, salubrity, and beauty, by any in the world. This territory, which is called Columbia, lies partly in Virginia, and partly in Maryland, and was ceded by those two states to the Republic; it was placed under the immediate government of Congress, and established as the seat of government in the year 1800. It is divided into squares or grand divisions, by streets running due north and south, and east and west, which form the ground-work of the plan. However, from the Capitol, the president's house, and some of the important areas in the city, run diagonal streets, from one material object to another, which not only produce a variety of charming prospects, but remove the insipid sameness which renders some other great cities unpleasant. The great leading streets are all 150 feet wide, including a pavement of 10 feet, and a gravel walk of 20 feet, bordered with trees on each side, which will leave 80 feet of paved street for carriages. The rest of the streets are in general
expedition, which was attended with great difficulty, Washington
he exhibited so much calmness and intrepidity, that the utmost confidence was reposed in his talents, and perfect obedience paid to his commands by the whole army.
After having been employed in a different and more successful expedition, to the river Ohio, the state of his health required him, about the year 1758, to resign his military situation; and in the sixteen following years, during which period he married Mrs Custis, a Virginia lady, of amiable character and respectable connections, it would appear that he resided chiefly at his beautiful seat of Mount Vernon, and was occupied in the cultivation of his estate.

When the disaffection of the Americans to the British government had become pretty general, and had at last spread to the colony of Virginia, Colonel Washington was appointed a delegate from that state to the congress which met at Philadelphia on the 26th October 1774, and soon after he was appointed to the command of the American army, which had assembled in the provinces of New England. The conduct of Washington during the whole of the war, as well as during the period that he presided in the government of the United States, has been so fully detailed in another part of this work, that it would be unnecessary repetition, even to give a general outline of it in this place. See America.

Washington resigned the presidency in 1796, after having published a farewell address to his countrymen. This address was remarkably distinguished for the simplicity and ingenuity, moderation and sobriety, the good sense, prudence and honesty, as well as sincere affection for his country and for mankind, which the author of it had always exhibited; it seemed to be a perfect picture of his whole life. From the time of his resignation till the month of July 1798, he lived in retirement at his seat of Mount Vernon. At this period, when the unprincipled actors in the French revolution were carrying on their wicked machinations in every part of the world to which their influence extended, the United States resolved to arm by land and sea in their own defence. General Washington was called from his retirement, and the command of the army was bestowed upon him. This he accepted, because he considered, as he himself expressed it, "everything we held dear and sacred was seriously threatened, although he had flattered himself that he had quit for ever the boundless field of public action, incessant trouble, and high responsibility, in which he had long acted so conspicuously a part."

In this situation he continued during the remaining short period of his life. On Thursday the 12th of December 1799, he was seized with an inflammation in the throat, and was carried off on Saturday the 14th of the same month, in the 68th year of his age. In his dying moments he displayed the same calmness, simplicity, and regularity, which had uniformly marked his conduct through life. He saw the approaches of death without fear; and he met them without parade. Even the perfectly well ordered state of the minutest particulars of his private business bears the stamp of that constant authority of prudence and practical reason over his actions which was always the most prominent feature of his character.

WASHINGTON is the name of many counties, towns, and villages in the American states; a circumstance which affords a striking proof in what degree of esteem
W A T C H, in the art of war, a number of men posted at any passage, or a company of the guards who go on the patrol.

Watch, in the navy, the space of time wherein one division of a ship's crew remains upon deck, to perform the necessary services, whilst the rest are relieved from duty, either when the vessel is under sail or at anchor.

The length of the sea-watch is not equal in the shipping of different nations. It is always kept four hours by our British seamen, if we except the dog-watch, between four and eight in the evening, which contains two reliefs, each of which are only two hours on deck. The intent of this is to change the period of the night-watch every 24 hours; so that the party watching from eight till 12 in one night, shall watch from midnight till four in the morning on the succeeding one. In France the duration of the watch is extremely different, being in some places six hours, and in others seven or eight; and in Turkey and Barbary it is usually five or six hours.

A ship's company is usually divided into two parties; one of which is called the larboard and the other the starboard watch. It is, however, occasionally separated into three divisions, as in a road or in particular voyages.

In a ship of war the watch is generally commanded by a lieutenant, and in merchant ships by one of the mates; so that if there are four mates in the latter, there are two in each watch; the first and third being in the larboard, and the second and fourth in the starboard watch; but in the navy, the officers who command the watch usually divide themselves into three parties, in order to lighten their duty.

Watch is also used for a small portable movement, or machine, for the measuring of time; having its motion regulated by a spiral spring.

Watches, strictly taken, are all such movements as show the parts of time; as clocks are such as publish it, by striking on a bell, &c. But commonly the name watch is appropriated to such as are carried in the pocket; and clock to the large movements, whether they strike the hour or not. See Clock.

The invention of spring or pocket watches belongs to the present age. It is true, we find mention made of a watch presented to Charles V. in the history of that prince; but this, in all probability, was more than a kind of clock to be set on a table, some resemblance whereof we have still remaining in the ancient pieces made before the year 1670. There was also a story of a watch having been discovered in Scotland belonging to King Robert Bruce; but this we believe has turned out altogether apocryphal. The glory of this very useful invention lies between Dr Hooke and Mr. Huygens; but to which of them it properly belongs has been greatly disputed; the English ascribing it to the former, and the French, Dutch, &c. to the latter. Mr Derham, Hoekewas the inventor; and adds, that he contrived

were divers sorts; some having a spiral spring to the balance for a regulator, and others without. But the way that prevailed, and which continues in mode, was with one balance, and one spring running round the upper part of the verge thereof: Though this has a disadvantage, as those with two springs, &c. were free from, in that a sudden jerk, or confused shake, will alter its vibrations, and put it in an unusual hurry.

The time of these inventions was about the year 1658; as appears among other evidences, from an inscription on one of the double balance watches presented to King Charles II. viz. Rob. Hooke inv. 1658. T. Tompion fecit, 1675. The mention presently got into reputation, both at home and abroad; and two of them were sent for by the dauphin of France. Soon after his M. Huygens's watch with a spiral spring got abroad, and made a great noise in England, as if the longitude could be found by it. It is certain, however, that his invention was later than the year 1673, when his book de Horlo. Oscillat. was published; in which he has not one word of this, though he has of several other contrivances in the same way.

One of these the lord Brunner sent for out of France, where M. Huygens had got a patent for them. This watch agreed with Dr Hooke's in the application of the spring to the balance; only M. Huygens had a longer spiral spring, and the pulses and beats were much slower. The balance, instead of turning quite round, as Dr Hooke's, turns several rounds every vibration.

Mr Derham suggests, that he has reason to doubt M. Huygens's fancy first was set to work by some intelligence he might have of Dr Hooke's invention from Mr Oldenburgh, or some other of his correspondents in England; and this, notwithstanding Mr Oldenburgh's attempt to vindicate himself in the Philosophical Transactions, appears to be the truth. Huygens invented divers other kinds of watches, some of them without any string or chain at all; which he called, particularly, pendulum watches.

Striking Watches are such as, besides the proper watch-part for measuring of time, have a clock part for striking the hours, &c.

Repeating Watches, are such as by pulling a string, &c. repeat the hour, quarter, or minute, at any time of the day or night. This repetition was the invention of Mr Barlow, and first put in practice by him in larger movements or clocks about the year 1676. The contrivance immediately set the other artists to work, who soon contrived divers ways of effecting the same. But its application to pocket-watches was not known before King James II.'s reign; when the ingenious inventor above mentioned, having directed Mr Thompson to make a repeating watch, was soliciting a patent for the same. The talk of a patent engaged Mr Quarre to resume the thoughts of a like contrivance, which he had had in view some years before: he now effected it; and being pressed to endeavour to prevent Mr Barlow's patent, a watch of each kind was produced before the king and council; upon trial of which, the preference was given to Mr Quarre's. The difference between them was, that Barlow's was made to repeat by pushing in two pieces on each side the watch-box; one of which repeated the hour, and the other the quarter; whereas Quarre's was made to repeat by a pin that struck out near the pendant, which being thrust in (as
W A T (643)

Watch. now it is done by thrusting in the pendulum itself, repeated both the hour and quarter with the same thrust.

Of the Mechanism of a Watch, properly so called.

Watches, as well as clocks, are composed of wheels and pinions, and a regulator to direct the quickness or slowness of the wheels, and of a spring which communicates motion to the whole machine. But the regulator and spring of a watch are vastly inferior to the weight and pendulum of a clock, neither of which can be employed in watches. In place of a pendulum, therefore, we are obliged to use a balance (fig. 1.) to regulate the motion of a watch; and a spring (fig. 2.) which serves in place of a weight, to give motion to the wheels and balance.

The wheels of a watch, like those of a clock, are placed in a frame formed of two plates and four pillars. Fig. 3. represents the inside of a watch, after the plate (fig. 4.) is taken off. A is the barrel which contains the spring (fig. 2.); the chain is rolled about the barrel, with one end of it fixed to the barrel A (fig. 5.), and the other to the fusee B.

When a watch is wound up, the chain which was upon the barrel winds about the fusee, and this means the spring is stretched; for the interior end of the spring is fixed by a hook to the immovable axis, about which the barrel revolves; the exterior end of the spring is fixed to the inside of the barrel, which turns upon an axis. It is therefore easy to perceive how the spring extends itself, and how its elasticity forces the barrel to turn round, and consequently obliges the chain which is upon the fusee to unfold and turn the fusee; the motion of the fusee is communicated to the wheel C (fig. 5.) then, by means of the teeth, to the pinion c, which carries the wheel D; then to the pinion d, which carries the wheel E: then to the pinion e, which carries the wheel F; then to the point f, upon which is the balance-wheel G, whose pivot runs in the pieces A called the potance, and B called a follower, which are fixed on the plate fig. 4. This plate, of which only a part is represented, is applied to that of fig. 3. in such a manner that the pivots of the wheels enter into holes made in the plate fig. 3. Thus the impressed force of the spring is communicated to the wheels, and the pinion f being then connected to the wheel F, obliges it to turn (fig. 5.). This wheel acts upon the pinions of the verge, r, 2, (fig. 1.), the axis of which carries the balance H (fig. 1.). The pivot I, in the end of the verge, enters into the hole c in the potance A (fig. 4.). In this figure the pinions are represented; but the balance is on the other side of the plates, as may be seen in fig. 6. The pivot 3 of the balance enters into a hole of the cock BC (fig. 7.), a perspective view of which is represented in fig. 8. Thus the balance turns between the cock and the potance c (fig. 4.) as in a kind of cage. The action of the balance wheel upon the pinions 1, 2, (fig. 1.), is the same with what we have described with regard to the same wheel in the clock; i.e. in a watch, the balance wheel obliges the balance to vibrate backwards and forwards like a pendulum. At each vibration of the balance a palette allows a tooth of the balance-wheel to escape; so that the quickness of the motion of the wheels is entirely determined by the quickness of the vibrations of the balance; and these vibrations of the balance and motion of the wheels are produced by the action of the spring.

But the quickness or slowness of the vibrations of the balance depend not solely upon the action of the great spring, but chiefly upon the action of the spring a, b, c, called the spiral spring (fig. 9.), situated under the balance H, and represented in perspective (fig. 6.). The interior end of the spiral is fixed to the pin a, (fig. 9.). This pin is applied near the plate in a, (fig. 6.) the interior end of the spiral is fixed by a peg to the centre of the balance. Hence if the balance is turned up itself, the plates remaining immovable, the spring will extend itself, and make the balance perform one revolution. Now, after the spiral is thus extended, if the balance be left to itself, the elastic force of the spiral will bring back the balance, and in this manner the alternate vibrations of the balance are produced.

In fig. 5. all the wheels above described are represented in such a manner, that you may easily perceive at first sight how the motion is communicated from the barrel to the balance.

In fig. 10. are represented the wheels under the dial plate by which the hands are moved. The pinion a is adjusted to the force of the prolonged pivot of the wheel D (fig. 5.), and is called a compass pinion. This wheel revolves in an hour. The end of the axis of the pinion a, upon which the minute-hand is fixed, is square; the pinion (fig. 10.) is indented into the wheel b, which is carried by the pinion a. Fig. 11. is a wheel fixed upon fig. 11. a barrel, into the cavity of which the pinion a enters, and upon which it turns freely. This wheel revolves in 12 hours, and carries along with it the hour-hand. For a full account of the principles upon which watches and all time-keepers are constructed, we must refer our readers to a short treatise, entitled Thoughts on the Means of improving Watches, by Dr. T.}

W A T  (643)

Watch-Glasses, in a ship, are glasses employed to measure the period of the watch, or to divide it into any number of equal parts, as hours, half-hours, &c. so that the several stations therein may be regularly kept and relieved, as at the helm, pump, look-out, &c.

W A T H  W o r k. There is one part of the movements of clocks and watches of which we have yet given no particular account. This is the method of applying the maintaining power of the wheels to the regulator of the motions, so as not to injure its power of regulation. This part of the construction is called Scapement, and falls to be described under the present article, to which we have referred from Scapement.

The motions of a clock or watch are regulated by Objects a pendulum or balance, without which check the wheels of scapemeants. Impelled by the weight in the clock, or spring in the watch, would run round with a rapidly accelerating motion, till this should be rendered uniform by friction, and the resistance of the air. If, however, a pendulum or balance be put in the way of this motion, in such a manner that only one tooth of a wheel can pass, the revolution of the wheels will depend on the vibration of the pendulum or balance.

We cannot here enter on an historical account of the improvements that have been made on the regulating powers of clocks and watches, nor can we detail the principles on which their action depends. It will be sufficient here to notice the most simple construction of scapements, and then to describe two or three of the most improved constructions that have been applied to time-keepers.

We know that the motion of a pendulum or balance
Watch is alternate, while the pressure of the wheels is constantly exerted in the same direction. Hence it is evident that some means must be employed to accommodate these different motions to each other. Now, when a tooth of the wheel has given the pendulum or balance a motion in one direction, it must quit it, that the pendulum or balance may receive an impulsion in the opposite direction. This escape of the tooth has given rise to the term *scapement*.

The ordinary scapement is extremely simple, and may be thus illustrated. Let ABC, fig. 13, represent a horizontal axis, to which the pendulum p is attached by a slender rod. This axis has two leaves a and d, one near each end, and not in the same plane, but so that when the pendulum hangs perpendicularly at rest, it spreads a few degrees to the right, and d as much to the left. These are called the pallets. Let A, B represent a wheel, turning on a perpendicular axis e f in the order a f b. The teeth of this wheel are in the form of those of a saw, leaning forward in the direction of the rim's motion. This wheel is usually called the crown-wheel, or in watches the balance-wheel. See CLOCK and WATCH. It generally contains an odd number of teeth. In the figure the pendulum is represented at the extremity of its excursion towards the right, the tooth a having just escaped from the pallet c, and b having just dropped on d. Now it is evident that while the pendulum is moving to the left, in the arch pg, the tooth b still presses on the pallet d, and thus accelerates the pendulum, both in its descent along p a, and its ascent up h g, and that when d, by turning round the axis x y, raises its point above the plane of the wheel, the tooth b escapes from it, and d drops on c, now nearly perpendicular. Thus c is pressed to the right, and the motion of the pendulum along f p is accelerated.

Again, while the pendulum hangs perpendicularly in the line x a, the tooth b, by pressing on d, will force the pendulum to the left, in proportion to its weight, and if it be not too heavy, will force it so far from the perpendicular, that b will escape, and s will catch on c, and force the pendulum back to p, when the same motion will be repeated. This effect will be more remarkable, if the rod of the pendulum be continued through x y, and have a ball q on the other end, to balance p. When b escapes from d, the balls are moving with a certain velocity and momentum, and in this condition the balance-wheel is checked when it catches on c. It is not, however, instantly stopped, but continues to move a little to the left, and s is forced a little backward by the pallet c. It cannot make its escape over the top of the tooth s, as all the momentum of the balance was generated by the force of b, and s is of equal power. Besides, when s catches on c, and the motion of c to the left continues, the lower point of c is applied to the face of s, which now acts on the balance by a long lever, soon stops its motion in that direction, and continuing to press on c, urges the balance in the opposite direction. It is easy to see that the motion of the wheel here must be hobbing and unequal, which has given this scapement the name of the reclining scapement.

In considering the utility of the following improved scapement for clocks, we must keep in mind the following proposition, which, after the above illustration, scarcely requires any direct proof. It is, that the natural vibrations of a pendulum are *isochronous*, or are performed in equal times. The great object of the scapement, however, is to preserve this isochronous motion of the pendulum.

As the defect of the reclining scapement was long apparent, several ingenious artists attempted to substitute in its place a scapement that should produce a more perfect, regular, and uniform motion. Of these, the scapement contrived by Mr. Cumming appears to be one of the most ingenious in its construction, and most perfect in its operation. The following construction is similar to that of Mr. Cumming, but rendered rather less complex for the purpose of shortening the description.

Let ABC, fig. 13, represent a portion of the swing-wheel, of which O is the centre, and A one of the teeth; Z is the centre of the crutch, pallets, and pendulum. The crutch is represented of the form of the letter A, having in the circular cross piece a slit k, also circular, Z being the centre. The arm ZE forms the first detent, and the tooth A is represented as locked on it at E. D is the first pallet on the end of the arm Z d movably round the same centre with the detents, but independent of them. The arm d to which the pallet D is attached, lies wholly behind the arm ZE of the detent, being fixed to a round piece of brass having pivots turning concentric with the axis of the pendulum. To the same piece of brass is fixed the horizontal arm e H, carrying to its extremity the ball H of such size, that the action of the tooth A on the pallet D is just able to raise it up to the position here drawn. ZF p represents the fork, or pendulum rod, behind both detent and pallet. A pin p projects forward, coming through the slit i k, without touching either margin of it. Attached to the fork is the arm m n, of such length that, when the pendulum rod is perpendicular, the angular distance of the left side of the pin p from the left end i of the slit i k.

Now, the natural position of the pallet D is at k, represented by the dotted lines, resting on the back of the detent F. It is naturally brought into this position by its own weight, and still more by the weight of the ball H. The pallet D, being set on the foreside of the arm at Z, comes into the same plane with the detent F and the swing-wheel, though here represented in a different position. The tooth C of the wheel is supposed to have escaped from the second pallet, on which the tooth A immediately seizes the pallet D, situated at 1, forces it out, and then rests on the detent E, the pallet D leaning on the tip of the tooth. After the escape of C, the pendulum, moving down the arch of semivibration, is represented as having attained the vertical position. Proceeding still to the left, the pin p reaches the extremity i of the slit i k; and, at the same instant, the arm n touches the rod e H in q. The pendulum proceeding a hairbreadth further, withdraws the detent F from the tooth, which now even pushes off the detent, by acting on the inclining face of it. The wheel being now unlocked, the tooth following C on the other side sets on its pallet, pushes it off, and rests on its detent, which has been rapidly brought into a proper position by the action of A on the inclining face of E. By a similar action of C on its detent at the moment of escape, it was brought into a position proper for the wheels being locked by the tooth A. As the pendulum still goes on, the ball H, and pallet connected with it, are carried by the arm m n, and before the pin p again reaches the end.
end of the slit, which had been suddenly withdrawn by
the action of A on F, the pendulum comes to rest. It
now returns towards the right, loaded with the ball H
on the left, and thus the motion lost during the last vi-
briation is restored. When the pin p, by its motion to
the right, reaches the end k of i k, the wheel on the
right is unlocked, and at the same instant the weight
H being raised from the pendulum by the action of a
tooth like B on the pallet D, ceases to act.

In this scapement, both pallets and detents are de-
tached from the pendulum, except in the moment of un-
locking the wheel, so that, except during this short in-
terval, the pendulum may be said to be free during its
whole vibration, and of course its motion must be more
equable and undisturbed.

The constructing of a proper scapement for watches
requires peculiar delicacy, owing to the small size of the
machine, from which the error of \( \pi \) of an inch has as
much effect as the error of a whole inch in a common
clock. From the necessary lightness of the balance, too,
it is extremely difficult to accumulate a sufficient quan-
tity of regulating power. This can be done only by
giving the balance a great velocity, which is effected by
concentrating as much as possible of its weight in the
rim, and making its vibrations very wide. The balance
rim of a tolerable watch should pass through at least ten
inches in every second.

In considering the most proper scapements for watches,
we may assume the following principle, viz. that the
oscillations of a balance urged by its spring, and undi-
sturbed by extraneous forces, are isochronous.

In ordinary pocket watches, the common recoil-
scapement of clocks is still employed, and answers the
common purposes of a watch tolerably well, so that, if
properly executed, a good ordinary watch will keep time
within a minute in the day. These watches, however,
are subject to great variation in their rate of going, from
any change in the power of the wheels.

The following is considered as the best construction of
the common watch scapement, and is represented by
fig. 14. as it appears when looking straight down on the
end of the balance arbor. C marks the centre of the
balance and verge; CA represents the upper pallet, or
that next the balance, and CB the lower pallet; F and
D are two teeth of the crown wheel, moving from left
to right; E and G are two teeth in the lower part, moving
from right to left. The tooth D appears as having just
escaped from the point of CA, and the tooth E as
having just come in contact with CB. In practice, the
scapement should not be quite so close, as by a small in-
equality of the teeth, D might be kept from escaping at
all. The following are thought the best proportions:

The distance between the front of the teeth (that is, of
G, F, E, D), and the axis C of the balance, is \( \frac{2}{3} \) of FA,
the distance between the points of the teeth. The
length CA, CB of the pallets is \( \frac{1}{2} \) of the same degree,
and the distance DH or FK of the teeth makes an angle
of 30° with the axis of the crown wheel. The sloping
side of the tooth must be of an epicycloidal form, suited
to the relative motion of the tooth and pallet.

It appears from these proportions, that by the action of
the tooth D, the pallet A can throw out till it reach
a, 120° from CL, the line of the crown-wheel axis. To
this if we add BCA = 95°, we shall have LC = 125°.
Again, B will throw out as far on the other side.

Now, if from 240°, the sum of the extent of vibration
of both pallets, we take 95° the angle of the pallets,
the remainder 145° will express the greatest vibration
which the balance can make, without striking the front
of the teeth. From several causes, however, this mea-
sure is too great, and 120° is reckoned a sufficient vi-
briation in the best ordinary scapement.

Of the improvements on the scapements of watches, Graham's
one of the most important is that by Mr George Graham, for
horizontal scapement, which we shall proceed to describe. DE, fig. 15. re-
presents part of the rim of the balance wheel; A and
C, two of its teeth with their faces b e formed into
planes, inclined to the circumference of the wheel in an
angle of about 15°, so that the length be of the face
may be nearly quadruple of its height. em. Let a cir-
cular arc ABC be described round the centre of the
wheel, and through the middle of the faces of the teeth.
The axis of the balance will pass through some point B
of this arch, and the mean circumference of the teeth
may be said to pass through the centre of the verge. On
this axis is fixed a portion of a thin hollow cylinder bcd,
made of hard tempered steel, or of some hard and tough
stone, such as ruby or sapphire. By this construction
the portion of the cylinder occupies 210° of the circum-
ference. The edge b, to which the tooth approaches
from without, is rounded off on both edges. The
other edge d is formed into a plane, inclined to the ra-
dius about 30°. Now, suppose the wheel pressed for-
ward in the direction AC, the point b of the tooth,
touching the rounded edge, will push it outwards, turn-
ring round the balance in the direction bcd. The
heel e of the tooth will escape from this edge when it is
in the position h, and e is in the position f. The point b
of the tooth will now be at d, but the edge of the cy-
linder will be at f. The tooth therefore rests in the in-
side of the cylinder, while the balance continues its vi-
briation in a little way, in consequence of the impulse it
has received from the action of the inclined plane.

When this vibration is ended, by the opposition of the
balance spring, the balance will return, and the tooth
now in the position B, rubbing on the inside of the cy-
linder, the balance comes back into its natural position
dc, with an accelerated motion by the action of its
spring, and would of itself vibrate as far as the other
side. It is, however, assisted again by the tooth, which
presses on the edge d, pushes it aside till it attain the po-
position k, when the tooth entirely escapes from the cy-
linder. At this instant the other edge of the cylinder,
having attained the position l, is in the way of the next
tooth, which is now in the position A, while the balance
continues its vibration, the tooth resting and rubbing on
the outside of the cylinder. When this vibration is fin-
ished, the balance, by the action of the spring, resumes its
first motion, and as soon as the balance gets into its na-
tural position, the tooth begins to act on the edge b,
pushes it aside, escapes from it, and drops as before in the
inside of the cylinder. In this manner the arch of ac-
don of action or scapement is 30° or twice the angle
which the face of a tooth makes with the circumference.

It is necessary to explain how the cylinder is con-
ected with the verge, so as to make such a great revolu-
tion round the tooth of the wheel. The triangular tooth
b e m is placed on the top of a little pillar fixed into
the end of the piece of brass m D formed in the rim of
the wheel. Thus the plane of the wedge tooth is pa-
relad
Watch.

The verge is represented at fig. 16, and consists of a long hollow cylinder of cast steel, having a great portion of the metal cut out. If spread out flat, this cylinder would assume the form of fig. 17; and if we conceive this flat piece rolled up till the edges G H unite, we shall have the exact form.

The part acted on by the point of the tooth is denoted by the dotted line d.d. and the part D, I, F, E serves to connect the two ends.

This scapement of Mr. Graham is called a horizontal scapement, because the balance is parallel to the other wheels.

Another scapement of a superior construction was contrived by M. Lepaute of Paris, and is of such a singular form as to render it extremely difficult to illustrate it by a figure. The representations at fig. 18. and 19, will, however, give general readers some idea of its mode of action, and a skilful artist will easily see how the several parts may be adapted to each other. ABC fig. 18. represents part of the rim of the balance wheel, having the pins 1, 2, 3, 4, 5, &c., projecting from its faces; the pins 1, 3, 5, being on the side next the eye, and the pins 2 and 4 on the opposite side. D is the centre of the balance and verge, and the small circle round D represents its thickness. But the verge in this place is crooked, that the rim of the wheel may not be intercepted by it. To it is attached a piece of hard tempered steel a b c d, of which the parts a b c is a concave arch of a circle, having D for its centre. It wants about 30° of a semicircle. The rest of c is also an arch of a circle having the same radius with the balance-wheel. In the natural position of the balance, a line drawn from D, through the middle of the face c d, is a tangent to the circumference of the wheel. But if the balance be turned round till the point of the horn come to d', and the point of the D comes to 2, the circle in which the pins are placed, the pin pressing on the beginning of the horn or pallet, pushes it aside, slides along it, and escapes at d', having generated a certain velocity in the balance. Let another pallet similar to that now described be placed on the other side of the wheel, but in a contrary position, with the acting face of the pallet turned away from the centre of the wheel.

Let it be placed at E, that the moment the pin 1 on the upper side of the wheel escapes from the pallet c d, the pin 4 on the lower side of the wheel falls on the end of the circular arch e f g of the other pallet. Now, if the pallets be connected by equal pulleys G and F on the axis of each, and a thread round both so that they shall turn one way, the balance on the axis D having received an impulse from the pin 1, will continue its motion from A towards i, and will carry the other pallet with a similar motion round the centre E from h to k. The pin 4 will therefore rest in the concave arch g f e as the pallet turns round. When the force of the balance is spent, the pallet c d returns towards its first position. The pallet arrived at h, the beginning of g of the other arrives at the pin concave arch e f g, and slides along the pallet g h, pushing the centre E, and the balance on the axis D round at the same time, and in the same direction. The pin 4 escapes from the pallet g h, when h arrives at 3; but while the pin 4 is sliding along the yielding pallet g h, the pin 1 is moving in the circumference B D A; and the instant that the pin 4 escapes from h at 3, the pin 3 arrives at 2, where the beginning c of the concave arch e b c is ready to receive it. It therefore rests on this arch, while the balance continues its motion, and this may continue till the point d of the arch comes to 2. The balance now stops, its force being spent, and then returns; and the pin 3 escapes from the circle at a, slides along the yielding pallet c d, and when it escapes at 1, another pin at the lower side of the wheel arrives at 4, and finds the arch g f e ready to receive it. And thus the vibration of the balance will be continued.

From the above description we may deduce the proper dimensions of the parts of the pallet. Thus, the length of the pallet c or g h, must be equal to the interval between two succeeding pins, and the distance of the centres D E, must be double of that interval. The radius D e or F g, may be as small as we choose. The concave arches e b a and b g f, must be continued so as to allow a pin to rest on them during the whole excursion of the balance. The angle of scapement, in which the balance remains under the influence of the wheels, is obtained by drawing the lines d e and D g, and we shall find that this angle c D d is here about 5°, though it may be made either greater or less than this.

Fig. 19. explains how the two pallets may be combined on one verge. KL is the verge with a pivot at each end. It is bent like a crank M N O, to admit the balance wheel between its branches. BC represents this wheel, seen edgewise, with its pin alternately on different sides. The pallets are also represented by bed and g h f, sized to the inside of the branches of the crank, forming each other. The position of their acting faces may be seen in the preceding figure, on the verge D, where the pallet g h is represented by the dotted line 2, as situated behind the pallet c d. The remote pallet 2 i is so placed, that when the point d in the near pallet is quitted by a pin 1 on the upper side of the wheel, the angle formed by the face and the arch of rest of the other pallet is just ready to receive the next pin 2, which lies on the lower side of the rim. It is plain that the action hereafter will be the same as if the pallets were on separate axes. The pin 1 escapes from d, and the pin 2 is received on the arch of rest, and locks the wheel, while the balance continues in motion. When the balance returns, 2 gets off the arch of rest, pushes aside the pallet 2 i, escapes from it when i gets to 1, and then the pin 3 is ready to receive the pin 3, &c. The vibrations may be increased by giving a sufficient impulse through the angle of scapement, but they cannot exceed a certain quantity, otherwise N, the top of the crank, would strike the rim of the wheel. The vibrations may be easily increased to 180°, by placing the pins at the very edge of the wheel; and by placing them at the points of long teeth, so that the crank may get in between them, the vibrations may be carried to a much greater extent.

The construction just described is exceedingly ingenious; and if the machinery be well executed, the scapement will exceed the horizontal scapement of Graham, both as it has but two acting faces to form, and as it admits of making the circle of rest extremely small, without lessening the action face of the pallet. The construction is, however, very delicate and difficult, and must require a very nice workman.
An excellent scapement of much more easy construction, is that commonly called Duplais's scapement, and with this we shall conclude our account of watch-work. Fig. 20. represents the essential parts somewhat magnified. AD a portion of the balance-wheel, having teeth j, h, g, at the circumference. These teeth are for producing the rest of the wheel, while the balance is making excursions beyond the scapement. This is effected by an agate cylinder s p g, on the verge. This cylinder has a notch o. When the cylinder turns round in the direction b p a, the tooth B which is resting on the cylinder surface; but when it returns in the direction b p o, the tooth B gets into the notch and follows it, pressing on one side of it till the notch comes into the position o. The tooth being then in the position k, escapes from the notch, and another tooth drops on the convex surface of the cylinder at B. The balance-wheel is also furnished with a set of flat-sided pins, standing upright on its rim represented by a D. There is likewise fixed on the verge a larger cylinder G F C of steel or copper, on one a O, with its lower surface clear of the wheel, and having a pallet C, of sapphire, firmly indented in it, and projecting so far as to keep clear of the pins on the wheel. The position of this cylinder, with respect to the smaller one below it, is such that the tooth b being escaped from the notch, the pallet C has just past the pin a, which was at A while B rested on the small cylinder; but it moved from A to a, while B moved to b. The wheel being now at liberty, the pin a exerts its pressure on the pallet C in the most direct manner, and gives it a strong impulse, following and accelerating it till another tooth stops on the little cylinder. The angle of scapement depends partly on the projection of the pallet, and partly on the diameter of the small cylinder, and the advance of the tooth B into the notch. Independent of the action on the small cylinder, the angle of scapement would be the whole arch of the large cylinder between C and a. But stops before it be clear of the pallet, and the arch of impulsion is shortened by all the space described by the pin while a tooth moved from B to b. It stops at d.

For an account of other scapements we must refer our readers to the Memoirs of the Academy of Sciences at Paris for 1748, Cummin's Elements of Clock and Watch-work, a French work entitled Machines approuvées par l'Académie des Sciences, and Young's Lectures on Natural Philosophy, vol. i. p. 193, and Plate 16, vol. ii. p. 193.

WATCHING, in Medicine, is when the patient cannot sleep. In fevers it is a dangerous symptom, and if long continued ends in a delirium.

WATER, a well-known fluid, diffused through the atmosphere, and over the surface of the globe, and abounding in a certain proportion in animals, vegetables, and minerals.

The uses of water are so universally known, that it would be superfluous to enumerate them in this article. It is essential to animal and vegetable life; it makes easy the intercourse between the most distant regions of the world; and it is one of the most useful powers in the mechanic arts. It is often found combined with various substances, and is then frequently beneficial in curing or alleviating diseases.

Those properties of water which fit it for answering mechanical purposes are explained in other articles of this work (see Hydrodynamics, Pneumatics, No. 3, Resistance, and Rivers); and for the discovery of the composition of water, see Chemistry Index.

Mineral Waters. For the method of analysing them, see also Chemistry Index.

Under the title of Mineral Waters, we have given an analysis of the most remarkable waters in Europe.

Holy Water, which is made use of in the church of Rome, as also by the Greeks, and by the other Christians of the East of all denominations, is water with a mixture of salt, blessed by a priest according to a set form of benediction. It is used in the blessing of persons, things, and places; and is likewise considered as a ceremony to excite pious thoughts in the minds of the faithful.

The priests, in blessing it, first, in the name of God, commands the devils not to hurt the persons who shall be sprinkled with it, nor to abuse the things, nor disorder the places, which shall likewise be so sprinkled: He then prays that health, safety, and the favour of heaven, may be enjoyed by such persons, and by those who shall use such things, or dwell in such places. Vestments, vessels, and other such things that are set apart for divine service, are sprinkled with it. It is sometimes sprinkled on cattle, with an intention to free or preserve them from diabolical enchantments; and in some spiritual books there are prayers to be said on such occasions, by which the safety of such animals, as being a temporal blessing to the possessors, is begged of God, whose providential care is extended to all his creatures. The hope which Catholics entertain of obtaining such good effects from the devout use of holy water, is grounded on the promise made to believers by Christ (St. Mark xvi. 17.), and on the general efficacy of the prayers of the church; the petition of which prayers God is often pleased to grant; though sometimes, in his Providence, he sees it not expedient to do so. That such effects have been produced by holy water in a remarkable manner, has been asserted by many authors of no small weight; as, namely, by St. Epiphanius, Haer. 50th; St. Hieron. in the Life of St. Hilarion; Theod. Hist. Eccl. lib. v. cap. 21.; Palladius, Hist. Laws.; Bede, lib. v. cap. 4.

As a ceremony (says the Catholic), water brings to our remembrance our baptism; in which, by water, we were cleansed from original sin. It also puts us in mind of that purity of conscience which we ought to endeavour always to have, but especially when we are going to worship our God. The salt, which is put into the water to preserve it from corrupting, is also a figure of divine grace, which preserves our souls from the corruption of sin; and is likewise an emblem of that wisdom and discretion which ought to season every action that a Christian does, and every word that he says. It is wont to be blessed and sprinkled in churches on Sundays, in the beginning of the solemn office. It is kept in vessels at the doors of the same churches, that it may be taken by the faithful as they enter in. It is also often kept in private houses and chambers.

Putrid Water, is that which has acquired an offensive smell and taste by the putrefaction of animal or vegetable substances contained in it. It is in the highest degree noxious to the human frame, and capable of bringing on mortal diseases even by its smell. It is not always from the apparent muddiness of waters that we can.
can judge of their disposition to putrefy; some which are seemingly very pure, being more apt to become putrid than others which appear much more mixed with heterogeneous matters. Under the article Animalcula, No. 33, is mentioned a species of insects which have the property of making water stink to an incredible degree, though their bulk in proportion to the fluid which surrounds them is less than that of one to a million. Other substances no doubt there are which have the same property; and hence almost all water which is confined from the air is apt to become offensive, even though kept in glass or stoneware vessels. Indeed it is a common observation, that water keeps much longer sweet in glass vessels, or in those of earthen or stoneware than in those of wood, where it is exceedingly apt to putrefy. Hence, as ships can only be supplied with water kept in wooden casks, sailors are extremely liable to those diseases which arise from putrid water; and the discovery of a method by which water could easily be prevented from becoming putrid at sea would be exceedingly valuable. This may indeed be done by quicklime; for when water is impregnated with it, all putresect matters are either totally destroyed, or altered in such a manner as never to be capable of undergoing the putrefactive fermentation again. But a continued use of lime-water could not fail of being pernicious, and it is therefore necessary to throw down the lime, after which the water will have all the purity necessary for preserving it free from putrefaction. This can only be done by means of fixed air; and more exposure in broad vessels to the atmosphere would do it without anything else, only taking care to break the crust which formed upon it. Two methods, however, have been thought of for doing this with more expedition. The one, invented by Dr. Alston, is, by throwing into the water impregnated with lime a quantity of magnesia. The lime attracts fixed air more powerfully than magnesia; in consequence of which the latter parts with it to the lime: and thus becoming insoluble, falls along with the caustic magnesia to the bottom, and thus leaves the water perfectly pure. Another method is that of Mr. Henry, who proposes to throw down the lime by means of an effervescing mixture of oil of vitriol and chalk put down to the bottom of the water cask. His apparatus for this purpose is as simple as it can well be made, though it is hardly probable that sailors will give themselves the trouble of using it; and Dr. Alston’s scheme would seem better calculated for them, were it not for the expense of the magnesia; which indeed is the only objection made to it by Mr. Henry. Putrid water may be restored and made potable by a process of the same kind.

Of late it has been discovered that charcoal possesses many unexpected properties, and, among others, that of preserving water from corruption, and of purifying it after it has been corrupted. Mr. Lowitz, whose experiments on charcoal have been published in Crell’s Chemical Journal, has turned his attention to this subject in a memoir read to the Economical Society at Petersburg. He found that the effect of charcoal was rendered much more speedy by using along with it some sulphuric acid. One ounce and a half of charcoal in powder, and 24 drops of concentrated sulphuric acid (oil of vitriol), were sufficient to purify three pints and a half of corrupted water, and do not communicate to it any sensible acidity. This small quantity of acid renders it unnecessary to use more than a third part of the charcoal powder which would otherwise be wasted; and less of that powder is employed, the less is the quantity of water lost by the operation, which, in sea-voyages, is an object worthy of consideration. In proportion to the quantity of acid made use of, the quantity of charcoal may be diminished or augmented. All acids produce nearly the same effects: neutral salts also, particularly nitré and sea-salt, may be used, but sulphureous acids preferable to any of these; water which is purified by means of this acid and charcoal will keep a longer time than that which is purified by charcoal alone.

When we mean to purify any given quantity of corrupted water, we should begin by adding to it as much powder of charcoal as is necessary to deprive it entirely of its bad smell. To ascertain whether that quantity of powdered charcoal was sufficient to effect the clarification of the said water, a small quantity of it may be passed through a linen bag, two or three inches long; if the water, thus filtrated, still has a turbid appearance, a fresh quantity of powdered charcoal must be added, till it be come perfectly clear: the whole of the water may be passed through a filtering bag, the size of which should be proportioned to the quantity of water. If sulphuric acid, or any other, can be procured, a small quantity of it should be added to the water, before the charcoal powder.

The cleaning of the casks in which water is to be kept in sea-voyages should never be neglected: they should be well washed with hot water and sand, or with any other substance capable of removing the micaceous particles, and afterwards a quantity of charcoal dust should be employed, which will entirely deprive them of the musty or putrid smell they may have contracted. — The charcoal used for purifying water should be well burnt, and afterwards be fitted into a fine powder.

Sea-Water. See Salt-Water.

Water-Carts, carriages constructed for the purpose of watering the roads for several miles round London; a precaution absolutely necessary near the metropolis, where, from the vast daily influx of carriages and horses, the dust would otherwise become quite insufferable in hot dry weather. Pumps are placed at proper distances to supply these carts.

Water-Derived. See Ordeal.

Water, among jewellers, is properly the colour or lustre of diamonds and pearls. The term, though less properly, is sometimes used for the hue or colour of other stones.

Water-Bellows. See Machines for blowing air into Furnaces.

Water-Colour, in Painting, are such colours as are only diluted and mixed up with gum-water, in contradistinction to oil-colours. See Colour-Making.

Water-Gang, a channel cut to drain a place by carrying off a stream of water.

Wasser-Hen. See Parra, Ornithology Index.

Water-Lines of a Ship, certain horizontal lines supposed to be drawn about the outside of a ship’s bottom, close to the surface of the water in which she floats. They are accordingly higher or lower upon the bottom, in proportion to the depth of the columns of water required to float her.

Water Logged, the state of a ship when, by receiving a great quantity of water into the hold, by leaking, etc. the
The doctor, in proceeding to explain his conceptions, begins to be allowed two or three positions, as a foundation for his hypothesis. 1. That the lower region of the air is often more heated, and so more rarified, than the upper, and by consequence specifically lighter. The coldness of the upper region is manifested by the hail, which falls from it in warm weather. 2. That heated air may be very moist, and yet the moisture so equally diffused and rarified as not to be visible till colder air mixes with it; at which time it condenses and becomes visible. Thus our breath, although invisible in summer, becomes visible in winter.

These circumstances being granted, he presupposes a tract of land or sea, of about 60 miles in extent, unsheathed by clouds and unrefreshed by the wind, during a summer's day, or perhaps for several days without intermission, till it becomes violently heated, together with the lower region of the air in contact with it; so that the latter becomes specifically lighter than the superincumbent higher region of the atmosphere, wherein the clouds are usually floated: he supposes also that the air surrounding this tract has not been so much heated during those days, and therefore remains heavier. The consequence of this, he conceives, should be, that the heated lighter air should ascend, and the heavier descend; and as this rising cannot operate throughout the whole tract at once, because that would leave too extensive a vacuum, the rising will begin precipitately in that column which happens to be lightest or most rarified; and the warm air will flow horizontally from all parts of that column, where the several currents meeting, and joining to rice, a whirl is naturally formed, in the same manner as a whirl is formed in a tub of water, by the descending fluid receding from all sides of the tub towards the hole in the centre.

And as the several currents arrive at this central rising column with a considerable degree of horizontal motion, they cannot suddenly change it to a vertical motion: therefore as they gradually, in approaching the whirl, decline from right to curve or circular lines, having joined the whirl, they ascend by a spiral motion; in the same manner as the water descends spirally through the hole in the tub before mentioned.

Lastly, as the lower air nearest the surface is more rarified by the heat of the sun, it is more impressed by the current of the surrounding cold and heavy air which is to assume its place, and consequently its motion towards the whirl is swiftest, and so the force of the lower part of the whirl strongest, and the centrifugal force of its particles greatest. Hence the vacuum which incloses the axis of the whirl should be greatest near the earth or sea, and diminish gradually as it approaches the region of the clouds, till it ends in a point.

This circle is of various diameters, sometimes very large.

If the vacuum passes over water, the water may rise in a body or column therein to the height of about 32 feet. The whirl of air may be as invisible as the air itself, though reaching in reality from the water to the region of cool air, in which our low summer thunderclouds commonly float; but it will soon become visible at its extremities. The agitation of the water under the whirling of the circle, and the swelling and rising of the water in the commencement of the vacuum, render it visible below. It is perceived above by the
WATER-WORKS.

Under this name may be comprehended almost every hydraulic structure or contrivance; such as canals, conduits, locks, mills, water engines, &c. But they may be conveniently arranged under two general heads, 1st. Works which have for their object the conducting, raising, or otherwise managing, of water; and, 2dly, Works which derive their efficacy from the impulse or other action of water. The first class comprehends the methods of simply conducting water in aqueducts or in pipes for the supply of domestic consumption or the working of machinery: It comprehends also the methods of procuring the supplies necessary for these purposes, by means of pumps, water, or fire engines. It also comprehends the subsequent management of the water thus conducted, whether in order to make the proper distribution of it according to the demand, or to employ it for the purpose of navigation, by lockage, or other contrivances.

And in the prosecution of these things many subordinate problems will occur, in which practice will derive great advantages from a scientific acquaintance with the subject. The second class of water-works is of much greater variety, comprehending almost every kind of hydraulic machine; and would of itself fill volumes. Many of these have already occurred in various articles of this Dictionary. In describing or treating them, we have tacitly referred the discussion of their general principles, in which they all resemble each other, to some article where they could be taken in a connected body, susceptible of general scientific discussion, independent of the circumstances which of necessity introduced the particular modifications required by the uses to which the structures were to be applied. That part of the present article, therefore, which embraces these common principles, will chiefly relate to the theory of water mills, or rather of water wheels; because, when the necessary motion is given to the axis of the water-wheel, this may be set to the performance of any task whatever.

CLASS I.

1. Of the Conducting of Water.

This is undoubtedly a business of great importance, and makes a principal part of the practice of the civil engineer: It is also a business so imperfectly understood, that we believe that very few engineers can venture to say, with tolerable precision, what will be the quantity of water which his work will convey, or what plan and dimensions of conduit will convey the quantity which may be proposed. For proof of this we shall only refer our readers to the facts mentioned in the article RIVERS, No. 27, &c.

In that article we have given a sort of history of the progress of our mechanical philosophy which seems to have been entirely unknown to the ancients. Even Archimedes, the author of almost all that we know in hydrostatics, seems to have been entirely ignorant of any principles by which he could determine the motion of water. The mechanical science of the ancients seems to have reached no farther than the doctrine of equilibrium among bodies at rest.GUIGLIELMINI first ventured to consider the motion of water in open canals and in rivers. His
W A T E R W O R K S.

tached scraps by others, but not so as to make a body of doctrine. Sir Isaac Newton first endeavoured to render hydraulics susceptible of mathematical demonstration: But his fundamental proposition has not yet been freed from very serious objections; nor have the attempts of his successors, such as the Bernoullis, Euler, D'Alembert, and others, been much more successful: so that hydraulics may still be considered as very imperfect, and the general conclusion which we are accustomed to receive as fundamental propositions are not much better than matters of observation, little supported by principle, and therefore requiring the most scrupulous caution in the application of them to any hitherto untied case. When experiments are multiplied so as to include as great a variety of cases as possible; and when these are cleared of extraneous circumstances, and properly arranged, we must receive the conclusions drawn from them as the general laws of hydraulics.

The experiments of abbé Bousot, narrated in his Hydrodynamique, are of the greatest value, having been made in the cases of most general frequency, and being made with great care. The greatest service, however, has been done by the chevalier Buat, who saw the folly of attempting to deduce an accurate theory from any principles that we have as yet learned, and the necessity of adhering to such a theory as could be deduced from experiment alone, independent of any more general principles. Such a theory must be a just one, if the experiments are really general, unaffected by the particular circumstances of the case, and if the classes of experiment are sufficiently comprehensive to include all the cases which occur in the most important practical questions. Some principle was necessary, however, for connecting these experiments. The sufficiency of this principle was not easily ascertained. Mr. Buat's way of establishing this was judicious. If the principle is ill-founded, the results of its combination in cases of actual experiments must be irregular; but if experiments, seemingly very unlike, and in a vast variety of dissimilar cases, give a train of results which is extremely regular and consistent, we may presume that the principle, which in this manner harmonizes and reconciles things so unlike, is founded in the nature of things; and if this principle be such as is agreeable to our clearest notions of the internal mechanism of the motions of fluids, our presumption approaches to conviction.

Proceeding in this way, the chevalier Buat has collected a prodigious number of facts, comprehending almost every case of the motion of fluids. He first clasped them according to their resemblance in some one particular, and observed the differences which accompanied their differences in other circumstances; and by considering what could produce these differences, he obtained general rules, deduced from fact, by which these differences could be made to fall into a regular series. He then arranged all the experiments under some other circumstances of resemblance, and pursued the same method; and by following this out, he has produced a general proposition, which applies to the whole of this numerous list of experiments with a precision far exceeding our utmost hopes. This proposition is contained in No. 59. of the article RIVERS, and is there offered as one of the most valuable results of modern science.

We must, however, observe, that of this list of experiments there is a very large class, which is not direct, but requires a good deal of reflection to enable us to draw a confident conclusion; and this is in cases which are very frequent and important, viz. where the declivity is exceedingly small, as in open canals and rivers. The experiments were of the following forms:

Two large cisterns were made to communicate with each other by means of a pipe. The surface of the water in these cisterns were made to differ only by a small fraction of an inch; and it is supposed that the motion in the communicating pipe will be the same as in a very long pipe, or an open canal, having this very minute declivity. We have no difficulty in admitting the conclusion; but we have seen it contested, and it is by no means intuitive. We had entertained hopes that this important case would have been determined by direct experiments, which the writer of this article was commissioned to make by the Board for Encouraging Improvements and Manufactures in Scotland: But the infirm state of his health was always an effectual bar to the accomplishment of this desirable object. This, however, need not occasion any hesitation in the adoption of M. Buat's general proposition, because the experiments which we are now criticising fall in precisely with the general train of the rest, and show no general deviation which would indicate a fallacy in principle.

We apprehend it to be quite unnecessary to add much to what has been already delivered on the motion of waters in an open canal. Their general progressive motion, and consequently the quantity delivered by an aqueduct of any slope and dimension, are sufficiently determined; and all that is wanted is the tables which we promised in No. 65. of the article RIVERS, by which any person who understands common arithmetic may, in five minutes time or less, compute the quantity of water which will be delivered by the aqueduct, canal, conduit, or pipe; for the theorem in No. 59. of this article applies to them all without distinction. We therefore take this opportunity of inserting these tables, which have been computed on purpose for this work with great labour.

**Table**
TABLE I. consists of three columns.—Column 1, entitled $d$, contains the hydraulic mean depths of any conduit in inches. This is set down for every 10th of an inch in the first 10 inches, that the answers may be more accurately obtained for pipes, the mean depth of which seldom exceeds three or four inches. The column is continued to 100 inches, which is fully equal to the hydraulic mean depth of any canal.

Column 2. contains the logarithms of the values of $\sqrt{d-0.1}$, multiplied by 397, that is, the logarithm of the numerator of the fraction $\frac{397}{\sqrt{d-0.1}}$ in N° 65 of the article RIVERS.

Column 3. contains the product of the values of $\sqrt{d-0.1}$ multiplied by 0.3.

TABLE II. consists of two columns.—Column 1, entitled $s$, contains the denominator of the fraction expressing the slope or declivity of any pipe or canal; that is, the quotient of its length divided by the elevation of one extremity above the other. Thus, if a canal of one mile in length be three feet higher at one end than the other, then $s = \frac{5280}{3} = 1760$.

Column 2. contains the logarithms of the denominators of the above-mentioned fraction, or of the different values of the quantity $\sqrt{1-s^2}$. These quantities were computed true to the third decimal place. Notwithstanding this, the last figure in about a dozen of the first logarithms of each table is not absolutely certain to the nearest unit. But this cannot produce an error of 1 in 100,000.

Examples of the Use of these Tables.

Example 1. Water is brought into the city of Edinburgh in several mains. One of these is a pipe of five inches diameter. The length of the pipe is 14,637 feet, and the reservoir at Comiston is 44 feet higher than the reservoir into which it delivers the water on the Castle Hill. Query. The number of Scotch pints which this pipe should deliver in a minute?

1. We have $d = 5$, and the logarithm referring to $d$ is nearly the mean between the logarithms corresponding to 1.2 and 1.3 is 2.49472.

2. We have $s = 14.637$, or 332.7. The logarithm corresponding to this in Table II is by taking proportional parts for the difference between the logarithms for $s = 350$ and $s = 349$, and is 1.18533.

3. From 2.49472

Take 1.18533

Remains 1.30936, the logarithm of 20.385 inches.

4. In column 3. of Table I, opposite to $d = 12$ and $d = 13$ are 0.3 and 0.31, of which the mean is 0.305 inches, the correction for viscosity.

5. Therefore the velocity in inches per second is 20.385 - 0.305 = 20.08.

6. To obtain the Scotch pints per minute (each containing 103.4 cubic inches), multiply the velocity by 5", and this by 0.7854 (the area of a circle whose diameter is 1), and divide by 144, or by logarithms,

Add the log. of 20.08 log. of 60° log. of 5" or 25 log. of 0.7854

$\log \frac{5}{144} = 3.24131$

Subtract the log. of 103.4

Remains the log. of 228.4 pints

13.91$

Example 2. The canal mentioned in the article RIVERS, No. 63, was 18 feet broad at the surface, and 7 feet at the bottom. It was 4 feet deep, and had a declivity of 4 inches in a mile. Query. The mean velocity?

1. The slant side of the canal, corresponding to a 4 feet deep and 4½ projection, is 6.5 feet; therefore the border touched by the water is 6.5 + 4.5 = 20 feet. The area is $4 \times \frac{18+7}{2} = 50$ square feet. Therefore $\frac{50}{20.6^4} = 2.47$ feet, or 29.14 inches. The logarithm corresponding to this in Table I is 3.21113, and the correction for viscosity from the third column of the same Table is 1.15.

2. The slope is one-third of a foot in a mile, or 0.3 foot in three miles. Therefore $s = 15.840$. The logarithm corresponding to this is 2.08280.

3. From 3.21113 Subtract 2.08280

Remains 1.1283 = log. of 13.428 inches.

Subtract for viscosity 1.15$

Velocity per second = 118.38

This velocity is considerably smaller than what was observed by Mr. Watt. And indeed we observe, that in the very small declivities of rivers and canals, the formula is a little different. We have made several comparisons with a formula which is essentially the same with Buat's, and comes nearer in these cases. Instead of taking the hyperbolic logarithm of $\sqrt{1-s^2}$, multiply its common logarithm by 24, or multiply it by 9 and divide the product by 4; and this process is vastly nearer than taking the hyperbolic logarithm.

We have not, however, pretended to calculate tables on the authority of our own observations, thinking too respectfully of this gentleman's labours and observations. But this subject will, ere long, be fully established by a series of observations on canals of various dimensions and declivities, made by several eminent engineers during the execution of them. Fortunately Mr. Buat's formula is chiefly founded on observations on small canals; and in these cases must, in our opinion, be rather than working machinery.

We now proceed to take notice of a few circumstances which deserve attention, in the construction of canals, in addition to those delivered in the article RIVERS.

When a canal or aqueduct is brought off from a bare
WATER-WORKS.

or larger stream, it ought always to be widened at the entry, if it is intended for drawing off a continued stream of water: For such a canal has a slope, without which it can have no current. Suppose it filled to a dead level at the farther end; Take away the bar, and the water immediately begins to flow off at that end. But it is some time before any motion is perceived at the head of the canal, during all which time the motion of the water is augmenting in every part of the canal; consequently the slope is increasing in every part, this being the sole cause of its stream. When the water at the entry begins to move, the slope is scarcely sensible there; but it sensibly steepens every moment with the increase of velocity, which at last attains its maximum relative to the slope and dimensions of the whole canal; and this regulates the depth of water in every point down the stream. When all has attained a state of permanency, the slope at the entry remains much greater than in any other part of the canal; for this slope must be such as will produce a velocity sufficient for supplying its train.

And it must be remembered, that the velocity which must be produced greatly exceeds the mean velocity corresponding to the train of the canal. Suppose that this is 2½ inches. There must be a velocity of 30 inches at the surface, as appears by the Table in the article Rivers, No. 58. This must be produced by a real fall at the entry.

In every other part the slope is sufficient, if it merely serves to give the water (already in motion) force enough for overcoming the friction and other resistances. But at the entry the water is stagnant, if in a basin, or it is moving past laterally, if the aqueduct is derived from a river; and, having no velocity whatever in the direction of the canal, it must derive it from its slope.

The water therefore which has acquired a permanent form in such an aqueduct, must necessarily take that form which exactly performs the office requisite in its different portions. The surface remains horizontal in the basin, as to K.C (fig. 1), till it comes near the entry of the canal AB, and there it acquires the form of an undulated curve CDE; and then the surface acquires an uniform slope EF, in the lower part of the canal, where the water is in train.

If this is a drain, the discharge is much less than might be produced by the same bed if this sudden slope could be avoided. If it is to be navigated, having only a very gentle slope in its whole length, this sudden slope is a very great imperfection, both by diminishing the depth of water, which might otherwise be obtained along the canal, and by rendering the passage of boats into the basin very difficult, and the coming out very hazardous.

All this may be avoided, and the velocity at the entry may be kept equal to that which forms the train of the canal, by the simple process of enlarging the entry. Suppose that the water could accelerate along the slopes of the canal, as a heavy body would do on a finely polished plane. If we now make the width of the entry in its different parts inversely proportional to the fictitious velocities in those parts, it is plain that the slope of the surface will be made parallel to that of the canal which is in train. This will require a form somewhat like a bell or speaking trumpet, as may easily be shown by a mathematical discussion. It would, however, be so much raised at the basin as to occupy much room, and it would be very expensive to make such an excavation. But we may, at a very moderate expense of money and room, make the increase of velocity at the entry almost insensible. This should always be done, and it is not all expense: for if it be not done, the water will undermine the banks on each side, because it is moving very swiftly, and will make an excavation for itself, leaving all the mud in the canal below. We may observe this enlargement at the entry of all natural derivations from a basin or lake. It is a very instructive experiment, to fill up this enlargement, continuing the parallel sides of the drain quite to the side of the lake. We shall immediately observe the water grow shallower in the drain, and its performance will diminish. Supposing the ditch carried on with parallel sides quite to the side of the basin, if we build two walls or dykes from the extremities of those sides, bending outwards with a proper curvature (and this will often be less costly than widening the drain), the discharge will be greatly increased. We have seen instances where it was nearly doubled.

The enlargement at the mouths of rivers is generally owing to the same cause. The tide of flood up the river produces a superficial slope opposite to that of the river, and this widens the mouth. This is most remarkable when the tides are high, and the river has little slope.

After this great fall at the entry of the canal, in which all the filaments are much accelerated, and the inferior ones most of all, things take a contrary turn. The water, by rubbing on the bottom and the sides, is retarded; and therefore the section must, from being shallow, become a little deeper, and the surface will be convex for some distance till all comes into train. When this is established, the filaments nearest the bottom and side are moving slowest, and the surface (in the middle especially) retains the greatest velocity, gliding over the rest. The velocity in the canal, and the depth of the section, adjust themselves in such a manner that the difference between the surface of the basin and the surface of the uniform section of the canal corresponds exactly to the velocity. Thus, if this be observed to be two feet in a second, the difference of height will be ⅜ths of an inch.

All the practical questions that are of considerable importance respecting the motion of water in aqueducts, may be easily, though not elegantly, solved by means of the tables.

But it is to be remembered, that these tables relate only to uniform motion, that is, to water that is in train, and where the velocity suffers no change by lengthening the conduit, provided the slope remain the same. It is much more difficult to determine what will be the velocity, &c. in a canal of which nothing is given but the form, and slope, and depth of the entry, without saying how deep the water runs in it. And it is here that the common doctrines of hydraulics are most in fault, and unable to teach us how deep the water will run in a canal, though the depth of the basin at the entry is perfectly known. Between the part of the canal which is in train and the basin, there is an interval where the water is in a state of acceleration, and is afterwards retarded.

The determination of the motions in this interval is exceedingly
WATER- WORKS.

Exceedingly difficult, even in a rectangular canal. It was one great aim of M. Buat's experiments to ascertain this by measuring accurately the depth of the water. But he found that when the slope was but a very few inches in the whole length of his canal, it was not in train for want of greater length; and when the slope was still less, the small fractions of an inch, by which he was to judge of the variations of depth, could not be measured with sufficient accuracy. It would be a most desirable point to determine the length of a canal, whose slope and other dimensions are given, which will bring it into train; and what is the ratio which will then obtain between the depth at the entrance and the depth which will be maintained. Till this be done, the engineer cannot ascertain by a direct process what quantity of water will be drawn off from a reservoir by a given canal. But as yet this is out of our reach. Experiments, however, are in view which will promote the investigation.

But this and similar questions are of such importance, that we cannot be said to have improved hydraulics, unless we can give a tolerably precise answer. This we can do by a sort of retrograde process, proceeding on the principles of uniform motion established by the Chevalier Buat. We may suppose a train maintained in the canal, and then examine whether this train can be produced by any fall that is possible at the entry. If it can, we may be certain that it is so produced, and our problem is solved.

We shall now point out the methods of answering some chief questions of this kind.

**Quest. 1.** Given the slope $s$ and the breadth $w$ of a canal, and the height $H$ of the surface of the water in the basin above the bottom of the entry; to find the depth $h$ and velocity $V$ of the stream, and the quantity of water $Q$ which is discharged?

The chief difficulty is to find the depth of the stream where it is in train. For this end, we may simplify the hydraulic theorem of uniform motion in No. 59 of the article RIVER; making $V = \sqrt{Ngd \over \sqrt{S}}$, where $g$ is the velocity (in inches) acquired in a second by falling, $d$ is the hydraulic mean depth, and $\sqrt{S}$ stands for $\sqrt{S-L+{d^2 \over 4S}}$. $N$ is a number to be fixed by experiment (see RIVERS, No. 53) depending on the contraction or obstruction sustained at the entry of the canal, and it may in most common cases be taken as 244; so that $\sqrt{Ng}$ may be somewhat less than 307. To find it, we may begin by taking for our depth of stream a quantity $h$, somewhat smaller than $H$ the height of the surface of the basin above the bottom of the canal. With this depth, and the known width $w$ of the canal, we can find the hydraulic depth $d$ (See RIVERS, No. 49). Then with $\sqrt{d}$ and the slope find $V$ by the Table: make this $V = \sqrt{Ngd \over \sqrt{S}}$. This gives $Ng = V \sqrt{S} \over \sqrt{d}$. This value of $Ng$ is sufficiently exact; for a small error of depth hardly affects the hydraulic mean depth. After this preparation, the expression of the mean velocity in the canal will be $\sqrt{Ng \over \sqrt{w+2d}}$. The

height which will produce this velocity is $N \sqrt{w^2 \over 2G}$. Hence we deduce

$$h = \frac{\left(\frac{Ng}{2GS} + 1\right)^2 - 2H}{4} + \left(\frac{w}{2GS} + 1\right)^2 - 2H$$

If there be no contraction at the entry, $f = G$ will

$$\frac{Q}{2G} = \frac{1}{2}$$

Having thus obtained the depth $h$ of the stream, we obtain the quantity of water by combining this with the width $w$ and the velocity $V$.

But as this was but an approximation, it is necessary to examine whether the velocity $V$ be possible. This is very easy. It must be produced by the fall $H-h$. We shall have no occasion for any correction of our last assumption, if $h$ has not been extravagantly erroneous, because a small mistake in $h$ produces almost the same variation in $d$. The test of accuracy, however, is, that $h$, together with the height which will produce the velocity $V$, must make up the whole height $H$. Assuming $h$ too small, leaves $H-h$ too great, and will give a small velocity $V$, which requires a small value of $h$. The error of $H-h$ therefore is always greater than the error we have committed in our first assumption. Therefore when this error of $H-h$ is but a trifle, such as one-fourth of an inch, we may rest satisfied with our answer.

Perhaps the easiest process may be the following:

Suppose the whole stream in train to have the depth $H$. The velocity $V$ obtained for this depth and slope by the Table requires a certain productive height $w$. Make $H+w = H = h$, and $h$ will be exceedingly near the truth. The reason is obvious.

**Quest. 2.** Given the discharge (or quantity to be furnished in a second) $Q$, the height $H$ of the basin above the bottom of the canal, and the slope; to find the dimensions of the canal?

Let $x$ and $y$ be the depth and mean width. It is plain that the equation $Q = \sqrt{2G \over \sqrt{h}}$ will give a value of $y$ in terms of $x$. Compare this with the value of $y$ obtained from the equation $Q = \sqrt{Ng \over \sqrt{S}}$.

This will give an equation containing only $x$ and known quantities. But it will be very complicated, and we must have recourse to an approximation. This will be best understood in the form of an example.

Suppose the depth at the entry to be 18 inches, and the slope 44. Let 1200 cubic feet of water per minute be the quantity of water to be drawn off, for working machinery or any other purpose; and let the canal be
WATER-WORKS.

be supposed of the best form, recommended in No. 69.

of the article River, where the base of the sloping side is fourths of the height.

The slightest consideration will show us that if \( V \) be taken for the height producing the velocity, it cannot exceed 3 inches, nor be less than 1. Suppose it \( = 2 \), and therefore the depth of the stream in the canal to be 16 inches; find the mean width of the canal by the equation \( w = \frac{Q}{\sqrt{\frac{V}{S} - 0.3}} \) in which \( Q \) is 20 cubic feet (the 6th part of 1200), \( \sqrt{S} \) is \( \frac{28.152}{\sqrt{1000} - \frac{L}{1000} \frac{1}{1.6}} \), and \( \frac{h}{V} = 16 \). This gives \( w = 5.52 \) feet. The section \( n = 7.36 \) feet, and \( V = 32.6 \) inches. This requires a fall of 1.52 inches instead of 2 inches. Take this from 18, and there remains 16.48, which we shall find not to differ one-tenth of an inch from the exact depth which the water will acquire and maintain. We may therefore be satisfied with assuming 3.5 feet as the mean width, and 3.5 feet for the depth at the bottom.

This approximation proceeds on this consideration, that when the width diminishes by a small quantity, and in the same proportion that the depth increases, the hydraulic mean depth remains the same, and therefore the velocity also remains, and the quantity discharged changes in the exact proportion of the section. Any minute error which may result from this supposition, may be corrected by increasing the fall producing the velocity, in the proportion of the first hydraulic mean depth to the mean depth corresponding to the new dimensions found for the canal. It will now become 1.53 and \( V \) will be 32.72, and the depth will be 16.47. The quantity discharged being divided by \( V \), will give the section \( = 7.355 \) feet, from which, and the new depth, we obtain 3.344 for the width.

This and the foregoing are the most common questions proposed to an engineer. We asserted with some confidence that few of the profession are able to answer them with tolerable precision. We cannot offend the professional gentlemen by this, for when we inform them that the Academy of Sciences at Paris were occupied during several months with an examination of a plan proposed by M. Parcieux, for bringing the waters of the Yvette into Paris; and after the most mature consideration, gave in a report of the quantity of water which M. De Parcieux's aqueduct would yield, and that their report has been found erroneous in the proportion of at least 2 to 5: For the waters have been brought in, and exceeded the report in this proportion. Indeed long after the giving in the report, M. Perronet, the most celebrated engineer in France, affirmed that the dimensions proposed were much greater than were necessary, and said that an aqueduct of 5 feet wide, and 3 feet deep with a slope of 15 inches in a thousand fathoms, would have a velocity of 12 or 13 inches per second, which would bring in all the water furnished by the proposed sources. The great diminution of expense occasioned by the alteration encouraged the community to undertake the work. It was accordingly begun, and a part executed. The water was found to run with a velocity of near 19 inches when it was 39 feet deep. M. Perronet founded his computation on his own experience alone, acknowledging that he had no theory to instruct him. The work was carried no farther, it being found that the city could be supplied at a much smaller expense by steam engines erected by Boulton and Watt. But the facts which occurred in the partial execution of the aqueduct are very valuable.

If M. Perronet's aqueduct be examined by our general formula, \( x \) will be found \( = -0.008 \), and \( d = 18.72 \), from which we deduce the velocity \( = 18 \), agreeing with the observation with astonishing precision.

The experiments at Turin by Michaelotti on canals were very numerous, but complicated with many circumstances which would render the discussion too long for this place. When cleared of these circumstances, which we have done with scrupulous care, they are also abundantly conformable to our theory of the uniform motion of running waters. But to return to our subject:

Should it be required to bring off at once from the basin a mill-course, having a determined velocity for driving an undershot wheel, the problem becomes easier, because the velocity and slope combined determine the hydraulic mean depth at once; and the depth of the stream will be had by means of the height which must be taken for the whole depth at the entry, in order to produce the required velocity.

In like manner, having given the quantity to be discharged, and the velocity and the depth at the entry, we can find the other dimensions of the channel; and the mean depth being found, we can determine the slope.

When the slope of a canal is very small, so that the depth of the uniform stream differs but a little from that at the entry, the quantity discharged is but small. But a great velocity, requiring a great fall at the entry, produces a great diminution of depth, and therefore it may not compensate for this diminution, and the quantity discharged may be smaller. Improvable as this may appear, it is not demonstrably false; and hence we may see the propriety of the following

Question 5. Given the depth \( H \) at the entry of a rectangular canal, and also its width \( w \); required the slope, depth, and velocity which will produce the greatest possible discharge?

Let \( x \) be the unknown depth of the stream. \( H = x \) is the productive fall; and the velocity is \( \sqrt{2 \frac{G}{H}} \). This multiplied by \( w \) will give the quantity discharged. Therefore \( w \times \sqrt{2 \frac{G}{H}} = x \) must be made a maximum. The common process for this will give the equation, \( 2H = 3x \), or \( x = \frac{2}{3} H \). The mean velocity will be \( \sqrt{2 \frac{G}{H}} \), the section will be \( \frac{w H}{2} \), and the discharge \( = \sqrt{2 \frac{G}{H}} w \frac{H}{2} \). With these data the slope is easily had by the formula for uniform motion.

If the canal is of the trapezoidal form, the investigation is more troublesome, and requires the resolution of a cubic equation.

It may appear strange that increasing the slope of a canal beyond the quantity determined by this problem can diminish the quantity of water conveyed. But one of these two things must happen; either the motion will not acquire uniformity in such a canal for, want of
WATER WORKS.

length, or the discharge must diminish. Supposing, however, that it could augment, we can judge how far this can go. Let us take the extreme case by making the canal vertical. In this case it becomes a simple weir or wasteboard. Now the discharge of a wasteboard is \( \frac{1}{4} \sqrt{2} G w \left( h^2 - \frac{3}{4} h \right) \). The maximum determined by the preceding problem is to that of the wasteboard of the same dimensions as \( H \sqrt{\frac{1}{3}} = H \left( \frac{1}{4} H \right) \), or as \( H \sqrt{\frac{1}{3}} = H \sqrt{\frac{1}{3}} = 5773 ; \)

Having given the dimensions and slope of a canal, we can discover the relation between its expenditure and the time: or we can tell how much it will sink the surface of a pond in 24 hours, and the gradual progress of this effect; and this might be made the subject of a particular problem. But it is complicated and difficult. In cases where this is an interesting object, we may solve the question with sufficient accuracy, by calculating the expenditure at the beginning, supposing the basin kept full. Then from the known area of the pond, we can tell in what time this expenditure will sink an inch; do the same on the supposition that the water is one-third lower, and that it is two-thirds lower (noticing the contraction of the surface of the pond occasioned by this abstraction of its waters). Thus we shall obtain three rates of diminution, from which we can easily deduce the desired relation between the expenditure and the time.

Aqueducts derived from a basin or river are commonly furnished with a sluice at the entry. This changes exceedingly the state of things. The slope of the canal may be precisely such as will maintain the mean velocity of the water which passes under the sluice; in which case the depth of the stream is equal to that of the sluice, and the velocity is produced at once by the head of water above it. But if the slope is less than this, the velocity of the issuing water is diminished, and the water must rise in the canal. This must check the efflux at the sluice, and the water will be as it were stagnant above what comes through below it. It is extremely difficult to determine what precise slope the water will begin to check the efflux. The contraction at the lower edge of the board hinders the water from attaining at once the whole depth which it acquires afterwards, when its velocity diminishes by the obstructions. While the regorging which these obstructions occasion does not reach back to the sluice, the efflux is not affected by it. Even when it does reach to the sluice, there will be a less depth immediately behind it than farther down the canal, where it is in train; because the swift moving water which is next the bottom drags with it the regorged water which lies on it: but the canal is too rapid to make this difference of depth sensible. In ordinary canals, with moderate slopes and velocities, the velocity at the sluice may be safely taken as if it were that which corresponds to the difference of depths above and below the sluice, where both were in train.

Let therefore \( H \) be the depth above the sluice, and \( h \) the depth in the canal. Let \( e \) be the elevation of the sluice above the sole, and let \( b \) be its breadth. The discharge will be \( b \sqrt{H-h} \sqrt{2} G \) for the sluice, and

\[
\text{for the canal. These must be in the same. This gives the equation } b \sqrt{H-h} \sqrt{2} G = w \sqrt{\frac{N e}{s}} = \sqrt{\frac{w h}{s}} = \sqrt{\frac{w h}{w + 2 h}} \text{ containing the solution of all the questions which can be proposed. The only uncertainty is in the quantity } G, \text{ which expresses the velocity competent to the passage of the water through the orifice, circumstances as it is, namely, subjected to contraction. This may be regulated by a proper form given to the entry into this orifice. The contraction may be almost annihilated by making the orifice a cycloidal form on both sides, and also at the lower edge of the sluice-board, so as to give the orifice a form resembling fig. 5, D, in the article RIVERS. If the skin is thin in the face of a basin, the contraction will reduce \( 2 G \) to \( 296 \). If the sluice be as wide as the canal, \( G \) will be nearly \( 200 \).

Question 4. Given the head of water in the basin \( H \), the breadth \( b \), and the elevation \( e \) of the sluice, and the breadth \( w \) and slope \( s \) of the canal, to find the depth \( h \) of the stream, the velocity, and the discharge?

We must (as in Question 2), make a first supposition for \( h \), in order to find the proper value of \( d \). Then the equation

\[
\frac{1}{2} \sqrt{H-h} \sqrt{2} G = w \sqrt{\frac{N e}{s}} \text{ gives } h = \frac{G e b s}{2 G s} + \sqrt{\frac{G e b s}{2 G s} \left( \frac{G e b s}{2 G s} + \frac{G e b s}{2 G s} \right)}.
\]

If this value shall differ considerably from the one which we assumed in order to begin the computation, make use of it for obtaining a new value of \( d \), and repeat the operation. We shall rarely be obliged to perform a third operation.

The following is of frequent use:

Question 5. Given the dimensions and the slope, with the velocity and discharge of a river in its ordinary state, required the area or section of the sluice which will raise the waters to a certain height, still allowing the same quantity of water to pass through? Such an operation may render the rivers navigable for small craft or rafts above the sluice. The problem is reduced to the determination of the size of orifice which will discharge this water with a velocity competent to the height to which the river is to be raised; only we must take into consideration the velocity of the water above the sluice, considering it as produced by a fall which makes a part of the height productive of the whole velocity at the sluice. Therefore \( H \), in our investigation, must consist of the height to which we mean to raise the waters, and the height which will produce the velocity with which the water approach the sluice; \( h \), or the depth of the stream, is the ordinary depth of the river. Then (using the former symbols) we have

\[
Q = \sqrt{\frac{2 G}{(H-h)}} \frac{Q^2}{2 G e b s} \text{ for the expression of the rise of the water.}
\]
WATER-WORKS.

Water works.

\[ Q = \frac{2 Q}{G \sqrt{D}} \]

expresses the height that produces the velocity under the sluice, must be equal to the depth of the river, and \( H - a \) will be \( w \).

The performance of aqueduct drains is a very important thing, and merits our attention in this place. While the art of managing waters, and of conducting them so as to answer our demands, renders us a very important service by employing our habitations, or promoting our commercial intercourse, the art of draining creates as it were new riches, fertilizing tracts of bog or marsh, which was not only useless, but hurtful by its unholy somnolences, and converting them into rich pastures and gay meadows. A wild country, occupied by marshes which are inaccessible to herds or flocks, and serve only for the haunts of water-fowls, or the retreat of a few poor fishermen, when once it is freed from the waters in which it is drowned, opens its lap to receive the most precious seeds, is soon clothed in the richest garb, gives life and abundance to numerous herds, and never fails to become the delight of the industrious cultivator who has enfranchised it, and is attached to it by the labour which it cost him. In return, it procures him abundance, and supplies him with the means of daily augmenting its fertility. No species of agriculture exhibits such long-continued and progressive improvement. New families flock to the spot, and there multiply; and there nature seems the more eager to repay their labours, in proportion as she has been obliged, against her will, to keep her treasures locked up for a longer time, chilled by the waters. The countries newly inhabited by the human race, as is a great part of America, especially to the southward, are still covered to a great extent with marshes and lakes; and they would long remain in this condition, if population, daily making new advances, did not increase industry, by multiplying the cultivating hands, at the same time that it increases their wants. The Author of this beautiful world has at the beginning formed the great masses of mountain, has scooped out the dales and sloping hills, has traced out the courses, and even formed the beds of the rivers: but he has left to man the care of making his place of abode, and the field which must feed him, dry and comfortable. For this task is not beyond his powers, as the others are. Nay, having given this to him in charge, he is richly repaid for his labour by the very state in which he finds those countries into which he penetrates for the first time. Being covered with lakes and forests, the juices of the soil are kept for him as it were in reserve. The air, the burning heat of the sun, and the continual washing of rains, would have combined to expend and dissipate their vegetative powers, had the fields been exposed in the same degree to their action as the inhabited and cultivated countries, the most fertile moulds of which are long since lodged in the bottom of the ocean. All this would have been completely lost through the whole extent of South America, had it not been protected by the forests which man must cut down, by the rank herbage which he must burn, and by the marsh and bog which he must destroy by draining. Let not ungrateful man complain of this. It is his duty to take on himself the task of opening up treasures, preserved on purpose for him with so much judgment and care. If he has discernment and sensibility, he will even thank the Author of all good, who has thus husbanded them for his use. He will co-operate with his beneficent views, and will be careful not to proceed by wantonly snatching at present any partial good, and by picking out what is most easily got at, regardless of him who is to come afterwards to uncover and extract the remaining riches of the ground. A wise administration of such a country will think it their duty to leave a just share of this inheritance to their descendants, who are entitled to expect it as the last legatees. National plans of cultivation should be formed on this principle, that the steps taken by the present cultivators for realizing part of the riches of the infant country shall not obstruct the works which will afterwards be necessary for also obtaining the remainder. This is carefully attended to in Holland and in China. No man is allowed to conduct the drains, by which he recovers a piece of marsh, in such a way as to render it much more difficult for a neighbour, or even for his own successor, to drain another piece, although it may at present be quite inaccessible. There remain in the middle of the most cultivated countries many marshes, which industry has not yet attempted to drain, and where the legislature has not been at pains to prevent many little abuses which have produced elevation in the beds of rivers, and rendered the complete draining of some spots impossible. Administration should attend to such things, because their consequences are great. The sciences and arts, by which alone these difficult and costly jobs can be performed, should be protected, encouraged, and cherished. It is only from science that we can obtain principles to direct these arts. The problem of draining canals is one of the most important, and yet has hardly ever occupied the attention of the hydraulic speculator. We approve that M. Buat's theory will throw great light on it; and regret that the very limited condition of our present work will hardly afford room for a slight sketch of what may be done on the subject. We shall, however, attempt it by a general problem, which will involve most of the chief circumstances which occur in works of that kind.

Quest. 6. Let the hollow ground A (fig. 2.) be inundated by rains or springs, and have no outlet but the canal AB, by which it discharges its water into the neighbouring river BCDE, and that its surface is nearly on a level with that of the river at D. It can only drain when the river sinks in the droughts of summer; and even if it could then drain completely, the putrid marsh would only be an infecting neighbour. It may be proposed to drain it by one or more canals; and it is required to determine their lengths and other dimensions, so as to produce the best effects?

It is evident that there are many circumstances to determine the choice, and many conditions to be attended to.

If the canals AC, AD, AG, are respectively equal to the proportions BC, BD, BF, of the river, and have the same slopes, they will have the same discharge; but they are not for this reason equivalent. The long canal AE may drain the marsh completely, while the short...
WATER WORKS.

one AC will only do it in part; because the difference of level between A and C is but inconsiderable. Also the freshes of the river may totally obstruct the operation of AC, while the canal AE cannot be hurt by them, E being so much lower than C. Therefore the canal must be carried so far down the river, that no freshes there shall ever raise the waters in the canal so high as to reduce the slope in the upper part of it to such a level that the current shall not be sufficient to carry off the ordinary produce of water in the marsh.

Still the problem is indeterminate, admitting many solutions. This requisite discharge may be accomplished by a short but wide canal, or by a longer and narrower. Let us first see what solution can be made, so as to accomplish our purpose in the most economical manner, that is, by means of the smallest equation. We shall give the solution in the form of an example.

Suppose that the daily produce of rains and springs raises the water 1 1/2 inches on an area of a square league, which gives about 120,000 cubic fathoms of water. Let the bottom of the basin be three feet below the surface of the freshes in the river at B in winter. Also, that the slope of the river is 2 inches in 100 fathoms, or 1/500 of a foot, and that the canal is to be 6 feet deep.

The canal being supposed nearly parallel to the river, it must be at least 1800 fathoms long before it can be admitted into the river, otherwise the bottom of the bog will be lower than the mouth of the canal, and even then a hundred or two more fathoms added to this will give it so little slope, that an immense breadth will be necessary to make the discharge with so small a velocity.

On the other hand, if the slope of the canal be made equal to that of the river, an extravagant length will be necessary before its admission into the river, and many obstacles may then intervene. And even then it must have a breadth of 13 feet, as may easily be calculated by the general hydraulic theorem. By receding from each of these extremes, we shall diminish the expense of excavation. Therefore.

Let x and y be the breadth and length, and h the depth (6 feet), of the canal. Let y be the depth of the bog below the surface of the river, opposite to the basin, D the discharge in a second, and 1/3 the slope of the river. We must make h, x, y a minimum, or x y + y x = 0.

The general formula gives the velocity

\[ V = \sqrt{N g \left( \sqrt{d - 0.1} \right)^{0.3}} + \sqrt{S - 1.5 \sqrt{s + 1.6}}. \]

This would give x and y; but the logarithmic term renders it very complicated. We may make use of the simple form

\[ V = \sqrt{N g d \over S}, \text{ making } \sqrt{N g} \text{ nearly } 2 \sqrt{h} \delta. \]

When this is exactly equal to the velocity, the system is properly balanced. I have found the following results: 

<table>

</table>

We have considered this important problem in its most simple state. If the basin is far from the river, so that the drains are not nearly parallel to it, and therefore have less slope attainable in their course, it is more difficult. Perhaps the best method is to try two very extreme cases and a middle one, and then fourth, nearer to that extreme which differs least from the middle one in
the quantity of excavation. This will point out on which side the minimum of excavation lies, and also the law by which it diminishes and afterwards increases.

Then draw a line, on which set off from one end the lengths of the canals. At each length erect an ordinate representing the excavation; and draw a regular curve through the extremities of the ordinates. From that point of the curve which is nearest to the base line, draw another ordinate to the base. This will point out the best length of the canal with sufficient accuracy. The length will determine the slope, and this will give the width, by means of the general theorem. N.B. These draining canals must always come off from the basin, with evasated entries. This will prevent the loss of much fall at the entry.

Two canals may sometimes be necessary. In this case expense may frequently be saved, by making one canal flow into the other. Thus, however, must be at such a distance from the basin, that the swell produced in the other by this addition may not reach back to the immediate neighbourhood of the basin, otherwise it would impede the performance of both. For this purpose, recourse must be had to Problem III. in No. 104. of the article River. We must here observe, that in this respect canals differ exceedingly from rivers; rivers enlarge their beds, so as always to convey every increase of waters; but a canal may be gorged through its whole length, and will then greatly diminish its discharge. In order that the lower extremity of a canal may convey the waters of an equal canal admitted into it, their junction must be so far from the basin that the swell occasioned by raising its waters nearly \( \frac{3}{4} \) more (viz. in the subduplicate ratio of 1 to 2) may not reach back to the basin.

This observation points out another method of economy. Instead of one wide canal, we may make a narrower one of the whole length, and another narrow one reaching part of the way, and communicating with the long canal at a proper distance from the basin. But the lower extremity will now be too shallow to convey the waters of both. Therefore raise its banks by using the earth taken from its bed, which must at any rate be disposed of. Thus the waters will be conveyed, and the expense, even of the lower part of the long canal, will scarcely be increased.

These observations must suffice for an account of the management of open canals; and we proceed to the consideration of the conduct of water in pipes.

This is much more simple and regular, and the general theorem requires very trifling modifications for adapting it to the cases or questions that occur in the practice of the civil engineer. Pipes are always made round, and therefore \( d \) is always \( \frac{1}{4} \)th of the diameter. The velocity of water in a pipe which is in train, is

\[
V = \frac{307}{\sqrt{2} - \sqrt{L}} \sqrt{d - 0.1} - 0.3 (\sqrt{d - 0.1} - 0.3).
\]

The chief questions are the following:

Quest. 1. Given the height \( H \) of the reservoir above the place of delivery, and the diameter and length of the pipe, to find the quantity of water discharged in a second.

Let \( L \) be the length, and \( H \) the fall which would produce the velocity with which the water enters the pipe, and actually flows in it, after overcoming all obstructions. This may be expressed in terms of the velocity by \( \frac{V}{2G} \), \( G \) denoting the acceleration of gravity, corresponding to the manner of entry. When no methods are adopted for facilitating the entry of the water, by a bell-shaped funnel or otherwise, \( V \) may be assumed as \( 307 \) inches, or 42 feet, according as we measure the velocity in inches or feet. The slope is \( \frac{1}{s} = \frac{V}{L} \), which must be put into the general formula.

This would make it very complicated. We may simplify it by the consideration that the velocity is very small in comparison of that arising from the height \( H \) consequently \( H \) is very small. Also, in the same pipe, the resistances are nearly in the duplicate ratio of the velocities when these are small, and when they differ little among themselves. Therefore make \( b = \frac{L}{H} \), taking \( H \) by guess, a very little less than \( H \). Then compute the mean velocity \( v \) corresponding to these data, or take it from the table. If \( H = \frac{V}{2G} \), we have found the mean velocity \( V = v \). If not, make the following proportion:

\[
\frac{H + \frac{V^2}{2G}}{2G} = \frac{V}{2G} : \frac{V^2}{2G} \quad \text{which is the same with}
\]

\[
H + \frac{V^2}{2G} = \frac{V}{2G} : \frac{V^2}{2G}, \quad \text{and} \quad V^2 = \frac{V^2 H}{H + \frac{V^2}{2G}}.
\]

If the pipe has any bendings, they must be calculated for in the manner mentioned in the article River, No. 101; and the head of water necessary for overcoming this additional resistance being called \( \frac{V^2}{2G} \), the last proportion must be changed for

\[
H + \frac{V^2}{2G} \left( \frac{1}{H} + \frac{1}{m} \right) : \frac{V^2}{2G} = \frac{v^2}{2G} : \frac{V^2}{2G}.
\]

Quest. 2. Given the height of the reservoir, the length of the pipe, and the quantity of water which is to be drawn off in a second; to find the diameter of the pipe which will draw it off?

Let \( d \) be considered as \( \frac{1}{4} \)th of the diameter, and let \( 1 : e \) represent the ratio of the diameter of a circle to its circumference. The section of the pipe is \( 4 \pi d^2 \).

The quantity of water per second be \( Q \); then \( \frac{Q}{4\pi d^2} \) is the mean velocity. Divide the length of the pipe by the height of the reservoir above the place of delivery, diminished by a very small quantity, and call the quotient \( S \). Consider this as the slope of the conduit; the general formula now becomes

\[
Q = \frac{307(\sqrt{d - 0.1})}{\sqrt{2} - \sqrt{L}} \sqrt{d - 1.06} - 0.3 (\sqrt{d - 0.1}), \quad \text{or}
\]

\[
\frac{Q}{4\pi d^2} = \frac{307(\sqrt{d - 0.1})}{\sqrt{2} - \sqrt{L}} \sqrt{d - 1.06} - 0.3 (\sqrt{d - 0.1}), \quad \text{or}
\]
WATER-WORKS.

\[
Q = \frac{(307\sqrt{d - 0.1})}{\sqrt{S}} - 0.3 (\sqrt{d - 0.1}).
\]

We may neglect the last term in every case of civil practice, and also the small quantity \(0.1\). This gives the very simple formula,

\[
Q = \frac{307 \sqrt{d}}{\sqrt{S}}
\]

from which we readily deduce

\[
d = \frac{Q \sqrt{8}}{\frac{45}{3 \sqrt{307}}}
\]

This process gives the diameter somewhat too small. But we easily rectify this error by computing the quantity delivered by the pipe, which will differ a little from the quantity proposed. Then, observing, by this equation, that two pipes having the same length and the same slope give quantities of water, of which the squares are nearly as the fifth powers of the diameter, we form a new diameter in this proportion, which will be almost perfectly exact.

It may be observed that the height assumed for determining the slope in these two questions will seldom differ more than an inch or two from the whole height of the reservoir above the place of delivery; for in conduits of a few hundred feet long, the velocity seldom exceeds four feet per second, which requires only a head of three inches.

As no inconvenience worth minding results from making the pipes a tenth of an inch or so wider than is barely sufficient, and as this generally is more than the error arising from even a very erroneous assumption of \(h\), the answer first obtained may be augmented by one or two-tenths of an inch, and then we may be confident that our conduit will draw off the intended quantity of water.

We presume that every person who assumes the name of an engineer knows how to reduce the quantity of water measured in gallons, pints, or other denominations, to cubic inches, and can calculate the gallons, &c. furnished by a pipe of known diameter, moving with a velocity that is measured in inches per second. We further suppose that all care be taken in the construction of the conduit, to avoid obstructions occasioned by lumps of solder hanging in the inside of the pipes; and particularly, that all the cocks and plugs by the way have waterways equal to the section of the pipe. Undertakers are most tempted to fail here, by making the cocks too small, because large cocks are very costly. But the employer should be scrupulously attentive to this; because a simple contraction of this kind may be the throwing away of many hundred pounds in a wide pipe, which yields no more water than can pass through the small cock.

The chief obstructions arise from the deposition of sand or mud in the lower parts of pipes, or the collection of air in the upper parts of their bendings. The velocity being always very moderate, such depositions of heavy matters are unavoidable. The utmost care should therefore be taken to have the water freed from all such things at its entry by proper filtration; and there ought to be cleansing plugs at the lower parts of the bendings, or rather a very little way beyond them. When these are opened, the water issues with greater velocity, and carries the depositions with it.

It is much more difficult to get rid of the air which chokes the pipes by lodging in their upper parts. This is sometimes taken in along with the water at the reservoir, when the entry of the pipe is too near the surface. This should be carefully avoided, and it costs too trouble to do so. If the entry of the pipe is two feet under the surface, no air can ever get in. Fins should be placed above the entries, having lids hanging from them, which will shut the pipe before the water ran too low.

But air is also disengaged from spring-water by merely passing along the pipe. When pipes are supplied by an engine, air is very often drawn in by the pump in a disengaged state. It is also disengaged from its state of chemical union, when the pumps have a suction-pipe of 10 or 12 feet, which is very common. In whatever way it is introduced, it collects in all the upper part of bendings, and chokes the passage, so that sometimes a drop of water is delivered. Our cocks should be placed there, which should be opened frequently by persons who have this in charge. Desaguliers describes a contrivance to be placed on all such eunices, which does this of itself. It is a pipe with a cock, terminating in a small cistern. The key of the cock has a low ball of copper at the end of a lever. When there is no air in the main pipe, water comes out by this discharger, fills the cistern, raises the ball, and thus shuts the cock. But when the bend of the main contains air, it rises into the cistern, and occupies the upper part of it. Thus the floating ball falls down, the cock opens, and lets out the air, and the cistern again fills with water; the ball rises, and the cock is again shut.

A very neat contrivance for this purpose was invented by the late Professor Russel of Edinburgh. The cylindrical pipe BCDE (fig. 5), at the upper end of \(\frac{1}{4}\); bending of the main, is screwed on, the upper end of which is a flat plate perforated with a small hole \(F\). This pipe contains a hollow copper cylinder \(G\), in the upper part of which is fastened a piece of soft lead \(H\). When there is air in the pipe, it comes out by the hole \(A\), and occupies the discharger, and then escapes through the hole \(F\). The water follows, and, rising in the discharger, lifts up the hollow cylinder \(G\), causing the leather \(H\) to apply itself to the plate \(CD\), and shut the hole. Thus the air is discharged without the smallest loss of water.

It is of the most material consequence that there be no contraction in any part of a conduit. This is evident; but it is also prudent to avoid all unnecessary enlargements. For when the conduit is full of water moving along it, the velocity in every section is inversely proportional to the area of the section: it is therefore diminished wherever the pipe is enlarged; but it must again be increased where the pipe contracts. This cannot be without expending force in the acceleration. This consumes part of the impelling power, whether this be a head of water, or the force of an engine. See what is said on this subject in the article Forces, &c. Nothing is gained by any enlargement; and every contraction, by requiring an augmentation of velocity, employs a part of the impelling force precisely equal to the weight of a column of water whose base is the contracted passage, and whose height is the fall which would produce a velocity equal to this augmentation.

This point seems to have been quite overlooked by engineers of the first eminence, and has in many instances
WATER WORKS.

greatly diminished the performance of their best works. It is no less detrimental in open canals; because at every contraction a small fall is required for restoring the velocity lost in the enlargement of the canal, by which the general slope and velocity are diminished.

Another point which must be attended to in the conducting of water, is, that the motion should not be subserviency, but continuous. When the water is to be driven along a main by the strokes of a reciprocating engine, it should be forced into an air-box, the spring of which may preserves it in motion along the whole subsequent main. If the water is brought to rest at every successive stroke of the piston, the whole mass must again be put in motion through the length of the main. This requires the same useless expenditure of power as to communicate this motion to as much dead matter; and this is over and above the force which may be necessary for raising the water to a certain height; which is the only circumstance that enters into the calculation of the power of the pump-engine.

An air-box removes this imperfection, because it keeps up the motion during the returning stroke of the piston. The compression of the air by the active stroke of the piston must be such as to continue the impulse in opposition to the contrary pressure of the water (if it is to be raised to some height), and in opposition to the friction or other resistances which arise from the motion that the water really acquires. Indeed a very considerable force is employed here also in changing the motion of the water, which is forced out of the capacious air-box into the narrow pipe; and when this change of motion is not judiciously managed, the expenditure of power may be as great as if all were brought to rest and again put in motion. It may even be greater, by causing the water to move in the opposite direction to its former motion. Of such consequence is it to have all these circumstances scientifically considered. It is in such particulars, unheeded by the ordinary herd of engineers or pump-makers, that the superiority of an intelligent practitioner is to be seen.

Another material point in the conduct of water in pipes is the distribution of it to the different persons who have occasion for it. This is rarely done from the rising main. It is usual to send the whole into a cistern, from which it is afterwards conducted to different places in separate pipes. Till the discovery of the general theorem by the chevalier Basset, this has been done with great inaccuracy. Engineers think that the different purchasers from water-works receive in proportion to their respective bargains when they give them pipes whose areas are proportional to these payments. But we now see, that when these pipes are of any considerable length, the waters of a larger pipe run with a greater velocity than those of a smaller pipe having the same area. A pipe of two inches diameter will give much more water than four pipes of one inch diameter; it will give as much as five and a half such pipes, or more; because the squares of the discharges are very nearly as the fifth powers of the diameters. This point ought therefore to be carefully considered in the bargains made with the proprietors of water-works, and the payments made in this proportion. Perhaps the most unexceptionable method would be to make a double distribution. Let the water be first let off in its proper proportions into a secondary series of small cisterns, and let each have a pipe which will convey the whole water that is discharged into it. The first distribution may be made entirely by pipes of one inch in diameter; this would leave nothing to the calculation of the distributor, for every man would pay in proportion to the number of such pipes which run into his own cistern.

In many cases, however, water is distributed by pipes derived from a main. And here another circumstance comes into action. When water is passing along a pipe, its pressure on the sides of the pipe is diminished by its velocity; and if a pipe is now derived from it, the quantity drawn off is also diminished in the subduplicature ratio of the pressures. If the pressure is diminished to one-fourth, one-ninth, one-sixteenth, &c. the discharge from the lateral pipe is reduced to one-half, one-third, one-fourth, &c.

It is therefore of great importance to determine, what this diminution of pressure is which arises from the motion along the main.

It is plain, that if the water suffered no resistance in its main, its velocity would be that with which it entered, and it would pass along without exciting any pressure. If the pipe were shut at the end, the pressure on the sides would be the full pressure of the head of water. If the head of water remained the same, and the end of the tube be contracted, but not stopped entirely, the velocity in the pipe is diminished. If we would have the velocity in the pipe with this contracted mouth augmented to what it was before the contraction was made, we must employ the pressure of a piston, or of a head of water. This is propagated through the fluid, and again behind the resistance. New obstructions of any kind, arising from friction or any other cause, will reduce the pressure and velocity in the pipe. When the natural velocity is checked, the particles react on what obstructs their motion; and this action is uniformly propagated through a perfect fluid in every direction. The resistance therefore which we thus ascribe to friction, produces the same lateral pressure, which a contraction of the orifice, which equally diminishes the velocity in the pipe, would do. Indeed this is demonstrable from any distinct notions that we can form of these obstructions. They proceed from the want of perfect smoothness, which obliges the particles next the sides to move in undulated lines. This excites transverse forces in the same manner as any constrained curvilinear motion. A particle in its undulated path tends to escape from it, and acts on the lateral particles in the same manner that it would do if moving singly in a capillary tube having the same undulations; it would press on the concave side of every such undulation. Thus a pressure is exerted among the particles, which is propagated to the sides of the pipe; or the diminution of velocity may arise from a viscosity or want of perfect fluidity. This obliges the particle immediately pressed to drag along with it another particle which is withheld by adhesion to the sides. This requires additional pressure from a piston, or an additional head of water; and this pressure also is propagated to the sides of the pipe.

Hence it should follow, that the pressure which water in motion exerts on the sides of its conduit is equal to that which is competent to the head of water which impels.
WATER WORKS.

The pressure in the water pipe is diminished by the head of water, so that it is proportional to the actual velocity with which it moves along the pipe. Let $H$ represent the head of water, which impels it into the entry of the pipe, and $A$ the head which would produce the actual velocity; then $H-A$ is the column which would produce the pressure exerted on its sides.

This is abundantly verified by very simple experiments. Let an upright pipe be inserted into the side of the main pipe. When the water runs out by the mouth of the main, it will rise in this branch till the weight of the column balances the pressure that supports it; and if we then ascertain the velocity of the issuing water by means of the quantity discharged, and compute the head or height necessary for producing this velocity, and subtract this from the height of water above the entry of the main, we shall find the height in the branch precisely equal to their difference. Our readers may see this by examining the experiments related by Gravendie, and still better by consulting the experiments narrated by Boson, § 558, which are detailed with great minuteness; the results corresponded accurately with this proposition. The experiments indeed were not heights of water supported by this pressure, but water expelled by it through the same orifice. Indeed the truth of the proposition appears in every way we can consider the motion of water. And as it is of the first importance in the practice of conducting water (for reasons which will presently appear), it merits a particular attention. When an inclined tube is in train, the accelerating power of the water (or its weight diminished in the proportion of the length of the oblique column to its vertical height, or its weight multiplied by the fraction $\frac{1}{2}$, which expresses the slope), is in equilibrium with the obstructions; and therefore it exerts no pressure on the pipe but what arises from its weight alone. Any part of it would continue to slide down the inclined plane with a constant velocity, though detached from what follows it. It therefore derives no pressure from the head of water which impelled it into the pipe. The same must be said of a horizontal pipe infinitely smooth, or opposing no resistance. The water would move in this pipe with the full velocity due to the head of water which impels it into the entry. But when the pipe opposes an obstruction, the head of water is greater than that which would impel it into the pipe with the velocity that it actually has in it; and this additional pressure is propagated along the pipe, where it is balanced by the actual resistance, and therefore excites a quaquus versus on pressure on the pipe. In short, whatever part of the head of water in the reservoir, or of the pressure which impels it along the tube, is not employed in producing velocity, is employed in acting against some obstruction, and excites (by the refection of this obstruction) an equal pressure on the tube. The rule therefore is general, but is subject to some modifications which deserve our attention.

In the simply inclined pipe $BC$ (fig. 4.) the pressure on any point $S$ is equal to that of the head $AB$ of water which impels the water into the pipe, wanting or minus that of the head of water which would communicate to it the velocity with which it actually moves. This we shall call $z$, and consider it as the weight of a column of water whose length is $x$. In like manner $H$ may be the column $AB$, which impels the water into the pipe, and would communicate a certain velocity; and $A$ may represent the column which would communicate the actual velocity. We have therefore $z = H-A$.

In the pipe $HIKL$, the pressure at the point $I$ is $AH=AIO=H-AIO$; and the pressure at $K$ is $H-A+PK$.

And in the pipe $DEFG$, the pressure on $E$ is $AE=AH-EH-AEM$; and the pressure at $F$ is $H-A+FN$.

We must carefully distinguish this pressure on any square inch of the pipe from the obstruction or resistance which that inch actually exerts, and which is part of the cause of this pressure. The pressure is (by the law of hydrostatics) the same with that exerted on the water by a square inch of the piston or forcing head of water. This must balance the united obstructions of the whole pipe, in as far as they are not balanced by the relative weight of the water in an enclosed pipe. Whatever is the inclination of a pipe, and the velocity of the water in it, there is a certain part of this resistance which may not be balanced by the tendency which the water has to slide along it, provided the pipe be long enough; or if the pipe is too short, the tendency down the pipe may more than balance all the resistances that obtain below.

In the first case, this overplus must be balanced by an additional head of water; and in the latter case the pipe is not in train, and the water will accelerate. Then something in the mechanism of these motions which makes a certain length of pipe necessary for bringing it into train; a certain portion of the surface which acts in concert in obstructing the motion. We do not completely understand this circumstance, but we can form a pretty distinct notion of its mode of acting. The film of water contiguous to the pipe is withheld by the obstruction, but glides along; the film immediately within this is withheld by the outer film, but glides through it: and thus all the concentric films slide within those around them, somewhat like the sliding tubes of a syringe, when we draw it out by taking hold of the end of the innermost. Thus the second film passes beyond the first or outermost, and becomes the outermost, and rubs along the tube. The third does the same in turn; and thus the central filaments continue last to the outside, and all sustain their greatest possible obstruction. When this is accomplished, the pipe is in train. This requires a certain length, which we cannot determine by theory. We see, however, that pipes of greater diameter must require a greater length, and this is a proportion which is probably that of the number of filaments, or the square of the diameter. But the supposition agrees well enough with his experiments. A pipe of one inch in diameter sustained no change of velocity by gradually shortening it till it reduced it to six feet, and then it discharged a little more water. A pipe of two inches diameter gave a sensible augmentation of velocity when shortened to 25 feet. He therefore says, that the square of the diameter in inches, multiplied by 72, will express (in inches) the length necessary for putting any pipe in train.

The resistance exerted by a square inch of the pipe makes but a small part of the pressure which the whole
WATER-WORKS.

resistances occasion to be exerted there before they can be overcome. The resistance may be represented by

\[ \frac{d}{s} \]

when \( d \) is the hydraulic depth (one-fourth of the diameter), and \( s \) the length of a column whose vertical height is one inch, and it is the relative weight of a column of water whose base is a square inch, and height is \( d \). For the resistance of any length \( s \) of pipe which is in train, is equal to the tendency of the water to slide down (being balanced by it); that is, is equal to the weight of this column multiplied by \( \frac{1}{s} \). The magnitude of this column is had by multiplying its length by its section. The section is the product of the border \( b \) or circumference, multiplied by the mean depth \( d \), or it is \( b \cdot d \). This multiplied by the length, is \( b \cdot d \cdot s \); and this multiplied by the slope \( \frac{1}{s} \) is \( b \cdot d \), the relative weight of the column whose length is \( s \). The relative weight of one inch is therefore \( \frac{b \cdot d}{s} \); and this is in equilibrio with the resistance of a ring of the pipe one inch broad.

This, when unfolded, is a parallelogram \( b \) inches in length. One inch of this therefore is \( \frac{d}{s} \), the relative weight of a column of water having \( d \) for its height and a square inch for its base. Suppose the pipe four inches in diameter, and the slope = 253, the resistance is one grain; for an inch of water weighs 253 grains.

This knowledge of the pressure of water in motion is of great importance. In the management of rivers and canals it instructs us concerning the damages which they produce in their beds by tearing up the soil; it informs us of the strength which we must give to the banks: but it is of more consequence in the management of close conduits. By this we must regulate the strength of our pipes; by this also we must ascertain the quantities of water which may be drawn off by lateral branches from any main conduit.

With respect to the first of these objects, where security is our sole concern, it is proper to consider the pipes which are the most unfavourable circumstances, viz. when the end of the main is shut. This case is not unfrequent. Nay, when the water is in motion, its velocity in a conduit seldom exceeds a very few feet in a second. Eight feet per second requires only one foot of water to produce it. We should therefore estimate the strain on all conduits by the whole height of the reservoir.

In order to adjust the strength of a pipe to the strain, we may conceive it as consisting of two half cylinders of insuperable strength, joined along the two seams, where the strength is the same with the ordinary strength of the materials of which it is made. The inside pressure tends to burst the pipe by tearing open these seams; and each of these two seams is equal to the weight of a column of water whose height is the depth of the seam below the surface of the reservoir, and whose base is an inch broad and a diameter of the pipe in length. This follows from the common principles of hydrostatics.

Suppose the pipe to be of lead, one foot in diameter and 100 feet under the surface of the reservoir. Water

Vol. XX. Part II.

weight 625 pounds per foot. The base of our column is therefore \( \frac{1}{4} \) of a foot, and the tendency to burst the pipe is \( 100 \times 625 \times \frac{1}{4} \approx 521 \) pounds nearly. Therefore an inch of one seam is strained by 260\( \frac{1}{2} \) pounds. A rod of lead one inch square is pulled asunder by 860 pounds, (see STRENGTH of Materials, N° 40.). Therefore if the thickness of the seam is \( \frac{1}{16} \) inch, or one-third of an inch, it will just withstand this strain. But we must make it much stronger than this, especially if the pipe leads from an engine which sends the water along it by starts. Belidor and Desaguliers have given tables of the thickness and weights of pipes which experience has found sufficient for the different materials and depths. Desaguliers says, that a leaden pipe of three-fourths of an inch in thickness is strong enough for a height of 140 feet and diameter of seven inches. From this we may calculate all others. Belidor says, that a leaden pipe 12 inches diameter and 60 feet deep should be half an inch thick: but these things will be more properly computed by means of the list given in N° 40. of the article STRENGTH of Materials.

The application which we are most anxious to make of the knowledge of the pressure of moving waters is the derivation from a main conduit by lateral branches. This occurs very frequently in the distribution of waters among the inhabitants of towns; and it is so imperfectly understood by the greatest part of those who take the name of engineers, that individuals have no security that they shall get even one half of the water they bargain and pay for; yet this may be as accurately ascertained as any other problem in hydraulics by means of our general theorem. The case therefore merits our particular attention.

It appears to be determined already, when we have ascertained the pressures by which the water is impelled into these lateral pipes, especially after we have said that the experiments of Bossut on the actual discharges from a lateral pipe fully confirm the theoretical doctrine. But much remains to be considered. We have seen that there is a vast difference between the discharge made through a hole, or even through a short pipe, and the discharge from the far end of a pipe derived from a main conduit. And even when this has been ascertained by our new theory, the discharge thus modified will be found considerably different from the real state of things: for when water is flowing along a main with a known velocity, and therefore exerting a known pressure on the circle which we propose for the entry of a branch, if we insert a branch there water will flow along it: but this will generally make a considerable change in the motion along the main, and therefore in the pressure which is to expel the water. It also makes a considerable change in the whole quantity which passes along the anterior part of the main, and a still greater change on what moves along that part of it which lies beyond the branch: it therefore affects the quantity necessary for the whole supply, the force that is required for propelling it, and the quantity delivered by other branches. This part therefore of the management of water in conduits is of considerable importance and intricacy. We can propose in this place nothing more than a solution of such leading questions as involve the chief circumstances, recommending to our readers the perusal of original works on this subject. M. Bossut's
is the head necessary for the main with a branch, \( M \), may institute this proportion, \( H = \frac{x(H-y)}{y} \) and this 4th term will express the head producing the velocity in the main beyond the branch (as \( H-y \) would be done in a main without a branch). This velocity beyond the branch will be \( \sqrt{2G \frac{x(H-y)}{y}} \), and the discharge at the end will be \( A \sqrt{2G \frac{x(H-y)}{y}} + D \sqrt{x} \). From this we deduce the value of \( x \) being substituted in the equation of the discharge of the branch, which was \( D \sqrt{\frac{x}{H}} \) will give the discharges required, and they will differ so much the more from the discharges calculated according to the simple theory, as the velocity in the main is greater. By the simple theory, we mean the supposition that the lateral discharges are such as would be produced by the head \( H-b \), where \( H \) is the height of the reservoir, and \( b \) the head due to the actual velocity in the main.

And thus it appears that the proportion of the discharge by a lateral pipe from a main that is shut at the far end, and the discharge from a main that is open, depends not only on the pressures, but also on the size of the lateral pipe, and its distance from the reservoir. When it is large, it greatly alters the train of the main, under the same head, by altering the discharge at its extremity, and the velocity in it beyond the branch; and if it be near the reservoir, it greatly alters the train, because the diminished velocity takes place through a greater extent, and there is a greater diminution of the resistances.

When the branch is taken off at a considerable distance from the reservoir, the problem becomes more complicated, and the head \( x \) is resolved into two parts; one of which balances the resistance in the first part of the main, and the other balances the resistances beyond the lateral pipe, with a velocity diminished by the discharge from the branch. A branch at the end of the main produces very little change in the train of the pipe.

When the lateral discharge is great, the train may be so altered, that the remaining part of the main will not run full, and then the branch will not yield the same quantity. The velocity in a very long horizontal tube may be so small (by a small head of water and great obstructions in a very long tube) that it will just run full. An orifice made in its upper side will yield nothing; and yet a small tube inserted into it will carry a column almost as high as the reservoir. So that we cannot judge in all cases of the pressures by the discharges, and vice versa.
WATER-WORKS.

If there be an inclined tube, having a head greater than what is competent to the velocity, we may bring it into train by an opening on its upper side near the reservoir. This will yield some water, and the velocity will diminish in the tube till it is in train. If we should now enlarge the hole, it will yield no more water than before.

And thus we have pointed out the chief circumstances which affect these lateral discharges. The discharges are afterwards modified by the conduits in which they are conveyed to their places of destination. These being generally of small dimensions, for the sake of economy, the velocity is much diminished. But, at the same time, it approaches nearer to that which the same conduit would bring directly from the reservoir, because its small velocity will produce a less change in the train of the main conduit.

We should now treat of jets of water, which still make an ornament in the magnificent pleasure grounds of the wealthy. Some of these are indeed grand objects, such as the two at Peterhof in Russia, which spout about 60 feet high a column of nine inches diameter, which falls again, and shakes the ground with its blow. Even a spout of an inch or two inches diameter, lancing to the height of 150 feet, is a gay object, and greatly enlivens a pleasure ground; especially when the changes of a gentle breeze bend the jet to one side. But we have no room left for treating this subject, which is of some nicety; and must conclude this article with a very short account of the management of water as an active power for impelling machinery.

II. Of Machinery driven by Water.

This is a very comprehensive article, including almost every possible species of mill. It is no less important, and it is therefore matter of regret, that we cannot enter into the detail which it deserves. The mere description of the immense variety of mills which are in general use, would fill volumes, and a scientific description of their principles and forms of construction would almost form a complete body of mechanical science. But this is far beyond the limits of a work like ours. Many of these machines have been already described under their proper names, or under the articles which give an account of their manufactories; and for others we must refer our readers to the original works, where they are described in minute detail. The great academical collection Des Arts et Metiers, published in Paris in many folio volumes, contains a description of the peculiar machinery of many mills; and the volumes of the Encyclopédie Methodique, which particularly relate to the mechanical arts, already contain many more. All that we can do in this place is, to consider the chief circumstances that are common to all water-mills, and from which all must derive their efficacy. These circumstances are to be found in the manner of employing water as an acting power, and most of them are comprehended in the construction of water-wheels. When we have explained the principles and the maxims of construction of a water-wheel, every reader conversant in mechanics knows, that the axis of this wheel may be employed to transmit the force impressed on it to any species of machinery. Therefore nothing subsequent to this can with propriety be considered as water-works.

Water-wheels are of two kinds, distinguished by the manner in which water is made an impelling power, viz. by its weight, or by its impulse. This requires a very different form and manner of adaptation; and this forms an ostensible distinction, sufficiently obvious to give a name to each class. When water is made to act by its weight, it is delivered from the spout as high on the wheel as possible, that it may continue long to press it down; but when it is made to strike the wheel, it is delivered as low as possible, that it may have previously acquired a great velocity. And thus the wheels are said to be OVERSHOT or UNDERSHOT.

Of Overshot Wheels.

This is nothing but a frame of open buckets, so disposed round the rim of a wheel as to receive the water delivered from a spout; so that one side of the wheel is loaded with water, while the other is empty. The consequence must be, that the loaded side must descend. By this motion the water runs out of the lower buckets while the empty buckets of the rising side of the wheel come under the spout in their turn, and are filled with water.

If it were possible to construct the buckets in such a manner as to remain completely filled with water till they come to the very bottom of the wheel, the pressure with which the water urges the wheel round its axis would be the same as if the extremity of the horizontal radius were continually loaded with a quantity of water sufficient to fill a square pipe, whose section is equal to that of the bucket, and whose length is the diameter of the wheel. For let the buckets BD and EF (fig. 5.) be compared together, the arches DB and EF are equal. The mechanical energy of the water contained in the bucket EF, or the pressure with which its weight urges the wheel, is the same as if all this water were hung on that point T of the horizontal arm CF, where it is cut by the vertical or plumb-line BT. This is plain from the most elementary principles of mechanics. Therefore the effect of the bucket BD is to that of the bucket EF as CT to CF or CB. Draw the horizontal lines PB b, QD d. It is plain, that if BD is taken very small, so that it may be considered as a straight line, BD : BO = CB : BF, and EF : b d = CF : CT, and EF x CT = b d x CF. Therefore if the prism of water, whose vertical section is b b d d, were hung on at F, its force to urge the wheel round would be the same as that of the water lying in the bucket BD. The same may be said of every bucket; and the effective pressure of the whole ring of water A/HKF /L, in its natural situation, is the same with the pillar of water a h a hung on at F. And the effect of any portion BF of this ring is the same with that of the corresponding portion b F /b of the vertical pillar. We do not take into account the small difference which arises from the depth b or F , because we may suppose the circle described through the centres of gravity of the buckets. And in the farther prosecution of this subject, we shall take similar liberties, with the view of simplifying the subject, and saving time to the reader.

But such a state of the wheel is impossible. The bucket at the very top of the wheel may be completely filled with water; but when it comes into the oblique position BD, a part of the water must run over the outer edge 2, and the bucket will only retain the quan-
WATER-WORKS.

which will fill the space $FABC$ will all be counted in the bucket when it shall come into such a position as that $AD$ is a horizontal line; and the line $AB$ will then make an angle of nearly $33^\circ$ with the vertical, or the bucket will be $23^\circ$ from the perpendicular. If the bucket descend so much lower that one half of the water runs out, the line $AB$ will make an angle of $23^\circ$, or $24^\circ$ nearly, with the vertical. Therefore the miter, filled to the degree now mentioned, will begin to be water at about $4\frac{1}{2}$th of the diameter from the bottom, and half of the water will be discharged from the least bucket, about $4\frac{1}{4}$th of the diameter farther down. The situations of the discharging bucket are marked at $T$ and $V$ in fig. 6. Had a greater proportion of the buckets been filled with water when they were under the spout, the discharge would have begun at a greater height from the bottom, and we should lose a greater portion of the whole fall of water. The loss by the present construction is less than $10^\circ$ (supposing the water to be delivered into the wheel at the very top, and may be estimated at about $1\frac{1}{4}$th of the diameter. Theversed sines of the angles which the radius of the buckets makes with the vertical. Theversed sines of $37^\circ$ nearly $\frac{3}{4}$th of the radius (being $0.18285$), or $\frac{3}{5}$th of the diameter. It is evident, that if only $\frac{3}{5}$ of this water were supplied to each bucket as it passes the spot, it would have been retained for $10^\circ$ more of a revolution, and the loss of fall would have been only about $\frac{1}{9}$th.

These observations serve to show, in general, that an advantage is gained by having the buckets so spaced that the quantity of water which each can receive as it passes the spout may not nearly fill it. This may be accomplished by making them of a sufficient length, that, by making the wheel sufficiently broad between the two shroudings, economy is the only objection to this practice, and it is generally very ill placed. When the work to be performed by the wheel is great, the addition of power gained by a greater breadth will not compensate for the additional expense.

The third plane $CD$ is not very frequent; and millwrights generally content themselves with continuing the board all the way from the elbow $B$ to the outer edge of the wheel at $H$; and $AB$ is generally no more than one-third of the depth $AI$. But $CD$ is a very evident improvement, causing the wheel to retain a very sensible addition to the water. Some indeed make this addition more considerable, by bringing $BC$ more outward, so as to meet the rim of the wheel at $H$, for instance, and making $HD$ coincide with the rim. But this makes the entry of the water somewhat more difficult during the very short time that the opening of the bucket passes the spout. To facilitate this as much as possible, the water should get a direction from the spout, such as will send it into the buckets in the most perfect manner. This may be obtained by delivering water through an aperture that is divided by thin plates of board or metal, placed in the proper position, as we have represented in fig. 6. The form of bucket last mentioned, having the wrought concavity of the rim, is unfavourable to the ready admission of the water; whereas an oblique wrest conducts the water which has missed one bucket into the next below.

The mechanical considerations of this subject also shows us, that a deep shrouding, in order to make a capacious bucket,
bucket, is not a good method: it does not make the buckets retain their water any longer; and it diminishes the effective fall of water: for the water received at the top of the wheel immediately falls to the bottom of the bucket, and thus shortens the fictitious pillar of water, which we showed to be the measure of the effective or useful pressure on the wheel: and this concurs with our former reasons for recommending as great a breadth of the wheel, and length of buckets, as economical considerations will permit.

A bucket wheel was some time ago executed by Mr Robert Burns, at the cotton mills of Houston, Burns, and Co., at Cartside in Renfrewshire, of a construction entirely new, but founded on a good principle, which is susceptible of great extension. It is represented in fig. 8. The bucket consists of a start AB, an arm BC, and a wrest CD, concentric with the rim. But the bucket is also divided by a partition LM, concentric with the sole and rim, and so placed as to make the inner and outer portions of nearly equal capacity. It is evident, without any further reasoning about it, that this partition will enable the bucket to retain its water much longer. When they are filled one-third, they retain the whole water at 12° from the bottom; and they retain one-half at 11°. They do not admit the water quite so freely as buckets of the common construction; but by means of the contrivance mentioned a little ago for the spout (also the invention of Mr Burns, and furnished with a rackwork, which raised or depressed it as the supply of water varied, so as at all times to employ the whole fall of the water), it is found, that a slow-moving wheel allows one-half of the water to get into the inner buckets, especially if the partition does not altogether reach the radius drawn through the lip D of the outer bucket.

This is a very great improvement of the bucket wheel; and when the wheel is made of a liberal breadth, so that the water may be very shallow in the buckets, it seems to carry the performance as far as it can go. Mr Burns made the first trial on a wheel of 24 feet diameter; and its performance is manifestly superior to that of the wheel which it replaced, and which was a very good one. It has also another valuable property: When the supply of water is very scanty, a proper adjustment of the apparatus in the spout will direct almost the whole of the water into the outer buckets; which, by placing it at a greater distance from the axis, makes a very sensible addition to its mechanical energy.

We said that this principle is susceptible of considerable extension; and it is evident that two partitions will increase the effect, and that it will increase with the number of partitions: so that when the practice now begins, of making water-wheels of iron, shall become general, and therefore very thin partitions are used, their number may be greatly increased without any inconvenience: and it is obvious, that this series of partitions must greatly contribute to the stiffness and general firmness of the whole wheel.

There frequently occurs a difficulty in the making of bucket wheels, when the half-taught millwright attempts to retain the water a long time in the buckets. The water gets into them with a difficulty which he cannot account for, and spills all about, even when the buckets are not moving away from the spout. This arises from the air, which must find its way out to admit the water, but is obstructed by the entering water, and occasion a great spluttering at the entry. This may be entirely prevented by making the spout considerably narrower than the wheel. This will leave room at the two ends of the buckets for the escape of the air. This obstruction is vastly greater than one would imagine; for the water drags along with it a great quantity of air, as is evident in the water-blast described by many authors.

There is another and very serious obstruction to the motion of an overshot or bucketed wheel. When it moves in back water, it is not only resisted by the water, when it moves more slowly than the wheel, which is very frequently the case, but it lifts a great deal in the rising buckets. In some particular states of back water, the descending bucket fills itself completely with water; and, in other cases, it contains a very considerable quantity, and air of common density; while in some rarer cases it contains less water, with air in a condensed state. In the first case, the rising bucket must come up filled with water, which it cannot drop till its mouth get out of the water. In the second case, part of the water goes out before this, but the air remains, and therefore there is still some water dragged or lifted up by the wheel, by suction as it is usually called. In the last case there is no such back load on the rising side of the wheel, but (which is as detrimental to its performance) the descending side is employed in condensing air; and although this air aids the ascent of the rising side, it does not aid it so much as it impedes the descending side, being (by the form of the bucket), nearer to the vertical line drawn through the axis.

All this may be completely prevented by a few holes made in the start of each bucket. Air being at least 800 times rarer than water, will escape through a hole almost 50 times faster with the same pressure. Very moderate holes will therefore suffice for this purpose: and the small quantity of water which these holes discharge during the descent of the buckets, produces a loss which is altogether insignificant. The water which runs out of one runs into another, so that there is only the loss of one bucket. We have seen a wheel of only 14 feet diameter working in nearly three feet of back water. It laboured prodigiously, and brought up a great load of water, which fell from it in abrupt dashes, which rendered the motion very hobbled. When three holes of an inch diameter were made in each bucket (12 feet long), the wheel laboured no more, there was no more plunging of water from its rising side, and its power on the machinery was increased more than one-fourth.

These practical observations may contain information that is new even to several experienced millwrights. To persons less informed they cannot fail of being useful. We now proceed to consider the action of water thus lying in the buckets of a wheel; and to ascertain its energy as it may be modified by different circumstances of fall, velocity, etc.

With respect to variations in the fall, there can be little room for discussion. Since the effective pressure is measured by the pillar of water reaching from the horizontal plane where it is delivered on the wheel, to the horizontal plane where it is spilled by the wheel, it is evident that it must be proportional to this pillar, and therefore we must deliver it as high and retain it as long as possible.

This maxim obliges us, in the first place, to use a wheel...
WATER-WORKS.

Wheel whose diameter is equal to the whole fall. We shall not gain any thing by employing a larger wheel; for although we should gain by using only that part of the circumference where the weight will act more perpendicularly to the radius, we shall lose more by the necessity of discharging the water at a greater height from the bottom: For we must suppose the buckets of both the wheels equally well constructed; in which case, the heights above the bottom, where they will discharge the water, will increase in the proportion of the diameter of the wheel. Now, that we shall lose more by this than we gain by the more direct application of the weight, is plain, without any further reasoning, by taking the extreme case, and supposing our wheel enlarged to such a size, that the useless part below is equal to our whole fall. In this case the water will be spilled from the buckets as soon as it is delivered into them. All intermediate cases, therefore, partake of the imperfection of this.

When our fall is exceedingly great, a wheel of an equal diameter becomes enormously big and expensive, and is of itself an unmanageable load. We have seen wheels of 48 feet diameter, however, which worked extremely well; but they are of very difficult construction, and extremely apt to warp and go out of shape by their weight. In cases like this, where we are unwilling to lose any part of the force of a small stream, the best form of a bucket wheel is an inverted chain pump. Instead of employing a chain pump of the best construction, ABCDEA (fig. 11.) to raise water through the upright pipe CB, by means of a force applied to the upper wheel A, let the water be delivered from a spout F, into the upper part of a pipe BC, and it will press down the plugs in the lower and narrower bored part of dead level of C. This weight will urge round the wheel in such a manner that any fall of water whatever can be applied, and exceeds the most perfect overshot wheel. But though it excels all chains of buckets in economy and in effect, it has all the other imperfections of this kind of machinery. Though the chain of plugs be of great strength, it has so much motion in its joints that it needs frequent repairs; and when it breaks, it is generally in the neighbourhood of A, on the loaded side, and all comes down with a great crash. There is also a loss of power by the immersion of so many plugs and chains in the water; for there can be no doubt but that if the plugs were big enough and light enough, they would buoy and even draw up the plugs in the narrow part at the force with which this plug is pressed down.

The velocity of an overshot wheel is a matter of very great nicety; and authors, both speculative and practical, on the subject. Mr Belidor, whom the engineers in Europe have long been accustomed to regard as sacred authority, maintains, that there is a certain velocity related to that obtainable by the whole fall, which will procure to an overshot wheel the greatest performance. Others, maintain, that there is no such relation, and that as it moves more slowly by an increase of its load of work, Belidor maintains, that the active power of wa-

ter lying in a bucket wheel of any diameter is equal to that of the impulse of the same water on the flat of a undershot wheel, when the water issues from a sluice in the bottom of the dam. The other writers when we have named assert, that the energy of an undershot wheel is but one half of that of an overshot, actuated by the same quantity of water falling from the same height.

To a manufacturing country like ours, which derives astonishing superiority, by which it more than compensates for the impediments of heavy taxes and excessive living, chiefly from its machinery, in which it leaves all Europe far behind, the decision of this question, is not a manner shall leave no doubt or misconception in the mind even of an unlettered artist, must be considered as a material service: and we think that this is easily attainable.

When any machine moves uniformly, the accelerating force or pressure actually exerted on the impelled pint of the machine is in equilibrio with all the resistances which are exerted at the working point, with those arising from friction, and those that are excited in different parts of the machine by their mutual actions. This is an incontestable truth; and though little attended to by the mechanicians, is the foundation of all practical knowledge of machines. Therefore, when an overshot wheel moves uniformly, with any velocity whatever, the water is acting with its whole weight: for gravity would accelerate its descent, if not completely balanced by some reaction; and in this balance gravity and the acting part of the machine exert equal and opposite pressures, and thus produce the uniform motion of the machine. We are thus particular on this point, because we observe mechanicians of the first name employing a mode of reasoning on the question now before us which is spurious, and appears to prove the conclusion which they draw; but is nevertheless contrary to true mechanical principles. They assert, that the slower a body is descending (suppose in a scale suspended from an axis in peritrochoi), the more does it press on the scale, and the more does it urge the machine round: and therefore the slower an overshot wheel turns, the greater is the force with which the water urges it round, and the more work will be done. It is very true that the machine is more forcibly impelled, and that more work is done; but this is not because a pound of water presses more strongly, but because there is more water pressing on the wheel; for the spout supplies at the same rate, and each bucket receives more water as it passes by it.

Let us therefore examine this point by the unquestionable principles of mechanics.

Let the overshot wheel AFGH (fig. 12.) receive the water from a spout at the very top of the wheel; and in order that the wheel may not be retarded by dragging into motion the water simply laid into the uppermost bucket at A, let it be received at B, with the velocity (directed in a tangent to the wheel) acquired by the head of water AP. This velocity, therefore, must be equal to that of the rim of the wheel. Let this be v, or let the wheel and the water move over v inches in a second. Let the buckets be of such dimensions that all the water which each receives as it passes the spout is retained till it comes to the position B, where it is discharged at once. It is plain that, in place of the separate quantities of water lying in each bucket, we may substitute a continued ring of water, equal to their

3
WATER-WORKS.

This constitutes a ring of uniform thickness. Let the area of its cross section A B and F / P be called \( a \). We have already demonstrated, that the mechanical energy with which this water on the circumference of the wheel urges it round, is the same with what would be exerted by the pillar \( b / r \) pressing on \( F / P \) acting by the lever \( C / F \). The weight of this pillar may be expressed by \( a \times b \), or \( a \times P \); and if we call the radius \( CF \) of the wheel \( R \), the momentum or mechanical energy of this weight will be represented by \( a \times P \times R \).

Now, let us suppose that this wheel is employed to raise a weight \( W \), which is suspended by a rope wound round the axis of the wheel. Let \( r \) be the radius of this axle. Then \( W \times r \) is the momentum of the work. Let the weight rise with the velocity \( v \) when the rim of the wheel turns with the velocity \( v \), that is, let it rise \( v \) inches in a second.

Since a perfect equilibrium obtains between the power and the work when the motion is uniform, we must have \( W \times r = a \times P \times R \). But it is evident that \( R = \frac{v}{\omega} \). Therefore \( W = a \times P \times \frac{v}{\omega} \).

Now the performance of the machine is undoubtedly measured by the weight and the height to which it is raised in a second, or by \( W \times v \). Therefore the machine is in its best possible state when \( a \times v \times P \) is a maximum. But it is plain that \( a \times v \) is an invariable quantity; for it is the cubic inches of water which the spout supplies in a second. If the wheel moves fast, little water lies in each bucket, and \( a \) is small. When \( v \) is small, \( a \) is great, for the opposite reason; but \( a \times v \) remains the same. Therefore we must make \( P \) a maximum, that is, we must deliver the water as high up as possible. But this diminishes \( AP \), and this diminishes the velocity of the wheel: and as this has no limit, the proposition is demonstrated; and an overshot wheel does the more work as it moves slower.

Convincing as this discussion must be to any mechanic, we are anxious to impress the same maxim on the minds of practical men, unaccustomed to mathematical reasoning of any kind. We therefore beg indulgence for adding a popular view of the question, which requires no such investigation.

We may reason in this way: Suppose a wheel having 30 buckets, and that six cubic feet of water are delivered in a second on the top of a wheel, and discharged without any loss by the way at a certain height from the bottom of the wheel. Let this be the case, whatever is the rate of the wheel's motion; the buckets being of sufficient capacity to hold all the water which falls into them. Let this wheel be employed to raise a weight of any kind, suppose water in a chain of 30 buckets, to the same height, and with the same velocity. Suppose, farther, that when the load on the rising side of the machine is one half of that on the wheel, the wheel makes four turns in a minute, or one turn in 15 seconds. During this time 90 cubic feet of water have flowed into the 30 buckets, and each has received three cubic feet. Then each of the rising buckets contains 1 1/2 feet; and 45 cubic feet are delivered into the upper cistern during one turn of the wheel, and 180 cubic feet in one minute.

Now, suppose the machine so loaded, by making the rising buckets more capacious, that it makes only two turns in a minute, or one turn in 30 seconds. Then each descending bucket must contain six cubic feet of water. If each bucket of the rising side contained three cubic feet, the motion of the machine would be the same as before. This is a point which no mechanic will controvert. When two pounds are suspended to one end of a string which passes over the pulley, and one pound to the other, the descent of the two pounds will be the same with that of a four pound weight, which is employed in the same manner to draw up two pounds. Our machine would therefore continue to make four turns in the minute, and would deliver 90 cubic feet during each turn, and 360 in a minute. But, by supposition, it is making but two turns in a minute: this must proceed from a greater load than three cubic feet of water in each rising bucket. The machine must therefore be raising more than 90 feet of water during one turn of the wheel, and more than 180 in the minute.

Thus it appears, that if the machine be turning twice as slow as before, there is more than twice the former quantity in the rising buckets, and more will be raised in a minute by the same expenditure of power. In like manner, if the machine go three times as slow, there must be more than three times the former quantity of water in the rising buckets, and more work will be done.

But we may go farther, and assert, that the more we retard the machine, by loading it with more work of a similar kind, the greater will be its performance. This does not immediately appear from the present discussion: But let us call the first quantity of water in the rising bucket \( A \); the water raised by four turns in a minute will be \( 4 \times 30 \times A = 120 \times A \). The quantity in this bucket, when the machine goes twice as slow, has been shown to be greater than \( 2 \times A \) (call it \( 2A + x \)); the water raised by two turns in a minute will be \( 2 \times 30 \times 2A + x = 120 \times A + 60x \). Now, let the machine go four times as slow, making but one turn in a minute, the rising bucket must now contain more than twice \( 2A + x \), or more than \( 4A + 2x \); call it \( 4A + 2x + y \). The work done by one turn in a minute will now be \( 30 + 4A + 2x + y = 120 \times A + 60x + 30y \).

By such an induction of the work, done with any rates of motion we choose, it is evident that the performance of the machine increases with every diminution of its velocity that is produced by the mere addition of a similar load of work or that it does the more work the slower it goes.

We have supposed the machine to be in its state of permanent uniform motion. If we consider it only in the beginning of its motion, the result is still more in favour of slow motion: For, at the first action of the moving power, the inertia of the machine itself consumes part of it, and it acquires its permanent speed by degrees; during which, the resistances arising from the work, friction, &c. increase, till they exactly balance the pressure of the water; and after this the machine accelerates no more. Now the greater the power and the resistance arising from the work are, in proportion to the inertia of the machine, the sooner will all arrive at its state of permanent velocity.

There is another circumstance which impairs the performance of an overshot wheel moving with a great velocity, viz. the effects of the centrifugal force on the
WATER-WORKS.

Our millwrights know well enough, that too great velocity will throw the water out of the buckets; but few, if any, know exactly the diminution of power produced by this cause. The following very simple construction will determine this:

Let AOB (fig. 10.) be an overshot wheel, of which AB is the upright diameter, and C is the centre. Make CF the length of a pendulum, which will make two vibrations during one turn of the wheel. Draw MC to the elbow of any of the buckets. The water in this bucket, instead of having its surface horizontal, as NO, will have it in the direction NO perpendicular to MC very nearly.

For the time of falling along half of FC is to that of two vibrations of this pendulum, or to the time of a revolution of the wheel, as the radius of a circle is to its circumference: and it is well known that the time of moving along half of AC, by the uniform action of the centrifugal force, is to that of a revolution as the radius of a circle to its circumference. Therefore the time of describing one half of AC by the centrifugal force, is equal to the time of describing one half of FC by gravity. These spaces, being similarly described in equal times, are proportional to the accelerating forces. Therefore, ½ FC : ½ AC, or FC : AC = gravity : centrifugal force. Complete the parallelogram FCEK.

A particle at E is urged by the weight in the direction KE, with a force which may be expressed by FC or KE; and it is urged by the centrifugal force in the direction CE, with a force = AC or CE. By their combined action it is urged in the direction FE. Therefore, as the surface of standing water is always at right angles to the action of gravity, that is, to the plumb-line, so the surface of the water in the revolving bucket is perpendicular to the action of the combined force FE.

Let NEO be the position of the bucket, which just holds all the water which it received as it passed the spout when not affected by the centrifugal force; and let NDO be its position when it would be empty. Let the vertical lines through D and E cut the circle described round C with the radius CF in points H and M. Draw HC, IC, cutting the circle AOB in points L and F. Make the arc DF equal to AL, and the arc CF equal to AM. Then C and C will be the positions of the bucket on the revolving wheel, corresponding to CDO and CEO on the wheel at rest. Water will begin to run out at E, and it will be all gone at E. The demonstration is evident.

The force which now urges the wheel is still the weight, really in the buckets: For though the water be urged in the direction with the force FE, one of its components, CE, has no tendency to impel the wheel; and KE is the only impelling force.

It is but of late years that mills have been constructed or attended to with that accuracy and scientific skill which are necessary for deducing confidential conclusions from any experiments that can be made with them; and the opinions of millwrights have been so different on this subject. There is a natural wish to see a machine moving briskly: it has the appearance of activity: but a very slow motion always looks as if the machine were overloaded. For this reason millwrights have always yielded slowly, and with some reluctance, to the repeated advices of the mathematicians: but they have yielded; and we see them adopting maxims of construction more agreeable to sound theory; making their wheels of great breadth, and loading them with a great deal of work. Mr. Eson says, that the performance of the best mill cannot exceed that of the worst above 4th: but we have seen a mill stream of water completely expended in driving a small flax mill, which now drives a cotton mill of 250 spindles, with all its carding, reeling, and drawing machinery, besides the lathes and other engines of the smith and carpenters workshops, exerting a force not less than ten times what sufficed for the flax mill.

The above discussion only demonstrates a great advantage of slow motion; but does not point out any degree the relation between the rate of motion and the work performed, nor even the principles on which it depends. Yet this is a subject fit for a mathematical investigation; and we would prosecute it in this plan, if it were necessary for the improvement of practical mechanics. But we have seen that there is not, in the nature of things, a maximum of performance attachable to any particular rate of motion which should therefore be preferred. For this reason we omit this discussion of more speculative curiosity. It is very intricate: for we must not now express the pressure on the wheel by a constant pillar of water incumbent on the extremity of the horizontal arm, as we did before when we supposed the buckets completely filled; nor by a smaller constant pillar, corresponding to a smaller but equal quantity flowing in every bucket. Each different velocity puts a different quantity of water into the bucket as it passes the spout; and this occasions a difference in the place where the discharge is begun and completed. This circumstance is some obstacle to the advantages of very slow motions, because it brings on the discharge room. All this may indeed be expressed by a simple equation of easy management; but the whole process of the mechanical discussion is both intricate and tedious, and the results are so much diversified by the forms of the buckets, that they do not afford any rule of sufficient generality to reward our trouble. The curious reader may see a very full investigation of this subject in two dissertations by Elvius in the Swedish Transactions, and in the Hydrodynamique of Professor Karstner of Gattings; who has abridged these dissertations of Elvius, and considerably improved the whole investigation, and has added some comparisons of his deductions with the actual performance of some great works. These comparisons, however, are not very satisfactory. There is also a valuable paper on this subject by Mr. Lambert in the Memoirs of the Academy of Berlin for the year 1775. From these dissertations, and from the Hydrodynamique of the abbe Bonnot, the reader will get all that theory can teach of the relation between the pressures of the power and work on the machine and the rates of its motion. The practical reader may rest with confidence on the simple demonstration we have given, that the performance is improved by diminishing the velocity.

All we have to do, therefore, is to load the machine, and thus to diminish its speed, unless other physical circumstances throw obstacles in the way: but there are such obstacles. In all machines there are little irregularities of action that are unavoidable. In the action of a wheel and pinion, though made with the utmost judgment and care, there are such inequalities...
WATER-WORKS.

crease by the changes of form occasioned by the wearing
of the machine—much greater irregularities arise from
the subsoilary motions of cranks, stampers, and other
parts which move unequally or reciprocally. A ma-
chine may be so loaded as just to be in equilibrium
with its work, in the favourable position of its parts. When
this changes into one less favourable, the machine may
stop; if not, it at least staggers, hobbles, or works un-
equally. The rubbing parts bear long on each other,
with enormous pressures, and cut deep, and increase fric-
tion. Such slow motions must therefore be avoided.
A little more velocity enables the machine to get over
those increased resistances by its inertia, or the great
quantity of motion inherent in it. Great machines pos-
sess this advantage in a superior degree, and will there-
fore work steadily with a smaller velocity. These
circumstances are hardly susceptible of mathematical
discussion, and our best reliance is on well-disabled
experience.

For this purpose, the reader will do well to peruse
with care the excellent paper by Mr Smeaton in the
Philosophical Transactions for 1759. This dissertation
contains a numerous list of experiments, most judici-
ously contrived by him, and executed with the accu-

racy and attention to the most important circumstances,
which is to be observed in all that gentleman's perform-
ances.

It is true, these experiments were made with small
models; and we must not, without great caution, trans-
fer the results of such experiments to large works. But
we may safely transfer the laws of variation which re-
sult from a variation of circumstances, although we must
not adopt the absolute quantities of the variations them-
selves. Mr Smeaton was fully aware of the limitations
to which conclusions drawn from experiments on models
are subject, and has made the applications with his usual
sagacity.

His general inference is, that, in smaller works, the
rim of the overshot-wheel should not have a greater ve-
locity than three feet in a second; but that larger mills
may be allowed a greater velocity than this. When
every thing is executed in the best manner, he says that
the work performed will amount to fully two-thirds of
the power expended; that is, that three cubic feet of
water descending from any height will raise two to the
same height.

It is not very easy to compare these deductions with
observations on large works; because there are few cases
where we have good measures of the resistances opposed
by the work performed by the machine. Mills employ-
ed for pumping water afford the best opportunities. But
the inertia of their working gear diminishes their useful
performance very sensibly; because their great beams,
pump-rods, &c. have a reciprocating motion, which
must be destroyed, and produced anew in every stroke.
We have examined some machines of this kind which
are esteemed good ones; and we find few of them whose
performance exceeds one half of the power expended.

By comparing other mills with these, we get the best
information of their resistances. The comparison with
mills worked by Watt and Boulton's steam-engines is
perhaps a better measure of the resistances opposed by
different kinds of work, because their power is very
distinctly known. We have been informed by one of the
most eminent engineers, that a ton and a half of

water per minute falling one foot will grind and dress
one bushel of wheat per hour. This is equivalent to 9
tons falling 10 feet.

If an overshot-wheel opposed no resistance, and only
one bucket were filled, the wheel would acquire the ve-
locity due to a fall through the whole height. But
when it is in this state of accelerated motion, if another
bucket of water is delivered into it, its motion must be
checked at the first, by the necessity of dragging for-
ward this water. If the buckets fall in succession as they
pass the spout, the velocity acquired by an unresisting
wheel is but half of that which one bucket would give.
In all cases, therefore, the velocity is diminished by the
inertia of the entering water when it is simply laid into
the upper buckets. The performance will therefore be
improved by delivering the water on the wheel with
that velocity with which the wheel is really moving.
And as we cannot give the direction of a tangent to the
wheel, the velocity with which it is delivered on the
wheel must be so much greater than the intended ve-
locity of the rim, that it shall be precisely equal to it when
it is estimated in the direction of the tangent. Three or
four inches of fall are sufficient for this purpose; and it
should never be neglected, for it has a very sensible in-
fluence on the performance. But it is highly improper
to give it more than this, with the view of impelling
the wheel by its stroke. For even although it were
proper to employ part of the fall in this way (which we
shall presently see to be very improper), we cannot pro-
cure this impulse; because the water falls among other
water, or it strikes the boards of the wheel with such
obliquity that it cannot produce any such effect.

It is a much debated question among millwrights,
Whether the diameter of the wheel should be such as
that the water will be delivered at the top of the wheel;
or larger, so that the water is received at some distance
from the top, where it will not more perpendicularly to
the arm? We apprehend that the observations formerly
made will decide in favour of the first practice. The
space below, where the water is discharged from the
wheel, being proportional to the diameter of the wheel,
there is an undoubted loss of fall attending a large wheel;
and this is not compensated by delivering the water at a
greater distance from the perpendicular. We should
therefore recommend the use of the whole descending
side, and make the diameter of the wheel no greater
than the fall, till it is so much reduced that the cen-
trifugal force begins to produce a sensible effect. Since
the rim can hardly have a smaller velocity than three
feet per second, it is evident that a small wheel must
revolve more rapidly. This made it proper to insert
the determination that we have given, of the loss of
power produced by the centrifugal force. But even
with this in view, we should employ much smaller wheels
than are generally done on small falls. Indeed the loss
of water at the bottom may be diminished, by nicely
fitting the arch which surrounds the wheel, so as not to
allow the water to escape by the sides or bottom. When
this improvement remains in good order, and the wheel
entire it produces a very sensible effect; but the passage
widens continually by the wearing of the wheel. A
bit of a stick or stone falling in about the wheel tears
off part of the shrouding or bucket, and frosty weather
frequently binds all fast. It therefore seldom answers
expectations. We have nothing to add on this case
to what we have already extracted from Mr Smeston's
Dissertation on the Subject of Breast or half Overshot
Wheels.

There is another form of wheel by which water is
made to act on a machine by its weight, which merits
consideration. This is known in this country by the
name of Barker's mill, and has been described by Desa-
guliers, vol. ii. p. 460. It consists of an upright pipe
or trunk AB (fig. 11.), communicating with two hori-
zontal branches BC, D E, which have a hole C, near
their ends, opening in opposite directions, at right angles
to their lengths. Suppose water to be poured in at the
top from the spout F, it will run out by the holes C
and E with the velocity corresponding to the depth of
these holes under the surface. The consequence of this
must be, that the arms will be pressed backwards; for
there is no solid surface at the hole C, on which the
lateral pressure of the water can be exerted, while it acts
with its full force on the opposite side of the arm. This
unbalanced pressure is equal to the weight of a column
having the orifice for its base, and twice the depth under
the surface of the water in the trunk for its height.
This measure of the height may seem odd, because if
the orifice were shut, the pressure on it is the weight
of a column reaching from the surface. But when it is
open, the water issues with nearly the velocity acquired
by falling from the surface, and the quantity of motion
produced is that of a column of twice this length, mov-
ing with this velocity. This is actually produced by
the pressure of the fluid, and must therefore be accom-
panied by an equal reaction.

Now suppose this apparatus set on the pivot E, and
have a spindle AD above the trunk, furnished with a
cylindrical bobbin D, having a rope wound round it,
and passing over a pulley G. A weight W may be
suspended there, which may balance this backward pres-
sure. If the weight be too small for this purpose, the
retrograde motion of the arms will wind up the cord,
and raise the weight; and thus we obtain an acting
machine, employing the pressure of the water, and ap-
licable to any purpose. A runner millstone may be
put on the top of the spindle; and we should then pro-
duce a flour mill of the utmost simplicity, having neither
wheel nor pinion, and subject to hardly any wear. It
is somewhat surprising, that although this was invented
at the beginning of this century, and appears to have
such advantage in point of simplicity, it has not come
into use. So little has Mr Desaguliers's account been
attested to (although it is mentioned by him as an ex-
cellent machine, and highly instructive to the hy-
draulist), that the same invention was again brought
forward by a German professor (Segner) as his own,
and has been honoured by a series of elaborate dis-
juctions concerning its theory and performance by Euler
by John Bernoulli. Euler's Dissertations are to be
found in the Memoirs of the Academy of Berlin, 1751,
and in the Nouv. Comment. Petropol. tom. vi. Ber-
noulli's are at the end of his Hydraulics. Both these
authors agree in saying, that this machine excels all as
it appears, its true theory, and the best form of con-
struction, are most abstruse and delicate subjects; and it
will be understood by an ordinary reader.

We see, in general, that the machine must press back-
wards; and little investigation suffices for understand-
ing the intensity of this pressure, when the machine is at
rest. But when it is allowed to run backwards, with a
force from the pressure, the intensity of it is diminished,
and if no other circumstances intervene, it might not
be difficult to say what particular pressure corresponded
to any rate of motion. Accordingly, Desagulier's, pre-
suming on the simplicity of the machine, affirm the
pressure to be the weight of a column, which would
produce a velocity of efflux equal to the difference of
the velocity of the fluid and of the machine; and hence
he deduces, that its performance will be the greatest
possible, when its retrograde velocity is one-third of
the velocity acquired by falling from the surface, in which
case it will raise 3/12ths of the water expended to the
same height, which is double of the performance of a
mill acted on by the impulse of water.

But this is a very imperfect account of the operation.
When the machine (constructed exactly as we have
described) moves round, the water which issues from
in the vertical trunk, and the water moving along the ho-
izontal arms, partakes of this circular motion. This ex-
cites a centrifugal force, which is exerted against the
ends of the arms by the intervention of the fluid. The
whole fluid is subjected to this pressure (increasing for
every section across the arm in the proportion of its dis-
tance from the axis), and every particle is pressed with
the accumulated centrifugal forces of all the sections
that are nearer to the axis. Every section therefore
sustains an actual pressure proportional to the square of
its distance from the axis. This increases the velocity
of efflux, and this increases the velocity of revolution;
and this mutual co-operation would seem to terminate in
an infinite velocity of both motions. But, on the other
hand, this circular motion must be given anew to every
particle of water as it enters the horizontal arm. This
can be done only by the motion already in the arm, and
at its expense. Thus there must be a velocity which
cannot be overpassed even by an unloaded machine.
But it is also plain, that by making the horizontal arm
very capacious, the motion of the water from the axis to
the jet may be made very slow, and much of this dis-
centre of circular motion prevented. Accordingly
Euler has recommended a form by which this is done
in the most eminent degree. His machine consists of a
hollow conoidal ring, of which fig. 12 is a section.
The part AH A a is a sort of funnel basin, which re-
ceives the water from the spout F; and it is directed
pointing towards the axis, but in the direction, and with
the precise velocity, of its motion. This prevents any
retardation by dragging forward the water. The water
then passes down between the outer conoid AC c a and
the inner conoid HG h g along spiral channels formed
by partitions soldered to both conoids. The curves of
these channels are determined by a theory which aims at
the annihilation of all unnecessary and improper motions
of the water, but which is too abstruse to find a place
here. The water thus conducted arrives at the bottom
CG c g. On the outer circumference of this bottom
are arranged a number of spouts (one for each channel),
which are all directed one way in tangents to the cir-
cumference.

Adopting the common theory of the reaction of fluids,
this should be a very powerful machine, and should raise
1\text{ylls} of the water expended. But if we admit the re-

WATER-WORKS.

action to be equal to the force of the issuing fluid (and we do not see how this can be refused), the machine must be nearly twice as powerful. We therefore repeat our wonder, that it has not been brought into use. But it appears that no trial has been made even of a model; so that we have no experiments to encourage an engineer to repeat the trial. Even the late author, Professor Segner, has not related anything of this kind in his *Exercitationes Hydraulicae*, where he particularly describes the machine. This remissness probably has proceeded from fixing the attention on Euler's improved construction. It is plain that this must be a most cumbrous mass, even in a small size requiring a prodigious vessel, and carrying an unwieldy load. If we examine the theory which recommends this construction, we find that the advantages, though real and sensible, bear but a small proportion to the whole performance of the simple machine as invented by Dr Barker. It is therefore to be regretted, that engines have not attempted to realize the first project. We beg leave to recommend it, with an additional argument taken from an addition made to it by Mr Mathon de la Cour, in *Rozier's Journal de Physique*, January and August 1775. This gentleman brings down a large pipe FEH (fig. 13.) from a reservoir, bends it upward at H, and introduces it into two horizontal arms, DA, DB, which have an upright spindle DK, carried as in the style of Dr Barker's mill. The ingenious mechanic will have no difficulty of contriving a method of joining these pipes, so as to permit a free circular motion without losing much water. The operation of the machine in this form is evident. The water, pressed by the column FG, flows out at the holes A and B, and the unbalanced pressure on the opposite sides of the arms forces them round. The comprehensiveness and other advantages of this construction are more striking, allowing us to make use of the greatest fall without any increase of the size of the machine. It undoubtedly enables us to employ a stream of water too scanty to be employed in any other form. The author gives the dimensions of an engine which he had seen at Bourg Argental. AB is 92 inches, and its diameter 3 inches; the diameter of each orifice is 1½; FG is 21 feet; the pipe D was fitted into C by grinding; and the internal diameter of D is 2 inches.

When the machine was performing no work, or was unloaded, and emitted water by one hole only, it made 11½ turns in a minute. This gives a velocity of 46 feet per second for the hole. This is a curious fact: for the water would issue from this hole at rest with the velocity of 374. This great velocity (which was much less than the velocity with which the water actually quitted the pipe) was undoubtedly produced by the prodigious centrifugal force, which was nearly 17 times the weight of the water in the orifice.

The empty machine weighed 80 pounds, and its weight was half-supported by the upper pressure of the water, so that the friction of the pivots was much diminished. It is a pity that the author has given no account of any work done by the machine. Indeed it was only working ventilators for a large hall. His theory by no means embraces all its principles, nor is it well-founded.

We think that the free motion round the neck of the feeding-pipe without any loss of water or any consider-

able friction, may be obtained in the following manner: AB (fig. 14.) represents a portion of the revolving horizontal pipe, and CE part of the feeding pipe. The neck of the first is turned truly cylindrical, so as to turn easily, but without shake, in the collar CE of the feeding-pipe, and each has a shoulder which may support the other. That the friction of this joint may not be great, and the pipes destroy each other by wearing, the horizontal pipe has an iron spindle EF, fixed exactly in the axis of the joint, and resting with its pivot F in a step of hard steel, fixed to the iron bar GH, which goes across the feeding-pipe, and is firmly supported in it. This pipe is made bell-shaped, widening below. A collar or hose of thin leather is fitted to the inside of this pipe, and is represented (in section) by LKM &c. This is kept in its place by means of a metal or wooden ring N, thin at the upper edge, and taper-shaped. This is drawn in above the leather, and stretches it, and causes it to apply to the side of the pipe all around. There can be no leakage at this joint, because the water will press the leather to the smooth metal pipe; nor can there be any sensible friction, because the water gets at the edge of the leather, and the whole unbalanced pressure is at the small crevice, between the two metal shoulders. These shoulders need not touch, so that the friction must be insensible. We imagine that this method of tightening a turning joint may be used with great advantage in many cases.

We have only further to observe on this engine, that any imperfection by which the passage of the water is diminished or obstructed produces a saving of water, which is in exact proportion to the diminution of effect. The only inaccuracy that is not thus compensated is when the jets are not at right angles to the arms.

We repeat our wishes, that engineers would endeavour to bring this machine into use, seeing many situations where it may be employed to great advantage. Suppose, for instance, a small quantity of water from a great height applied in this manner to a centrifugal pump, or to a hair belt passing over a pulley, and dipping in the water of a deep well. This would be a hydraulic machine exceeding all others in simplicity and durability, though inferior in effect to some other constructions.

2. Of Undershot Wheels.

All wheels go by this name: where the motion of the water is quicker than that of the partition or boards of the wheel, and it therefore impels them. These are called the float boards, or floats, of an undershot wheel. The water, running in a mill-row, with a velocity derived from a head of water, or from a declivity of channel, strikes on these floats, and occasions, by its reflections sidewise and upwards, a pressure on the floats sufficient for impelling the wheel.

There are few points of practical mechanics that have been more considered than the action of water on the floats of a wheel; hardly a book of mechanics being silent on the subject. But the generality of them, at least such as are intelligible to persons who are not very much conversant in dynamical and mathematical discussion, have hardly done any thing more than copied the earliest deductions from the simple theory of the resistance of fluids. The consequence has been, that our practical knowledge is very imperfect; and it is still chiefly
chiefly from experience that we must learn the performance of undershot wheels. Unfortunately this stops their improvement; because those who have the only opportunities of making the experiments are not sufficiently acquainted with the principles of hydraulics, and are apt to ascribe differences in their performance to trifling improprieties in their construction, or in the manner of applying the impulse of the water.

We have said so much on the imperfection of our theories of the impulse of fluids in the article Resistance of Fluids, that we need not repeat here the defects of the common explanations of the motions of undershot wheels. The part of this theory of the impulse of fluids which agrees best with observation is, that the impulse is in the duplicate proportion of the velocity with which the water strikes the float. That is, if \( v \) be the velocity of the stream, and \( u \) the velocity of the float, we shall have \( F \cdot \frac{v}{u} \), the impulse on the float when held fast to its impulse \( f \) on the float moving with the velocity \( u \), 

as \( v^2 \) to \( u^3 \), and \( f = F \cdot \frac{v^2}{u^3} \). This is the pressure acting on the float, and urging the wheel round its axis. The wheel must yield to this motion, if the resistance of the work does not exert a superior pressure on the float in the opposite direction. By yielding, the float withdraws from the impulse, and this is therefore diminished. The wheel accelerates, the resistances increase, and the impulses diminish, till they become an exact balance for the resistances. The motion now remains uniform, and the momentum of impulse is equal to that of resistance. The performance of the mill therefore is determined by this; and, whatever be the construction of the mill, its performance is best when the momentum of impulse is greatest. This is had by multiplying the pressure on the float by its velocity. Therefore the momentum will be expressed by 

\[ F \cdot \frac{v^2}{u^3} \cdot \frac{v}{u} \]

but since \( F \) and \( v \) are constant quantities, the momentum will be proportional to \( u \cdot \frac{v^2}{u^3} \).

Let \( x \) represent the relative velocity. Then \( v - x = u \), and the momentum will be proportional to \( u \cdot \frac{v^3 - x^3}{x^3} \), and will be a maximum when \( v - x \cdot x^2 = 0 \), or when \( v = x = x^2 \). This will be discovered by making its fluxion \( = 0 \). That is, 

\[ 2u \cdot x = -3x^2 \cdot \frac{dx}{dx} \]

or 

\[ 2v - 3x = 0 \]

and 

\[ 2v = 3x \]

and 

\[ x = \frac{2v}{3} \]

and therefore \( v = \frac{3}{2} \).

That is, the velocity of the float must be one-third of the velocity of the stream. It only remains to say what is the absolute pressure on the float thus circumstanced. Let the velocity \( v \) be supposed to arise from the pressure of a head of water \( h \). The common theory teaches that the impulse on a given surface at rest is equal to the weight of a column \( AS \); put this in place of \( E \), and \( \frac{v}{u} \) in place of \( u^3 \), and \( \frac{v}{u} \) for \( u \). This gives us \( AS \cdot \frac{v}{u} \cdot \frac{v}{u} \) for the momentum. Now that the velocity \( u \) therefore the greatest performance of water that drives it to the same height.

But this is too small an estimation; for the pressure exerted on a plane surface, situated as the float of a mill-

wheel, is considerably greater than the weight of the column \( SA \). This is nearly the pressure on a surface wholly immersed in the fluid. But when a small jet strikes a larger plane, so as to be deflected on all sides in a thin sheet, the impulse is almost double of this. This is in some measure the cause of a mill wheel. When the stream strikes it, it is heaped up along its face, and falls back again—and during this motion it is in a sheet with a hydrostatic pressure on it. When the wheel dips into an open river, this accumulation is less remarkable, because much escapes laterally. But if a mill wheel it may be considerable.

We have considered only the action on one float, but several generally act at once. The impulse on most of them must be oblique, and is therefore less than what the same stream impinges perpendicularly; and this diminution of impulse is, by the common theory, is the proportion of the sine of the obliquity. For this reason it is maintained, that the impulse of the whole stream on the lowest floatboard, which is perpendicular to the stream, is equal to the sum of the impulses made on all the floats which then dip into the water; or that the impulse on any oblique float is precisely equal to its impulse in which that part of the stream would have made on the lowest floatboard had it not been interrupted. Therefore it has been recommended to make such a number of floatboards, that when one of them is at the bottom of the wheel, and perpendicular to the stream, the next in succession should be just entering into the water. But since the impulse on a float by no means annihilates all the motion of the water, and it load round it and hits the one behind with its remaining force, there must be some advantage gained by employing a greater number of floats than this rule will permit.

This is abundantly confirmed by the experiments of Smeaton and BowUNT. Mr. BowUNT formed three or four suppositions of the number of floats, and calculated the impulse on each; according to the observations made in a course of experiments by the Academy of Sciences, and inserted by us in the article Resistance of Fluids; and when he summed them up, and compared the results with his experiments, he found the agreement very satisfactory. He deduces a general rule, that if the velocity of the wheel is one-third of that of the stream, and if 72 degrees of the circumference are immersed in the stream, the wheel should have 36 floats. Each will dip one-fifth of the radius. The velocity being still supposed the same, there should be more or fewer floats according as the arch is less or greater than 72 degrees.

Such is the theory, and such are the circumstances which it leaves undetermined. The accumulation of the water on a floatboard, and the force with which it exerts its additional pressure, are too intricate to be assigned with any tolerable precision: For such reasons we must acknowledge that the theory of undershot wheels is still very imperfect, and that recourse must be had to experience for their improvement. We therefore strongly recommend the perusal of Mr. Smeaton's experiments on undershot wheels, contained in the same dissertation with these we have quoted on overshot wheels.

We have only to observe, that to an ordinary reader the experiments will appear too much in favour of undershot wheels. His aim is partly to establish a theory, which will state the relation between their performance and the velocity of
of the stream, and partly to state the relation between the power expended and the work done. The velocity in his experiments is always considerably below that which a body would acquire by falling from the surface of the head of water; or it is the velocity acquired by a shorter fall. Therefore if we estimate the power expended by the quantity of water multiplied by this diminished fall, we shall make it too small; and the difference in some cases is very great: yet, even with these concessions, it appears that the utmost performance of an undershot wheel does not surpass the raising one-third of the expended water to the place from which it came. It is therefore far inferior to an overshot wheel expending the same power; and Mr. Beldor has led engineers into very mistaken maxims of construction, by saying that overshot wheels should be given up, even in the case of great falls, and that we should always bring on the water from a sluice in the very bottom of the dam, and bring it to the wheel with as great a velocity as possible. Mr. Smolton also says, that the maximum takes place when the velocity of the wheel is two-fifths of that of the stream, instead of two-sixths according to the theory; and this agrees with the experiments of Mons. But he measured the velocity by means of the quantity of water which ran past. This must give a velocity somewhat too small; as will appear by attending to Boul's observations on the superficial, the mean, and the bottom velocities.

The rest of his observations are most judicious, and well adapted to the instruction of practitioners. We have only to add to them the observations of Des Parcieux and Bossut, who have evinced, by very good experiments, that there is a very sensible advantage gained by inclining the floatboards to the radius of the wheel about 20 degrees, so that the lowest floatboard shall not be perpendicular, but have its point turned up the stream about 20 degrees. This inclination causes the water to heap up along the floatboard, and act by its weight. The floats should therefore be made much broader than the tube which they are interrupted by to turn up.

Some engineers, observing the great superiority of overshot wheels above undershot wheels driven by the same expense of power, have proposed to bring the water home to the bottom of the wheel on an even bottom, and to make the floatboard no deeper than the aperture of the sluice, which would permit the water to run out. The wheel is to be fitted with a close sole and sides, exactly fitted to the end of this trough, so that if the wheel is at rest, the water may be dammed up by the sole and floatboard. It will therefore press forward the floatboard with the whole force of the head of water. But this cannot answer; for if we suppose no floatboards, the water will flow out at the bottom, propelled in the manner those persons suppose; and it will be supplied from behind, the water coming slowly from all parts of the trough to the hole below the wheel. But now add the floats, and suppose the wheel in motion with the velocity that is expected. The other floats must drag into motion all the water which lies between them, giving to the greatest part of it a motion vastly greater than it would have taken in consequence of the pressure of the water behind it; and the water out of the reach of the floats will remain still, which it would not have done independent of the floatboards above it, because it would have contributed to the expense of the hole. The motion therefore which the wheel will acquire by this construction must be so different from what is expected, that we can hardly say what it will be.

We are therefore persuaded that the best way of delivering the water on an undershot wheel is in a close mill-course, to let it slide down a very smooth channel, without touching the wheel till near the bottom, where the wheel should be exactly fitted to the course; or, to make the floats exceedingly broader than the depth of the vein of water which glides down the course, and allow it to be partly intercepted by the first floats, and heap up along them, acting by its weight, after its impulse has been expended. If the bottom of the course be an arch of a circle described with a radius much greater than that of the wheel, the water which slides down will be thus gradually intercepted by the floats.

Attempts have been made to construct water-wheels which receive the impulse obliquely, like the sails of a common wind-mill. This would, in many situations, be a very great acquisition. A very slow but deep river could in this manner be made to drive our mills; and although much power is lost by the obliquity of the impulse, the remainder may be very great. It is to be regretted, that these attempts have not been more zealously prosecuted; for we have no doubt of their success in a very serviceable degree. Engineers have been deterred, because when such wheels are plunged in an open stream, their lateral motion is too much impeded by the motion of the stream. We have seen one, however, which was very powerful: It was a long cylindrical frame, having a plate standing out from it about a foot broad, and surrounding it with a very oblique spiral like a cork-screw. This was plunged about one-fourth of its diameter (which was about 12 feet), having its axis in the direction of the stream. By the work which it was performing, it seemed more powerful than a common wheel which occupied the same breadth of the river. Its length was not less than 20 feet: it might have been twice as much, which would have doubled its power, without occasioning more of the water-way. Perhaps such a spiral, continued to the very axis, and moving in a hollow canal wholly filled by the stream, might be a very advantageous way of employing a deep and slow stream.

But mills with oblique floats are most useful for employing small streams, which can be delivered from a spout with a great velocity. Mr. Bossut has considered these with due attention, and ascertained the best modes of construction. There are two which have nearly equal performances: 1. The vane being placed like those of a wind-mill, round the rim of a horizontal or vertical wheel, and being made much broader than the vein of water which is to strike them, let the spout be so directed that the vein may strike them perpendicularly. By this measure it will be spread about on the vane in a thin sheet, and exert a pressure nearly equal to twice the weight of a column whose base is the orifice of the spout, and whose height is the fall producing the velocity. Mills of this kind are much in use in the south of Europe. The wheel is horizontal, and the vertical axis carries the millstone; so that the mill is of the utmost simplicity; and this is its chief recommendation; for its power is greatly inferior to that of a wheel constructed in the usual manner.

2. The vanes may be arranged round the rim of the wheel.
WATER- WORKS.

A very curious hydraulic machine was erected at Zurich by H. Andreas Witzt, a tinplate water wheel, not like the sails of a wind-mill, but in planes inclined to the radii, but parallel to the axis, or to the planes passing through the axis. They may either stand on a pole, like the oblique floats recommended by De Parcieux, as above mentioned: or they may stand on the side of the rim, not pointing to the axis, but aside from it.

This disposition will admit the spout to be more conveniently disposed either for a horizontal or a vertical wheel.

We shall conclude this article by describing a contrivance of Mr. Burns, the inventor of the double bucket wheel, for fixing the arms of a water-wheel. It is well known to millwrights that the method of fixing them by making them to pass through the axle, weakens it exceedingly, and by lodging water in the joint, soon causes it to rot and fail. They have, therefore, of late years put cast-iron flanges on the axis, to which each arm is bolted: or the flanges are so fashioned as to form boxes, serving as mortises to receive the ends of the arms. These answer the purpose completely, but are very expensive; and it is found that arms further bolted into flanges of iron, are apt to work loose.

Mr. Burns has made wooden flanges of a very curious construction, which are equally firm, and cost much less than the iron ones.

This flange consists of eight pieces, four of which compose the ring represented in fig. 15. meeting in the joints $a, b, a, b, a, b$, directed to the centre $O$. The other four are covered by these, and their joints are represented by the dotted lines $a, b, a, b$. These two rings break joint in such a manner that an arm $MN$ is contained between the two nearest joints $a, b$ of the one, and $a, b$ of the other. The tenon formed on the one end of the arm $A$, &c., is of a particular shape: one side, $G F$, is directed to the centre $O$; the other side, $B C D E$, has a small shoulder $B C$; then a long side $C D$ directed to the centre $O$; and then a third part $D E$ parallel to $G F$, or rather diverging a little from it, so as to make up at $E$ the thickness of the shoulder $B C$; that is, a line from $B$ to $E$ would be parallel to $C D$. This side of the tenon fits exactly to the corresponding side of the mortise; but the mortise is wider on the other side, leaving a space $G K A$ a little narrower at $F K$ than at $G A$. These tenons and mortises are made extremely true to the square; the pieces are put round the axle, with a few blocks or wedges of soft wood put between them and the axle, leaving the space empty opposite to the place of each arm, and firmly bolted together by bolts between the arm-mortises. The arms are then put in, and each is pressed home to the side $C D E$, and a of the mortise and driven home. When it comes through through is cut off with a thin chisel, and the wedge is driven better home. The spaces under the ends of the arms are now filled with wedges, which are driven home from opposite sides, till the circle of the arms stands quite perpendicular on the axle, and all is fast. It needs no hoops to keep it together, for the wedging it up the arms, and it cannot start at its joint till it is when all is once wedged up, but it would be improper to put them on before this be done.

Fig. 16, is a sketch of the section of the machine, as it was first erected by Witzt at a dyehouse in Linn, in the suburbs or vicinity of Zurich. It consists of a hollow cylinder, like a very large grindstone, turning on a horizontal axis, and partly plunged in a cistern of water. The axis is hollow at one end, and communicates with a perpendicular pipe $C B Z$, part of which is hid by the cylinder. This cylinder or drum is fitted into a spiral canal by a plate coiled up within it like the main-spring of a watch in its box; only the spiral is at a distance from each other, so as to form a conduit for the water of uniform width. This spiral portion is well joined to the two ends of a cylinder, and no water escapes between them. The outermost turn of the spiral begins to widen about three-fourths of circumference from the end, and this gradual enlargement continues from $Q$ to $S$ nearly a semicircle: this part may be called the Horn. It then widens suddenly, forming a Scoop or shovel $S S$, the cylinder is supported so as to dip several inches into the water, whose surface is represented by $V V$.

When this cylinder is turned round its axis in the direction $A B E O$, as expressed by the two dots, the scoop $S S$ dips at $V$, and takes up a certain quantity of water before it emerges again at $V$. This quantity is sufficient to fill the taper part $S Q$, which we have called the Horn; and this is nearly equal in capacity to the outermost uniform spiral round.

After the scoop has emerged, the water passes along the spiral by the motion of it round the axis, and drives the air before it into the rising-pipe, where it escapes. In the mean time, air comes in at the mouth of the scoop; and when the scoop again dips into the water, it again takes in some. Thus there is an empty part filled with water and a part filled with air. Continuing this motion, we shall receive a second round of water and another of air. The water in any turn of the spiral will have its two ends on a level; and the air between the successive columns of water will be in its natural state; for since the passage into the rising-pipe or Main is open, there is nothing to force the water and air into any other position. But since the spires gradually diminish in their length, it is plain that the column of water will gradually occupy more and more of the circumference of each. At last it will occupy a complete turn of some spiral that is near the centre; and when sent farther in, by the continuance of the motion, some of it will run back over the top of the succeeding spiral. Thus it will run over at $K A$ into the right-hand side of the third spiral. Therefore it will push the water of this spire backwards, and raise its other end, so that it also will run over backwards before the next turn be completed. And this change of disposition will at last reach the first or outermost spiral, and some water will run over into the horn and scoop, and finally into the cistern.

But as soon as water gets into the rising-pipe, and
WATER WORKS.

It is evident that this disposition of the air and water will raise the water to the greatest height, because the hydrostatic height of each water column is the greatest possible, viz. the diameter of the spire. This disposition may be obtained in the following manner: Take CL to CB as the density of the external air to its density in the last column next the rising-pipe or main; that is, make CL to CB as 33 feet (the height of the column of water which balances the atmosphere), to the sum of 33 feet and the height of the rising-pipe. Then divide BL into such a number of turns, that the sum of their diameters shall be equal to the height of the main; then bring a pipe straight from L to the centre C. The reason of all this is very evident.

But when the main is very high, this construction will require a very great diameter of the drum, or many turns of a very narrow pipe. In such cases it will be much better to make the spiral in the form of a corkscrew, as in fig. 17, instead of this flat form like a Fig. 17.

watch-spring. The pipe which forms the spiral may be lapped round the frustum of a cone, whose greatest diameter is to the least (which is next to the rising-pipe) in the same proportion that we assigned to CB and CL. By this construction the water will stand in every round so as to have its upper and lower surfaces tangents to the top and bottom of the spiral, and the water columns will occupy the whole ascending side of the machine, while the air occupies the descending side.

This form is vastly preferable to the flat: it will allow us to employ many turns of a large pipe, and therefore produce a great elevation of a large quantity of water.

The same thing will be still better done by lapping the pipe on a cylinder, and making it taper to the end, in such a proportion that the contents of each round may be the same as when it is lapped round the cone. It will raise the water to a greater height (but with an increase of the impelling power) by the same number of turns, because the vertical or pressing height of each column is greater.

Nay, the same thing may be done in a more simple manner, by lapping a pipe of uniform bore round a cylinder. But this will require more turns, because the water columns will have less differences between the heights of their two ends. It requires a very minute investigation to show the progress of the columns of air and water in this construction, and the various changes of their arrangement, before one is attained which will continue during the working of the machine.

We have chosen for the description of the machine that construction which made its principle and manner of working most evident, namely, which contained the same material quantity of air in each turn of the spiral, more and more compressed as it approaches to the rising-pipe. We should otherwise have been obliged to investigate in great detail the gradual progress of the water, and the frequent changes of its arrangement, before we could see that one arrangement would be produced which would remain constant during the working of the machine. But this is not the best construction.

We see that, in order to raise water to the height of a column of 34 feet, which balances the atmosphere, the air in the last spire is compressed into half its bulk; and the quantity of water delivered into the main at each turn is but half of what was received into the first spire, the rest flowing back from spire to spire, and being discharged at the spout.

But it may be constructed so as that the quantity of water in each spire may be the same that was received into the first; by which means a greater quantity (double in the instance now given) will be delivered into the main, and raised to the same height by very nearly the same force.—This may be done by another proportion of the capacity of the spires, whether by a change of their caliber or of their diameters. Suppose the bore to be the same, the diameter must be made such that the constant column of water, and the column of air, compressed
WATER-WORKS.

Water-works.

pressed to the proper degree, may occupy the whole circumference. Let $A$ be the column of water which balances the atmosphere, and $\theta$ the height to which the water is to be raised. Let $A$ be to $A + \theta$ as 1 to $m$.

It is plain that $m$ will represent the density of the air in the last spire, if its natural density be 1, because it is pressed by the column $A + \theta$, while the common air is pressed by $A$. Let $\theta$ represent the constant water column, and therefore nearly equal to the air column in the first spire. The whole circumference of the last spire must be $1 + \frac{\theta}{m}$, in order to hold the water, and the air compressed into the space $\frac{\theta}{m}$ or $A + \theta$.

The circumference of the first spire is $1 + 1$ or 2. Let $D$ and $d$ be the diameters of the first and last spires; we have $2 : 1 + \frac{\theta}{m} = D : d$, or $2m : m + 1 = D : d$.

Therefore if a pipe of uniform bore be lapped round a cone, of which $D$ and $d$ are the end diameters, the spirals will be very nearly such as will answer the purpose. It will not be quite exact, for the intermediate spirals will be somewhat too large. The conoidal frustum should be formed by the revolution of a curve of the logarithmic kind. But the error is very trifling.

With such a spiral, the full quantity of water which was confined in the first spire will find room in the last, and will be sent into the main at every turn. This is a very great advantage, especially when the water is to be much raised. The saving of power by this change of construction is always in proportion of the greatest compression of the air.

The great difficulty in the construction of any of these forms is in determining the form and position of the horn and the scope; and on this greatly depends the performance of the machine. The following instructions will make it pretty easy.

Let $ABEO$ (fig. 18) represent the first or outermost round of the spiral, of which the axis is $O$. Suppose it immersed up to the axis in the water $VV$, we have seen that the machine is most effective when the surfaces $KB$ and $O n$ of the water columns are distant the whole diameter $BO$ of the spiral. Therefore let the pipe be first supposed of equal caliber to the very mouth of the water. The surface $O n$ is kept there, in opposition to the pressure of the water column $BAO$, and in the quadrant which lies behind $EB$, and in the quadrant as supported by the columns behind, between this spire and the rising pipe. But the air in the outermost quadrant $EB$ is in its natural state, communicating as yet with the external air. When, however, the mouth standing in it in the same manner, leaving the half space confined only what filled the quadrant $BE$. It is plain, to take in and confine a much greater quantity of air; contain air sufficiently dense to support the column $AO$.

But this is not enough: For when the wide mouth, now at $A$ is, rises up to the top, the surface of the water in it rises also, because the part $AO$ of $a$ is more spacious than the cylindric part $OE$ which is $\frac{A}{m}$ or $A + \theta$, and which cannot contain all the water that it has.

Since, then, the water in the spire rises above $A$, will press the water back from $O$ to some other position $m'$, and the pressing height of the water column will be diminished by this rising on the other side of $O$. In short, the horn must begin to widen, not from $B$, but from $A$, and must occupy the whole semicircle $ABE$; and its capacity must be to the capacity of the opposite cylindrical side as the sum of $BO$, and in height of a column of water which balances the atmosphere to the height of that column. For then the $A$ which filled it, when of the common density, will fill the uniform side $BEO$, when compressed so as to increase the vertical column $BO$. But even this is not enough; for it has not taken in enough of air.

When it dipped into the cistern at $E$, it carried air down with it, and the pressure of the water in the cistern caused the water to rise into it a little way; and some water must have come over at $B$ from the other side, which was drawing narrower. Therefore when the horn is in the position $EOA$, it is not full of water. Therefore when it comes into the situation $OBD$, it cannot be full nor balance the air on the opposite side. Some will therefore come out at $O$, and rise up through the water. The horn must therefore, 1st, Extend at least from $O$ to $B$, or occupy half the circumference; and, 2dly, It must contain at least twice as much water as would fill the side $BEO$. It will do little harm though it be much larger; because the surplus of air which it takes in at $E$ will be discharged, as the end $E$ of the horn rises from $O$ to $B$, and it will leave the precise quantity that is wanted. The surplus water will be discharged as the horn comes round to dip again into the cistern. It is possible, but requires a discussion too intricate for this place, to make it so that such a size and shape, that while the mouth moves from $E$ to $B$, passing through $O$ and $A$, the surface of the water in it shall advance from $E$ to $O n$, and exactly at $O$ when the beginning or narrow end of the horn arrives there.

We must also secure the proper quantity of water.

When the machine is so much immersed as to be up to the axis in water, the capacity which thus secures the proper quantity of air will also take in the proper quantity of water. But it may be erected so as that the spirals shall not even reach the water. In this case it will answer our purpose if we join to the end of the horn a scoop or shovel QRSB (fig. 19.), which is so formed as to take in at least as much water as will fill the horn. This is all that is wanted in the beginning of the motion along the spiral, and more than is necessary when the water has advanced to the succeeding spire; but the surplus is discharged in the way we have mentioned. At the same time, it is needless to load the machine with more water than is necessary, merely to throw it out again. We think that if the horn occupies fully more than one half of the circumference, and contains as much as will fill the whole round, and if the scoop lifts as much as will certainly fill the horn, it will do very well.

N. B. The scoop must be very open on the side next the axis, that it may not confine the air as soon as it enters the water. This would hinder it from receiving water enough.

The

WATER-WORKS.

The following dimensions of a machine erected at Florence, and whose performance corresponded extremely well with the theory, may serve as an example. The spiral is formed on a cylinder of 10 feet diameter, and the diameter of the pipe is 6 inches. The smaller end of the horn is of the same diameter; and it occupies three-fourths of the circumference, and is 7½ inches wide at the outer end. Here it joins the scoop, which lifts as much water as fills the horn, which contains 4340 Swedish cubic inches, each =. 1.577 English. The machine makes six turns in a minute, and raises 1354 pounds of water, or 22 cubic feet, 10 feet high in a minute.

The above account will, we hope, sufficiently explain the manner in which this singular hydraulic machine produces its effect. When every thing is executed by the maxims which we have deduced from its principles, we are confident that its performance will correspond to the theory; and we have the Florentine machine as a proof of this. It raises more than 7½ times what the theory promises, and it is not perfect. The spiral is of equal caliber, and is formed on a cylinder. The friction is so inconsiderable in this machine, that it need not be mended; but the great excellency is that whatever imperfection there may be in the arrangement of the air and water columns, this only affects the elegance of the execution, causing the water to make a few more turns in the spiral before it can mount to the height required: but wastes no power, because the power employed is always in proportion to the sum of the vertical columns of water in the rising side of the machine, and the height to which the water is raised by it is in the very same proportion. It should be made to move very slowly, that the water be not always dragged up by the pipes, which would cause more to run over from each column, and diminish the pressure of the remainder.

If the rising-pipe be made wide, and thus room be made for the air to escape freely up through the water, it will rise to the height assigned: but if it be narrow, so that the air cannot get up, it rises almost as slow as the water, and by this circumstance the water is raised to a much greater height mixed with air, and this with hardly any more power. It is in this way that we can account for the great performance of the Florentine machine, which is almost triple of what a man can do with the finest pump that ever was made: indeed the performance is so great, that one is apt to suspect some imprecision in the accounts. The entry into the rising-pipe should be no wider than the last part of the spiral; and it would be advisable to divide it into four channels by a thin partition, and then to make the rising-pipe very wide, and to put into it a number of slender rods, which would divide it into slender channels that would completely entangle the air among the water. This will greatly increase the height of the heterogeneous column. It is surprising that a machine that is so very promising should have attracted so little notice. We do not know of any being erected out of Switzerland except at Florence in 1778. The account of its performance was in consequence of a very public trial in 1779, and honorable declaration of its merit, by Sig. Lorenzo Ciniari, who erected another, which fully equaled it. It is shortly mentioned by Professor Sulzer of Berlin, in the Sammlungen Vermischten Schriften for 1754. A description of it is published by the Philosophical Society of Zurich in 1766, and in the descriptions published by the Society in London for the encouragement of arts in 1766. The celebrated Daniel Bernoulli has published a very accurate theory of it in the Petersburg Commentaries for 1772, and the machines at Florence were erected according to his instructions.

Baron Astronomer in Sweden caused a glass model of it to be made, to exhibit the internal motions for the instruction of artists, and also ordered an operative engine to be erected; but we have not seen any account of its performance. It is a very intricate machine in its principles; and an ignorant engineer, say the most intelligent, may erect one which shall hardly do anything; and yet, by a very trifling change, may become very powerful. We presume that failures of this kind have turned the attention of engineers from it; but we are persuaded that it may be made very effective, and we are certain that it must be very durable. Fig. 20, is a section of the man-which the author has formed the communication between the spiral and the rising pipe. P is the end of the hollow axis which is united with the solid iron axis. Adjoining to P, on the under side, is the entry from the last turn of the spiral. At Q is the collar which rests on the supports, and turns round in a hole of bell-metal. Ff is a broad flange cast in one piece with the hollow part. Beyond this the pipe is turned somewhat smaller, very round and smooth, so as to fit into the mouth of the rising pipe, like the key of a cook. This mouth has a plate e e attached to it. There is another plate d d, which is broader than e e, and is not fixed to the cylindrical part, but moves easily round it. In this plate are four screws, such as g g, which go into holes in the plate f f, and thus draw the two plates f f and d d together, with the plate e e between them. Pieces of thin leather are put on each side of e e; and thus all escape of water is effectually prevented, with a very moderate compression and friction.

WATERFORD.

WATERFORD, a city and sea-port of Ireland, in a county of the same name, with a bishop's see. It is the second place in the kingdom, and is a wealthy, populous city, enjoying many ample privileges. The streets are narrow, and the air is not very healthy; but it has an excellent harbour, seated as well for trade as any in the world, and ships of the greatest burden may ride at the quay. It stands on the river Sure, 8 miles north of St George's Channel, 25 miles south of Kilkenny, and 75 miles west of Dublin. W. Long. 7. 8. N. Lat. 52. 14.

Vol. XX. Part II.
WATSON. [ 682 ]

WAX

and his history of Philip III. published after his death, has added to his fame. Of this last performance, however, he has only completed the first four books; the two last were written by the editor of his manuscript, at the desire of the guardian of his children.

On the death of Principal Tuldiph, Dr Watson was appointed his successor; in which station he lived only a few years. He married a lady of singular beauty and virtue, daughter to Mr Shaw, professor of divinity in St Mary's college, St Andrew's. By this lady he had five daughters, who survived him.

WATT, JAMES, the celebrated improver of the steam engine, see SUPPLEMENT.

WATTS, DR ISAAC, a learned and eminent dissenting minister, was born at Southampton in 1674, of parents eminent for piety, and considerable sufferer for conscience-sake. In 1690 he was sent up to London for academical education under the tuition of the Rev. Mr Thomas Rowe; and in 1696 was himself engaged as tutor to the son of Sir John Hartopp, Bart. at Stuke Newington. He began to preach in 1698, and met with general acceptance; and after officiating as assistant to the Rev. Dr Isaac Chauncy, he succeeded in his pastoral charge in 1702, and continued to preside over that church as long as he lived. Though his whole income did not amount to an hundred a-year, he assisted one third of it to the poor. He died in 1748. His numerous works have rendered his name famous among people of every denomination, both in this and other countries, and have been translated into a variety of languages. His Lyric Poems, his Psalms and Hymns, and his Divine Songs for Children, have had an amazing number of editions. His logic and philosophy have been much admired. He also wrote works upon a variety of other subjects, and printed several volumes of his sermons. He was admired for the mildness and benevolence of his disposition. After his death, his works were collected, and published in six volumes quarto.

WAVE, in Philosophy, a cavity in the surface of water, or other fluids, with an elevation above it.

The waves of the sea are of two kinds, natural and accidental. The natural waves are those which are exactly proportioned in size to the strength of the wind, whose blowing gives origin to them. The accidental waves are those occasioned by the wind's resting upon itself by repercussion from hills and mountains, or high shores, and by the washing of the waves themselves, otherwise of the natural kind, against rocks and shoals: all these causes give the waves an elevation, which they can never have in their natural state. For the height of the waves, see SEA.

Stilling WAVES by means of Oil. See SEA.

WAVERED, in Heraldry, is said of a bordure, or any ordinary or charge, in a coat of arms, having its outlines indented in manner of the rising and falling of waves: it is used to denote, that the first of the family in whose arms it stands, acquired its honours by service.

WAVERING, in the sea-language, is the making signs to a vessel to come near or keep off.

WAX, or Bees wax, in Natural History, a firm and solid substance, moderately heavy, and of a fine yellow colour, formed by the bees from the pollen of flowers. See APIS.
The best sort is that of a lively yellow colour, and a
agreeable smell, somewhat like that of honey: when
new, it is toughish, yet easy to break; but by age it
becomes harder and more brittle, loses its fine colour,
and in a great measure its smell.

It appears that wax and honey have for their basis
a fat oil, which passes to the state of resin by its combi-
nation with oxygen. If the nitric or muriatic acid be
digested upon a fixed oil for several months, it passes to a
state resembling wax. Wax, by repeated distillations,
affords an oil which possesses all the properties of volatile
oils. It is reduced into water and carbonic acid by
combustion. The colouring matter of wax is insoluble
in water and in alcohol.

Fixed alcalies dissolve wax, and render it soluble in
water. It is this saponaceous solution which forms the
pungent wax. It may be used as the basis of several co-
lours, and may be made into an excellent paste for
washing the hands. Ammoniacal likewise dissolves it;
and as this solvent is evaporable, it ought to be pre-
ferred when it is proposed to use the wax as a varnish.

From the common yellow wax, by bleaching, is form-
ed white-wax, sometimes called, very improperly, vir-
gin-wax. The greater the surface is in proportion to the
quantity, the sooner and more perfectly this opera-
tion is performed. The usual way is to melt the wax in
hot water; when melted, they press it through a strainer
of tolerable fine linen, and pour it into round and very
shallow moulds. When hardened by cooling, it is taken
out and exposed to the sun and air, sprinkling it now
and then with water, and often turning it: by this
means it soon becomes white. The best sort is of a
clear and almost transparent whiteness, dry, hard, brittle,
and of an agreeable smell, like that of the yellow
wax, but much weaker.

The common yellow wax is of very great use both in
medicine and in many of the arts and manufactures. It
has been sometimes given internally in syrups and
ercisions of the intestines; but its great use is in the
making ointments and plasters, and the greater part of
those of the shops owe their consistence to it. The
white wax is also an ingredient in some of the cerates
and ointments of the shops; and it is used in making
 candles, and in many of the finer arts and manufactures
where wax is required.

Sealing-wax, or Spanish-wax, is a composition of
gum lac, melted and prepared with resins, and coloured
with some suitable pigment.

There are two kinds of sealing-wax in use; the one
hard, intended for sealing letters, and other such pur-
poses; the other soft, designed for receiving the impres-
sions of seals of office to charters, patents, and such writ-
en instruments. The best hard red sealing-wax is made
by mixing two parts of shell lac, well powderd, and
resin and vermilion, powdered, of each one part, and
melting this combined powder over a gentle fire; and
when the ingredients seem thoroughly incorporated,
working the wax into sticks. Seed-lac may be substitut-
ed for the shell-lac; and instead of resin, boiled Ven-
icontin may be used. A coarser hard red sealing-
wax may be made, by mixing two parts of resin, and
of shell-lac, or vermilion and red lead, mixed in the
proportion of one part of the vermilion to two of the red
lead, of each one part; and proceeding as in the former
preparation. For a cheaper kind, the vermilion may be
omitted, and the shell-lac also, for very coarse uses. Wax
of other colours is made by substituting other colouring
matters for vermilion, as verditer for blue, ivory black
for black wax. For uncoloured soft sealing-wax, take
of bees wax, one pound; of turpentine, three ounces;
and of olive oil, one ounce; place in a proper
vessel over the fire, and let them boil for some time;
and the wax will be then fit to be formed into rolls or
cakes for use. For red, black, green, blue, yellow, and
purple soft sealing-wax, add to the preceding composi-
tion an ounce or more of any ingredients directed above
for colouring the hard sealing-wax, and stir the mass
till the colouring ingredients be incorporated with the
wax.

Wax-work, the representation of the faces, &c. of
persons living or dead; made by applying plaster of
Paris in a kind of paste, and thus forming a mould con-
taining the exact representation of the features. Into
this mould melted wax is poured, and thus a kind of
masks are formed; which being painted and set with
glass eyes, and the figures dressed in their proper habits,
they bear such a resemblance that it is difficult to di-
istinguish between the copy and the original.

WAY, a passage or road.

The Roman ways are divided into consular, praetor-
ian, military, and public; and of these we have four
remarkable ones in England: the first, Watling-street,
or Watling-street, leading from Dover to London,
Dunstable, Worcester, Atterton, and the Severn, extend-
iting as far as Anglesea in Wales. The second, called
Hikenild or Ikemild street, stretches from Southampton
over the river Isis at Newbridge; thence by Camden
d and Litchfield; then passes the Derwent near Derby,
and ends at Timmouth. The third, called Fosse-way,
because in some places it was never perfected, but lies
as a large ditch, leads from Cornwall through Devon-
shire, to Tethbury, near Stow in the Wolds; and be-
side Coventry to Leicester, Newark, and so to Lincoln.
The fourth, called Erming or Erminage street, ex-
tends from St David's, in Wales, to Southampton.

Way Covert, Gang, Hatch. See COVENT WAY,
Gang, &c.

Way of a Ship, is sometimes the same as her rake,
or run forward or backward: but this term is most com-
monly understood of her sailing.

Way-Leaves, in the coal business. See COALERY,
N° 3.

Right of Way, in Law. This may be grounded on
a special permission; as when the owner of the land
grants to another a liberty of passing over his grounds,
to go to church, to market, or the like: in which case
the gift or grant is particular, and confined to the gran-
tee alone; it dies with the person; and if the grantee
leaves the country, he cannot assign over his right to
any other; nor can he justify taking another person in
his company. A way may be also by prescription; as
if all the owners and occupiers of such a farm have im-
memorially used to cross another's ground; for this
immemorial usage supposes an original grant, whereby a
right of way thus appurtant to land may clearly be
created. A right of way may also arise by act and ope-
ration of law; for if a man grants me a piece of ground
in the middle of his field, he at the same time tacitly
and impliedly gives me a way to come at it; and I may
cross his land for that purpose without trespass. For

When

WAYWARDING tree. See Viburnum, Botany

WAYFHER, or Wafts, a word which is used only in the plural number, and signifies haunt boys. It is now applied to the performers on these and other musical instruments, by a translation from the instruments themselves, and particularly to those performers who parade the streets by night, about the Christmas season of the year.

WAYMORE, a title formerly given to the governors of the chief places in the dominions of the czar of Moscovy. The palatines, or governors of provinces in Poland, also bear the quality of wayward or weaver. The Poles likewise call the princes of Wallachia and Moldavia waywardues; as esteeming them no better than on the foot of governors; pretending that Wallachia and Moldavia are provinces of Poland. Everywhere else these are called hospodars. Du Cange says, that the name waywardue is used in Dalmatia, Croatia, and Hungary, for a general of an army; and Leonclauis, in his Pandects of Turkey, tells us, it usually signifies captain or commander.

WEAVING, putting a child away from the breast, and bringing it to use common food.

WEAR, or Weer, a great stalk or dam in a river, fitted for the taking of fish, or for conveying the stream to a mill. New wears are not to be made, or others altered, to the nuisance of the public, under a certain penalty. See River.

WEARING, or Veering, in Seamanship. See

WEASEL. See Mustela, Mammalia Index.

WEATHER denotes the state of the atmosphere with regard to heat and cold, wind, rain, and other meteors. See Meteorology.

Weather, in sesea-language, is used as an adjective, and applied by mariners to every thing lying to windward of a particular situation: thus, a ship is said to have the weather-gage of another, when she is farther to windward. Thus also, when a ship under sail presents either of her sides to the wind, it is then called the weather-side or weather board; and all the rigging and furniture situated thereon are distinguished by the same epithet, as the weather-shrouds, the weather-lifts, the weather-braces, &c.

To Weather, in seasea-language, is to sail to windward of some ship, bank, or headland.

Weathercock, a movable vane, in form of a cock, or other shape, placed on high, to be turned round according to the direction of the wind, and point out the quarter from whence it blows.

Weather Glass. See Barometer.

WEATHERING, among sailors, signifies the doubling or sailing by a headland or other place.

WEAVING, the art of working a web of cloth, silk, or other stuff, in a loom with a shuttle. For an idea of the manner in which this is performed, see Woven Cloth.

Weaving-Loom, a machine for weaving cloth, silk, &c. by raising the threads of the warp in order to throw in the weft, and strike it close. Of these there are various kinds, distinguished by the different sorts of cloths, stuffs, silks, &c. in which they are employed, and which are chiefly distinguished by the number and variety of the threads they raise in order to work the warp, either plain or in figures, by making more or less of the warp or weft appear through the warp. In order to give a general idea of weaving, we shall here describe the parts of the common weaver's loom. Fig. 1, is which stands...
Weaving.

with the other hand at the other side, it is obvious, that when the web is a breadth too great for a man to reach from one side of it to the other, two workmen must be employed and much time lost. To remedy this inconvenience, a new shuttle has, in this country, been lately brought into very general use, and called the "flying shuttle," because it flies through the warp with wonderful rapidity on two steel rollers RR (fig. 3). This shuttle is not thrown with the hand, but moved backwards and forwards by a very simple piece of machinery, of which fig. 4 will give the reader a sufficiently accurate conception. To each end of the batten or lay L is fastened a kind of open box B, b, with the bottom or horizontal side exactly on a level with the threads of the warp of the intended web. In each of these boxes is a vertical piece of wood D, d, of considerable thickness, called a driver. This driver is moved easily on an iron spindle or axis from one end of the box to the other by means of a slender rope CCCD, and a handle H is seen in the figure. When the weaver is to begin his work, he lays the shuttle on its rollers in the box B with the iron tip T (fig. 3.) touching, or almost touching, the driver D (fig. 4.). Then moving the handle H, with a sudden jerk, towards the box b, the driver D forces the shuttle with a rapid motion through the warp till it strikes d, which is impelled by the stroke to the further end of the box b. The two drivers D and d have now changed their positions in their respective boxes; so that the driver which was at the front of its box before, is now at the further end of it, and vice versa. Then by a sudden jerk of the hand towards B the shuttle is driven back till it strike D; and thus the work continued without the weaver having occasion ever to stretch his arms from one margin of the web to the other. That the shuttle may not, by the unsteadiness of the workman's hand, be driven along through the warp or out of the place in which it ought to move, the guiding or driving rope CCCD is made to pass through smooth holes or loops C, C, at the ends of the ropes EC, EC, suspended either from the cross bar on the top of the loom or from the swords of the batten.

This shuttle, we should think, a great improvement in every kind of weaving-loom, though some of the older trademen, with whom we have conversed on the subject, contend, that it is valuable only in what they call light work, such as cotton or linen cloth, or when the web, if woollen, is very broad.

But as the labour of weaving is pretty severe, Mr Robert Millar, an ingenious calico-printer in the country of Dunbarton, Scotland, wishing to lessen it, invented, some years ago, a weaving-loom, which may be wrought by water, steam, horses, or any other power, for which invention he received a patent in 1798. The following is his own description of his patent weaving-loom:

Fig. 5 represents a side view of the loom, AA, BB, CC, DD, being the frame. a is an axis (which we shall call the spindle) across the frame. On this axis is a sheave b, two inches thick, having a groove round it, two inches deep, and half an inch wide. The bottom of this groove is circular, except in one part c, where it is filled up to the top; a lever d rests on the bottom of this groove, and is lifted up by it when the elevation c comes round to the situation represented in the figure. By this motion, the lever d acts on the catch-wheel e by the catch t, and draws it forward one tooth, each revolution of the sheave. This ratchet wheel is in an iron frame g g, which also properly carries the two catches t and u, which are connected with it at v. The catch w holds the ratchet-wheel in its position, while the lever d and the catch t, are moved by the groove c in the sheave. On the axis of the ratchet is a small pinion k, working in the wheel f; this wheel is fixed at the end of the roller e of fig. 7. On the side of the sheave b is fixed a wiper k, which lifts the treadle l. This treadle turns on its joints in the sheave E, which is fixed to the side of the frame A and D; it is kept pressing on the bottom of the groove in the sheave by a spring m, fixed to the frame side A, and having a slender rod n from its extremity, joining it with the treads l. From the point of the treads there goes a belt o, which passes over the pulley p, which is seen edgewise in this figure, and is joined to the top of the fly-pin q, of fig. 6. At the end of the frame A is the short post F; on this rests the yarn-beam j, having a sheave s, over which passes a cord, having a weight t suspended to it. The other end of this cord is fastened to the spring v; the weight causes the yarn-beam to stretch the web from the ratchet-wheel e, with its catch u; and the spring v allows the rope to slide on the sheave as the ratchet is drawn round during the working.

Fig. 6 is a front view of the loom. a a is the spin-
dle which carries the sheave b, and the wipers d and e, which move the treadles w, w, of fig. 5. These use the treadles of the healds, with which they are connected by cords from the shafts of the healds e, e.

From the upper shaft there go two leathern belts f, f, to the roller y, furnished each with a buckle, for tightening them at pleasure. The two wipers c, c, on the shaft x, which serve for taking back the lay, have the two treadles, x, x, in fig. 7, with a belt from each passing over the roller A 2 of fig. 6, and fixed to the sword of the lay. From the swords of the lay forward is fixed a belt to each end of the roller r; from this roller there goes a cord to the spring j, which serves for taking forward the lay which is hinged on the rockin-tree t. The star-wheel b of fig. 3, and the sheave b of fig. 1, are fixed to the opposite ends of the spindle a without the frame; and both the wheel and sheave have a wiper k fixed to them for moving the treadles. In order to drive the shuttle, the belts o, o, go from the points of the treadles, over the pulleys p, p, to the top of the fly-pin q. This turns on a pin joint in a rail r, which goes across the loom. From its lower end there go two small cords to the shuttle drivers g, g, which slide on the iron rods n, n. A long iron rod v goes across the lay, and is hung on two centres at the ends. In this rod v are fixed two small crooked wires w, w, which are more distinctly marked in the little figure w above, which represents a section of the lay. The dot at the lower end of the wire w, in this figure, is the section of the rod v. The shuttle passes between these wires and the lay every shot, and lifts them up, causing the rod v to turn round a little. But if the shuttle should not pass these wires, nor lift them, it would be drawn home by the lay, and destroy the web. To prevent this, there is fixed on one end of the rod o a stout crooked wire s, having a broad or flat head, which naturally rests on a plate of iron, marked and fixed to the back of the lay. This plate has a slit in
Weaving.

its middle about an inch deep. In this slit rests the rod a z of fig. 7, on which is a short stud, which is caught by the wire z when the wire w is not lifted back by the passing shuttle. This will stop the lay from coming home, and will set off the loom.

Fig. 7. is another side view of the loom opposite to fig. 5. On the spindle a is the star wheel b, on the outside of the loom frame, on the arms of which wheel is fixed the wiper k, as the similar wiper is fixed to the sheaves on the other end of the spindle. The wipers which drive the shuttles are fixed on opposite squares of the spindle, and work alternately. Below the star wheel is a pinion c, which is on a round spindle, turned by the water-wheel, by means of a wheel on this spindle. In a wheel on this spindle are two studs, on which the pinion e slides off and on, as the loom is set off and on by the lever d. At the farther end of this lever is the weight s, hanging by a chord which passes over a pulley t, fixed at the outer end of the spring-catch on which the lever d rests; and thus the loom is drawn in at the upper end of the lever d. But when the shuttle does not lift the wire z, it catches on the stud on the rod a z, which is connected with the spring-catch, and the lever d lies off, with the weight s, and the loom stops working. On the head of the post F is the yarn-beam. The rollers e and f are cylinders, pressed together by a screw-lever, and take away the cloth between them at a proper rate. In the roller f is a groove for a band for driving the roller g, on which the cloth winds itself as it is wrought. Wherever springs are mentioned to be used in the above description, weights may be used in their stead, and to the same effect, and more especially upon the treads of fig. 5. for driving the shuttle.

Fig. 8. is a representation of a ribband loom. 1. Is the frame of the loom. 2. The castle, containing 48 pulleys. 3. The branches, on which the pulleys turn. 4. The tires, or the riding-cords, which run on the pulleys, and pull up the high-lisses. 5. The list-sticks, to which the high-lisses are tied. 6. The high-lisses, or lists, are a number of long threads, with platines, or plate-leads at the bottom; and ringlets, or loops, about their middle, through which the cords or cross-threads of the ground-harness ride. 7. The plate-leads, or platines, are flat pieces of lead, of about six inches long, and three or four inches broad at the top, but round at the bottom; some use black slates instead of them: theirs is to pull down those lisses which the workman had raised by the treads, after his foot is taken off. 8. The branches or cords of the ground harness, which go through the loops in the middle of the high-lisses: on the well ordering of these cords chiefly depends the art of ribbon-weaving, because it is by means of this contrivance that the weaver draws in the thread or silk that makes the flower, and rejects or excludes the rest. 9. The batton: this is the wooden frame that holds the reed or shuttle, and beats or closes the work: where observe, that the ribbon weaver does not beat his work; but as soon as the shuttle is passed, and his hand is taken away, the batton is forced, by a spring from the top, to beat the work close. 10. The shuttle, or reed. 11. The spring of the batton, by which it is made to close the work. 12. The long-harness are the front-reeds, by which the figure is raised. 13. The linguas are the long pieces of round or square lead, tied to the end of each thread of the long-harness to keep them tight. 14. The broad piece of wood, about a foot square, leaning somewhat forward, intended to be used as he stoops to his shuttle; it is fixed in the middle of the breast-beam. Some weavers, instead of this, have a contrivance of a cord or rope that is fastened to the breast-frame, and comes across his breast; this is called a stopfall. 15. The seat-bench: this leans forward very much. 16. The foot-stop to the treadles. 17. The breast-beam, being a cross-bar that passes from one of the standards to the other, so as to front the workman's breast: to this breast-bar is fixed a roll, upon which the ribbon passes in its way, to be rolled upon the roller, that turns a little below. 18. The clamps, or pieces of wood, in which the broaches that confine the treadles rest. 19. The treadles are long narrow pieces of wood, to the ends of which the cords that move the lisses are fastened. 20. The treadle-cords are only distinguished from the riding-cords by a board full of holes, which divide them, in order to prevent the plate-leads, which are tied to the high-lisses, from pulling them too high when the workman's foot is off the treadle: which stop is made by a knot in the treadle-cord, too big to be forced through that hole in the board. 21. The lisses are two pieces of thin narrow boards only used in plain works, and then to supply the place of the long-harness. 22. The knee-roll, by which the weaver rolls up the ribbon as he sees proper, or by bit and bit as it is finished. 23. The back-rolls, on which the warp is rolled. It is to be observed, that there is always as many rolls as colours in the work to be wove. 24. The clamps which support the rollers. 25. The returning-stick, or, as others call them, the return, or the tumblers, or pulleys, to which the tiers are tied, to clear the course of cords through the high-lisses. 26. The catch-board for the tumblers. 27. The treads. 28. The buttons for the knee-rolls and treadle-board, described No. 20.

It is stated in the proceedings of the National Institute of France, that a report was presented to that body concerning a new machine for weaving ribbed stockings. The advantages which this machine possesses are said to be, that it may be erected at one half of the expense of the English stocking frame, and that its movements are much lighter. The experience of its operations for two years has confirmed these advantages. Of the nature and construction of this machine we have had no opportunity of obtaining any information but what we thought it worth while to insert this short notice, with the view of directing the attention of such of our readers as may be interested in the improvement of such manufactures.

WEB, a sort of tissue or texture formed of threads interwoven with each other; some whereof are extended in length, and called the warp; others are drawn across, and called the woof.

WEBERA, a genus of plants belonging to the class order pentandria monogynia. See Botant. Index.

WEBSTER, Alexander, D. D. was the son of James Webster, minister of the Tolbooth church in Edinburgh, and born in that city about the year 1707. He was only 13 years of age at the death of his father, and of course could derive little from parental instruction or example. He studied at the university of Edinburgh, the several branches of learning with great application, particularly...
particularly those connected with the mathematics, for which he discovered an early predilection. He afterwards attended the lectures of the professor of divinity, and in the year 1733 he was ordained minister of the parish of Culross, and in June 1737, he was admitted to be one of the ministers of the Tolbooth church of Edinburgh. His eloquence was noble and manly, his piety conspicuous, and the discharge of his pastoral duties faithful and laborious. To these qualities he added an enlightened zeal for the external interests of the church, a jealousy of corruption, a hatred of false politics and tyrannical measures, which sometimes exposed him to calumny from the guilty, but secured him the esteem of all who could value independence of soul and integrity of heart.

The prosperity of fortune which placed Mr Webster in the church of his father, and restored him to the polished society of his native city, was not confined to these favours. Eleven days after his settlement in Edinburgh, he obtained the hand of Mary Erskine, a young lady of considerable fortune, and nearly related to the noble family of Dundonald. The genius of Mr Webster now began to unfold itself. Family connections extended his acquaintance with the nobility. Edinburgh then possessed a number of men, both in civil and ecclesiastical stations, who had saved or adorned their country. With these he was soon to co-operate in defending the Protestant interests from the arms and artifices of rebellion.

In the year 1733, five or six ministers seceded from the church, and being anxious to draw away as many as possible from the communion which they had renounced, they invited down to Scotland in 1741, Mr George Whitefield, a young preacher of great piety and extraordinary pulpit talents. On his way to Dunfermline, he was met and entertained at Edinburgh by Mr Webster and some of his brethren. From them he learned the state of church parties in Scotland; and though he kept his promise of preaching first in Fife, he declined connecting himself with any particular sect. Disappointed of his influence and assistance, the Seceders ascribed the effects of his preaching to sorcery and the devil, while Mr Webster, in a pamphlet which he published on the occasion, attributed them to the influence of the Holy Spirit, an opinion regarded by the Seceders as unspeakable wickedness.

In the year 1745, Mr Webster remained in the city when it was taken by the rebels, and employed his universal popularity and vigorous eloquence in retaining the minds of the people in the interests of the house of Hanover. His exertions in this were not overlooked by most of the spirited gentlemen who acted in quelling the rebellion. He became an intimate friend of Duncan Forbes of Culloden, Lord Milton, and others.

He preserved to the latest period of his career, that activity both of mind and body, which distinguished him in the prime of life, obtaining at last his frequent wish and prayer, an easy and peaceful death, after a very short indisposition, on the 25th of January 1784. His remains were deposited in the Greyfriars churchyard; and it is not a little remarkable that neither private friendship nor public generosity has yet come forward to testify its regard for two of the most eminent characters of the church of Scotland. The ashes of Webster and Blair repose in the same cemetery, undistinguished from the less illustrious dead. No monumental stone marks the place of their dust.

Nature endowed Mr Webster with strong faculties, which were afterwards improved by a considerable share of erudition. He was a master in the knowledge of the world and of human nature; his address was engaging; his wit strong as his mind; his convivial powers, as they are called, enchanting. He had a constitutional strength against intoxication, which made it dangerous in most men to attempt bringing him into such a state. His character as a minister was popular in the extreme. His voice was harmonious, and his figure noble. To the poor he was a father and a friend, a liberal patron to poor students. In his person he was tall, and of a thin and meagre habit. His features were strongly marked, and the conformity of the whole indicated genius and independence.

To him the widows of the clergy are indebted for the establishment of the celebrated Scheme, the plan of which he matured in his mind soon after he was appointed a minister of the Tolbooth church. By it the widows of ministers are entitled to the annual sum of 10, 15, 20, or 25 pounds, according as the clergy pay into the fund yearly, 2l. 12s. 6d.—3l. 18s. 9d.—5l. 5s. or 6l. 1is. 3d, or to their children in sums of 100—150—200—or 250l. in favour of which an act of parliament was obtained in terms of a petition (17 Geo. II.) with liberty to employ the surplus of the annual payments and expenses in loans of 50l. each among the contributors, and to put out the remainder at interest, on proper security. A second act was procured in the 22d year of the same reign (1748) granting liberty to raise the capital to 80,000l. including the sums lent to contributors. The fund is conceived to commence from the 25th March 1744. This was followed by another act in the year 1775, discontinuing the loan granted to contributors, and granting liberty to raise the capital to 100,000l.; and the whole economy of the institution was then fixed and determined, a report of the state of the fund being ordered to be made annually to the General Assembly by the trustees, which was to be afterwards printed. The success of the scheme has been complete.

WEDGE, one of the mechanical powers. See MECHANICS.

WEDNESDAY, the fourth day of the week, so called from a Saxon idol named Weden, supposed to be Mars, worshipped on this day.

Ash-WEDNESDAY, the first day of Lent, so called from the custom observed in the ancient Christian church of penitents expressing their humiliation at this time, by appearing in sackcloth and ashes. WEED, a common name for all rank and wild herbs, that grow of themselves, to the detriment of other useful herbs they grow among.

PEED, in the miners' language, denotes the degeneracy of a load or vein of fine metal into an useless marcasite.

PEEDS, also denote a peculiar habit, worn by the relics of persons deceased, by way of mourning. WEEK, in chronology, a division of time comprising seven days. See PLANETARY DAYS and SABBATH.

Passion-WEEK, or the Holy WEEK, is the last week in Lent, wherein the church celebrates the mystery of our Saviour's death and passion.
WEI

Weeks, Ember. See Ember.
Feast of Weeks. See Pentecost.
Weever. See Trachinus Ichthyology Index.
Weevil. In Zoology, a species of curcule. See Curculio, Entomology Index; and for the method of destroying this troublesome and destructive insect, see Granary and Vermin.
Weigelia, a genus of plants belonging to the class and order pentandria monogynia. See Botany Index.

Weigh, a weight of cheese, wood, &c. containing 356 pounds avoirdupois. Of corn, the weight contains 40 bushels; of barley or malt, six quarters. In some places, as Essex, the weight of cheese is 300 pounds.

Weighing, the act of examining a body in the balance to find its weight.

Weighing Anchor, is the drawing it out of the ground it had been cast into, in order to set sail, or quit a port, road, or the like.

Weight, in Physics, a quality in natural bodies, whereby they tend downwards towards the centre of the earth. Or, weight may be defined in a less limited manner, to be a power inherent in all bodies, whereby they tend to some common point, called the centre of gravity, or to speak more accurately, to one another: and that with a greater or less velocity, as they are more or less dense, or as the medium they pass through is more or less rare. See Mechanics.

Weight, in commerce, denotes a body of a known weight appointed to be put in the balance against other bodies whose weight is required.

The security of commerce depending, in a good measure, on the justness of weights, which are usually of lead, iron, or brass, most nations have taken care to prevent the falsification thereof, by stamping or marking them by proper officers, after being adjusted by some original standard. Thus, in England, the standard of weights is kept in the exchequer by a particular officer, called the clerk of the market.

Weights may be distinguished into the ancient and modern.

I. ANCIENT WEIGHTS.

1. Those of ancient Jews, reduced to the English troy weight, will stand as in the following table:

<table>
<thead>
<tr>
<th>Shekel</th>
<th>1 lib. 9 drams 22 grains</th>
</tr>
</thead>
<tbody>
<tr>
<td>60 Maneh</td>
<td>236 grains = 3 6 10½</td>
</tr>
<tr>
<td>3000 Talent</td>
<td>113 10 1 10½</td>
</tr>
</tbody>
</table>

2. Roman weights, reduced to English troy weight, will stand as in the following table:

<table>
<thead>
<tr>
<th>Lentes</th>
<th>24 Silique</th>
<th>12 Obolus</th>
<th>25 6 Scriptulum</th>
</tr>
</thead>
<tbody>
<tr>
<td>72 18 6 Drachma</td>
<td>96 24 8 Sextula</td>
<td>144 36 2 Dicarius</td>
<td>192 48 16 Doppia</td>
</tr>
<tr>

</tr>
</tbody>
</table>

II. MODERN WEIGHTS.

1. English Weights.—Mr. Renton, in a paper published in the Philosophical Transactions, has proved, that at first there was but one weight in England, and that this was the avoirdupois. Troy weight was introduced in the time of Henry VII. At present, both the troy and avoirdupois weights are used in England. Troy weight seems to have derived its name from Troyes, a town in France, where a celebrated fair was kept. It is used for weighing gold, silver, jewels, silk, and all liquor. The avoirdupois is used for weighing other things.

**Table of Troy Weight, as used by the Goldsmiths, &c.**

</tr>
</tbody>
</table>

The avoirdupois pound is equal to 7202.4 troy grains, the avoirdupois ounce to 437.75 troy grains; and it follows of consequence, that the troy pound is to the avoirdupois ounce as 88 to 107 nearly; for as 89 to 107, so is 7763 to 7202.636; that the troy ounce is to the avoirdupois ounce as 80 to 73 nearly; for as 82 to 72, so is 480 to 438. An avoirdupois pound is equal to 1 lb. 2 oz. 11 dwt. 20 gr. troy; a troy ounce is equal to 1 oz. 1.55 dr. avoirdupois; an avoirdupois dram contains 27.34375 grains; 175 troy pounds are equal to 144 avoirdupois pounds.

The moneyers have a peculiar subdivision of the grain troy: thus,

- Grain
- Mite
- Droit
- Poiriot

The English weights are used in the United Provinces of America.

2. French Weights.—Different weights were formerly used in most of the different provinces of France. These, however, have undergone very material alterations since the revolution in that kingdom. See Measure. But as a knowledge of the ancient weights of that country is of importance, on account of the books in which they are used, we insert the following tables. The Paris pound contains 16 ounces, and is divided two ways.

Grains.

Vol. XX. Part II.
The Amsterdam pound used in commerce is divided into 16 ounces, 32 drams, or 128 drams. This pound contains 2 marcs troy, and ought therefore to weigh only 102.40 oz.; but it weighs 102.80; so that it is a little heavier than the Troy pound of Amsterdam: 3.26 lb. of commerce are equal to 2.57 lb. troy of Holland. Two different pounds are used by apothecaries: the one containing 2 marcs, the other only 14. The first is called the "arsenic" pound; it contains 16 ounces, the ounce 8 drams, the dram 8 scruples, the scruple 20 grains. The second is called the "apothecary's" pound; it is divided into 12 ounces, or 24 drams. Three arsenic pounds are equal to 4 apothecary's pounds.

The Dutch stone — 8 commercial lb.
The Lisdondt, or LI. — 15
The hundred weight — 100
The Schippondt, or Sch. lb. — 300

4. **Spanish Weights.** — The marc of Castile, used for weighing gold and silver, is divided as follows:

<table>
<thead>
<tr>
<th>Grains (gold weight)</th>
<th>1/17</th>
<th>Grain (silver weight)</th>
</tr>
</thead>
<tbody>

</tbody>
</table>

The marc, according to Tillet, is equal to 7 oz. 4 gros, 8 grains French, which is equal to 478.5 as of Holland. One hundred marcs of Castile = about 93.4 marcs of Holland; 100 marcs of Holland = 107 marcs of Castile. Medicines are sold by the same marc; but it is divided differently, containing 8 ounces, 64 draehms, 192 scruples, 384 oboles, 1152 carateras, 4608 grains.

The Spanish commercial pound is divided into two marcs, called "marcs of Tefn," each of which is equal to the marc of Castile. This pound is divided into 16 ounces, 256 adarmes, 9,216 grains.

5. **Weights of Portugal.** — The Lisbon marc for essaying silver coin of 12 deniers, and the denier of 24 grains. The marc of Portugal for weighing gold and silver is equal, according to Tillet, to 7 ounces 3 1/2 gros, and 34 grains French, which makes 4776 as of Holland; so that it is exactly the same with the Lisbon pound. It is divided into 8 ounces, 64 outavos, 192 scruples, 4608 grains.

The pound consists of 2 marcs, 16 ounces, or 96 outavos; the arroba of 32 lb.; the quintal of 8 arrobas, or 27 lb.; 100 Oporto pounds make 874 1/4 lb. pounds of commerce of Amsterdam.

6. **Weights of Italy.** — Genoa. Two kinds of weights are used at Genoa, the "peso grosso" (heavy weight), and the "peso sottile" (light weight); the latter is not for weighing gold and silver, the former for other things. The pound of the peso sottile is equal, according to Tillet, to 1 marc, 2 ounces, 24 gros, 32 grains French. It is divided into 8 ounces, the ounce into 24 deniers, or the denier into 24 grains. The pound of the peso grosso is equal to 1 marc, 2 ounces, 3 gros, 5 grains, French. It is divided into 12 ounces:

- The cantaro = 100 lbs. peso grosso.
- The rubbo = 25 lbs.
- The rotolo = 15 lbs.

100 lbs. peso grosso = 64 1/4 lb. of commerce of Amsterdam.

Rome. The Roman pound consists of 12 ounces, 24 deniers, the denier of 24 grains. The Roman pound, according to Tillet, is equal to 1 marc, 3600 gros, 14 grains, French.

Venice. The marc for weighing gold and silver contains 8 ounces, 32 quarti, 1152 carati, or 4608 grains. An hundred marces of Venice = 575 lbs. troy of Holland, 100 marces of Holland = 103 of Venice. In Venice they also use a peso grosso and peso sottile. 100 lbs. peso grosso = 94 1/2 commercial lbs. of Amsterdam.

7. **Swedish Weights.** — The marc for weighing gold and silver is equal to 16 lbs, 64 quanti, or 454 as. The pound of 32 lbs, used for weighing food, is equal, according to Tillet, to 1 marc, 5 ounces, 7 gns, 8 grains French, which makes 88 5/8 as of Troy of Holland. This answers exactly to the weight of the different pounds, as fixed in Sweden, viz. 88 5/8 as is the pound for weighing articles of food; 78 31/3 as is used in the mines; 74 5/8 as is used in towns and in the country; 70 3/8 as is used for weighing iron; 74 1/8 as is pound used in medicine.

- The skippond = 400 lbs. for weighing food.
- The centner = 120 lbs.
- The wagg = 165 lbs.
- The sten = 32 lbs.

7. The Swedish pound = 1 as of Holland troy.

8. **German Weights.** — Vienna. The marc of Vienna for weighing gold and silver is divided into 16 lethes, 64 quintals, or 256 deniers or pfennigs; the licht into 4 quintals, or 16 pfennings. This marc, according to Tillet, is equal to 1 marc, 1 ounce, 1 gros, 16 grains, French, = 383 as of Troy of Holland. The pound of Vienna is divided into 2 marces, or 4 vingtes; the mark into 8 ounces, 16 lethes, 64 quintals, or 256 pfennings.

Hambrug. The marc for essaysing gold is divided into 24 carats; the carat into 12 grains. The marc for silver is divided into 16 lethes, and the licht into 18 grains. These marces consist each of 288 grains, and are therefore equal. This marc, used in Hambrug for gold and silver, is the marc of Cologne, which is equal, according to Tillet, to 7 ounces, 5 1/2 gros, 71 grains, French, = 4866 as of Troy of Holland. It is divided into 8 ounces, 16 lethes, 64 quintals, 256 pfennings, or 65 55 6/6 recht pfennings thelve. The apothecary pound used in Hambrug, and almost all Germany, is divided into 12 ounces, 96 drachms, 288 scruples, or 5760 grains; an ounce is equal to 0.21 as of Holland.
The weights of Siam are the piece, containing two shans or cattis; but the Siamese catti is only half the Japanese, the latter containing 20 taels and the former only 10; though some make the Chinese catti only 16 taels, and the Siamese 8. The tael contains 4 baots, or ticals, each about a Paris ounce; the baot 4 selings or mayuns; the mayun 2 founages; the founage 4 payes; the paye 2 clams; the sompaye half a founage.

It is to be observed, that these are the names of their coins as well as weights; silver and gold being commodities there sold, as other things, by their weights.

In the isle of Java, and particularly at Bantam, they use the gantan, which amounts to near 3 Dutch pounds. In Golkonda, at Visapour, and Goa, they have the furtelie, containing 1 pound 14 ounces English; the mangalis, or mangelin, for weighing diamonds and precious stones, weighing at Goa 5 grains, at Golkonda, &c. 5½ grains. They have also the rotolo, containing 1½ ounces English; the meticol, containing the sixth part of an ounce; the wall for piastrs and ducats, containing the 73d part of a rial.

In Persia they use two kinds of batmans or mans; the one called cahi or cheray, which is the king's weight, and the other batman of Taurus. The first weighs 13 pounds 10 ounces English; the second 64 pounds. Its divisions are the ratel, or a 16th; the derhem, or drachm, which is the goth; the meschal, which is half the derhem; the dung, which is the sixth part of the meschal, being equivalent to 6 carat grains; and, lastly, the grash, which is the fourth part of the dung. They have also the vakie, which exceeds a little our ounce; the sah-cherry, equal to the 1170th part of the derhem; and the toman, used to weigh out large payments of money without telling; its weight is that of 50 abasses.

11. Weights at Cairo in Egypt.—Almost every kind of goods has its own weight; these are regulated by the cantaren or principal weight.

Ratel.
The ordinary cantaren, or hundred weight, weighs 100 shillings.

The rate or rotoli is nearly equal to the pound of Marseilles; 108 lbs. of Marseilles are equal to 100 ratels. The Marseilles pound consists of 73 ounces of Paris; so that the 100 lbs. of Marseilles are equal to 81 lbs. Paris, and 100 lbs. Paris = 123 lbs. of Marseilles.

We shall subjoin here Mr. Ferguson's table for comparing the English avoirdupois pound with foreign pounds:

Vienna 1.23

In order to show the proportion of the several weights used throughout Europe, we shall add a reduction of them to one standard, viz. the London pound.

The 100 lb. of England, Scotland, and Ireland are equal to
lb. oz.
91 8 of Amsterdam, Paris, &c.
96 8 of Antwerp or Brabant.
88 0 of Rouen, the viscounry weight.
106 0 of Lyons, the city weight.
90 9 of Rochelle.
107 11 of Toulouse and Upper Languedoc.
113 0 of Marseilles or Provence.
81 7 of Geneva.
93 5 of Hamburg.
89 7 of Francefort, &c.
96 1 of Leipsic, &c.
137 4 of Genoa.
132 11 of Leghorn.
153 6 of Milan.
152 0 of Venice.
154 10 of Naples.
97 0 of Seville, Cadiz, &c.
124 13 of Portugal.
96 5 of Liege.
112 7 of Russia.
107 7 of Sweden.
89 7 of Denmark.

A curious weighing machine was some time ago invented by M. Hanin of Paris, whereby the weights of the principal countries in Europe, and the relative proportions they bear to each other, are shown at one view. For this he received a bounty of 20 guineas from the Society instituted at London for the Encouragement of Arts, Manufactures, and Commerce. The following is a description of this ingenious machine.

Figure 1. represents the back of the machine, which being suspended by the ring A, and a weight hung to the hook B, the spring C, C, made fast by strong screws at g, is drawn downwards; and the bar D having a rack thereto, at c, turns the pinion f, in proportion to the weight of the body hanging thereon. Figure 2. shows the face of the machine, on which is a number of concentric circles, and the weights of several countries of Europe engraved thereon, as expressed by the words on a line with them. In the centre of this face is a ring fixed to the small plate, turned by the pinion f, shown at figure 1. From this ring a hand projects, which, by the turning of the pinion, points to such part of the circle as is marked with the weight hung to the hook B; and thereby shows what weight any of the countries mentioned, is equal to the pounds of Troy, which are engraved on the outer circle, second circle, and so of the rest. A slider moves on the hand, which may be brought to any of the circles at pleasure, in order to point out the relative weight or greater precision.

Many attempts have been made to introduce an uniformity of weights and measures into the commercial world; but hitherto they have all failed. The accomplishment of such an undertaking would be of infinite advantage to mankind, and certainly claims the strictest attention of those who by their situation are alone to bring it about. The undertaking is indeed difficult, but surely not impossible. Something of this kind has been attempted and adopted in France; and as the method is simple, and exceedingly well adapted for calculation, it surely deserves to be imitated.

Measure.

Weight of Air. See Pneumatics, No. 14-19.
Regulation of Weights and Measures, is a branch of the king's prerogative. See Prerogative of Measure.

As weight and measure are things in their nature arbitrary and uncertain, it is therefore expedient that they be reduced to some fixed rule or standard, which standard it is impossible to fix by any written law or proclamation; for no man can, by words only, give man an adequate idea of a foot, or a pound weight. It is therefore necessary to have recourse to some tangible, palpable, material standard; by forming a comparison with which all weights and measures may be reduced to one uniform size; and the prerogative of fixing this standard, our ancient law vested in the crown, as it was now held by the king, to the duke. This standard was originally kept at Winchester: and we find in the law of King Edgar, near a century before the Conquest, an injunction that the one measure, which was kept at Winchester, should be observed throughout the realm. Nations have regulated the standard of measures of length by comparison with the parts of the human body;—the palm, the hand, the span, the foot, the cubit, the ell (vina or arm), the pace, and the fathom. But there are of different dimensions in men of different proportions; our ancient historians inform us, that a new standard of longitudinal measure was ascertainment by King Henry the First; who commanded that the inch, or el, which answers to the modern yard, should be made of the exact length of his own arm. And one standard of measure of length being gained, all others are easily derived from thence; those of greater length by multiplying, those of less by dividing, that empirical standard. Thus, by the statute called computus virorum et peregrinarum, five yards and a half make a per; and the yard is subdivided into three feet, and each foot into 12 inches; which inches will be each of the length of three grains of barley. Superficial measures are derived by squaring those of length; and measures of capacity by cubing them. The standard of weights was originally taken from corns of wheat, whereas the lower denomination of weights we have is still called a grain, 32 of which are directed, by the statute called computus membrorum, to compose a pennyweight, whereof make an ounce, 12 ounces a pound, and so upwards. And upon these principles the first standards were made; which being originally so fixed by the crown, their subsequent regulations have been generally made by the king in parliament. Thus, under Richard I., in his parliament held at Westminster, A.D. 1157, it was ordained that there should be only one weight and one
measure throughout the kingdom, and that the custody of the assize, or standard of weights and measures, should be committed to certain persons in every city and borough; from whence the ancient office of the king's aubager seems to have been derived, whose duty it was, for a certain fee, to measure all cloths made for sale, till the office was abolished by the statute 11th and 12th William III. c. 20. In King John's time this ordinance of King Richard was frequently dispensed with for money; which occasioned a provision to be made for enforcing it, in the great charters of King John and his son. These original standards were called pondus regis and mensura domini regis, and are directed by a variety of subsequent statutes to be kept in the exchequer chamber, by an officer called the clerk of the market, except the wine garden, which is committed to the city of London, and kept in Guildhall.

The Scottish standards are distributed among the oldest boroughs. The elawn is kept at Edinburgh, the pint at Stirling, the pound at Lanark, and the florin at Linlithgow.

Various statutes have been enacted for regulating and enforcing an uniformity of weights and measures; and by the articles of union, the English standards are established by law over all Great Britain. But the force of custom is so strong, that these statutes have been ill observed. The Scottish standards are still universally retained for many purposes; and likewise a variety of local weights and measures are used in particular places of both countries, which differ from the general standards of either. A report was made by a committee of the House of Commons on the subject of weights and measures, 24th June, 1819, recommending alterations of a very limited nature; but nothing farther has been done.

Weinmannia, a genus of plants of the class octandria, order monogynia, and arranged in the natural classification with those plants the order of which is doubtful.

Weld, or Wold. See Reseda, Botany Index, and Dyeing.

Welding, in smithery, a degree of heat given to iron, &c. sufficient to make the surfaces of two pieces incorporate upon being beaten together with a hammer.

WELL, a hole under ground, usually of a cylindrical figure, and walled with stone and mortar: its use is to collect the water of the strata around it.

WELD, an apartment formed in the middle of a ship's hold to inclose the pumps, from the bottom to the lower decks. It is used as a barrier to preserve those machines from being damaged by the friction or compression of the materials contained in the hold, and particularly to prevent the entrance of ballast, &c. by which the tubes would presently be choked, and the pumps rendered incapable of service. By means of this inclosure, the artificers may likewise more readily descend into the hold, in order to examine the state of the pumps, and repair them as occasion requires.

WELL, of a Boat. The place in the bottom where the water lies between the ceiling and the platform of the stern-sheets, whence it is thrown out into the sea with a scoop.

WELL. See Burning-Spring.

WELL, of a Fishing-vessel, an apartment in the middle of the hold, which is entirely detached from the rest, being lined with lead on every side, and having the bottom thereof penetrated with a competent number of small holes passing also through the ship's floor; so that the salt-water running into the well is always kept as fresh as that in the sea, and yet prevented from communicating itself to the other parts of the hold.

WELT-hole, in building, is the hole left in a floor for the stairs to come up through.

WELLS, a city of Somersetshire, and seat of a bishop; the bishop of Bath being also that of Wells. It is supposed to take its name from the many springs and wells that are near it. It is not very large; but is adorned with handsome buildings, and contained 5136 inhabitants in 1811. Its cathedral is a very beautiful structure, adorned with images and carved stone work. The bishop's palace joins to the cathedral; and on the other side are the houses for the prebendaries. In the market-place is a fine market house, supported by pillars. It is governed by a mayor, and sends two members to parliament. The chief manufacture is knit hose. W. Long. 2. 42. N. Lat. 51. 12.

WEN, a tumor or excrescence arising on different parts of the body, and containing a cystus or bag filled with some peculiar kind of matter. See Nævus, Surgery Index.

Weregild, the price of homicide; paid partly to the king for the loss of a subject, partly to the lord whose vassal he was, and partly to the next of kin of the person slain.

WERST, WURST, or Verst, a Russian measure equal to 3500 English feet. A degree of a great circle of the earth contains about 4000 verstes and a half.

Werturian or Urallian Mountains, a famous chain of mountains forming part of the boundary of Asia. It begins distinctly (for it may be traced unintermittedly farther south) near the town of Kungur, in the government of Kasan, in latitude 57° 25', runs north, and ends opposite to the Waygatz strait, and rises again in the island of Nova Zembla. The Russians also call this range Semenov Pous, or, the girdle of the world; from a supposition that it encircled the universe. These were the Riphaei montes: Pars mundi damnata a natura rerum, et divina mersa culagine; of which only the south- Pictini ern part was known to the ancients, and that so little as Hdt. Nat. to give rise to numberless fables. Beyond these were placed the happy Hybers, a fiction most beautifully related by Pomponius Mela. Moderns have not been behind-hand in exaggerating several circumstances relative to these noted hills. Ysbrand Ides, who crossed them in his embassy to China, asserts that they are 5000 toises or fathom; some others, that they are covered with eternal snow. The last may be true in their more northern parts; but in the usual passages over them, they are free from it three or four months.

The heights of part of this chain have been taken by M. 1. Ablé d'Auteroche: who, with many assurances of his accuracy, says, that the height of the mountain Kyria near Solikamskiaia, in latitude 50°, does not exceed 471 toises from the level of the sea, or 286 from the ground on which it stands. But according to M. Gmelin, the mountain Pauida is much higher, being 752 toises above the sea. From Petersburgh to this chain is a vast plain, mixed with certain elevations or platforms, like islands in the midst of an ocean. The eastern side descends gradually to a great distance into the wooded and morassy Siberia, which forms an immense
Wesley, John, a very extraordinary character, and founder of the sect of Methodists, was the son of the Reverend Samuel Wesley, rector of Epworth in the vale of Axholme in Lincolnshire, and born in that village in the year 1703. His very infancy was distinguished by an extraordinary accident; for when he was only six years old, the parsonage-house at Epworth was burnt to the ground, and the flames had speeded with such rapidity, that few things of value could be saved. His mother, in a letter to her son Samuel Wesley, then on the foundation at Westminster school, thanks God that no lives were lost, although for some time they gave up Poor Jacky, as she expresses herself; for his father had twice attempted to rescue the child, but was beaten back by the flames. Finding his efforts ineffectual, he resigned him to Divine Providence. But parental tenderness prevailed over human fears, and Mr. Wesley once more attempted to save his child. By some means equally unexpected and accountable, the boy got round to a window in the front of the house, and was taken out, by one man's leaping on the shoulders of another, and thus getting within his reach. Immediately on his rescue from this very perilous situation, the roof fell in. This extraordinary escape explains a certain device, in a print of Mr. John Wesley, engraved by Vertue, in the year 1745, from a painting by Williams. It represents a house in flames, with this motto from the prophet, "Is he not a brand plucked out of the burning?" Many have supposed this device to be merely emblematical of his spiritual deliverance; but from this circumstance it is apparent that it has a primary as well as a secondary meaning; it is real as well as allusive.

In the year 1713 he was entered a scholar at Charter-house in London, where he continued seven years under the tuition of the celebrated Dr. Walker, and of the Rev. Andrew Tooke author of The Pantheon. Being elected to Lincoln college, Oxford, he became a fellow of that college about the year 1725, took the degree of Master of Arts in 1726, and was joint tutor with the Rev. Dr. Hutchinson. He discovered very early an elegant turn for poetry. Some of his gayier poetical effusions are proofs of a lively fancy and a fine classical taste; and some translations from the Latin poets, while at college, are allowed to have great merit. He had early a strong impression, like Count Zinzendorff, of his designation to some extraordinary work. This impression received additional force from some domestic incidents; all which his active fancy turned to his own account. His wonderful preservation, already noticed, naturally tended to cherish the idea of being designed by Providence to accomplish some purpose or other; that was out of the ordinary course of human events. The late Rev. Samuel Badcock, in a letter inserted in the Bibliotheca Topographica Britannica, No. XX, says, "There were some strange phenomena perceived at the parsonage at Epworth, and some uncommon noises heard there from time to time, which he was very curious in examining into, and very particular in relating. I have little doubt that he considered himself the chief object of this wonderful visitation. Indeed his father's credulity was in some degree affected by it; since he collected all the evidences that tended to confirm the story, arranged them with scrupulous exactness, in a manuscript consisting of several sheets, which is still in being. I know not what became of the ghost of Epworth; unless, considered as the prude to the noise Mr. John Wesley made on a more ample scale, it ceased to speak when he began to tell." The dawn of Mr. Wesley's public mission (continues Mr. Badcock) was clouded with mysticism; this species of it affects silence and solitude; certain inexplicable introversion of the mind, which abstracts the passions from all sensible objects; and as the French Quietists express it, perfects itself by an absorption of the will and intellect, and all the faculties, into Deity." In this path the obscure the excellent Penn led himself, when he foreshadowed the shades of Plato, a wanderer in quest of pure love with Madame Guyon! Mr. Wesley pursued for a while the same igitur footsteps with Mr. William Law and the Ghost of Dr. Bentley. A state, however, so torpid and ignoble, ill suited the active genius of this singular man. His elastic mind gained strength by compression; thence bursting glorious, he passed (as he himself somewhere says) "the immense chasm, upborne on an eagle's wings." The reading of the writings of this Mr. William Law, the celebrated author of Christian Perfection, and of a Serious Address to the Christian World, contributed moreover, to lead Mr. John Wesley and his brother Charles with a few of their young fellow-students, into a more than common strictness of religious life. They received the sacrament of the Lord's Supper every week; observed all the fasts of the church; visited the prisons; rose at four in the morning; and refrained from all amusements. From the exact method in which they disposed of every hour, they acquired the appellation of Methodists; by which their followers have been ever since distinguished.

But a more particular account of the origin of the sect, we shall give from a celebrated publication. "The Methodists (says the editor of this work) form a very considerable class, principally of the lower people in this country. They sprung up about fifty years ago at Oxford, and were soon divided into two parties; one under the direction of Mr. George Whitefield, and the other under that of two brothers, John and Charles Wesley. These leaders, and, if we except Mr. William Law, founders of the Methodists, were educated at Oxford, received episcopal ordination, and always professed themselves advocates for the articles and liturgy of the established church; though they more commonly practiced the dissenting mode of worship. But conceiving a design of forming separate communities, superior in sanctity and perfection to all other Christian churches, and impressed to a very considerable degree by a zeal of an extravagant and enthusiastic kind, they became itinerant preachers; and, being excluded from most of our churches, exercised their ministry in private houses;
fields, &c. not only in Great Britain and Ireland, but also in America; thus collecting a very considerable number of hearers and proselytes, both among the members of the established church and the dissenters. The theological system of Mr. Whitefield and his followers is Calvinistic; that of Mr. Wesley and his disciples Arminian; and the latter maintains the possibility of attaining sinless perfection in the present state. The subordinate teachers of both these classes of Methodists are generally men of no liberal education; and they pretend to derive their ministerial abilities from special Communications of the Spirit. The Methodists of both parties, like other enthusiasts, make true religion to consist principally in certain affections and inward feelings which it is impossible to explain; but which, when analysed, seem to be mechanical in their spring and operation; and they generally maintain, that Christians will be most likely to succeed in the pursuit of truth, not by the dictates of reason, or the aids of learning, but by laying their minds open to the direction and influence of divine illumination; and their conduct has been directed by impulses."

Our readers will judge for themselves, according to their various modes of education, and to the different lights in which they may respectively view the doctrines of our common Christianity, whether this representation of the origin of the Methodists, and of their distinguishing tenets, be accurate and just. — Not presuming to sit in judgment on the religious opinions of any man, we shall only observe, that an appellation originally given in reproach, has been glorified in ever since by those who have distinguished themselves as the followers either of Mr. Whitefield or of Mr. Wesley. "After the way called Methodists, so worship they the God of their fathers." But the ridicule and contempt which the singularity of their conduct produced, both John and Charles Wesley were well qualified to bear. They were not to be intimidated by danger, actuated by interest, or deterred by disgrace.

The boundaries of this island were soon deemed by Mr. Wesley too confined for a zeal which displayed the piety of an apostle, and of an intrepidity to which few missionaries had been superior. In 1735 he embarked for Georgia, one of our colonies, which was at that time in a state of political infancy; and the great object of this voyage was to preach the gospel to the Indian nations in the vicinity of that province. He returned to England in 1737. Of his spiritual labours, both in this country and in America, he himself has given a very copious account, in a series of Journals printed at different periods. These journals drew upon our laborious preacher and his coadjutors some severe animadversions from two right reverend prelates; Dr. George Livington bishop of Exeter, and Dr. William Warburton bishop of Gloucester. The former published, in three parts, The Enthusiasm of the Methodists and Papists compared; the third part of this performance containing a personal charge of immoral conduct. Mr. Wesley, in his vindication, published a letter to his lordship, which produced a reply from the latter.

Bishop Warburton's attack is contained in his celebrated treatise, entitled The Doctrine of Grace: or, The Office and Operations of the Holy Spirit vindicated from the Insults of Infidelity, and the Abuses of Fanaticism: concluding with some thoughts, humbly offered to the consideration of the Established Clergy, with regard to the Right Method of defending Religion against the Attacks of either party; 2 vols. small 8vo, 1762. There is much acute reasoning, and much poignant and sprightly wit, in his Doctrine of Grace; but there is too much levity in it for a grave bishop, and too much abuse for a candid Christian. On this occasion, Mr. Wesley published a letter to the bishop, in which, with great temper and moderation, as well as with great ingenuity and address, he endeavoured to shelter himself from his lordship's attacks; not only under the authority of the Holy Scriptures, but of the church itself, as by law established.

On his return from Georgia, Mr. Wesley paid a visit to Count Zinzendorf, the celebrated founder of the sect of Moravians, or Hurnhutters, at Hornhut in Upper Lusatia. In the following year he appeared again in England, and with his brother Charles, at the head of the Methodists. He preached his first field-sermon at Bristol, on the 2d of April 1738, from which time his disciples have continued to increase. In 1744, attempting to preach at an inn at Taunton, he was regularly silenced by the magistrates. Although he chiefly resided for the remainder of his life in the metropolis, he occasionally travelled through every part of Great Britain and Ireland, establishing congregations in each kingdom. In 1750 he married a lady, whom he was afterwards separated. By this lady, who died in 1781, he had no children.

We have already mentioned Mr. Wesley as a very various and voluminous writer. Divinity, both devotional and controversial, biography, history, philosophy, politics, and poetry, were all, at different times, the subjects of his pen; and, whatever opinion may be entertained of his theological sentiments, it is impossible to deny him the merit of having done very extensive good among the lower classes of people. He certainly possessed great abilities, and a fluency which was well accommodated to his hearers, and highly acceptable to them. He had been gradually declining for three years before his death; yet he still rose at four in the morning, and preached, and travelled, and wrote as usual. He preached at Leatherhead in Surrey, on the Wednesday before that event. On the Friday following, appeared the first symptoms of his approaching dissolution. The four succeeding days he spent in praising God; and he left this scene, in which his labours had been so extensive and so useful, at a quarter before ten in the morning of the 2d of March 1771, in the 89th year of his age. His remains, after lying in a kind of state at his chapel in the city-road, dressed in the sacerdotal robes which he usually wore, and on his head the old clerical cap, a bible in one hand, and a white handkerchief in the other, were, agreeably to his own directions, and after the manner of the interment of the late Mr. Whitefield, deposited in the cemetery behind his chapel, on the morning of the 9th March, amidst an innumerable concourse of his friends and admirers; many of whom appeared in deep mourning on the occasion. One singularity was observable in the funeral services. Instead of, "We give thee hearty thanks, for that it hath pleased thee to deliver this our brother," it was read "our father." A sermon, previously to the funeral, had been preached by Dr. Thomas Whitehead, one of the physicians to the London.
WESLEY, London hospital; and on the 13th the different chapels of his persuasion in London were hung with black.

It has been justly observed of Mr. Wesley, that his labours were principally devoted to those who had no instructor; to the highways and hedges; to the miners in Cornwall, and the colliers in Kingwood. These unhappy creatures married and buried themselves, and often committed murders with impunity, before the Methodists sprang up. By the humane and active endeavours of Mr. Wesley and his brother Charles, a sense of decency, morals, and religion, was introduced into the lowest classes of mankind; the ignorant were instructed, the wretched relieved, and the abandoned reclaimed. His personal influence was greater, perhaps, than that of any other gentleman in any country. —But the limits of this article will not permit us to expatiate further on the character of this extraordinary man.

WEST, Gilbert, was the son of Dr. West, prebendary of Winchester, and chaplain to King George I. but at 12 years of age lost his father. He studied at Winchester and Eton schools, and from thence was placed in Christ-church college, Oxford. His studious and serious turn inclined him to take orders; but Lord Cobham, his uncle, diverted him from that pursuit, and gave him a cornetcy in his own regiment. This profession he soon quitted, on account of an opening of another nature, which presented itself to him, with a flattering prospect of advancement in life. A number of young gentlemen were elected from the universities, and, at the expense of government, were to be taught foreign languages; and then sent to the secretaries office, to be initiated into business, and trained there for public services, as envoys, ambassadors, &c. Mr. Gilbert West was one of the few pitched upon; and on his first introduction into that office, Lord Townsends, secretary of state, treated him with singular marks of regard, and the strongest inclinations to serve him were testified from all quarters. But his uncle Lord Cobhams strong opposition to the measure of the government, rendered these advantages entirely fruitless; and the ministers honestly told Mr. West, that he must not expect them to distinguish his merit, as any favours conferred upon him would be imputed as done to his uncle Lord Cobham. Mr. West now left that office, and all his views of making his fortune; and entering into marriage, retired to Wickham in Kent, where he lived in great domestic comfort and tranquil happiness. He was there visited by his valuable friends, who held the most delightful converse of wit, humour, and learning, supported upon the principles of virtue, sound reasoning, and solid friendship, which rendered the whole cheerful, animating, and instructive. Mr. William Pitt, who was one of those that pointed Mr. West treasurer to Chelsea-hospital; and he obtained a seat at the council board, in consequence of a friendship contracted at the school with one of the duke of Devonshires sons, who procured of his grace that office. Towards the latter part of Mr. Wests life, he wholly applied himself to the study of the Scriptures; being extremely anxious to try his utmost endeavours to reconcile the seeming inconsistencies which gave the enemies to revealed religion a handle to doubt and dispute. His observations on the resurrection, which, it has been said, were untrue to the wavering faith of his great friends Patee and Lyttleton, bear ample testimony to his reasonings, and the sincerity of his religion; while his translation of Pindar show him to have been an emulator, scholar, and very considerable poet. He had a rare replete with virtue, and was an honour to his country; but died at 50 years of age.

WEST, one of the cardinal points of the horizon, diametrically opposite to the east; and strictly defines the intersection of the prime vertical with the horizon at that side the sun sets in.

WESTMINSTER, a city which forms the north part of the capital of Britain, but has a government distinct from the rest. This city had its name from the situation of its abbey, anciently called a minster, in respect of that of St. Paul. That part of the city called the city of Westminster, comprehending the parishes of St. John and St. Margaret, was once an island formed by the Thames, called Thorney Island, from the thorn with which it was ornamented; and the abbey that stood in it, Thorney abbey. The liberties of Westminster consist of several parishes of St. Martin in the Fields, St. James the Less, St. Anne, St. Paul, Covent Garden, St. Mary's Strand, St. Clement Danes, St. George, Hanover Square, and the precinct of the Savoy. The government, both of the city and liberties, is under the jurisdiction of the dean and chapter of Westminster, in civil as well as ecclesiastical affairs; and their authority extends to the precinct of St. Martin-le-Grand, by Nottingham, and in some towns of Essex, which are exempted from the jurisdiction of the bishop of London and the archbishop of Canterbury; but the management of the civil part has ever since the Reformation, been in the hands of men, elected from time to time, and confirmed by the dean and chapter. The chief of these lamas are the high-steward, the deputy-steward, and the highebuild, who hold their offices for life. These are also burgesses and their assistants, out of which are elected head-burgesses, one for the city, and the other for the liberties. Another officer is the high-custos, who has all the other constables under his direction.

WESTMORELAND, a county of England, bounded on the north and north-west by Cumberland; on the south and south-east by Yorkshire; and on the east and south-west by Lancashire. Its extent from north-east to south, is 42 miles, and its breadth from the east projection to that in the west, 42. It is generally divided into the baronies of Kendall and Westmorland; the former is very mountainous, but the latter a large and extensive country. These are the only principal divisions of this county, which contains eight market towns, 26 parishes, and in 1811 the number of inhabitants was 45,922. It lies partly in the diocese of Chester, and partly in that of Carlisle. The Earl of Thanet is hereditary sheriff of the county, which sends only four members to parliament. The air is clear, sharp, and salubrious, the natives being seldom troubled with diseases, and generally living to old age. The soil is various; that on the mountains is very barren, while that in the valleys is fertile, producing good corn and grass, especially in the meadows near the rivers. In the hilly parts on the western borders it is generally believed there are vast quantities of copper ore, and veins of gold; some mines of copper are worked, but most of the ore lies so deep that
it will not answer the expense. This county yields the finest slate, and abundance of excellent hams are cured here. The principal rivers are, the Eden, the Lone, and the Ken. It has also several fine lakes, the principal of which is Windermere. In the forest of Martindale, to the south of Ulswater, the breed of red deer still exists in a wild state.—Appleby is the county town. See Westmoreland, Supplement.

WESTPHALIA, formerly a duchy of Germany, bounded to the east by the bishopric of Paderborn, and the territories of Waldeck and Hesse; to the south by the counties of Wittgenstein and Nassau, and the duchy of Berg; to the north by the bishopric of Munster and the county of Lippe. It is about 40 miles in length and 30 in breadth. The lower part of it is very fruitful, yielding plenty of corn and cattle, and some salt springs. The higher affords iron ore, calamine, lead, copper, some silver and gold, fine woods, cattle, game, fish, with a little corn. The rivers, that either pass through the duchy or along its borders, are the Rähr, the Lenn, the Bigge, the Dimsel, and the Lippe. There are 28 towns in it, besides boroughs and cloisters. The provincial diets were held at Aachenberg. In the year 1852, the emperor Frederick I. made a donation of this duchy to the archbishopric of Cologne, which was confirmed by succeeding emperors; and in 1638, the last duke of Aachenberg ceded it to also the county of Aachenberg.

WESTPHALIA, one of the circles of Germany. Anciently the people inhabiting between the Weser and the Rhine, were called Westphalians; and hence that tract got the name of Westphalia: but the circle of that name is of a larger extent, being surrounded by the circle of Burgundy, the Austrian Netherlands, the United Provinces, and the North sea, with the circles of the Upper and Lower Rhine, and comprising a great many different states.

With respect to religion, Westphalia is partly Protestant and partly Catholic; but the Protestants predominate, and are, at least the greater part of them, Calvinists. The air of this country is not reckoned very wholesome, and towards the north is extremely cold in winter. The soil in general is marshy and barren; yet there is some good corn and pasture land; but the fruit is chiefly used to feed hogs; and hence it is that their bacon and hams are so much valued and admired.

After the peace of Tilsit in 1807, the principalities of Hanover, Brunswick, Magdeburg, Old Mark, Hesse Cassel, with some other territories, were erected into the kingdom of Westphalia, which was governed by Jerome Bonaparte. This state disappeared on the overthrow of the French power in 1814, and the territories which composed it were restored to their former princes. Jerome Bonaparte's court was kept at Cassel, the capital of the principality of Hesse.

WESTRINGIA, a genus of plants, formed from cunita fruticosa, which was discovered by Dr Solander in New Holland. Dr Smith describes it as approaching nearer to rosemary, and places it after teucrum in the class didynamia.

WET-COVERED, tawing-heap, a term used by the malters for one of the principal articles of malt-making. See Brewing, No. 4.

WETSTEIN, JOHN JAMES, a learned German divine, was born at Basel in 1693. On his admission to Vol. XXI. Part II.

the ministry, he maintained a thesis De variis Novi Testamenti Lectio, in which he showed that the great variety of readings of the New Testament afford no argument against the authenticity of the text. He had made these various readings the object of his attention; and travelled into foreign countries to examine all the MSS. he could come at. In 1730, he published Prolegomena ad Novi Testamenti Graeci editio em accuratissimam, &c. Some divines, dreading his unsettled present text, procured a decree of the senate of Basil against his undertaking, and even got him prohibited from officiating in the ministry; on which he went to Amsterdam, where the Remonstrants named him to succeed the famous Le Clerc, then superannuated, as a professor of philosophy and history. At last he published his edition of the New Testament, in 2 vols. folio, 1752; in which he left the text as he found it, placing the various readings, with a critical commentary, underneath; subjoining two epistles of Clement Romanus, till then unknown to the learned; but discovered by him in a Syriac MS. of the New Testament. He also published some small works; and is said to have been not only an universal scholar, but to have abounded in good and amiable qualities. He died at Amsterdam in 1754.

WETTERAVIA, the southern division of the landgrave of Hesse in Germany, lying along the northern bank of the river Maine, and comprehending the counties of Hanau and Nassau.

WEXFORD, a county of Ireland, in the province of Munster, 38 miles in length, and 24 in breadth; bounded on the north by Wicklow, on the east by St George's channel, on the south by the Atlantic ocean, on the west by Waterford and Kilkenny, and on the north by Catherlough. It contains 159 parishes, and formerly sent 16 members to the Irish parliament. It is a fruitful country in corn and grass. See Wexford, Supplement.

WEXFORD, a sea-port of Ireland, capital of a county of the same name. It was once reckoned the chief city in Ireland, being the first colony of the English, and is still a large handsome town, with a very commodious harbour at the mouth of the river Slana, on a bay of St George's channel, 63 miles south of Dublin. W. Long. 6° 21'. N. Lat. 52° 18'.

WHALE. See Baleen and Phytster, Cetology Index.

WHALE, one of the constellations. See Astronomy.

WHALE-Bone. For its natural history, see Cetology Index.

A patent was granted in October 1856 to Robert Bowman of Leith, in Scotland, for making hats, caps, and bonnets for men and women, of whalebone; harps for harping or cleansing corn or grain; and also the bottoms of sieves and riddles, and girths for horses; and also a cloth or webbing for making into hats, caps, &c.; and for the backs and seats of chairs and sofas, gigs, coaches, and other similar carriages; and the bottoms of beds; as also reeds for weavers.

WHALE-Fishery. See Cetology.

WHALE, a space on the banks of a haven, creek, or hille, provided for the convenient loading and unloading of vessels.

WHARTON, PHILIP DUKE OF, a nobleman of the most brilliant parts, but of the most whimsical, extravagant, and inconsistent turn of mind, was educated by his father...
father's express order at home. He very early married a young lady, the daughter of Major-General Holmes, which disappointed his father's views of disposing of him in such a marriage as would have been a considerable addition to the fortune and grandeur of his illustrious family; yet that amiable lady deserved infinitely more felicity than she met with by this alliance. This precipitate marriage is thought to have hastened the death of his father; after which the duke, being free from paternal restraints, plunged into those excesses which rendered him, as Pope expresses it, "A tyrant to the wife his heart approv'd; A rebel to the very king he lov'd."

In the beginning of the year 1716, he began his travels; and as he was de-joined to be instructed in the strictest Whig principles, Geneva was thought a proper place for his residence. He first passed through Holland, and visited several courts of Germany; and being arrived at Geneva, conceived such a disgust against his governor, that he left him, and set out post for Lyons, where he wrote a letter to the Chevalier de St George, who then resided at Avignon, and presented him a very fine stout horse; which the chevalier no sooner received than he sent him a quality of wine, who took him privately to his court, where he was entertained with the greatest marks of esteem, and had the title of Duke of Northumberland conferred upon him. He, however, remained there but one day, and then returned post to Lyons, whence he set out for Paris. He likewise paid a visit to the consort of James II. who then resided at St Germain, to whom he also paid his court. During his stay at Paris, his finishing address and abilities gained him the esteem and admiration of all the British subjects of rank of both parties.

About the latter end of December 1716, he arrived in England, whence he soon after set out for Ireland, where, though under age, he was allowed the honour to take his seat in the house of peers, and immediately distinguished himself, notwithstanding his former conduct, as a violent partisan for the ministry; in consequence of which zeal the king created him a duke. He no sooner came of age than he was introduced to the house of lords in England with the same blaze of reputation. In a little time he opposed the court, and appeared one of the most vigorous in defence of the bishop of Rochester; and soon after printed his thoughts twice a week, in a paper called the True Briton, several thousands of which were circulated.

The duke's boundless profusion had by this time so burdened his estate, that by a decree of Chancery it was vested in the hands of trustees for the payment of his debts, allowing him a provision of 200l. per annum for his subsistence. This being insufficient to support his title with suitable dignity, he went abroad, and shone to great advantage, with respect to his personal character, at the imperial court. From thence he made a tour to Spain: the English minister was alarmed at his arrival, fearing that his grace was received in the character of an ambassador: upon which the duke received a summons under the privy seal to return home; but instead of obeying it, he endeavoured to inflame the Spanish court against that of Great Britain, foreexercising an act of power, as he calls it, within the jurisdiction of his Catholic majesty. He then acted openly in the service of the Pretender, and was received at his court with its greatest marks of favour.

While his grace was thus employed, his revered duchess died in England on the 14th of April 1723, without issue. Soon after the duke fell violently in love with M. Oberne, one of the maids of honour to the queen of Spain, the daughter of an Irish colonel, whose fortune chiefly consisted in her personal accomplishments. All his friends, and particularly the queen of Spain, opposed the match; but he falling into a lingering fit, occasioned by his disappointment, the queen gave her consent, and they were soon after married. He spent some time at Rome, where he accepted of a like garter, assumed the title of Duke of Northumberland, and for a while enjoyed the confidence of the said prince. But not always keeping within the bounds of Italian gravity, it became necessary for him to remove from hence; when, going by sea to Barcelona, he wrote a letter to the king of Spain, acquainting him that he would assist at the siege of Gibraltar as a volunteer. Soon after he wrote to the chevalier de St George, expressing a desire to visit his court; but the chevalier invited him to draw near to England. The duke seemed resolved to follow his advice; and setting out with his duchess, arrived in Paris in May 1728, whence he soon after proceeded to Rouen, where he took up his residence; and was so far from making any concession to the government of England, that he did not give himself the least trouble about his estate, or any other concern there, though, on his arrival at Rouen, he had only about 600l. in his possession, and a bill of Indictment was preferred against him in England for high treason. Soon after the chevalier sent him 200l. which he squandered away in a course of extravagance; when, to save the charges of travelling by land, he went from Orleans to Nantes by water, and staid there till he got a remittance from Paris, which was squandered almost as soon as received. At Nant he was joined by his ragged servants, and from hence took shipping with them for Bilboa, when the queen of Spain took the duchess to attend her person. About the beginning of the year 1731, the duke, who commanded a regiment, was at Lérida, but declined his being that he could not move without assistance; yet when free from pain did not lose his gaiety. He, however, received benefit from some mineral waters in Catalon; but soon after relapsed at a small village, where he was utterly destitute of all the necessaries of life, till some charitable fathers of a Bernardine convent removed him to their house, and gave him all the relief in their power. Under their hospitable roof he languished a week, and then died, without one friend or acquaintance to close his eyes; and his funeral was performed in the same manner in which the fathers inter those of their own fraternity.

Thus died Philip duke of Wharton, who, like Buckingham and Rochester (says Mr Walpole), conformed all the grave and dull, by throwing away the brightest profusion of parts on witty foibles, debaucheries, and scrapes, which mix graces with a great character, but never can compose one.

"With attachment to no party, though with talents to govern any party, this happy man changed the fine air of Westminster for the gloom of the Escurial, the prospect of King George's garret for the Pretender's; and..."
and with indifference to all religion, the fruitlet lord who had written the ballad on the archbishop of Canterbury, died in the habit of a capuchin. It is difficult to give an account of the works of a man whose library was a tavern, and women of pleasure his muses. A thousand sallies of his imagination may have been lost. There are only two volumes in 8vo, called his Life and Writings. These contain nothing of the latter, but 74 numbers of the True Briton, and his speech in defence of the bishop of Rochester. His other works are the ballads above mentioned; the Drinking Match at Eden hall, in imitation of the Chevy Chace, printed in a miscellany called Whartoniana; and a song sung at the opera house by Mrs Tita. His lordship also began a play on the story of the queen of Scots.

WHEAT. See TRITICUM, BOTANY Index; and for the culture of wheat, see AGRICULTURE Index.

The three principal kinds of bad wheat are, the blightled, the smutty, and the worm-eaten. Blightled wheat is that of which the stalk is a little twisted and rickety, the blade being of a bluish green and curled up, the grain also is green and tubercled: smutty wheat appears as if great part of the ear had been burnt, some small parts only being free, and, in particular, the stem that rises in the centre of the ear, round which the grain is ranged: worm-eaten or rotten wheat is corrupted without losing much of its natural form, or external appearance; the husk is filled with a greasy black powder, that is insufferably fetid. It appeared, from the experiments of M. Tillet, that there was a kind of infectious quality in all those kinds of wheat: so that if sound wheat was sprinkled with the flour of smutty or rotten wheat, the crop produced would be rotten or smutty. It appeared also, that among the grain which was produced from ground manured with the straw of distempered wheat, there was a much greater proportion of distempered wheat than in that produced from ground manured with the straw of good wheat; the great secret then was to destroy the principle of this contagion in the wheat that was put into the ground; and M. Tillet found, as the result of a great number of experiments, that if the grain, before it is sowed, be well moistened with a solution of sea-salt, or nitre, in common water, none of the ensuing crop will be smutty, or otherwise defective, either in kind or quality; not only supposing the grain that is sowed to be sound, and the soil to be good, but even supposing the grain to be strewn with the flour of smutty wheat, and the ground manured with bad straw.

The following receipt for preventing smutty wheat was published in 1769 by order of the Society for the Encouragement of Arts: they received it from Mr John Reynolds of Addislem in Kent.

A tub is to be procured that has a hole at bottom, in which a staff and tap hose is to be fixed over a whip of straw, to prevent any small pieces of lime passing (as in the brewing way): this done, we put 70 gallons of water, then a corn bushel heap-full of stone-lime, unslaked, stirring it well till the whole is dissolved or mixed, letting it stand about 32 hours, and then run it off into another tub as clear as we can (as practised in beer): this generally produces a hogshead of good strong lime-water; then add three pecks of salt, 42 pounds, which, with a little stirring, will soon dissolve; thus we have a proper pickle for the purpose of bruising and liming our seed-wheat without any manner of obstacle, which is more than can be said in doing it the common way, and greatly facilitates the drilling.

Herein we steep the wheat in a broad-bottomed basket of about 24 inches in diameter, and 22 inches deep (for large sowing, made on purpose), running in the grain gradually in small quantities from 10 to 12 gallons up to 16 gallons, stirring the same. What floats, we skim off with a strainer, and is not to be sown: then draw up the basket to drain over the pickle, for a few minutes; all which may be performed within half an hour, sufficiently pickled; and so proceed as before. This done, the wheat will be fit for sowing in 24 hours, if required; but if designed for drilling, two hours pickled will be found best; and if prepared four or five days before-hand, in either case it makes no difference at all; but should the seed be clammy, and stick to the notches in the drill-box, more lime must be added to the lime-water: here the master must use his discretion, as the case requires; for some lime has much more drying or astringent qualities in it than others. If sea water can be obtained conveniently, much less salt will suffice, but lime will be found necessary even then, otherwise the light grains will not float, a thing of more consequence than is generally imagined, and it ought to be skimmed off and thrown aside for poultry, &c.

WHEEL, in Mechanics, a simple machine, consisting of a round piece of wood, metal, or other matter, which revolves on its axis. See MECHANICS.

WHEEL-CARRIAGES. See MECHANICS for an account of the general principles.

No kind of wheel-carriages are of more importance to a commercial and manufacturing country than stage coaches, and perhaps in no kingdom of Europe has the system of travelling in public vehicles been carried to greater perfection, as to comfort and speed, than in Britain. The danger, however, of travelling by these coaches makes considerable deduction from their accommodation otherwise: it is but too well known that this mode of travelling is liable to frequent and serious accidents. Every attempt therefore that promises to be useful in diminishing such danger should have all possible publicity. With this view we are much gratified in having an opportunity of laying before our readers the following account of an invention to render stage coaches more secure from danger, obligingly transmitted to us by the inventor, the reverend William Milton of Heckfield, Hants. For this invention that gentleman has obtained a patent.

The danger of stage coaches arises sometimes from overturning, and sometimes from breaking down. The overturn is, in general, occasioned either by taking two side-wheels into too deep a hole or ditch, or over too high a bank; or, secondly, by running down more quickly than the carriage is calculated to do, from the top to the sides of a rounded road; or, lastly, by turning a sharp corner with too great velocity. In the two first cases the danger arises from the centre of gravity of the total coach and load being placed too high; and in the last instance, of turning the sharp corner, from the same centre (but which we must now consider as the centre of the vis inertiæ) being also placed too high. The danger in the two first cases grows often out of the very circumstances of the road, and meets every one's comprehension.
comprehension: the last, which is less obvious, is generally owing to the mere will of the driver; and the better the road, the more is he tempted, without any intention, to go on to produce it: it requires therefore to be more generally understood than it is. It may be thus explained:—A carriage is going along a straight level road at the rate of nine miles an hour: then, though you imagine the horses or pulling power to be in an instant withdrawn, yet will the carriage continue its motion for ten, fifteen, or more yards, and at first with the same velocity, and in the same straight line, in consequence of the acquired motion. Supposing, now, the coach with its four horses going the nine miles an hour along a fine level road, but which has a sharp and sudden corner to turn;—the coachman knows it, and wishes to keep his velocity; the horses are aware of both—and by the animal dexterity with which they are gifted, contrive to make the turn without remitting anything of their speed. Not so the coach which follows them, has a tendency to persevere in its straight line; and the centre of its effort to do so is the centre of its vis inertiae, the very centre of its gravity. If this centre be low, the turn of the corner may be made with no other inconvenience than a short awkward slide of the hind wheels, onward in the original direction; whereas, if it be high, there will be no slide, but the coach will be overturned, and overturned nearly at that point where its borders is at rectangles to the straight line of road it has been thus forced to quit: for at that point the base against such an overturn will be the most disadvantageous, and the check to the onward motion the greatest. The remedy offered against all these causes of the overturn, (whether by a ditch, bank, rounded road, or sharp corner,) is to bring down this centre, by placing as much of the luggage as possible in a luggage-box, below the body of the carriage; the body not being higher than usual.

From the overturn, we pass to the consideration of the breaking-down; this we must reckon on happening as often in these patent stage coaches as in others. Wheels will come off or fail, or axles will break, in future, as they have done heretofore; but against the disastrous and fatal consequences of such accidents the remedy offered may be thus described.—On each side of the luggage-box, with their periphery below its floor, and each as near as may be requisite to its respective active wheel, there is placed a small strong idle wheel, ready in case of breaking down, on either side, to catch the falling carriage, and instantaneously to continue its previous velocity, till the coachman can pull up his horses, thereby preventing that sudden stop to rapid motion, which at present constantly attends the breaking-down; and which has so frequently proved fatal to the coachman and outside passengers. In case a fore-wheel comes off, end of each fore-carriage has its idle wheel. By this provision we shall be, to all effect of safety, continually travelling with two carriages under us. The bottom of this luggage-box is meant to be about fourteen inches from the ground; and the idle wheels seven, six, or five; but if at a still less distance, little inconvenience would result, for when either of them takes over an obstacle in the road, it instantly, and during the need, discharges its respective active wheel from the ground, and works in its stead. If these two principles of safety were applied to the description of the several stage-coach accidents we meet with, there is no doubt but a general conviction would arise, that the safety of these modes is (in vehicles of all kinds), perhaps as great as can consist with rapid locomotion; and that, sooner or later, legislative authority, in some shape or other, may judge it necessary to interpose, for the purpose of controlling a prejudice against the form casual to this mode of safety. The trial and proof which these principles have been brought to, have never been by public exhibition, and with preparation; but in all the suddenness, also, of actual heavy work: and the result in both cases has been so exactly the same, as to give continual assurance of the full effect of the remedy, as often as the casualties of the road shall bring it into action.

The aim in the arrangement of this coach of safety, has been to bring down the load, and consequently to centre of gravity, as low as possible: this is thought to make the coach look heavy; and this word, by the ready operation of a prejudice, has been transmitted to its going; and one specific reason added within, that because the load is low, the draught must be heavy. This point, however, has, in the presence of 10 or 12 competent persons, been brought to the most decisive proof; and it comes out, that it is as indifferent to draught, as it is material to danger or safety, whether a ton be placed on the roof of a coach, or a ton on the floor of the patent luggage-box, about 15 or 16 inches from the ground.

It has been asked, "What would this coach do in snow?" The question has been thus answered by the result of actual work; for the patent coach, after being detained on the road with several other coaches, by a sudden fall of snow, when at last they started together, came in six or seven hours before any of them. They were bound in prudence, to go cautiously along the ground, whose unevenness was invisible; while the passengers had nothing to do with the confidence safety of a post-chaise. See Plate DLXVII.

WHEEL-Animal. See ANIMALCULE, No. 16-29.
WHEEL, Persian. See AGRICULTURE.
WHEEL, Pottery's. See PORCELAIN.
WHEEL, is also the name of a kind of punishments which great criminals are put in various countries. In some, assassins, parricides, and robbers on the highway, are said to be condemned to the wheel, when they are to have their bones first broken with an iron bar or a scaffold, and then to be exposed, and left to expire on the circumference of a wheel. In Germany they break their bones on the wheel itself.—Of this cruel punishment, it is not certain who was the inventor: it was first used in Germany, and was, indeed, but rarely practised anywhere else, till the time of Francis I. of France, who, by an edict of the year 1534, appointed it to be inflicted on robbers on the highway.

WHEELER, Sir GEORGE, a learned traveller and divine, was the son of Colonel Wheeler of Charing in Kent, and was born in 1630 at Brede, where his parents as royalists were then in exile. He travelled through various parts of Greece and the East, in company with Dr James Spon of Lyons; and taking orders on his return, was installed a prebend of Durham, and vicar of Basingstoke, and afterward rector of Hooreslade Spring. He published an account of his Travels in 1682 in folio; and in 1689, his Observations on Ancient Edifices of Churches yet remaining in the East, compared...
WHEELENS, in the military art, are different motions made both by horse and foot, either to the right and left, or to the right and left about.

General Rules for Wheelegins.—The circle is divided into four equal points: whence, wheeleing to the right or left, is only a quarter of the circle; wheeleing to the right or left about, is one half of the circle.

When you wheel to the right, you are to close to the right, so near as to touch your right-hand man, but without pressing him; and to look to the left, in order to bring the rank about even.

When you wheel to the left, you are to close to the left, and look to the right as above directed. This rule will serve for all the wheeleing by ranks; as when a battalion is marching by subdivisions with their ranks open, then each rank wheels distinctly by itself, when it comes to the ground on which the ranks before it wheeled, but not before.

In wheeleing, the men are to take particular care neither to open nor close their ranks, and to carry their arms well.

In wheeleing, the motion of each man is quicker or slower, according to the distance he is from the right or the left; thus, when you wheel to the right, each man moves quicker than his right-hand man; and wheeleing to the left, each man moves quicker than his left-hand man; the circle that every man wheels being larger, according to the distance he is from the hand he wheels to; as may be seen by describing several circles within one another, at two feet distance from each, which is nearly the space every man is supposed to take up.

WHELK, a species of shell-fish. See Buccinum, Conchology Index.

WHELP, the young of a dog, fox, lion, or any wild beast.

WHELPS, in a ship, the seaman's term for those brackets which are set up on the capstan close under the bars; they give the sweep to it, and are so contrived that the cable windings about them may not surge so much as it might otherwise do if the body of the capstan were quite round and smooth.

WHESTONE, a stone so called, because it serves for the whetting of edge tools upon. See Mineralogy Index.

WHEY, the serum or watery part of milk.

WHIDAH, a kingdom of Africa, on the coast of Guinea, and to the west of the Gold Coast; extending about 10 miles along the sea. It is a populous country, well furnished with large villages; and there are so many small ones, that they are not above a musket-shot from each other.—The houses are small, round at the top, and encompassed with mud walls or hedges, together with a great number of all sorts of beautiful and lofty trees, which afford the most beautiful prospect in the world, insomuch that those that have been here represent it as a perfect paradise. The fields are always green, and they cultivate beans, potatoes, and fruits; nor will the negroes here let a foot of ground remain uncultivated. They sow again the very next day after they have reaped. The inhabitants are greatly civilized, very respectful to each other, especially to their superiors, and very industrious. The women brew the beer, dress the victuals, and sell all sorts of commodities at the market. Those that are rich employ their wives and slaves in tilling the land, and they carry on a considerable trade with the product, as well as in slaves; for some of them are able to deliver 1000 of the latter every month. The chief men have generally 40 or 50 wives, the principal captains 200 or 400, and the king 4000 or 5000. They are extremely jealous, and, on the least suspicion, will sell them to the Europeans for slaves. If any one happen to touch one of the king's wives accidentally, he is doomed to perpetual slavery. It is no wonder then that the women are not fond of being the king's wives; and some of them will prefer a speedy death to such a miserable life. They have no distinction of hours, days, weeks, months, or years. The rite of circumcision is used here; but they are not able to tell why they use it, nor when it is derived. They are such great gamblers, that they will stake all they have at play, not excepting their wives and children. They have a vast number of idols; and they defile the most contemptible animal that they see first in a morning, and even stocks and stones. Their principal regard is for snakes, very high trees, and the sea. An English factor, just arrived, found a snake in the house belonging to the factory, and killed it without the least scruple; which so incensed the negroes, that they were for revenging the death of the snake, not only on him that killed it, but upon the whole factory; but by means of presents, and the interposition of the people of the other factories, the affair was made up, and the snake honourably interred. However, to prevent such accidents, they gave them warning not to do the like for the future. They have oxen, cows, goats, sheep, hogs, turkeys, ducks, and hens; which last are extremely plentiful. There are many elephants, buffaloes, tigers, several kinds of deer, and a sort of hares. The fruits are citrons, lemons, oranges, bananas, tamarinds, &c., and they have vast numbers of palm-trees, from which they obtain wine. Whidah was conquered by the king of Dahomy. Their trade consists of slaves, elephants' teeth, wax, and honey. The English factory is 200 miles east of Cape Coast Castle, within land. Bows, arrows, beautiful assagays, and clubs, are the principal weapons of the nation.

WHIDAW-BIRD. See Emberiza, Ornithology Index.

WHIG, a person belonging to a political party in Britain, opposite to the Tories. See Tories, and Britain.

WHIMBREL. See Scopelax, Ornithology Index.

WHIN. See Ulex, Botany Index.

WHINCHAT. See Motacilla, Ornithology Index.

WHIRLPOOL, or Whirl-Staff, in a ship, a piece of timber, in form of a strong staff, fastened into the helm, for the steersman, in small ships, to hold in his hand, in order to move the rudder, and direct the ship.

WHIRLPOOL, an eddy, vortex, or gulf, where the water is continually turning round.

Those in rivers are very common, from various accidents, and are usually very trivial, and of little consequence. In the sea they are more rare, but more dangerous. Sibbald has related the effects of a very remarkable marine whirlpool among the Orcades, which would prove very dangerous to strangers, though it is...

3. With ace and king of any two suits, and only two or three small trumps, the aces and kings should be played out, in order to make as many tricks as possible; and having but two or three small trumps, he should never force his partner to trump, if he finds he cannot follow suit; but endeavour to throw the lead into his partner's hand.

4. He should in general return his partner's lead, unless he has some capital cards of his own.

5. As this game is played with the lurch, that is, to save half the stake, five points must be made before the game is out; he should not venture to play trumps when he is four of the game, unless he is very strong, having at least an honour and three trumps, or ace, king, and two small ones.

6. When the game is scored nine, at which stage the honours reckon for nothing, he should be still more cautious how he plays trumps, even if he is strong in hand, and give his partner an opportunity of trumping the adversaries suits, in case he is deficient in them.

7. If his adversaries are six or seven love of the game, he should play a forward or bold game, that he may have a chance, at the risk of a trick or two, to come up with them. If he has but three trumps and other good cards, he may play trumps, especially if he has a sequence, or queen, or a knave, and a small one.

8. He should always risk a trick or two when the game is much in his favour; because a new deal is of greater consequence to the adversary than one or two tricks are to him.

9. When the player finds there is a likelihood of either saving the game or his lurch, he should risk the odd trick; but if the game is five all, and he can make two tricks in his own hand, he should make them, in order to secure the difference of two points, which make the game near two to one in his favour.

10. A good player should begin with a small trump, when he has ace, king, and four small ones; for this reason, if his partner has a better trump than the last player, which is an equal wager but he has, he has a chance of fetching out all the trumps, by having three rounds of them.

11. The odds are always in his favour that his partner holds an honour; consequently if he has king, queen, and four small ones, he should begin with a small one.

12. When queen, knave, and four small trumps are dealt him, he should play a small one first, the odds being in his favour that his partner holds an honour; if he has knave, ten, and four small trumps, he should also begin with a small one, for the same reason.

13. If he has knave, ten, eight, and three small trumps, the knave should be played first, by which means the nine may be prevented from winning a trick, the odds being in his favour that three honours are played in two rounds.

14. If an honour is turned up against him on his left hand, and he has ten, nine, and eight, with two or three small trumps; when he is to play, he should play through the honours with the ten, which will force the dealer to play his honour to a disadvantage, if the dealer does not choose to leave it to the option of his adversary whether he will pass it or not; but if he has six trumps of a lower denomination, and not ten, nine, and eight, and no honour turned up against him, he should begin with a small one.

15. In general, when he has two capital cards in trumps, and two or three small ones, he should begin with a small one, for the reason assigned in No 12.

16. When he has ace, king, knave, and two small trumps, or even one small trump, by first playing the king, and putting the lead into his partner's hand, who will play a trump; judging him to have ace and knave, from his beginning with the king: in this case the knave should be finessed (A), nothing being against him but the queen.

17. If he has knave, ten, eight, and two small trumps, by playing the knave first, it is odds but in two rounds of trumps the nine falls, or he may finesse the eight, when his partner returns trumps.

18. With five trumps of a lower denomination, he should begin with the smallest, unless he has a sequence of ten, nine, and eight; then he should begin with the ten.

19. When he has king, queen, ten, and one small trump, he must begin with the king, and wait for his partner's return of the trumps, in order to finesse the ten, by which means he may win the knave.

20. In order to prevent the ten from winning, when he has queen, knave, nine, and one small trump, he must begin with the queen. And in case he has knave, ten, eight, and one small trump, he should begin with the nine, that the nine may not win.

21. If he has ten, nine, eight, and one small trump, he should begin with the ten; thereby he strengthens his partner's hand, leaving it at his option to take it or not.

22. He should begin with a small one, when he has the ten and three small trumps.

23. If he has a good suit, and ace, king, and four small trumps, he must play three rounds of trumps, in order to secure his strong suit from being trumped.

24. When he has king, queen, ten, and three small trumps, he should begin with the king, because he has a chance of the knave's coming down in the second round; and to secure his strong suit, he should not wait to finesse the ten. If he should have queen, knave, and three small trumps, and some good suit to make, he must begin with a small one.

25. If he has knave, ten, eight, and two small trumps, with a strong suit, he should begin with the knave, in order to make the nine fall in the second round; but if he has knave, ten, and three small trumps, with a good suit, he should play a small one first.

26. With ten, nine, eight, and one small trump, provided he has a good suit, he should begin with the ten; by which means he may get the trumps out, and have a chance of making his strong suit.

The following observations will enable a player to know that his partner has no more of a suit which either

(A) Finesse, is to play a small card which may win, keeping the superior card or cards to lay over the right hand adversary.
of them has played. Suppose he leads from queen, ten, nine, and two small cards of any suit, the second hand puts on the knave, his partner plays the eight; in this case, he having queen, ten, and nine, it is a demonstration, if his partner plays well, that he can have no more of that suit. By that discovery, he may play his game accordingly, either by forcing his partner to trump that suit, if he is strong in trumps, or by playing another suit. If he has king, queen, and ten of a suit, and he leads his king, his partner plays the knave; this also demonstrates he has no more of that suit. If he has king, queen, and many more of a suit, and begins with the king, in some cases it is good play in a partner, when he has the ace and one small card in that suit only, to win the king with the ace; for suppose the partner to be very strong in trumps, by taking the king with the ace, he gets the lead and trumps out, and having cleared the board of trumps, his partner returns his lead, and the ace being out, there is room for him to make that whole suit, which could not have been done if the partner had kept the ace. Suppose he has no other good card in his hand besides that suit, he loses nothing by the ace's taking his king; and if it should so happen that he has a good card to bring in that suit, he gains all the tricks which he makes to that suit by this method of play: as his partner has taken his king with the ace, and trumps out upon it, he has reason to imagine that his partner has one of that suit to return him for which reason he should not throw away any of that suit, even to keep a king or queen guarded.

Method of playing when an honour is turned up on the right hand. Suppose the knave is turned up on his right hand, and that he has king, queen, and ten; in order to win the knave, he must begin with the king; by which means, his partner may suppose him to have queen and ten—remaining, especially if he has a second lead, and he does not proceed to play the queen.

Suppose the knave turned up as before, and he has ace, queen, and ten, by playing his queen, it answers the purpose of the former rule.

When the queen is turned up on his right hand, and he has ace, king, and knave, by playing his king, it answers the same purpose of the former rule.

In case an honour is turned up on his left hand, supposing he should hold no honour, he should play trumps through the honour as soon as he gets the lead; but if he should hold an honour (except the ace), he must be cautious how he plays trumps, because, in case his partner holds no honour, his adversary will play his own game upon him.

Method of playing the sequences.—The highest in sequences of trumps should be played, unless he has ace, king, and queen; and then he should play the lowest, which informs his partner of the state of his game.

When he has king, queen, and knave, and two small ones, which are not trumps, he should begin with the knave, whether he is strong in trumps or not, as he makes way for the whole suit by getting the ace out.

If he is strong in trumps, and has a sequence of queen, knave, ten, and two small cards of a suit, he should play his highest of his sequence; for if either of the adversary should trump that suit in the second round, being also strong in trumps, he will make the remainder of that suit by fetching out the trumps. When he has knave, ten, and nine, and two small cards of a suit, he may play in the like manner.

If king, queen, and knave, and one small card of any suit, is the case, whether strong in trumps or not, he should play the king; and when there are only four or fewer number, the same method of play should be observed by inferior sequences.

When weak in trumps, he should begin by the lowest of the sequence, provided he has five in number, knave if his partner has the ace of that suit he will make it.

If he has the ace and four small cards of a suit, and weak in trumps, leading from that suit, he should play the ace. When strong in trumps, the game may be played otherwise.

How to make a slam, or win every trick.—Suppose A and B partners against C and D, and C to deal, A to have the king, knave, and nine, and seven of hearts, which are trumps, a queen-major in spades, a tierce-nier in diamonds, and the ace and king of clubs. Suppose B to have nine spades, two clubs, and two diamonds. Also suppose D to have ace, queen, ten, and eight of trumps, with nine clubs, and C to have five trumps and eight diamonds. A leads a trump, which D wins, and D is to play a club, which his partner C is to trump; C leads a trump, which his partner D wins; D then will lead a club, which C will trump; and C will play a trump, which D will win; and D having the best trump will play it; after which D having seven clubs in his hand, makes them, so that he flams A and B.

How to play any hand of cards according to the secret calculations of his partner's holding certain winning cards:

1. That he has not one certain winning card, is 2 to 1
2. That he has not two certain winning cards, is 17 to 1
3. That he has one card out of any three certain winning cards, is 5 to 1
4. That he has not three certain winning cards is about 31 to 1, or 65 to 21
5. That he has not two of them, is about 7 to 2, or 547 to 146
6. That he has not one of them, is about 7 to 6, or 378 to 375
7. That he holds one or two of them, is in his favour about 13 to 6, or 485 to 323
8. And about 5 to 2, that he holds 1, 2, or all three of them.

The use of these calculations is for a whist-player to play his cards to the most advantage. For instance, as the first calculation is two to one that his partner does not hold one certain winning card. Suppose that a suit is led, of which the second player has the king and a small one only, he should put on the king, because the odds are in his favour, that the third player cannot win it. For the same reason, when he is second player, and to lead, he should play a king in preference to a queen, because it is two to one the ace does not take it; but it is five to four the queen will be taken by either ace or king, which may be in the third hand.
According to the second calculation, of its being five to four that his partner holds one certain winning card out of any two: If he has two honours in any suit, he can play to an advantage, knowing it is five to four in favour of his partner’s having one of the two honours; and by the same rule, if he is second player, having a queen and one small card, by playing the queen he plays five to four against himself.

It is obvious, from the third calculation, which proves it to be five to two that his partner has one card out of any three certain winning cards, that he who plays the knave second hand, having but the knave and one small card of the same suit, must play five to two against himself, and discovers his game to a great disadvantage; for which reason, he should play the lowest of any sequence which he may hold in his hand, as the knave, if he has king, queen, and knave; the ten, if he has queen, knave, and ten, &c. By so doing, his partner has an opportunity of judging what card to play in that suit, according to the odds for or against him.

From the above calculation, if he has ace, king, and two small trumps, he is entitled to win four tricks out of six, provided he has four winning cards of any suit; or five tricks out of seven, if he has five winning cards of any suit: by playing two rounds of trumps, and taking out eight of them, it is five to two but his partner has a third trump; and if it should be so, he makes the tricks intended.

WHISTON, William, an English divine of great parts, uncommon learning, and of singular character, was born in 1667 at Norton near Twycross in the county of Leicester, where his father was rector. He was admitted of Clarehall, Cambridge, where he pursued his studies, particularly in the mathematics, and commenced tutor; which his ill health at length forced him to decline. Having entered into orders, he became chaplain to Dr More bishop of Norwich in 1693; and in this station he published his first work, entitled A New Theory of the Earth, &c. in which he undertook to prove the Mosaic doctrine of the earth perfectly agreeable to reason and philosophy. This work brought no small reputation to the author. In the beginning of the 18th century he was made Sir Isaac Newton’s deputy, and afterwards his successor, in the Lucasian professorship of mathematics; when he resigned a living he had in Suffolk, and went to reside at Cambridge. About this time he published several scientific works, explanatory of the Newtonian philosophy; and he had the honour to be one of the first, if not the very first, who rendered these principles popular and intelligible to the generality of readers. About the year 1710, he was known to have adopted Arian principles, and was forming projects to support and propagate them: among other things, he had translated the Apostle Constitutions into English, which favoured the Arian doctrine, and which he asserted to be genuine. The consequence was, that he was deprived of his professorship, and banished the university; nevertheless pursued his scheme, by publishing the next year his Primitive Christianity Revived, 4 vols. 8vo, for which the congregation fell upon him very vehemently. On his expulsion from Cambridge, Mr Whiston settled in London; where, without suffering his zeal to be intimidated, he continued to write, and propagate his Primitive Christianity, with as much ardour as if he had been in the most flourishing circumstances. In 1721, a subscription was made for the support of his family, which amounted to 470l. For though he drew profits from reading astronomical and philosophical lectures, and also from his publications, which were very numerous, yet these of themselves would have been very insufficient: nor, when joined with the benevolence and charity of those who loved and esteemed him for his learning, integrity, and piety, did they prevent his being frequently in great distress. He continued long a member of the church of England, and regularly frequented its service, though he disapproved of many things in it: but at last he went over to the Baptists, and attended Dr Forster’s meeting at Pinner’s hall, Broadstreet. Among other performances not specified above, he wrote Memoirs of his own life and writings, which contain some curious particulars.

He was remarkable for speaking the plainest truth on every occasion, and to persons of every degree. During the year 1725, that he, with Dr Clarke, Dr Berkeley, and others, had the honour to attend Queen Caroline on a certain day of every week, to talk of the progress of science, her majesty one evening took occasion to pay him a just compliment on his truth and integrity, requesting that he would, with his usual plainness, point out to her any fault that he might have observed in her conduct. At first he begged to be excused, adding, that few persons could bear to have their faults plainly told to them, and least of all royal personages, who, from their elevation, are necessarily surrounded by flatterers, to whose lips truth is a stranger. Her majesty replied, that he was to consider her not as a queen, but as a philosopher; and that philosophy is of very little use if it cannot enable its professors to bear without offence truths necessary to their own improvement. Upon this he told her, that the greatest fault which he had observed in her conduct, was her indecent behaviour in the house of God, which, he assured her, had made very unfavourable impressions on the minds of many persons, who coming from distant parts of the country, had gone to the chapel to obtain a sight of her majesty, the king, and the royal family. The queen made no reply, but in about six weeks afterwards renewed her request, that Mr Whiston would point out the most glaring improprieties in her conduct. To this he answered, that he had laid down a maxim, from which he could not deviate, never to point out to any person more than one fault at a time, and never to give a second reproof till he had observed some good consequence to have arisen from the first. Much to the queen’s honour, she was pleased with this plain dealing, and continued to think favourably of Mr Whiston. This honest, but whimsical and credulous man, died in 1762, at the advanced age of 99, with the remaining power of a good memory, and a just critical sense; and consisted in writing, and propagating his Primitive Christianity, with as much ardour as if he had been in the most flourishing circumstances. In 1721, a subscription was made for the support of his family, which amounted to 470l. For though he drew profits from reading astronomical and philosophical lectures, and also from his publications, which were very numerous, yet these of themselves would have been very insufficient: nor, when joined with the benevolence and charity of those who loved and esteemed him for his learning, integrity, and piety, did they prevent his being frequently in great distress. He continued long a member of the church of England, and regularly frequented its service, though he disapproved of many things in it: but at last he went over to the Baptists, and attended Dr Forster’s meeting at Pinner’s hall, Broadstreet. Among other performances not specified above, he wrote Memoirs of his own life and writings, which contain some curious particulars.

(1) Bishop Berkeley was present at these conversations, and from his son we received the account we have given of them. They are likewise mentioned, but not stated so accurately, by Bishop Newton in his own Life.
shop of Salisbury; who collated him in 1668 to the prebend of Yatesbury in that church, and soon after to that of Hushorn and Burbach. In 1672 he was admitted chanter of the said church, on the death of Mr John South, and then, or soon after, rector of St Edmund's church in Salisbury. He was made a prebendary of Taunton Regis in 1696, and died in 1726. He was ever strangely ignorant of worldly affairs, even to a degree that is scarcely to be conceived. His writings are numerous, and well known; particularly his Commentary on the New Testament.

White, a sea-port town in the north riding of Yorkshire, seated on the river Esk, near the place where it falls into the sea. The houses are neat, strong, and convenient; the number of inhabitants in 1811 was 6696. Ship-building is their principal employment.

White, one of the colours of natural bodies. White of the Eye, denotes the first white or coat of the eye, called albigena. See Anatomy, No 142.

White of Egg. See Albumen and Egg.

White Friars, a name common to several orders of monks, from being clothed in a white habit.

White Sea, is a bay of the Frozen ocean, so called in the north part of Muscovy, lying between Russian Lapland and Samoieda; at the bottom of which stands the city of Archangel. This was the chief port the Russians had before their conquest of Livonia.

White Colour, white lead for painting. See Chemistry, No 1836.

White Iron or Tin-plate, iron-plates covered over with tin; for the method of making which, see Latten, Chemistry, No 1936.

In 1681 tin-plates were manufactured in England by one Andrew Yarranton, who had been sent to Bohemia to learn the method of making them. But the manufacture was soon afterwards discontinued. It was revived in 1740, and has now arrived at as great, if not greater, perfection in this country than in any other.

White Lead. See Chemistry, No 1836.

White-Throat. See Motacilla, Ornithology.

Whitefield, George, the celebrated preacher among the people called Methodists, was born in the year 1714, at the Bell in the city of Gloucester, which was then kept by his mother. At about 12 years of age he was put to a grammar-school; but his mother entering into a second marriage, which proved a disadvantageous one, he, when about 15, put on a blue apron, and served her in the capacity of a draper or waiter.

After continuing about a year in this servile employment, she turned over the business to his brother; who marrying, and George not agreeing with his sister-in-law, he left the inn. Some time after, meeting with an Oxford, he was induced to attempt getting into the Mr Whitefield, who from his own account appears to have always had a strong tincture of enthusiasm in his constitution from his very childhood, distinguished himself by the austerity of his devotion, and acquired considerable eminence in some religious assemblies in that city. At the age of 21, the fame of his piety recommended him so effectually to Dr Benson, then bishop of Gloucester, that he made him a voluntary offer of election. Immediately after this regular admission to the ministry, Mr Whitefield applied himself to the extraordinary, the most indefatigable, duties of his character, preaching daily in prisons, fields, and open spaces; wherever he thought there would be a likelihood of making proselytes. Having at length made himself universally known in England, he embarked for America, where the tenets of Methodism began to spread very fast under his friends the Wesleys; and was examined upon the institution of the orphan-house of Georgia, which he afterwards effected. After a long course of peregrination, his fortune increased as his fame extended among his followers, and he erected many extensive buildings for public worship, under the name of Tabernacles; one in Tottenham-Court Road, and the other in Moorfields. Here, with the help of his assistants, he continued for several years, attended by very crowded congregations, and quieting the kingdom only occasionally. Besides the two tabernacles already mentioned, Mr Whitefield, by being chaplain to the countless dragoons of Huntington, was connected with two other religious meetings, one at Bath, and the other at Tunbridge, chiefly erected under that lady's patronage. By a lively, fertile, and penetrating genius, but most unruffled zeal, and by a forcible and persuasive delivery, he never failed of the desired effect upon his ever-crowded and admiring audiences. In America, however, which always engaged much of his attention, he was destined to finish his course; and he died at Newbury, about 40 miles from Boston in New England, in 1770.

Whitby, a sea-port town of Cumberland, with a market on Tuesday, and containing 10,106 inhabitants in 1811. It is seated on a creek of the inland sea, on the north end of a great hill, washed by the tide of flood on the west side, where there is a lofty rock or quarry of hard white stone, which gives name to the place, and with, the help of a strong stone wall, secures the harbour, into which small boats may enter. It is lately much improved in its buildings, and noted for its trade in pit-coal and salt, there being near it a valuable coal-mine, which runs a considerable way under the sea. They have a custom-house here; and they carry on a good trade to Ireland, Scotland, Chester, Bristol, and other parts. It is 10 miles north-west of Cockermouth, and 305 north-west of London.

Whiteness, the quality which denotes or constitutes a body white.

Whites, or Fluor Albus. See Medicine, No 250.

Whiting. See Gadus, Ichthyology. Indus.

Whitlow, or Whitloe. See Surgery, Indus.

Whitsuntide, otherwise called Simplicofthe or Quadrante Pentecostal, a composition for offerings which were annually made in Whitsuntide by every man in England, who occupied a house with a chimney, to the cathedral church of the diocese in which he lived.

Whitsunday, a solemn festival of the Christian church, observed on the fiftieth day after Easter, in memory of the descent of the Holy Ghost upon the disciples in the visible appearance of fiery cloven tongues, and of those miraculous powers which were then conferred upon them.
WHYTT, Dr Robert, an eminent physician, born at Edinburgh on the 6th September 1714, was the son of Robert Whytt, Esq. of Bennochy, advocate. This gentleman died six months before the birth of our author, who had also the misfortune to be deprived of his mother before he had attained the seventh year of his age. After receiving the first rudiments of school-education, he was sent to the university of St Andrews’; and after the usual course of instruction there, in classical, philosophical, and mathematical learning, he came to Edinburgh, where he entered upon the study of medicine, under those eminent medical teachers, Monroe, Rutherford, Sinclair, Plummer, Alston, and Innes. After spending what was to be his time at this university, in the prosecution of his studies he visited foreign countries; and after attending the most eminent teachers at London, Paris, and Leyden, he had the degree of Doctor of Physic conferred upon him by the University of Rhenius in 1736, being then in the 22d year of his age.

Upon his return to his native country, he had the same honour also conferred upon him by the University of St Andrew’s; where he had before obtained, with applause, the degree of Master of Arts.

Not long afterwards, in the year 1737, he was admitted a Licentiate of Medicine by the Royal College of Physicians of Edinburgh; and the year following he was raised to the rank of a Fellow of the College. From the time of his admission as a licentiate, he entered upon the practice of physic at Edinburgh; and the reputation which he acquired for medical learning, pointed him out as a fit successor for the first vacant chair in the university. Accordingly, when Dr Sinclair, whose eminent medical abilities, and perceptive powers of oratory, had contributed not a little to the rapid advancement of the medical school of Edinburgh, found that those conspicuous talents which he possessed could no longer be exerted in the manner which they once had been, when he enjoyed bodily vigour unimpaired by age and powers of mind unclouded by disease, he resigned his academical appointments in favour of Dr Whytt.

This admission into the college took place on the 29th of June 1736; and he began his first course of the institutions of medicine at the commencement of the next winter-session. The abilities which he displayed from his academical chair, in no particular disappointed the expectations which had been formed of his lectures. The Latin tongue was the language of the university of Edinburgh; and he both spoke and wrote in Latin with singular propriety, elegance, and perspicuity. At that time the system and sentiments of Dr Boerhaave, which, notwithstanding their errors, must challenge the admiration of latest ages, were very generally received by the most intelligent physicians in Britain. Dr Whytt had no such idle ardour for novelties as to throw them entirely aside because he could not follow them in every particular. The institutions of Dr Boerhaave, therefore, furnished him with a text for his lectures; and he was no less successful in explaining, illustrating, and establishing the sentiments of the author, when he could freely adopt them, than in refuting them by clear, connected, and decisive arguments, when he had occasion to differ from him. The opinions which he himself proposed, were delivered and enforced with such acuteness of invention, such display of facts and force of argument, as could rarely fail to gain universal assent from his numerous auditors; but free from that self-sufficiency which is ever the offspring of ignorance and conceit, he delivered his conclusions with becoming modesty and diffidence.

From the time that he first entered upon an academical appointment, till the year 1756, his prelections were confined to the institutions of medicine alone. But at that period his learned colleague Dr Rutherford, who then filled the practical chair, who had already taught medicine at Edinburgh with universal applause for more than thirty years, and who had been the first to begin the institution of clinical lectures at the Royal Infirmary, found it necessary to retire from the fatiguing duties of an office to which the progress of age rendered him unequal. On this crisis Dr Whytt, Dr Monro, sen. and Dr Cullen, each agreed to take a share in an appointment in which their united exertions promised the highest advantages to the university. By this arrangement students, who had an opportunity of daily witnessing the practice of three such teachers, and of hearing the grounds of that practice explained, could not fail to derive the most solid advantages.

In these two departments, the institutions of medicine in the university, and the clinical lectures in the Royal Infirmary, Dr Whytt’s academical labours were attended with the most beneficial consequences both to the students and to the university. But not long after the period we have last mentioned, his lectures on the former of these subjects underwent a considerable change. About this time the illustrious Gauhins, who had succeeded to the chair of Boerhaave, favoured the world with his Institutiones Pathologicae. This branch of medicine had indeed a place in the text which Dr Whytt formerly followed; but, without detracting from the character of Dr Boerhaave, it may justly be said, that the attention he had bestowed upon it was not equal to its importance. Dr Whytt was sensible of the improved state in which pathology now appeared in the writings of Boerhaave’s successor; and he made no delay in availing himself of the advantages which were then afforded.

In the year 1762, his pathological lectures were entirely new-modelled. Following the publication of Gauhins as a text, he delivered a comment, which was read by every intelligent student with the most unfeigned satisfaction. In these lectures he collected and condensed the fruits of accurate observation and long experience. Enriched by all the opportunities of information with singular propriety, elegance, and perspicuity. At
WHY

WHITT, which had enjoyed, and by all the discernment which he was capable of exerting, they were justly considered as his most finished production.

For a period of more than twenty years, during which he was justly held in the highest esteem as a lecturer at Edinburgh, it may readily be supposed that the extent of his practice corresponded to his reputation. In fact, he received both the first emoluments, and the highest honours, which could here be obtained. With extensive practice in Edinburgh, he had numerous consultations from other places. His opinion on medical subjects was daily requested by his most eminent contemporaries in every part of Britain. Foreigners of the first distinction, and celebrated physicians in the most remote parts of the British empire, courted an intercourse with him by letter. Besides private testimonies of esteem, many public marks of honour were conferred upon him both at home and abroad. In 1752, he was elected a fellow of the Royal Society of London; in 1761, he was appointed first physician to the king of Scotland; and in 1764, he was chosen president of the Royal College of Physicians at Edinburgh.

But the fame which Dr. Whitt acquired as a practitioner and teacher of medicine, were not a little increased by the information which he communicated to the medical world in different publications. His celebrity as an author was still more extensive than his reputation as a professor.

His first publication, An Essay on the Vital and other Involuntary Motions of Animals, although it had been begun soon after he had finished his academical course of medical education, did not come from the press till 1751; a period of fifteen years from the time that he had finished his academical course, and obtained a degree in medicine: but the delay of this publication was fully compensated by the matter which it contained, and the improved form under which it appeared.

The next subject which employed the pen of Dr. Whitt was one of a nature more immediately practical. His Essay on the Virtues of Lime-water and Soap in the Cure of the Stone, first made its appearance in a separate volume in 1752. Part of this second work had appeared several years before in the Edinburgh Medical Essays: but it was now presented to the world as a distinct publication, with many improvements and additions.

His third work, intitled Physiological Essays, was first published in the year 1755. This treatise consisted of two parts: 1st, An Inquiry into the Causes which promote the Circulation of the Fluids in the very small Vessels of Animals; and 2dly, Observations on the Sensibility and Irritability of the Parts of Men and other Animals, occasioned by Dr. Haller’s treatise on that subject. The former of these may be considered as an extension and farther illustration of the sentiments which he had already delivered in his Essay on the Vital Motions, while the latter was on a subject of a controversial nature. In both he displayed that acuteness of genius and strength of judgment which appeared in his former writings.

From the time at which his Physiological Essays were published, several years were probably employed by our author in preparing for the press a larger and perhaps a more important work than any yet mentioned, his Ob-

servations on the Nature, Causes, and Cure of the Disorders which are commonly called percus, hypochondria, and hysterics. The elaborate and useful work was published in the year 1764.

The last of Dr. Whitt’s writings is entitled Observations on the Droopy in the Brain. This treatise did not appear till two years after his death; when all his other works were collected and published in one quarto volume, under the direction of his son and of his intimate friend the late Sir John Pringle.

Besides these five works, he wrote many other papers, which appeared in different periodical publications; particularly in the Philosophical Transactions, the Medical Essays, the Medical Observations, and the Physical and Literary Essays.

At an early period of life, soon after he had settled as a medical practitioner in Edinburgh, he entered into his married state. His first wife was Miss Robertson, sister to General Robertson, governor of New York. Prior to this event he had two children; both of whom died in early infancy, and their mother did not long survive them. After years after the death of his first wife, he married a second wife Miss Balfour, sister to James Balfour, Esq. of Pitrig. By her he had fourteen children; but in these also he was in some respects unfortunate; out of them only survived him, three sons and three daughters, and of the former two are since dead. Although the feeling of Dr. Whitt, amidst the distresses of his family, must have often suffered that uneasiness and anxiety which in such circumstances is the unavoidable consequence of parental affection and conjugal love; yet he enjoyed a large share of matrimonial felicity. By his course of happiness was terminated by the death of his wife, which happened in the year 1764: and it is not improbable that this event had some share in hastening his own death; for in the beginning of the year 1765 his health was so far impaired, that he became incapable of his former exertions. A tedious consumption of chronicills, which chiefly arose under the form of diabetes, was not to be resisted by all the medical skill which Edinburgh could afford; and at length terminated in death, on the 15th of April 1766, in the 52d of his age.

WIBURGH, a considerable town of Denmark, is in North Jutland, with a bishop’s see, remarkable for being the seat of the chief court of justice in the province. The hall where the council assembles has the archives of the country, and escaped the terrible fire that happened in the year 1726, and which burned the cathedral church, that of the Black Friars, the town-house, and the bishop’s palace; but they have all been rebuilt more magnificent than before. It is seated on the lake Wiper, in a peninsula, 25 miles north-west of Slesvig, and 110 north-west of Copenhagen. E. Long. 9. 50. N. Lat. 56. 20.

WICK, a royal borough on the east coast of the county of Caithness. It is small, and the streets narrow, but a few of its buildings are an ornament to the place. The present harbour is very inconvenient, but it is proposed to erect a new one, which will be of great importance to the safety of navigation along that coast. The population of the whole parish in 1792 amounted to 600; that of the town alone, in 1811, 308.

WICKER, signifies made of small twigs.

WICKET, a small door in the gate of a fortified place.
from the Latin vulgate. In 1383 he was suddenly struck with a palsy; a repetition of which put an end to his life in December 1384. He was buried in his own church, where his bones were suffered to rest in peace till the year 1428, when, by an order from the pope, they were taken up and burnt.—Besides a number of works that have been printed, he left a prodigious number of manuscripts; an accurate list of which may be seen in Bishop Tanner's Bib. Brit. Libr. Some of them are in the Bodleian Library, others in the British Museum, &c.

Wickliff was doubtless a very extraordinary man, considering the times in which he lived. His natural sagacity discovered the absurdities and impostures of the church of Rome, and he had the honesty and resolution to promulgate his opinions, which a little more support would probably have enabled him to establish; they were evidently the foundation of the subsequent reformation.

WICKLOW, a county of Ireland, in the province of Leinster; bounded on the north by the county of Dublin; on the east by the Irish sea; on the south by Wexford; and on the west by Kildare and Catherlough. It is 33 miles in length, 20 in breadth, and its produce is chiefly agricultural. It contains 62 parishes, and sends two members to parliament. See Wicklow, Suplement.

WICKLOW, the capital of a county of the same name in Ireland; seated on the sea-side, with a narrow harbour, at the mouth of the river Leitrim, over which stands a rock, instead of a castle, surrounded by a strong wall, 24 miles south of Dublin. W. Long. 6. 7. N. Lat. 52. 55.

WIDGEON. See ANAS, Ornithology Index.

WIDOW, a woman who has lost her husband.

WIFE, a married woman, or one joined with, and under the protection of, an husband. See HUSBAND.

ISLE OF WIGHT, an island lying on the south coast of Hampshire, from which it is separated by a narrow channel. It is about 21 miles in length and 13 in breadth. It is nearly divided into equal parts by the river Medina or Cowes, which rising in the southern angle, enters at the northern, into the channel, opposite the mouth of Southampton bay. The south-coast is edged with very steep cliffs of chalk and freestone, hollowed into caverns in various parts. The west-side is fenced with ridges of rocks, of which the most remarkable are those called, from their sharp extremities, the Needles. Between the island and the main are various sand-banks, especially off the eastern part, where is the safe road of St Helen's. Across the island, from east to west, runs a ridge of hills, forming a tract of fine downs, with a chalky or marly soil, which feed a great number of fine-fleece sheep. Rabbits are also very plentiful here. To the north of this ridge the land is chiefly pasture: to the south of it is a rich arable country, producing great crops of corn. The variety of prospects which this island affords, its mild air, and the neat manner in which the fields are laid out, render it a very delightful spot. It is devoted almost solely to husbandry, and has no manufactury. It is one of the principal resources of the London market for unmalted barley. Among its products are to be reckoned a pure white pipe-clay, and a fine white crystalline sand; of the latter of which great quantities are exported for the use of the glass works in various parts. Its principal town is
William, of Malmbury, an history of considerable merit in the reign of King Stephen; but of whose life few particulars are known. According to Bale and Pits, he was surnamed Somertetus, from the county in which he was born. From his own preface to his second book De Regibus Anglorum, it appears that he was addicted to learning from his youth; that he applied himself to the study of logic, physic, ethics, and particularly to history. He retired to the Benedictine convent at Malmbury, became a monk, and was made precentor and librarian; a situation which much favoured his intention of writing the history of this kingdom. In this monastery he spent the remainder of his life, and died in the year 1142. He is one of our most ancient and most faithful historians. His capital work is entitled De Regibus Anglorum, in five books; with an Appendix, which he styles Historia Nova, in two more. It is a judicious collection of whatever he found on record relative to England, from the invasion of the Saxons to his own times.

William of Newbury, so called from a monastery in Yorkshire, of which he was a member, wrote a history which begins at the Conquest and ends at the year 1197. His Latin style is preferred to that of Matthew Paris; and he is entitled to particular praise, for his honest regard to truth, in treating the fables of Jeffrey of Monmouth with the contempt they deserve; as well as for expressing his approbation of Henry II.'s design of reforming the clergy, by bringing them under the regulation of the secular power.

William of Wykeham, bishop of Winchester, was born in the village of Wykeham, in the county of Southampton, in 1324. He was educated at Winchester and Oxford; and having continued near six years in the university, his patron Nicholas Wedal, governor of the province of Southampton, took him into his family, and appointed him his counsellor and secretary. He could not have made choice of a fitter person for that employment, no man in that age writing or speaking more politely than Wykeham. For this reason Edington, bishop of Winchester, lord high treasurer of the kingdom, appointed him his secretary three years after, and also recommended him to King Edward III., who took him into his service. Being skilled in geometry and architecture, he was appointed surveyor of the royal buildings, and also chief justice in eyre: he superintended the building of Windsor Castle. He was afterward chief secretary of state, a keeper of the privy seal; and in 1367 succeeded Edington in the see of Winchester. A little after he was appointed lord-high chancellor and president of the privy council. That he might well discharge the several functions of his employment, both ecclesiastical and civil, he endeavoured on one hand, to regulate his own life according to the strictest maxims, and to promote such parish priests only as were able to give due instructions to their parishioners, and at the same time led exemplary lives: on the other hand, he did all in his power to cause justice to be impartially administered. In 1371 he resigned his chancellorship, and some time after the great seal. He afterward returning to England, after having carried a very successful war in France, found his exchequer in great disorder. The duke of Lancaster, one of his own, at the head of several lords, having brought complain against the clergy, who then enjoyed the chief places in the kingdom, the king removed them from their employments. But the laymen, who were raised to them, behaved so ill that the king was forced to restore the ecclesiastics. The duke of Lancaster showed strong animosity to the clergy, and set every engine at work to ruin Wykeham. He impeached him of extortion, and disguing things, and obliged him to appear at the King's-bench. He got such judges appointed as condemned him; and not satisfied with depriving him of all the temporalities of his bishopric, he advised Edward to banish him: but this prince rejected the proposal, and afterward restored to Wykeham all that he had been divested of. Richard II. was but 11 years old when Edward died: so that the duke of Lancaster had an opportunity of reviving the accusations against the bishop of Winchester; nevertheless Wykeham defended himself. Then he founded two noble colleges, the one in Oxford, the other in Winchester. Whilst he was exerting his utmost endeavours to improve these two foundations, he was recalled to court, and in a manner forced to accept of the office of lord high-chancellor in 1389. Having excellently discharged the duties of that employment for three years, he obtained leave to resign it, foreseeing the disturbances that were going to break out. Being returned to his church, he finished his college, and built there so magnificent a cathedral, that it almost equals that of St. Paul's in London. He laid out several sums in things advantageous to the public and to the poor; notwithstanding which, in 1397 he was in great danger; for he and some others were impeached of high treason in open parliament: however, he was again fully cleared. From that time till his death he kept quiet in his diocese, and there employed himself in all the duties of a good prelate. He died in 1404, in the 81st year of his age.

William, the name of several kings of England. See England, No. 87—92, and Britain, No. 302.

Fort-William, a fortress in the Highlands of Scotland, erected in King William's reign, as was also a small town adjoining, called Maryburgh, in honour of his queen. It is situated in Inverness-shire, on a narrow arm of the sea called Loch Ed, which by the completion of the Caledonian canal, will be united to the Western sea. Fort-William is of a triangular form, having two bastions, and is capable of admitting a garrison of 800 men; but could not be defended against an attack, as it is commanded by several hills in the neighbourhood.

William's Fort, is a factory of Asia belonging to the East India Company, seated on one of the branches of the river Ganges, in the kingdom of Bengal. The fort was first built in the shape of an irregular tetragon of brick and mortar; and the town has nothing regular in it, because every one built a house as he liked best, and for his own convenience. The governor's house is within the fort, and is the best piece of architecture of these parts. Here there are also convenient lodges for the factors and writers, with store-houses for the company's
of providing for his family, died in 1670. He died at
his house in St. Martin's in 1675, and was buried near
her in Westminster-abbey. Dr Willis was extremely
modest and unambitious, and refused the honour of
knighthood. He was remarkably pious: As he rose
early in the morning, that he might be present at di-
vine service, which he constantly frequented before he
visited his patients, he procured prayers to be read be-
yond the accustomed times while he lived; and at his
death settled a stipend of 20l. per annum to continue
them. He was a liberal benefactor to the poor where-
ever he came, having from his early practice allotted
part of his profits to charitable uses. He was exact and
regular in all his hours; and though his table was the
resort of most of the great men of London, yet he was
remarkable for his plainness, and his being a man of
little discourse, complaisance, or society; but he was
justly admired for his deep insight into natural and ex-
perimental philosophy, anatomy, and chemistry; for his
successful practice: and for the elegance and purity of
his Latin style. He wrote, 1. A treatise in English,
intitled A plain and easy Method for preserving those
that are well from the Infection of the Plague, and for
curing such as are infected. 2. Several Latin works,
which were collected and printed at Amsterdam, in
1632, in 2 vols 4to.

WILLCROGHBY, FRANCIS, a celebrated natural hi-
storian, was the only son of Sir Francis Willughby,
knight. He was fond of study from his childhood, and
held idleness in abhorrence; he being so great an eco-
nomist with regard to his time, as not willingly to lose
or misapply the least part of it, by which means he at-
tained great skill in all branches of learning, and par-
ticularly in the mathematics. But to the history of ani-
imals, which was in a great measure neglected by his
countrymen, he particularly applied himself; and for
this purpose carefully read over what had been written
on that subject by others. He then travelled several
times over his native country; and afterwards into
France, Spain, Italy, Germany, and the Low Coun-
tries, attended by his ingenious friend Mr John Ray.
It is remarkable, that, notwithstanding the advantages
of birth, fortune, and parts, he was as humble as any
man of the meanest fortune; was sober, temperate, and
chaste; scrupulously just; and so true to his word and
promise, that a man might venture his estate and life upon
it; so faithful and constant to his friends, as never to de-
sert him when fortune frowned upon him; and remark-
ably pious, patient, and submissive to the divine will.
This is the character given of him by Mr Ray, whose
veracity none will doubt. This ingenious and learned
gentleman, died in 1672, at 37 years of age; having
impaired his health by his application. He wrote,
1. Ornithologiae libri tres, folio, which was afterwards
translated into English, with an Appendix, by Mr Ray,
in folio. 2. Historia Pisces libri quattuor, folio. 3.
Letters of Francis Willughby, Esq. added to Philoso-
phical Letters between the learned Mr Ray and several
of his correspondents, published, in 1680, by William
Derham. 4. Several ingenious papers in the Philoso-
phical Transactions.

WILMOT, JOHN, earl of Rochester, a great wit in
the reign of Charles II. the son of Henry earl of Ro-
chester, was born in 1648. He was taught grammar
and classical learning at the free-school at Burford;
where he obtained a quick relish of the beauties of the Latin tongue, and afterwards became well versed in the authors of the Augustan age. In 1659, he was admitted a nobleman of Wadham college, where he obtained the degree of master of arts. He afterwards travelled through France and Italy; and at his return was made one of the gentlemen of the bedchamber to the king, and comptroller of Woodstock Park. In 1665, he went to sea, and was in the Revenge, commanded by Sir Thomas Tiddiman, when an attack was made on the port of Bergen in Norway: during the whole action he showed the greatest resolution, and gained a high reputation for courage, which he supported in a second expedition, but afterwards lost it in a private adventure with Lord Malgrave.

Before the earl of Rochester travelled, he had indulged in the most disorderly and intemperate way of living; but at his return, however, he seemed to have got the better of it entirely. But falling into the company of the courtiers, who continually practised these excesses, he became so sunk in debauchery, that he was for five years together so given up to drinking, that during all that time he was never cool enough to be master of himself. His violent love of pleasure, and his disposition to extravagant mirth, carried him to great excesses. The first involved him in sensuality, and the other led him into many adventures and ridiculous frolics. Once disguising himself so that he could not be known by his nearest friends, he set up in Tower-street for an Italian mountebank, and there dispersed his nostrums for some weeks. He often disguised himself as a porter, or as a beggar, sometimes to follow a mean amanuensis; at other times, he would go about merely for diversion, in odd shapes; and acted his part so naturally, that he could not be known even by his friends. In short, by his constant indulgence in wine, women, and irregular frolics, he entirely wore out an excellent constitution before he was 30 years of age. In October 1679, when recovering from a violent disease, which ended in a consumption, he was visited by Dr. Burnet, upon an intimation that such a visit would be agreeable to him. Dr. Burnet published an account of his conferences with Lord Rochester; in which it appears, that though he had lived the life of a libertine and atheist, yet he died the death of a pious Christian. His death happened in 1685; since which time his poems have been various times printed, both separately and together; but when once he obtained the character of a lewd and obscene writer, every thing in that strain was ascribed to him; and thus many pieces not of his writing have crept into the later editions of his works. The author of the Catalogue of Royal and Noble Authors says, he was "a man whom the Muses were fond to inspire, and ashamed to avow, and who practised without the least reserve that secret which can make verses more read for their defects than their merits. Lord Rochester's Poems have much more obscurity than wit, more wit than poetry, and more poetry than politeness." His writings, besides those already mentioned, are: A Satire against Mankind; Nothing; a poem; Valentinian, a tragedy; Fifty four Letters to Henry Saville, and others; Sonnets to Dr. Burnet. He also left behind him several other papers, and a History of the Intrigues of the Court of Charles II.; but his mother, a very devout lady, destroyed all his papers to be burned.

WILSON, FLORENCE, known in the repulsiveness of letters by the name of Florentia Volosiana, was born at Elgin in the shire of Murray in Scotland, and educated in the university of Aberdeen. Travelling to England with an intention to improve his fortune, he laid the felicity to be introduced to Cardinal Wolsey, who appointed him tutor to one of his nephews. In that capacity he went to Paris, and continued there till the Cardinal's death. During his residence in that city he became acquainted with the learned Cardinal Belli, archbishop of Paris, who allowed him a pension, and went to have appointed him royal professor of the Greek and Latin languages in the university of Paris: but Belli being disgraced, Wilson's prospects faded with the fortunes of his patron, whom nevertheless he attended in his journey to Rome. Wilson was taken ill at Angoulême, and the cardinal proceeded without him. After his recovery, he paid a visit to the celebrated Cardinal Sabolet, the Mecenas of his time, who was also bishop of Carpentras, where he then resided. The cardinal was so charmed with his erudition, that he appointed him professor of the learned languages, with a stipend of 100 pistoles per annum.

During his residence at Carpentras, he wrote his celebrated treatise De Anima Tranquilitate. Mactonis says that he afterwards taught philosophy in Italy; and that, being at length desirous of returning to Scotland, he began his journey homeward, was taken ill at Venice in Dauphiné, and died there in the year 1647. He was generally esteemed an accomplished linguist, an admirable philosopher, and an excellent Latin poet. He wrote, beside the above treatise, 1. Poemata, London 1619, 4to. 2. Commentatio quaedam theologica, sive phorismos dissecta, per Seb. Gryph. 3. Philosophia Aristotelica Synopsis, lib. iv.

WILSON, Thomas, lord bishop of Sodor and Man, was born in 1663, at Burton, in the county of Chester. He received the rudiments of his education at the country town, and from thence was removed to the university of Dublin. His allowance at the university was 30l. a year; a sum, small as it may now appear, which was those days sufficient for a sober youth in so cheap a country as Ireland.

His first intention was to have applied to the study of physic; but from this he was diverted by Archibald Hewetson, by whose advice he dedicated himself to the church. He continued at college till the year 1686, when, on the 29th of June, he was ordained deacon.

The exact time of Mr. Wilson's leaving Dublin is not known: but on account of the political and religious disputes of those days, it was sooner than he intended. On the 10th of December, in the same year, he was licensed to the curacy of New Church in Winwick, of which Dr. Sherlock, his maternal uncle, was rector. His stipend was no more than 30l. a year; but being an excellent economist, and having the advantage of living with his uncle, this small income was not only sufficient to supply his own wants, but it enabled him to supply the wants of others; and for this purpose he set apart one-tenth of his income. In 1692 he was appointed domestic chaplain to William earl of Derby, and tutor to his son James Lord Strange, with a salary
of 30l. a-year. He was soon after elected master of the
alms-house at Latham, which brought him in 20l. a-
year more. Having now an income far beyond his ex-
pectations, or his wishes, except as it increased his abil-
ity to do good, he set apart one-fifth of his income for
pious uses, and particularly for the poor. In short, as
his income increased, he increased the portion of it
which was allotted to the purposes of charity. At first
he set apart a tenth, then a fifth, afterwards a third,
and lastly, when he became a bishop, he dedicated the
full half of his revenues to pious and charitable uses.

He had not been long in the service of Lord Derby,
because he was the offerable living of Budes-
worth in Yorkshire; which he refused to accept, as be-
ing inconsistent with the resolves of his conscience a-
against non-residence, Lord Derby choosing still to re-
tain him as chaplain and tutor to his son. In 1697 he
was promoted, not without some degree of compulsion
on the part of his patron, to the bishopric of the Isle of
Man; a preferment which he held 58 years. In 1698
he married Mary, daughter of Thomas Patten, Esq. of
Warrington. By this lady who survived her marriage
above six years, he had four children; none of whom
survived him, except the late Dr Wilson, prebendary of
Winchelsea.

"The annual receipts of the bishopric (says the au-
ther of his memoirs) did not exceed 300l. in money.
Some necessities in his house, as spices, sugar, wine,
books, &c. must be paid for with money; distressed or
shipwrecked mariners, and some other poor objects, re-
quired to be relieved with mony; but the poor of the
island were fed and clothed, and the house in general
supplied from his demesnes, by exchange, without mo-
ney. The poor, who could weave or spin, found the
best market at Bishop's-court, where they bartered the
produce of their labour for coffee and such other com-
modities as their shift in the house constantly employed,
to make into garments or shoes that cloth or leather which
his corn had purchased; and the aged and infirm were
supplied according to their several wants. Mr Moore
of Douglas informed the editor, that he was once wit-
ess to a pleasing and singular instance of the Bishop's
attention to some aged poor of the island. As he was
visiting the sick and destitute, the Bishop, with a smile,
spoke to him, saying that he saw, as they went with the
sick and poor, that the Bishop was pleased to instruct
his clergy in the visits, with a view to their being used
for the same purpose. These visits, it was said, would
help them to the use of a needle, to mend their clothes,
or if need be, to keep themselves free from vermin."

So great was the bishop's attachment to his flock,
that no temptation could seduce him from their service.
He more than once refused the offer of an English bi-
shopric. There is an anecdote of his lordship and Car-
dinal Fleury, which does great credit to them both.
The cardinal wanted much to see him, and sent over on
purpose to inquire after his health, his age, and the
date of his consecration, as they were the two best bi-
shopric, and he believed the poorest, in Europe; at the
same time inviting him to France. The bishop sent the
cardinal an answer, which gave him so high an opinion of
him, that the cardinal obtained an order that no
French privy-counsellor should ravage the isle of Man.

This good prelate lived till the year 1755, dying at
the advanced age of 93. His works have lately been
published in 2 vols. 4to.

WILTON, a market town in Wiltshire, three miles
west of Salisbury. It was once so considerable as to
give title to the county. It had formerly 12 churches;
and Odo, brother-in-law to William I., was bishop of
Wilton. Only one now remains, and its inhabitants in
1811 amounted to 1653. It sends members to parlia-
ment, and is the place where the knights of the shire are
chosen. It has a great manufacturing of carpets, which
are brought to high perfection. Wilton is famous for
Lord Pembroke's seat, so well known through Europe
for its containing a grand assemblage of the productions
of the greatest and most ancient masters in painting
and sculpture. Two fairs are held here annually.

WILTSHIRE, a county of England, bounded on
the west by Somersetshire, on the east by Berkshire
and Hampshire, on the north by Gloucestershire, and on
the south by Dorsetshire and part of Hampshire. The
distance to Salisbury is 39 miles; its breadth to 30; and its
circumference to 140. It contains 29 hundreds, 23
market-towns, 304 parishes, and in 1811 had 193,828
inhabitants. Besides two members for the shire, and
for the city of Salisbury, each of the following towns
 sends two members to parliament, viz. Wilton, Down-
ton, Hindon, Heytesbury, Westbury, Calne, Devizes,
Chippingham, Malmesbury, Cricklade, Great Bedwin,
Lodershall, Old Sarum, Wooton Bassett, Marlborough.

The soil of this county is very healthy, not only in
the more low and level parts, but also on the hills.
The soil of the vales is very rich, and produces corn
and grass in great plenty. The beautiful downs in the
south yield the finest pasture for sheep, with which they
are overspread. The greatest advantage the county
labours under is want of fuel, as there is no coal-pit,
but little wood. This county is noted for great quan-
tities of very fine cheese, and for its manufacture
of broad cloth, to which it was invited by the great
plenty and fineness of its wool. It is watered by the ri-
ers Isis, Kennet, Upper and Lower Avon, Willy,
Burne, and Nadder, which are well stored with fish.
See Wiltshire, Supplement.

WINCHELSEA, a town in Sussex, which has no
market, but has one fair on May 14th for cattle and
pedlar ware. It was an ancient place, at least the old
town, which was swallowed up by the ocean in 1290.
It is now dwindled to a mean place, though it retains
its privileges, and sends two members to parliament.
It is seated on a rocky cliff, on an inlet of the sea; and
had a haven, now choked up. It had 18 parish-churches,
now reduced to one. The market-house is in the
midst of the town, from whence run four paved streets,
at the end of which are four ways, which had formerly
buildings on each side for a considerable distance.
It is 71 miles south-east of London. It is governed by a
mayor and jurats, though it had but 652 inhabitants
in 1811. Three of the gates are still standing, but
much decayed. E. Long. c. 44. N. I. p. 50. 38.

WINCHELSEA, Anne Countess of, a lady of excellent
genius, especially in poetry, was maid of honour to the
duchess of York, second wife to King James II., and
was afterwards married to Heneage, second son of the
earl of Winchelsea. One of the most considerable of
the countess of Winchelsea's poems was that on the
4 X 2

Spleen.
W I N

Spleen. A collection of her poems was printed at London in 1713, containing a tragedy never acted, intitled Aristomenes. The countess died in 1720 without issue, as her husband did in 1706.

WINCHESTER, the capital of the county of Hampshire in England. It is a very ancient city, supposed to have been built several centuries before Christ. The Romans called it Venta Belgarum, the Britons Coer Givend, and the Saxons StanecestARENT: whence came the present name. It stands upon the river Itchen, in a bottom surrounded with chalky hills; and is generally allowed to have been a considerable place in the time of the Romans. Some of the first converts to Christianity are supposed to have lived here. In the castle, near the west gate, many of the Saxon kings anciently kept their court. The cathedral was founded by Keneguis, a king of the Mercians; but there were many Christians, and places for their worship here, long before that period. It is a large pile, and has a venerable look, but is not very elegant. Besides the tombs, there are many curious pieces of workmanship in it: the chief of which are, 1. The font, erected in the time of the Saxons. 2. Copper statues of James I. and Charles I. 3. The bishop's throne. 4. The stalls of the dean and prebendaries. 5. The ascent to the choir and altar. 6. The pavement inlaid with marble of diverse colours, in various figures. 7. The altar-piece, reckoned the noblest in England. 8. The paintings in the windows, especially the great east window. At the hospital of the Holy Cross, every traveller that knocks at the door may claim a bunchet of white bread and a cup of beer; of which a great quantity is provided every day for that purpose. This hospital was intended for the maintenance of a master and 30 pensioners, but only 14 are now maintained in it; and the master enjoys a revenue of 800l. a year. This city is about a mile and a half in compass, and almost surrounded with a wall of flint; has six gates, large suburbs, broad clean streets; but the private houses are in general but ordinary, many of them being very old. The city is interspersed with a great many gardens, which contribute to its beauty and healthiness. The corporation consists of a mayor, high-steward, recorder, aldermen, two cornerers, two bailiffs, 24 common-council men, a town-clerk, four constables, and four sergeants at arms; and the city gives title of margrave to the duke of Bolton. A Roman highway leads from hence to Alton; and went formerly, as it is thought, from thence to London. The charming downs in the neighbourhood contribute greatly to the health and pleasure of the inhabitants. The river Itchen is navigable for barges from hence to Southampton. The population in 1811 amounted to 6705 persons. W. Long. 1. 16. N. Lat. 50. 57.

WINCKLEMAN, ANNE JOHN, was born at Stendal, in the old Marche of Brandenburg, in 1718. His father was a shoemaker. This wonderful man, to appearance destined by his birth to superintend a little school in an obscure town of Germany, raised himself to the office of president of antiquities in the college of Seehausen near Balswade, he went in 1753 to Dresden, where he formed an acquaintance with the ablest artists, and particularly with M. Oescer, an excellent painter, and one of the best draughtsmen of the age. In that year he signed to Lutheranism, and embraced the Roman Catholic religion. In September 1755, he set out for Italy, and arrived at Bologna in December following. His principal object was to see the Vatican library, and to examine the ruins of Herculaneum.

Mr Winckleman carried with him into Italy a taste of beauty and art, which led him instantly to admire the masterpieces of the Vatican, and to which he longed to study them. He soon increased his knowledge; and it was not till after he had thus purified his taste and conceived an idea of ideal beauty, which led him into the greatest secrets of art, that he began to think of the explanation of other monuments, in which his past learning could not fail to distinguish him. His talent enabled him to fill up his principal plan of writing "History of Art." In 1756, he planned his "Retrospection of Ancient Statues," and a larger work on the Taste of the Greek Artists; and designed an account of the galleries of Rome and Italy, beginning with a volume on the Belvedere statues, in the manner of Richardson, who, he says, only ran over Rome. He intended a history of the corruption of taste in art, the restoration of statues, and an illustration of the chief points of mythology. All these different essays led him to his "History of Art," and his "Monumenti Inediti." It must, however, be confessed, that the first of these works has not all the clearness and precision that might be expected in its general plan and division of its parts and objects; but it has enlarged and extended the ideas both of antiquaries and collectors. The description of the gems and sculptures of the Strozzi cabinet contributed not a little to extend Mr Winckleman's knowledge. Few persons have opportunities of contemplating such vast collections. The engravings of Lipitz and Coni Cauilus are all that many can arrive at. Mr Winckleman's Monumenti Inediti, from which he had begun the third volume 1767, seem to have secured him the esteem of antiquaries. Had he lived, we should have had a work long wished for; a complete collection of the bas-reliefs discovered from the time of Bartoli to the present, the greater part of which are in the possession of Cardinal Albani.

When Cardinal Albani succeeded to the place of Librarian of the Vatican, he endeavoured to get a place for the Hebrew language for Winckleman, who refused a canonry, because he would not take the tonsure. The Elector of Saxony gave him, 1761, unsolicited, the place of Counsellor Richter, the direction of the royal cabinet of medals and antiquities at Dresden. Upon the death of the abbe Venuti, 1762, he was appointed president of the antiquities of the apostolic-chamber, with power over all discoveries and exportations of antiquities and pictures. This is a post of honour, with an income of 100 scudi per annum. He had a prospect of the place of president of antiquities in the Vatican going to be created at 100 scudi per month, and was named corresponding member of the Academy of Inscriptions. The king of Prussia offered him, by Col. Quintius Tullius, the place of librarian and director of his cabinet of medals and antiquities, voided by the death of M. Gastier de la Croze, with a handsome appointment. He made no scruple of accepting the offer; but when it came to the pope's ears, he added an appointment out of his own purse, and kept him at Rome.
In April 1786, he left Rome to go with M. Cava-cepelli over Germany and Switzerland. When he came to Vienna, he was so pleased with the reception he met with, that he made a longer stay there than he had intended. But, being suddenly seized with a secret uneasiness and extraordinary desire to return to Rome, he set out for Italy, putting off his visits to his friends in Germany to a future opportunity. As he passed through Trie, he was assassinated, June 8, 1786, by a wretch named on Ancanelli, a native of Campiglio, a town in the territory of Pistoia, with whom he had made an acquaintance on the road. This miscreant had been condemned for a robbery in six months, and then to be banished the Austrian territories, on an oath never to return. He had obtained a mitigation of one of his sentences, and retired to Venice; but, changing his quarters back and forth, he was so reduced in circumstances that he at length took up his lodging at the inn to which the Abbé happened to come. And his father put him at court, that he entirely gained his confidence; and having been favoured with a sight of the valuable presents which he had received at Vienna, formed a design to murder and rob him. He bought a new sharp knife on purpose; and as the Abbé (who had in the most friendly manner invited him to Rome) was sitting down in his chair, early in the morning, he threw a rope over his head, and before he could disengage himself, stabbed him in five different places. The Abbé had still strength to get down to the ground floor, and call for help, and being laid on a bed in the midst of the most violent pain, he had compose sufficient to receive the last sacraments, and to make his will, in which he appointed Cardinal Alexander Albani his residuary legatee, and expired in the afternoon. The murderer was soon after apprehended; and executed on the wheel opposite the inn, June 26.

Abbé Wincklemans was a middle-sized man; he had a very low forehead, sharp nose, and little black hollow eyes, which gave him an aspect rather gloomy than otherwise. If he had such a sensation as to his phrenology, it was his mouth. A fiery and impetuous disposition often threw him into extremes. Naturally enthusiastic, he often indulged an extravagant imagination; but as he possessed a strong and bold judgment, he knew how to give things a just and intrinsic value. In consequence of this turn of mind, as well as a neglected education, a cautious reserve was a quality he little knew. If he was bold in his decisions as an author, he was still more so in his conversation, and has often made his friends tremble for his temerity. If ever man knew what friendship was, that man was Mr. Wincklemans, who regularly practised all his duties; and for this reason he could boast of having friends among persons of every rank and condition.

WIND is a sensible agitation of the atmosphere, occasioned by a quantity of air flowing from one place to another. See METEOROLOGY.

Hot WIND. See SAMUEL.

WIND-Flower. See ANEMONY, BOTANY INDEX.

WIND-Mill, a kind of mill, the internal parts of which are much the same with those of a water mill; from which, however, it differs, in being moved by the impulse of the wind upon its sails or vanes, which are to be considered as a wheel in axis. See MECHANICS INDEX.

WIND-Gage. See WIND-GAGE.

WIND-Gall. See FARMERY INDEX.

WIND-Gun. See AIR GUN, under SCIENCE, Amusements of.

Instruments for measuring the strength, velocity, &c. of the WIND. See WIND-GAGE, ANEMOMETER and ANEMOSCOPE.

WIND-Hatch, in mining, a term used to express the place at which the ore is taken out of the mines.

WIND-Shell, a name given by our farmers to a distemper to which fruit trees, and sometimes timber trees, are subject. It is a sort of blight and shiver throughout the whole substance of the tree; but the bark being often not affected by it, it is not seen on the outside, while the inside is twisted round, and greatly injured. It is by some supposed to be occasioned by high winds; but others attribute it to lightning. Those trees are most usually affected by it whose branches grow more out on one side than on the other. The best way of preventing this in valuable trees, is to take care in the plantation that they are sheltered well, and to cut them frequently in a regular manner while young.

WIND-Taught, in sea language, denotes the same as stiff in the wind. Too much rigging, high masts, or any thing catching or holding wind aloft, is said to hold a ship wind-taught; by which they mean, that she steers too much in her sailing in a stiff gale of wind.

Again, when a ship rides in a main stress of wind and weather, they strike down her top masts, and bring her yards down, which else would hold too much wind, or be too much distended and wind-taught.

WIND-Sails, a sort of wide tube or funnel of canvas, employed to convey a stream of fresh air downward into the lower apartments of a ship.

This machine is usually extended by large hoops situated in different parts of its height. It is let down perpendicularly through the hatches, being expanded at the lower end like the base of a cone; and having its upper side open on the side which is placed to the windward, so as to receive the full current of wind; which entering the cavity, lifts the tube, and rushes downwards into the lower regions of the ship. There are generally three or four of these in our capital ships of war, which, together with the ventilators, contribute greatly to preserve the health of the crew.

WINDAGE of a Gun, is the difference between the diameter of the bore and the diameter of the ball.

WINDLASS, a machine used for raising huge weights, as guns, stones, anchors, &c.

It is very simple, consisting only of an axis or roller, supported horizontally at the two ends by two pieces of wood and a pulley; the two pieces of wood meet at top, being placed diagonally so as to prop each other; the axis or roller goes through the two pieces, and turns in them. The pulley is fastened at top where the pieces join. Lastly, there are two staves or handspikes which go through the roller, whereby it is turned, and the rope which comes over the pulley is wound off and on the same.

WINDLASS, in a ship, is an instrument in small ships, placed upon the deck, just abaft the fore mast. It is made of a piece of timber six or eight feet square, in form,

WIN [ 719 ]

The colour of wine is frequently artificial; a deep red is almost always the effect of artificial additions, as of the red woods, elder berries, bilberries, &c. In France no secret is made of these practices, the colouring matters being publicly thrown out after they have been used.

It is well known to be a common practice among Adula-terators bad wine in order to conceal its defects: if, for instance, the wine be sour, they throw into it a quantity of sugar of lead, which entirely takes away the sour taste. For similar purposes alum is often mixed with wine. Such substances, however, are well known to be extremely pernicious to the human constitution; it becomes of importance therefore to be able to detect them whenever they happen to be contained in wine.

Several chemists who have turned their attention to this subject, have furnished us with tests for this purpose.

To discover lead dissolved in wine, boil together in a To detect pint of water an ounce of quicklime and half an ounce lead in of flour of brimstone; and when the liquid, which will be of a yellow colour, is cold, pour into a bottle, and cork it up for use. A few drops of this liquor being dropt into a glass of wine or cyder containing lead, will vol. ii. change the whole into a colour more or less brown, according to the quantity of lead which it contains. If the wine be wholly free from lead, it will be rendered turbid by the liquor, but the colour will be rather a dirty white than a black brown.

By this test, however, iron is also precipitated when dissolved in wine, and is apt to be taken for lead; a mistake which has ruined several honest merchants.

The following test is therefore preferable, as not liable to the same inconvenience.

Take equal parts of calcined oyster-shells and crude sulphur in fine powder, and put them in a crucible, put into a fire, and raise the heat suddenly till it has been exposed to a white heat for 15 minutes. Then take it out, let it cool, beat the ingredients in powder, and put them into a well corked bottle. To prepare the test liquor, take 20 grains of this powder together with 120 grains of cream of tartar, and put them into a strong bottle, fill it up with water, boil it for an hour, and let it cool. Cork the bottle immediately, and shake it from time to time. After some hours repose, decant off the clear liquor into an ounce vial, having first put 22 drops of muriatic acid into each vial. Cork these vials accurately with a little wax mixed up with a little turpentine. One part of this liquor, mixed with three parts of suspected wine, will discover the presence of the smallest quantity of lead or copper, by a very sensible black precipitate, and of arsenic by an orange precipitate: but will have no effect on iron, if there be any.

The presence of which, however, may be ascertained by adding a little potash, which will turn the liquor black.

As this subject is of importance, we shall add M. State of Feypery’s observations on the state in which lead exists in wine, and on the methods of discovering its presence.

“Of the different principles which compose wine, there was no doubt (says he) but that acids were the only ones which were capable of dissolving oxide (calc.) of lead. But was it the tartaraceous acid always contained in larger or smaller quantity in wine, or the acetoxy acid developed in those which have become sharp, and which there is a greater temptation to sweeten? Expe-
WIN [ 720 ]

Wine. Experience had proved to me that the acidulous tartrate of potash, or the cream of tartar, takes oxide of lead from the acetous acid, and a precipitate of tartrate of lead is formed; the pure tartrate acid prepared in Scheele's method produces the same effect. In order to understand how the sharp wine which contains these two acids can hold the oxide of lead in solution, I made the experiments which gave me the following results: 1. The acidulous tartrate (crem. tard.) has no sensible action upon the oxides of lead. 2. The pure tartrate acid has a slight action upon the oxides, and forms on their superfine a little tartrate of lead (tartarised lead), in a white powder. 3. Wine which only contains the tartarous acid, would not have any action upon the semi-vitrious oxide of lead or litharge. 4. Sharp wine which we attempt to sweeten by this oxide of lead, acts first upon it by the acetous acid it contains. 5. When this acetate of lead is formed, the tartaric acid precipitates it in the form of tartrate of lead; this is proved by the precipitate which the solution of the acetate of lead or sugar of lead forms in the wine. 6. But the acetous acid, if it be in large enough quantity, redissolves the tartrate of lead in the wine just as distilled water would. Bergman has pointed out this solution of tartrate of lead in acetous acid for distinguishing the tartaric salt from the sulphate of lead (crystallised lead). 7. As this solution of tartrate of lead in the acetous acid is much quicker, and more easy in sharp wines than in distilled water and vinegar, it is probable that the cause of this difference depends upon the citric and malic acids which I have found in wine, and which I shall take notice of again on another occasion. 8. Lithargyrite wine, then, or wine sweetened with lead, contains tartrate dissolved in the acetous acid, and perhaps at the same time in the malic and citric acids.

It was necessary afterwards to know the properties of this combination. What experience has taught me in as follows: I particularly examined the tartrate of lead and its solution in acetous acid. The tartrate of lead is scarcely at all soluble in water; it is in the form of powder, or of small white grains which have no sensible taste; when it is dissolved in vinegar, the vinegar is softened, its sharpness is diminished remarkably, and the solution takes a slight sweetish taste, much less strong than that of the pure acetous acid. This taste proves that the union of the tartrate of lead with vinegar is not only a solution like that of salt in water, by which the properties of the salt are not changed, but a combination which gives occasion to new properties. It is a kind of a triple salt, different from those we have hitherto known, formed of two acids and of one base; whereas the other triple salts described hitherto are composed of one acid and two bases. I name this new triple salt acetato-tartrate of lead. The acetous acid adheres to it more than water in a common solution: what is remarkable in this combination is, that the two acids appear to adhere to the base with an equal force, although they produce this equilibrium, but to unite first the oxide of lead with the acid to which it adheres the most strongly, and afterwards to put this first compound in contact with the weaker acid.

"It was necessary, in order to discover easy and certain methods of ascertaining the presence of lead in wine, to examine with care the properties and phenomena of the decompositions of the acetato-tartrate of lead. End it with alkalis and ammonia (volatile alkali) precipitates this salt an oxide of lead, which is of a greyish blue colour; but as they occasion a precipitate in pure wine, they cannot be of any use. The sulphure (cubic) acid decomposes the acetato-tartrate of lead, and leaves with it instantly sulphate of lead; which being very little soluble, and very brassy, is precipitated. The oxalic, or pure succarbarumic acid, and the acidulous sulphate, or the salt of sorrel of the shops, likewise decompose this salt, and take it from the lead. The mode of lead is precipitated in great abundance: those in acids, the succinic and oxalic acids, not producing any precipitate in pure wine, are very proper to be in presence of lead in wine. The sulphate and acidulous lead, when they are precipitated from wine, are coloured, whereas they are very white when they are found in distilled water; but their red or brown colours do not prevent us from discovering them by very simple method. If the precipitates be collected with care, and are cautiously heated upon a coal with a blue-glass, they smoke, become white, exhalate vapours, pass successively through the states of the red and yellow oxide of lead, and at length are reduced into metallic globules at the instant they are perceived to be agitated by very evident effervescence: we cease to blow at this instant, we obtain globules upon the charcoal. But to this, it is necessary, however, that the charcoal be solid, and be not cracked, and that we should not have blown too strongly; otherwise the globules would be absorbed, and would disappear. The sulphate of lead requires a longer time to be reduced than the oxide of the same metal, and there is a greater hazard of losing the metallic particles, which, besides, are in small quantity.

"To these two first processes, already sufficiently certain of themselves, I wished to be able to add one which might be capable of pointing out instantly the presence of lead, by an appearance belonging exclusively to the metal, and which might unite to this advantage the manifesting very small quantities of it. Distilled water impregnated with sulphur or hydrogous gas, or barytic gas, extracted from solid alkaline sulphates (crystals of sulphur) by acids, presented me with these properties. This solution blackens very deeply that of the acetato-tartrate of lead, and renders very of this salt is water or in wine very sensible. The sensibility of this reactive is such, that we may dilute lithargyrite wine with a sufficient quantity of water to take away almost entirely the colour of the wine, and this reactive will still produce a very manifest alteration. The sulphurated water has, besides, the advantage not to occasion any change in the wines which do not contain a metallic substance, and it is not precipitated by the acids of wine, like the solutions of alkaline sulphates. In order to procure this reactive pure, it is necessary to prepare it at the instant of the experiment, by receiving in a vial full of distilled water, and inverted upon a shelf of a small hydro-pneumatic apparatus, filled with distilled water, the sulphurated hydrogous gas, separated from the solid sulphuret of potash by the sulphuric or nitric acid, and first filtered through water in another vial; when the second vial contains the third of its volume of the sulphurated hydrogous gas, the gas is shaken strongly with the water, which fills the two-thirds of the
WIN [ 721 ]

WIN

to prevent their fretting, which is done by keeping them in the same degree of heat. In spring and fall, the wines in Bourdeaux are subject to changes that may be dangerous, if not prevented by necessary racking; these changes are solely the effects of the seasons. If wines are chilled, and of course turn foul, from being shipped and landed in cold weather, they will soon recover by putting them in a warm vault, well covered with saw-dust. As soon as they are in the vault, they ought to be covered up. But if shipped and landed in summer, if the smallest degree of fermentation be found on them, it will be requisite to dip the bung cloths in brandy, and leave the bung loose for some days, to give it time to cool; and if in a fortnight or three weeks the fermentation do not cease, and the wine become bright, it will be proper to rack it (matching the hogsheads well with brimstone), and force it with the white of eight eggs. If it then becomes fine, bung it tight, and let it remain so until it is bottled. If wines new landed are wanted soon for the bottle, it will be necessary to force them immediately, and let them remain bunged close for at least a month, to recover from the forcing, or if two months the better; for wines bottled in high order come much sooner into drinking than if bottled when flat, which all wines are after forcing. Wine must never be bottled the least foul, which produces a tendency to fret; and if bottled in this state, will never come in order, but may possibly be lost; for this there is no remedy but repeated rackings; and care must be taken (after rinsing the hogsheads well and drawing them) to burn a good piece of match in them. This cools the wine, and there is no danger of hurting the colour, for it recovers it in a little time: but if it did, it is absolutely necessary; for if wine is suffered to continue on the fret, it will wear itself to nothing. Wines bottled in good order may be fit to drink in six months; but they are not in perfection before twelve: from that to two years they may continue so; but it would be improper to keep them longer, for wines in general have not the body they had formerly, from the wines being too much forced.

It sometimes happens that wines scummy and stubborn will not fall with one or even two forcings. It will then be proper to give them five or six gallons of good strong wine, and force them with the whites of a dozen eggs, with a tea-spoonful of sand produced from sawing-marble, or a small spoonful of fine salt. Bottled wine in winter should be well covered with saw-dust, and if the vaults are cold and damp, strew it deep on the floor; if saw-dust is thrown upon the hogsheads, and their sides are bedded some inches thick, it will keep them from the fret.

The same treatment is to be regarded with white wines, except that they require to be higher matched, particularly Muscat wines; such as Frontignac, Béziers, &c. which being often sweetened with honey, are very subject to fret; and these only frequent rackings, with a great deal of brimstone, can cool. Hermitage, from not being sufficiently dried, and possessing more richness than claret, is also very liable to come on the fret, and will require much the same treatment as the Muscat wines. Attention should be had to bottle in fine weather, when the wind is north; but to avoid cold or frosty weather. The months of April and October are favourable. The best time to bottle port wine is four years.
WIN

years after the vintage, and to keep them two years in

wine. When wines are

racked, and the new must is pressed through

filters into a new vessel, and passed through this

process twice, the wines may be used for drinking.

When wines are made for warm climates, it may

be proper to remove the impurities with a warm

shaker, and in bottling many raisins are used.

Wines that have not passed through the aperce-tert of a year

in a vat, and made over to our place, must never be

used in the country in which they were made,

since wines may be used in France, and not used in that

state, may not be used.

Wines may be injured by the same conditions

which injure wines, and as a few weeks after

they are made, wines are the same.

The following recipe for wine is that of a

great wine, and is made by putting a two-horse

bottle in a warm place.

As some of the wines for making wines in

Champagne may be useful in the manufacture of

the wines of this country, we insert the following

abridged account of the different processes

that are followed in making wine and red champagne.

Great care is necessary for making white wine. The

ripest bunches must be carefully gathered, freed from

rotten, dry, and bruised grapes, put into large baskets

covered with a cloth to keep them from the sun,
carried to the shade, and kept there till the evening,
when they are to be speedily pressed. The grapes being

laid on the bed of the press, they are covered with three

or four layers of flat stones, and the press turned.
The juice having run for four or five minutes, the press is

turned backward, the stones removed, the grapes which

have protruded thrust into the heap, the stones replaced,

and the press turned again. The juice from three of such

pre-suses, which will not require an hour, is put by it-

selves for the best wine into a vat, where it is left all night
to settle.

The next morning the juice is poured off from the

sediment, and put into new well rinsed casks. Before

becoming hominy at first, and afterward imported

into the United States in a state of fermentation. It is

taken off in a dry weather, on a clear day, and

fined with sugar. About a pound is sufficient for

preparation. The grape must is then pressed with a

shaker, and the wine taken from the press, put on it,

and the wine well strained in a new vessel until

the wine is cloudy. The wine from the following day

is then added, and the ferment takes place in a

other three or four days. When the fermentation is

complete, the wine is ready for use. The

wine is made to stop here, that the wine may get its

hard taste, which even time cannot destroy.

About the end of December, when the ferment

has ceased, the wine is racked off from the press,

the must of May is racked off again, the wine

are free from lees, and the wine is fit to be bottled.

When it is to be sent to the consumer, it is made

third time; the whites of five or six fresh eggs are

beaten up in a pint of water, for every quart, and

bottled into 2 2 bottles. Good red champagne will

bottles from six to twelve years.

Wine Press, a machine contrived to separate the

juice out of grapes, and consisting of several pieces

of timber, variously disposed, which compose three

columns of timber work, closely united to the axis, which

are as wings, whereby it may be moved by the vine.

Of these there are different sizes as well as diffe-

rections; for an account of which, see Miller's Gardener's Dictionary, article Wine.

SpiritoF WINE, or Alcohol, a name given by chemists
to every ardent spirit produced by distillation. See CHEMISTRY.

WING, that part of a bird, insect, &c, whereby it

is enabled to fly. See BIRD and ORNITHOLOGY.

WINGS, in military affairs, are the two flanks or ex-

tremes of an army, ranged in form of a battle; being

the right and left sides thereof. See SEASON, &c.

WINTER, one of the four seasons or quarters of the

year. See SEASON, &c.

Winter commences on the day when the sun's distance

from the zenith of the place is greatest, and ends on the
day when its distance is at a mean between the greatest
and least.
Under the equator, the winter as well as other seasons
returns twice every year; but all other places have only
one winter in the year: which in the northern hemi-
sphere begins when the sun is in the tropic of Capricorn,
and in the southern hemisphere when in the tropic of
Cancer; so that all places in the same hemisphere have
their winter at the same time.
*WINTER-Berry.* See Physalis, Botany Index.

*WINTERA,* a genus of plants of the class of poly-
andria, and in the natural system arranged under the
12th order, Holarchoce. See Botany and Materia
Medica Index.

*WINTON, ANDREW,* a Scottish poet and historian
of the 14th century; but very little is known of his
life. He was a canon regular of St Andrews, and was
prior of the monastery of St Serf in the island of Loch
Leven in Kinross-shire; for in the chartulary of the
priory of St Andrews there are several public instru-
ments of Andrew Winton, as prior of Loch Leven.
They are dated between the years 1397 and 1413, so
that Winton must have been contemporary with Bar-
bour, whose merits are on several occasions celebrated
by him. Winton is best known as the author of the
Orthogynale Crownkill of Scotland. This work was un-
taken at the request of Sir John Wemyss, the ancestor
of the noble family of that name. It remained neglect-
ated for several centuries, but in 1795 a splendid edition
of that part of it relative to Scottish affairs, was publish-
ed by Mr Macpherson. The time of Winton's death
is unknown; but, as he mentions the death of Robert
duke of Albany, which happened in 1422, the historian
must have been alive at that time.

*WIRE,* a piece of metal drawn through the hole of
an iron into a thread of a fineness answerable to the hole
it passed through.

Wires are frequently drawn so fine as to be wrought
along with other threads of silk, wool, flax, &c.

The metals most commonly drawn into wire are gold,
silver, copper, and iron. Gold-wire is made of cylin-
derical ingots of silver, covered over with a skin of gold,
and thus drawn successively through a vast number of
holes, each smaller and smaller, till at last it is brought
to a fineness exceeding that of a hair. That admirable
ductility which makes one of the distinguishing charac-
ters of gold, is nowhere more conspicuous than in this
gilt wire. A cylinder of 48 ounces of silver, covered
with a coat of gold, only weighing one ounce, as Dr Hal-
ey informs us, is usually drawn into a wire, two
yards of which weigh no more than one grain; whence
98 yards of the wire weigh no more than 49 grains, and
one single grain of gold covers the 98 yards; so that the
ten-thousandth part of a grain is above one-eighth of an
inch long.

In 1754, Mr Rosswag of Strasbourg presented to the
board of trade some gauze made of iron wire, for which
he received a reward; and the loom he invented for
making it was lodged in the collection of machines at
Vaucanson. In 1790 Mr Rochon made others, and
coated them with a transparent glue, to be substituted
instead of horn for ship lanterns, to be used between
decks, and in engagements by night. He has since
conceived, that with a thin coating of plaster they
might be employed to preserve ships from fire, and
buildings on shore still more easily; or at least that
they might render the ravages of fire less frequent, and
less terrible. These gauzes might be very useful too
for theatrical decorations, which would not be liable to
take fire. Their only inconvenience is their being so
little flexible; but Mr Rochon does not despair of
means being found by chemistry to remedy this imper-
fection, and it was with a view of calling attention to
this subject, that he read a paper on it to the class.

*WIRE of Lapland.* The inhabitants of Lapland
have a sort of shining slender substance in use among
them on several occasions, which is much of the thick-
ness and appearance of our silver wire, and is therefore
called, by those who do not examine its structure or
substance, *Lapland wire.* It is made of the sinews of
the rein deer, which being carefully separated in the
eating, are, by the women, after soaking in water and
beating, spun into a sort of thread, of admirable fine-
ness and strength, when wrought to the smallest fil-
ament; but when larger, is very strong, and fit for the
purposes of strength and force. Their wire, as it is
called, is made of the finest of these threads covered
with tin. The women do this business; and the way
they take, is to melt a piece of tin, and placing at the
edge of it a horn, with a hole through it, they draw
these sinewy threads, covered with the tin, through the
hole, which prevents their coming out too thick cover-
ed. This drawing is performed with their teeth; and
there is a small piece of bone placed at the top of the
hole, where the wire is made flat; so that we always
find it rounded on all sides but one, where it is flat.

This wire they use in embroidering their clothes, as
we do gold and silver; they often sell it to strangers,
under the notion of its having certain magical virtues.

*WISEDOM,* usually denotes a higher and more re-
fin'd notion of things immediately presented to the mind,
as it were, by intuition, without the assistance of ratio-
cination.

Sometimes the word is more immediately used, in a
moral sense, for what we call prudence, or discretion,
which consists in the soundness of the judgment, and a
conduct answerable thereto.

*WISDOM of Solomon,* one of the books of the Apo-
crypha. It abounds with Platonic language, and was
probably written after the Cabalistic philosophy was in-
troduced among the Jews.

*WIT,* a quality of certain thoughts and expressions,
which are more easily perceived than defined. According to Mr
Locke, wit lies in the assemblage of ideas, and putting
those together with quickness and variety, wherein can
be found any resemblance or congruity, thereby to make
up pleasant pictures and agreeable visions to the
fancy. Mr Addison limited this definition consider-
ably, by observing, that every resemblance of ideas
does not constitute wit, but those only which produce
delight and surprise. Mr Pope defined wit to be a
quick conception and an easy delivery; while, accord-
ing to a late writer, it consists in an assimilation of
distant ideas.

The word *wit* originally signified wisdom. A *wite*
was a wise man: the *witenagemot,* or Saxon
parliament, an assemblage of wise men. So late as the
reign of Elizabeth, a man of great *wite,* of great

---

Digitized by Google
WIT

wit, was a man of vast judgment. We still say, in his wits, out of his wits, for in or out of sound mind. The word, however, is now applied in a more limited sense.

Without attempting to expose the inaccuracy of the definitions above mentioned, or hazarding a definition of our own where so many eminent men have failed, we shall endeavour to show in what true wit consists.

It is evident that wit excites in the mind an agreeable surprise, and that this is owing entirely to the strange assemblage of related ideas presented to the mind. This end is effected, 1. By debasing things pompous or seemingly grave; 2. By aggrandizing things little or frivolous; 3. By setting ordinary objects in a particular and uncomon point of view, by means not only remote but apparently contrary. Of so much consequence are surprise and novelty, that, nothing is more tasteless, and sometimes disgusting, than a joke that has become stale by frequent repetition. For the same reason, even a pun or happy allusion will appear excellent when thrown out extemporaneous in conversation, which would be deemed execrable in print. In like manner, a witty repartee is infinitely more pleasing than a witty attack: for though, in both cases, the thing may be equally new to the reader or hearer, the effect on him is greatly injured, when there is access to suppose that it may be the slow production of study and premeditation. This, however, holds most with regard to the inferior tribes of witticism, of which their readiness is the best recommendation.

We shall illustrate these observations by subjoining a specimen or two of each of these sorts of wit:

Of the first sort, which consists in the debasement of things great and eminent, Butler, amongst a thousand other instances, hath given us those which follow:

And now had Phoebus in the lap
Of Thetis taken out his nap;
And, like a lobster boil'd, the morn
From black to red began to turn.

Hudibras, part ii. canto 2.

Here the low allegorical style of the first couplet, and the simile used in the second, afford us a just notion of this lowest species, which is distinguished by the name of the ludicrous. Another specimen from the same author you have in these lines:

Great on the bench, great in the saddle,
That could as well bind o'er as swaddle,
Mighty he was at both of these,
And stylist of war, as well as peace:
So some rats of amphibious nature,
Are either for the land or water.

Ibid. part i. canto 1.

In this coarse kind of drollery, those laughable translations or paraphrases of heroic and other serious poems, wherein the authors are said to be travestied, chiefly abound.

The second kind, consisting in the aggrandisement of little things, which is by far the most splendid, and displays a soaring imagination, these lines of Pope will serve to illustrate:

As Bercynthia, while her offspring vie
In homage to the mother of the sky,

WIT

Surveys around her in the blest abode,
An hundred sons, and every son a god:
Not with less glory mighty Dulness crown'd,
Shall take thro' Grubstreet her triumphant road;
And her Parnassus glancing o'er at once,
Behold a hundred sons, and each a Muse.

This whole similitude is spirited. The parent of celestial is contrasted by the daughter of sight of chaos; heaven by Grubstreet; gods by ducats. Besides, the parody it contains on a beautiful passage of Virgil adds a particular lustre to it. This species may term thrasonic, or the mock-majestic. It is often the most pompous language, and sonorous phraseology, as much as the other affects the reverse, the tinct of most grovelling dialect.

To this class also we must refer the application of grave reflections to mere trifles. For that great seriousness are naturally associated by the mind, and likewise little and trilling, is sufficiently evinced by the common modes of expression on these subjects used in every tongue. An apposite instance of such an application we have from Philips:

My galligaskins, that have long withstood
The winter's fury and encroaching frost,
By time subdu'd, (What will not time subdue)
An horrid chasm disclose. Splendid Stilling.

Of the third species of wit, which is by far the most multifarious, and which results from what may be called the queerness or singularity of the imagry, we shall give a few specimens that will serve to mark out one of its principal varieties. To illustrate all would be impossible. The first shall be where there is an apparent contrariety in the things she exhibits as common.

This kind of contrast we have in these lines of Gold:

Then Hydrops next appears amongst the throng;
Bloated and big she slowly sailes along:
But like a miser in excess she's poor,
And pines for thirst amidst her wat'ry store.

Dispensur.

A second sort is, where the things compared in what with dialecticians would come under the denomination of disparates, being such as can be ranked under no common genus. Of this we shall subjoin as an example from Young:

Health chiefly keeps an Atheist in the dark;
A fever argues better than a Clarke:
Let but the logic in his pulse decay,
The Grecian he'll renounce, and learn to pray.

Universal Passion.

A third variety in this species springs from confounding artfully the proper and the metaphorical sense of an expression. In this way, one will assign as a motive what is discovered to be perfectly absurd, when but ever so little attended to; and yet from the ordinary meaning of the words, hath a specious appearance of a single glance. Of this kind we have an instance in the subsequent lines:

While thus the lady talk'd, the knight
Turn'd th' outside of his eyes to view,
WIT

As men of inward light are wont
To turn their optics in upon.

Hudibras, part iii. canto 1.

For whither can they turn their eyes more properly
than to the light?
A fourth variety, much resembling the former, is
when the argument or comparison (for all argument is
a kind of comparison) is founded on the supposition of cor-
poral or personal attributes in what is strictly not sus-
ceptible of them ; as in this,

But Hudibras gave him a twitch
As quick as lightning in the breach,
Just in the place where honour's lodg'd,
As wise philosophers have judg'd:
Because a kick in that place more
Hurt honour than deep wounds before.

Ibid. part ii. canto 3.

The fifth, and only other variety which we shall
mention, is which arises from a relation, not in
the things signified, but in the signs of all relations, no
doubt the slightest. Identity here gives rise to puns
and clinches ; resemblance to quibbles, cranks, and
rhimes : Of these it is quite unnecessary to exhibit spe-
cimens.

WIT, John de, a celebrated pensionary of Holland,
and one of the greatest politicians of his time, was the
son of Jacob de Wit, burgomaster of Dort, and was
born in 1625. He became well skilled in civil law, po-
litics, mathematics, and other sciences ; and wrote a
treatise on the Elements of Curved lines, published by
Francis Schooten. Having taken his degree of doctor
of law, he travelled into foreign courts, where he be-
came esteemed for his genius and prudence. At his re-
turn to his native country in 1650, he became pension-
ary of Dort, then counsellor-pensionary of Holland and
West Friesland, intendant and register of the fiefs, and
keeper of the great seal. He was thus at the head
of affairs in Holland ; but his opposition to the re-
establishment of the office of stadtholder, which he
thought a violation of the freedom and independence of
the republic, cost him his life, when the prince of
Orange's party prevailed. He and his brother Corneli-
ius were assassinated by the populace at the Hague in
1674, aged 47.

WITCH a person guilty of witchcraft.

WITCHCRAFT, a supernatural power which per-
sons were formerly supposed to obtain the possession of
by entering into a compact with the devil. They gave
themselves up to him body and soul; and he engaged,
that they should want for nothing, and that he would
avenge them upon all their enemies. As soon as the
bargain was concluded, the devil delivered to the witch
an imp, or familiar spirit, to be ready at a call, and do
whatever it was directed. By the assistance of this imp
and the devil together, the witch, who was almost al-
ways an old woman, was enabled to transport herself in
the air on a broomstick or a spit to distant places to at-
tend the meetings of the witches. At these meetings
the devil always presided. They were enabled also to
transform themselves into various shapes, particularly
to assume the forms of cats and bares, in which they
most delighted; to inflict diseases on whomsoever they
thought proper; and to punish their enemies in a Witchcraft
variety of ways.

The belief that certain persons were endowed with
supernatural power, and that they were assisted by in-
vizable spirits, is very ancient. The saga of the Ro-
mans seem rather to have been sorcerers than witches;
indeed the idea of a witch, as above described, could
not have been prevalent till after the propagation of
Christianity, as the heathens had no knowledge of the
Christian devil.

Witchcraft was universally believed in Europe till
the 16th century, and even maintained its ground with to-
lerable firmness till the middle of the 17th. Vast num-
bers of reputed witches were convicted and condemned
to be burnt every year. The methods of discovering
them were various. One was, to weigh the supposed
criminal against the church bible, which, if she was
guilty, would preponderate : another, by making her
attempt to say the Lord's Prayer ; this no witch was
able to repeat entirely, but would omit some part or
sentence thereof. It is remarkable, that all witches
did not hesitate at the same place; some leaving out one
part, and some another. Teats, through which the
imps sucked, were indubitable marks of a witch: these
were always raw, and also insensible; and if squeezed,
sometimes yielded a drop of blood. A witch could not
weep more than three tears, and that only out of the
left eye. This want of tears was, by the witch-finders,
and even by some judges, considered as a very substan-
tial proof of guilt. Swimming a witch was another
kind of popular ordeal generally practised; for this she
was stripped naked, and cross-bound, the right thumb
to the left toe, and the left thumb to the right toe.
Thus prepared, she was thrown into a pond or river, in
which, if guilty, she could not sink; for having, by
her compact with the devil, renounced the benefit of
the water of baptism, that element, in its turn, renounced
her, and refused to receive her into its bosom. Sir Ro-
bert Filmer mentions two others by fire: the first, by
burning the thatch of the house of the suspected witch;
the other, burning any animal supposed to be bewitched
by her, as a hog or ox. These, it was held, would
force a witch to confess.

The trial by the stool was another method used for
the discovery of witches. It was thus managed: Hav-
ing taken the suspected witch, she was placed in the
middle of a room upon a stool or table, cross-legged, or
in some other uneasy posture; to which if she submitted
not, she was then bound with cords; there she was
watched, and kept without meat or sleep for the space
of 24 hours (for, they said, within that time they should
see her imp come and suck). A little hole was like-
wise made in the door for imp's to come in at; and lest
it should come in some less discernible shape, they that
watched were taught to be ever and anon sweeping the
room, and if they saw any spiders or flies, to kill them:
if they could not kill them, then they might be sure
they were imps. If witches, under examination or tor-
ture, would not confess, all their apparel was changed,
and every hair of their body shaven off with a sharp
rasor, lest they should secrete magical charms to pre-
vent their confessing. Witches were most apt to con-
fect on Fridays.

By such trials as these, and by the accusation of chil-

WIT

Witches, old women, and fools, were thousands of unhappy women condemned for witchcraft, and burnt at the stake. In the 18th volume of the Statistical Account of Scotland there is the trial of two witches, William Coke and Alison Dick, in Kirkaldy, in 1656. The evidence on which they were condemned is absolutely ridiculous: they were, however, burnt for witchcraft. The expenses which the town and kirk-session were put to on this occasion were as follows:

<table>
<thead>
<tr>
<th>Description</th>
<th>Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>In primis.—To Mr James Miller, when he went to Prestowne for a man to try them,</td>
<td>47s.</td>
</tr>
<tr>
<td>Item.—To the man of Culross, the exactioner, when he went away the first time,</td>
<td>12s. 0d.</td>
</tr>
<tr>
<td>Item.—For coal of the witches,</td>
<td>24s. 4d.</td>
</tr>
<tr>
<td>Item.—In purchasing the commission,</td>
<td>9s. 3d.</td>
</tr>
<tr>
<td>Item.—For one to go to Finnouth for the laird to sit upon their assize as judge,</td>
<td>6s. 0d.</td>
</tr>
<tr>
<td>Item.—For harden to be jumps to them,</td>
<td>3s. 10d.</td>
</tr>
<tr>
<td>Item.—For making of them,</td>
<td>8s. 0d.</td>
</tr>
</tbody>
</table>

Summa for the kirk's part L. 17 10 Scots.

The town's part of expenses debursed extraordinarily upon William Coke and Alison Dick.

For a considerable time after the inquisition was erected, the trials of witches (as heretics) were confined to that tribunal; but the goods of those who were condemned being confiscated to the holy office, its ministers were so active in discovering sorcerers, that the different governments found it necessary to deprive them of the cognizance of this crime. On the continent, commissioners were then appointed for the discovery and conviction of witches, who, though less active than the inquirers, were but too zealous in prosecuting their function. In 1494, Sprenger and Institor, two persons employed in this commission, published a collection of trials, most of which had come before themselves, under the title of Malarius Maleficarum: this served as a kind of institute for their successors.

The first writers against witchcraft were stigmatized as Atheists, though they only endeavoured to prove the imbecility of the persons accused, and the infatuation or the knavery of their accusers. Such were the epistles of Dr Henry More, and even by Cudworth himself. Wierus, the disciple of the celebrated Agrippa, gave rise to the first great controversy on this subject. His master had taught him humanly; and he endeavoured, but with so feeble a hand, to stop the bloody proceedings of the judges. Wierus appears to have been a well-disposed, weak man, with cunning reading on his subject, but too narrow-minded to comprehend it thoroughly. He involved himself in unspeakable difficulties, by admitting the action of supernatural powers in certain diseases, and in possession, while he denied that witches had any concurrence in them. These appearances (said he) are illusion of the devil, who persuades simple and melancholy persons that the mischief he himself performs, is done by them, and at their pleasure. He was weak enough to attempt an explanation of every story alleged by his antagonist, without questioning the truth of the facts.

Bodinus, a French lawyer of eminence, who assisted at several trials of witches, wrote against Wierus in his Demonomania. He urged the concurrent testimonies of sufficient witnesses, and the confessions of the witches themselves, to establish the existence of secrecy. Wierus owned that the unhappy persons believed themselves to be guilty of the crimes alleged against them, but that they were deceived by the devil. But what do you make of the witches' meetings, cried Bodinus? To witches (replied his antagonist) are attributis. This explanation was so unsatisfactory that Wierus passed him a magician, whom the devil had furnished with such arguments to save others from punishment. Letheon, Godeline, Ewihichis, Evallus, and some others, followed him, notwithstanding this stigma; but they were opposed by men of more acuteness and consistency than themselves; by Hemigius, who had condemned several hundreds of sorcerers to the flames; Doria, whose book is a complete Corpus Magic.; Cujas, Eratosthenes, Scibius, Camerarius, and a crowd of others.

In this country, while the belief in witchcraft was supported by royal authority (for James I. is universally known to have written on demonology) censured by Bacon, and generally adopted among the people, only one writer was hardy enough to oppose it. This was Reginald Scott, who published a collection of important detections, under the title of Discoveries of Witchcraft. James ordered the book to be burnt by the common executioner, and the judges continued to burn witches as usual. During the civil wars, upwards of eighty were hanged in Suffolk, on the accusation of Hopkins the witch-finder. Webster was the next writer against witchcraft; but he had a different fate from that of Scott, for most of his arguments were refuted by Glanville. This very acute writer was induced to publish his Philosophical Considerations about Witchcraft, by the apprehension, that the increasing disbelief of witches and apparitions tended to affect the evidences of religion, and even of a Deity. In respect of argument, he was certainly superior to his adversaries; his reasoning is perspicuous, though sometimes subtle, rested on the most specious foundations of evidence, and arranged with great skill.

On the continent, this controversy seemed almost forgotten, till Bekker published his Mondo Enchanted, in which he denied the existence of witches, on the Cartesian principle, that the Deity is the source of all action, consequently actions so opposite to his nature and attributes cannot be supposed to exist. He was answered by Frederick
WITCHCRAFT

Frederick Hoffman, the father of the modern theory and practice of medicine, in his dissertation De Diaboli Potentia in Corpora.

The latest witchcraft frenzy was in New England, about 1692, when the execution of witches became a calamity more dreadful than the sword or the pestilence. The accusers became so daring, that neither civil nor religious authority would have proved a security against their attacks, if all the prosecutions had not been suddenly dropped, and the prisoners set at liberty. So far did those witchcrafts proceed in absurdity, that a dog was accused of throwing persons into fits by looking at them. As soon as the prosecutions were stopped, all reports of witchcraft ceased.

It would be ridiculous to attempt a serious refutation of the existence of witches; and at present, luckily, the task is unnecessary. In this country, at least, the discouragement long given to all suspicion of witchcraft, and the repeal of the statutes against that crime, have very much weakened, though perhaps they have not entirely eradicated, the persuasion. On the continent, too, it is evidently on the decline; and notwithstanding the exertions of Dr. De Haen, and of the celebrated Lavater, we have little doubt but that in a short time popularity will wonder at the credulity of their ancestors.

That there ever were witches, is an opinion that cannot for a moment be believed by a thinking man. The actions imputed to them were either absurd or impossible; the witnesses by whose evidence they were condemned, either weak enthusiasts or downright villains; and the confessions ascribed to the witches themselves, effects of a disorder of imagination produced by cruel treatment and excessive watchings. As to the nightly meetings, demonologists themselves have been obliged to confess, that they were nothing else but uneasy dreams, often provoked by sorcerous compositions. The facts which have been brought forward by the advocates for witchcraft bear in their front the most evident marks of trick and imposture; and this has constantly been found out whenever these facts have been properly examined.

See Sorcery.

WITENA MOT, or WITENA GEMOT, among the Anglo-Saxons, was a term which literally signified the assembly of the wise men; and was applied to the great council of the nation, of latter days called the parliament.

WITHERS OF A HORSE, the juncture of the shoulder-bones at the bottom of the neck and mane, towards the upper part of the shoulder.

WITNESS, in Law, a person who gives evidence in any cause, and is sworn to speak the truth, the whole truth, and nothing but the truth.

Trial by Witness, a species of trial without the intervention of a jury. This is the only method of trial known to the civil law, in which the judge is left to form in his own breast his sentence upon the credit of the witnesses examined; but it is very rarely used in the English law, which prefers the trial by jury before it in almost every instance. Save only that when a widow brings a suit of dower, and the tenant pleads that the husband is not dead; this being looked upon as a dilatory plea, is in favour of the widow, and for greater expedition allowed to be tried by witnesses examined before the judges: and so, hath Finch, shall no other case in our law. But Sir Edward Coke mentions some others; as, to try whether the tenant in a real action was duly summoned, or the validity of a challenge to a juror; so that Finch's observation must be confined to the trial of direct and not collateral issues. And in every case Sir Edward Coke lays it down, that the affirmative must be proved by two witnesses at the least.

WITTENBERG, a city of Germany, capital of the circle of Upper Saxony, 50 miles north of Dresden. The town is not large; but is well fortified, and contains a famous university, in which Melancthon was a professor. In this place Martin Luther first began to preach against the pope's indulgences; and in the cathedral of All Saints he is said to have been buried. In the old citadel of this town the ancient Saxon electors used to reside. Besides the university, there is a Latin school in the town, with six masters. The library belonging to the university is said to be very valuable. In 1756, the Prussians being masters of the town, destroyed a part of its fortifications. This town belonged to the elector, now king of Saxony, but was included in the country which he was compelled to cede to Prussia in 1814. E. Long. 12. 47. N. Lat. 51. 49.

WOAD. See ISATIS, BOTANY INDEX; see also DYEING.

The preparation of woad for dyeing, as practised in France, is minutely described by Astruc, in his Memoirs for a Natural History of Languedoc. The plant puts forth at first five or six upright leaves, about a foot long and six inches broad: when these hang downwards, and turn yellow, they are fit for gathering: five crops are gathered in one year. The leaves are carried directly to a mill, much resembling the oil or tan mills, and ground into a smooth paste. If this process was deferred for some time, they would putrefy, and send forth an inappetible stench. The paste is laid in heaps, pressed close and smooth, and the blackish crust, which forms on the outside, reunited if it happens to crack; if this was neglected, little worms would be produced in the cracks, and the woad would lose a part of its strength. After lying for fifteen days, the heaps are opened, the crust rubbed and mixed with the inside, and the matter formed into oval balls, which are pressed close and solid in wooden moulds. These are dried upon hurdles: in the sun, they turn black on the outside; in a close place, yellowish, especially if the weather be rainy. The dealers in this commodity prefer the first, though it is said the workmen find no considerable difference between the two. The good balls are distinguished by their being weighty, of an agreeable smell, and when rubbed, of a violet colour within. For the use of the dye, these balls require a farther preparation: they are heated with wooden mullets, on a brick or stone floor, into a gross powder; which is heaped up in the middle of the room to the height of four feet, a space being left for passing round the sides. The powder, moistened with water, ferments, grows hot, and throws out a thick fetid fume. It is shovelled backwards and forwards, and moistened every day for twelve days; after which it is stirred less frequently, without watering, and at length made into a heap for the dye.

WOAIHOO, one of the Sandwich islands, lying to the north-west of Morotai, at the distance of seven leagues. From the appearance of the north-east and north-west parts, it is the finest island of the group. Nothing can exceed the verdure of the hills, the variety...
of wood and lawn, and rich cultivated valleys, which
the whole face of the country displays. A bay is
formed by the north and west extremities, into which a fine
river empties itself, through a deep valley; but as the
water is brackish for 200 yards from the entrance, wa-
tering in it is not convenient. It contains about 65,000
inhabitants. Lieutenant Hergest, commander of the
Daedalus store-ship, who had been sent from England,
in 1791, to New South Wales, and thence to the
Southern Pacific ocean, with a supply of provisions for
the Discovery sloop, Captain Vancouver, then on a voy-
age of discovery, was here surprised and murdered by
the natives, together with Mr Geo. the astronomer.
W. Long. 177. 57. N Lat. 21. 43.

WODEN. See Odin, and MYTHOLOGY, N° 40.

WODEVILLE, Anthony, Earl of Rivers, brother
to the queen of Edward IV. was born in the end of
1442, or in the beginning of 1443. Though one of
the most accomplished men of his age, very little is
known of his private history. He was early and con-
stantly employed either in the tumults of those turbulent
times, or in discharging the duties of some of the
highest offices of the state, with which he was invested.
Yet he found leisure to cultivate letters, and to be the
author of works which, though of little value now,
made some noise in that age, when learning was at a
low ebb in England. These consisted chiefly of transla-
tions from the French; and his lordship and his
printer Caxton, were the first English writers who had
the pleasure to see their works published from the press.
This accomplished, brave, and amiable nobleman was
fiercely imprisoned by Richard III. in Pembroke
castle, where, during his confinement, he composed a
short poem, which has been preserved by John Rous of
Warwick, and breathes, says Dr Henry, a noble spirit
of pious resignation to his approaching fate. He was
beheaded on the 23d of June 1483, in the 41st year of
his age.

WODROW, Robert, a clergyman of the west of
Scotland, who lived in the beginning of the 18th century,
well known as the author of an Ecclesiastical History
of that kingdom during the latter part of the preceding cen-
tury. His father, Mr James Wodrow, was a man of
learning and piety. He preached occasionally to the
persecuted presbyterians, and taught a little academy of
their students of philosophy and theology at Glasgow, before
the Revolution. About that time he was ordained one of
the ministers of that city, continuing his connexion
with the academy till he was elected professor of theo-
ology by the university in the year 1692. He taught
with reputation and success till his death in 1708.

His son Robert was born in the year 1679; his mo-
ther being then in the 51st year of her age. Her death
(though it did not happen till several years after), was
then fully expected; and his father, obnoxious to a ty-
ranical government, narrowly escaped imprisonment,
without any worse, by attempting to obtain a last short
house, he was marked, and soon followed by the soldiers
into his own house, and even into his wife's bedcham-
ber, where he was concealed. Their officer checked
this violence; sent them out of the room, and left
the house himself; placing, however, sentinels both within
and without, till the birth should be over. In half an
hour after, Mr Wodrow at his wife's suggestion as-
sumed the bonnet and great-coat of the servant of the
physician then in attendance; and carrying the little
before him, made an easy escape through the nere of
the guards. They soon renewed their march with
marks of irritation, thrusting their swords into the
bed where the lady lay; who pleasantly desired them
to desist, "for the bird (said she) is now born."

His son Robert went through the usual course of li-
terary education at Glasgow, entered the university in
1691; and prosecuted the study of the languages in
the different branches of philosophy, till he became a
student of theology under the tuition of his father. He
was chosen librarian to the university in the year 1698,
and continued in that office four years. Then he
began his researches into everything connected with
the ecclesiastical history of his country, which he con-
cluded to pursue to the end of his life; and also imbibed
in taste for medals, inscriptions, and whatever seemed vo-
rious or illustrative of Roman, Celtic, and British ant
iquities.

He was among the first in Scotland who attended to
the study of natural history. From a great number
of letters in his own hand-writing, begin about this time,
it appears that he was in habits of the utmost inquir-
with a select number of literary gentlemen, united
with the same ardent research; that they corresponded
regularly with one another, made collections of single
stones, of fossils, petrified plants, fishes, &c. and ex-
changed what they could spare from their respective
stores. Among his correspondents were Mr William
Nicolson, archdeacon, afterwards bishop of Carlisle, and
at last of Derry, author of the Historical Librarie;
Mr Edward Lhwyd keeper of the Ashmolean closet at
Oxford; Sir Robert Sibbald, physician in Edinburgh,
author of a natural history of Scotland, and another
of Fife; Lord Pitmedan; Messrs James Sutherland,
Laughian Campbell minister of Campbellton, and other.

In a letter to Mr Lhwyd, dated August 1759, Mr
Wodrow tells him his manse was but a little distance
from a place where they had been lithographing together,
during a visit of Mr Lhwyd to Scotland. "My par-
cinorial charge (he continues) does not allow me the same
time I had then for those subterranean studies; but my
inclination is equally strong, perhaps stronger. I take
it to be one of the best diversions from serious study, and
in itself a great duty, to admire my Maker's works. I
have gotten some store of fossils here from our marl,
limestone, &c. and heartily wish I had the knowing
Mr Lhwyd here to pick out what he wants; and help
me to class a great many species which I know not what
to make of." He informs him, in the end of the letter,
that he had 500 or 600 species of one thing or another
relative to natural history.

Mr Wodrow, when he left Glasgow, resided a short
time in the neighbourhood, in the house of a very distant
relation, Sir —— Maxwell of Nether Pollock, one of
the Scots judges. It being within the bounds of the
presbytery of Paisley, he offered himself to them for
probationary trials, and obtained their licence to
preach the gospel in March 1723. In the summer fol-
lowing, the parish of Eastwood, where Lord Pollock
lived, becoming vacant, by the death of Mr Matthew
Crawford (another Scots historian), a petition, with an
unanimous call or invitation from the parish to Mr
Wodrow to be their minister, was presented to the
presbytery;
and, the last to the commission of the General Assembly, and these courts thought proper to put no restraint on the minister's judgment or inclination, as he himself was certainly the best judge of his comparative usefulness in two different situations.

Mr Wodrow was equally conscientious and assiduous in the business of the ecclesiastical courts, as in his parochial duty. Notwithstanding his studious turn, he punctually attended the meetings of Presbytery, Synod, and General Assembly, when elected, as he often was, a member of that court; and also the commissions in November and March, which regularly met during that period of the church. His connexion with Lord Pollock made his journeys to Edinburgh easy; and after he began to collect materials for his voluminous history, his personal inspection of the public records and of the various MSS. accumulated in the Edinburgh libraries, made his visits to that capital frequent and necessary.

In common with the great body of the Presbyterians, he had strongly imbibed what are called Whig principles; in other words, he was warmly attached to the constitutional liberties of the people, as established by the revolution settlement. No wonder! The dreadful persecution and oppression they had suffered during the two preceding reigns were still fresh and galling to their minds: they considered the elevation of King William to the throne, and the Hanover succession, as the two chief bulwarks raised up by Providence, for the security both of their religion and liberty. They trembled at every dark appearance threatening to this security, such as the death of King William. That cloud, however, was soon dissipated by the perseverance of the queen's ministers in his views and measures, and the splendid victories of Marlborough and his allies over the armies of Louis XIV. But the elevation of the Tory ministry in the latter part of the queen's reign was a severe trial to the Scottish Presbyterians, and involved the conscientious part of the clergy in very serious difficulties and dangers. The oath of abjuration required at that time from clergymen, and enforced by civil penalties, and even the royal proclamation for a national thanksgiving, after the peace of Utrecht, pressed hard upon the scrupulous consciences of many of the clergy. The very language of the oath seemed to them dubious and Jesuitical, hostile to the elector of Hanover's newly acquired right to the crown, conferred on him by the parliament and the people; and, as to the other point, they had not freedom to lead their people, in a solemn thanksgiving to Heaven for a peace, termed safe and honourable, which they and the generality of their hearers considered as dangerous and disgraceful. Mr Wodrow, as might be expected, was one of the recursants of the oath; for nothing could move him to shuffle with his conscience. At the same time the liberality and equity of his mind led him to judge candidly of the consciences of others. Accordingly, he made every effort in his power to reconcile his clerical brethren, and his own people, to such of the clergy as had the freedom to take it, and by so doing, had rendered themselves obnoxious to popular prejudice and odium. With such, this good man still continued to live, not only in Christian, but ministerial communion; endeavouring to soften and remove the prejudices against them, and, in as far as his influence reached, to revive and cherish a spirit of mutual forbearance. Many proposals were made, and private **meetings**
meetings and conferences he held with his brethren, to prevent their differences from rising, as they threatened to do, into a schism; to prevent them especially from entering at all into the church courts; justly afraid of the sparks of animosity too apt to be kindled there. His endeavours and those of his friends were seconded by the prudence of the superior courts, especially the commission of the General Assembly. Whatever passed there in the way of admonition to the rest of the church, breathed the spirit of mutual forbearance and love. How he managed the other difficult and delicate point, the Thanksgiving, in a consistency with his duty, does not appear in his letters; nor is it now worth while to investigate this as a trait of his character, which might be done, perhaps, from his MS. sermons preached at the time. Only it is pleasing to remark from the letters, that the same spirit of wisdom and mild forbearance which animated the majority of the clergy in the west, seems also to have pervaded the officers of the crown, justices of the peace, and other civil magistrates in Scotland at the time. The oath was not pressed on the recusants, and the execution of the legal penalties incurred by the neglect of it avoided; for their general loyalty was undoubted.

A more severe stroke was inflicted on their adversaries by the Tory ministry in the year 1710, by an act of the British parliament which restored patronage to its former full force. An act of the Scotch parliament passed after the Revolution had extracted the chief sting of that grievance, by placing the election of the minister of every parish in the hands of the landed proprietors, called heritors, in conjunction with the elders, or members of the kirk session. A majority of that joint body, at a meeting appointed for the purpose, drew up a poll or written invitation, which they sub-eribed, to a particular candidate to be their minister. This was presented to the presbytery of the bounds, the proper judges of his learning and moral character; and if these were found unexceptionable, he was ordained, or solemnly consecrated and installed into the office. This Scotch act, having continued in force for twenty years, and being conceived to have become perpetual by the articles of the Union, was now repealed; and the choice of a minister to every parish was in effect placed in the power of a single person, a patron, because he had in fact the sole power of nominating the only candidate who could enjoy the benefice.

Mr. Wodrow was exceedingly averse from the revival of the power of patronage; and in this he was influenced both by his political and religious principles. In his letters, he seems to have looked upon a patron of a parish, as a kind of hereditary despot; or at least like a prince, who had no restraints laid on his prerogative, to prevent or check the abuse of it. The paramount power or trust committed to a patron, this con
certed councils, to commit the keeping of religious truth to faithful men, able also to instruct others. He thought it very improper to leave the choice of a religious instructor, in the first instance, to any single person whatever, especially to one generally a stranger to the circumstances of the parishioners; one who had little knowledge, and therefore little sympathy with them in their religious sentiments and feelings. He was persuaded that the purposes of edification, and the peace of the country, circumscribed as Scotland then was, were much better secured by the restraints laid on a patron in the act 1690, that is, by admitting the two principal bodies of the parish to a participation with him in his choice, than by trusting it wholly to himself; and he threw out many judicious hints in his letters, and even schemes or proposals to his brethren, on this difficult and important subject.

On the other hand, he wished nothing to be attempted in a constitutional way, in harmony with the civil power. Few men were so sensible as he was of the abuses incident to popular government, either in church or state, and of the danger of resisting, even unjust and oppressive laws, in a tumultuous or disorderly manner. The Presbyterian church, in the outward order of men of it, he viewed as a well regulated republic. He did not consider the people in their individual capacity as qualified to vote even on the choice of their own minister. The elders of the parish be looked upon as the representatives of the people in the ecclesiastical courts; and their number, in his own congregation, he restricted to a very few, four or five at most, to assist him in the exercise of church discipline within the parish. The rest of his session were deacons, whose jurisdiction was confined to the care of the poor, visiting the sick, distributing the bread and wine at the communion, he could not, like the former, be chosen to represent the parish in the presbytery and superior courts. In his sense of the necessity of order and subordination, he persevered to the end of his life. When, contrary to his judgment or vote, an unpopular brother was to be ordained in a parish within twelve or fifteen miles distant from Eastwood, in consequence of a sentence of the General Assembly, to be executed, perhaps with military assistance; this aged minister thought it his duty, regardless of personal danger or odium, to counteract the young brother, by joining with the rest of the clergy in laying their hands on him, inviting him afterwards to his pulpit, and exerting any influence he had to conciliate the irritated minds of that parish.

The only publication for which the world is indebted to Mr. Wodrow, is The History of the Singular Sufferings of the Church of Scotland during the twent
eight years immediately preceding the Revolution. It was written at a proper distance of time from the events it records; and printed at Edinburgh in the year 1717, in two large folio volumes, with two appendices consisting of copies of the public records, and of many private, family, and personal papers, letters, &c. inserted as vouchers of the historical facts. In collecting this body of information, the author was assisted by his friends, who cheerfully seconded his own most incredible industry and patience of research. In consequence of this, the book has more the appearance of a biographical, than of a historical work. It has, however, the form, and all the essentials of a regular history, divided into books, chapters, and sections, with proper margins and indexes; written in a plain, rather too familiar style, unavoidably interspersed with Scotiisms, yet these sufficiently intelligible to an English reader. It exhibi
bits a distinct sketch of the characters both of the principal sufferers, and of their persecutors; of the springs of the persecution, in the unjustifiable plans and measures of an arbitrary government; with the motives of the advisers and executors of them. The unfortunate and innocent
Wodrow. innocent sufferers, our author viewed in the light, not of a set of wild fanatics, as they were called by their contemporaries, and frequently too by later historians; many of them were most respectable for their rank in their country, as well as for their talents and virtues; but even those in the lower ranks of society, our author thought worthy of some public notice, as confessors and martyrs in the noble cause which they espoused, the support of the rights of conscience, and of national liberty.

The subject of the history is the most melancholy that could be chosen; a long and severe persecution of a people, who had been guilty of nothing untoward to their civil or ecclesiastical rulers; a series of open acts of injustice and tyranny, perpetrated under the colour of law, and this with such an increasing and merciless violence, as to sink the usual spirit of a free people, and easily quash one or two feeble ill-timed attempts to resist their oppressors. No wonder that the continued view of such a wretched and melancholy scene, without any thing joyful to interrupt it, should give a melancholy tinge to the mind of the writer, easily communicated to his readers. On the other hand, some things have happily an opposite tendency. The mass of biographical intelligence, though it must be confessed is much too voluminous, and too minute for the management of any historian whatsoever, yet furnishes a variety of anecdotes, which give some needful relaxation or relief to the sympathy of the reader. These indeed are in part the simple annals of the poor, without the varnish or easy elegance of polished life; but even in this shape they are not destitute, both of entertainment and instruction; and then the minutiae in the detail of names, of persons, places, and other particular circumstances, adds to the impression of the facts, by placing their certainty beyond all reasonable doubt.

If faithfully to record past facts, and transmit the knowledge of them to posterity, be the principal duty of a historian, this Wodrow has certainly aimed at; and also to repress any feelings hostile to his fidelity and impartiality; in short, to come as near as he was able to the motto prefixed to his volumes, Nec studio, nec odio. Doubtless, like all other men, he had some political, and many theological prejudices, the last chiefly imbiber from education, and confirmed by too high a veneration for the characters of our first reformers;—prejudices which warped his personal opinions and feelings on both subjects. But he seems to have made a considerable effort to prevent his party prejudices from warping or perverting his judgment of the truth or falsehood of stubborn historical facts. Nothing almost oratorical enters into his narratives, though there is room for admiration, and much scope for just indignation; no exaggerated encomiums on his friends, or strong opprobrious language in speaking of his and their enemies, the unprovoked persecutors of his church. He allows the facts which he has recorded to speak for both, and transmits to posterity a memorial to their honour or their infamy.

The chief fault of this historical collection already hinted at, is its minuteness, and excessive copiousness. The prodigious multitude of facts it embraces, though different from one another in their circumstances, are in other respects somewhat similar. This must necessarily occasion some repetition and satiety, especially to a fastidious reader, who has it, however, in his power to gratify his taste by selecting what is most agreeable to it.

Nevertheless a candid and patient reader can be at no loss to form a proper judgment of the principal transactions of the period, from the authentic accounts of them before him, to appreciate the true characters of the actors, or of the motives and views from which they acted. And an inquisitive and penetrating reader will be gratified by seeing not a little of the peculiar principles, opinions, sentiments, habits, and manners of that age, as distinguished from the present; and may thus estimate the gradual progress towards much noble and useful improvement; and on the other hand, the progress towards a very hurtful corruption and degeneracy of manners, which have both taken place during the last hundred and twenty years.

At the time of its first publication, the book met with less general attention than might have been expected in Scotland, and scarcely any attention in England, except from professed readers. As it came to be more studied, it was the more valued, except where there was an evident bias on the opposite side. Few can be at a loss to see why such historians as Hume, Macpherson, and Dalrymple should neglect or undervalue such a book. Our later Scotch historians, Somerville and Laing, have done it more justice. In truth, there is a very near coincidence in the narrative and the characters they draw, and their accounts of the facts they relate, in common with Wodrow. But especially our late illustrious patriot Charles Fox, whose high abilities, uncommon candour, and sweetness of disposition, almost remove the suspected bias of his party spirit—Mr Fox has, in the historical fragment published since his death, given a very honourable testimony to the fidelity and accuracy of our historian. After mentioning the execution of three females, he adds, page 131. To relate all the instances of cruelty which occurred would be endless. But it may be necessary to remark, that no historical facts are better ascertained, than the accounts of them which are to be found in Wodrow. In every instance, where there has been an opportunity of comparing these accounts with the records, and other authentic monuments, they appear to be quite correct.

The collection of the materials for writing the church history from the public records, and many other authentic sources, must have cost the author a prodigious labour and time. The pecuniary expense incurred was considerable, and scarcely refunded from the sale of the book. The only neat profit, he has been heard to say, which accrued from it, was one or two hundred pounds that he received from the king, to whom it was dedicated.

The last twelve years of Mr Wodrow's life were chiefly occupied in drawing up a biography of the principal persons concerned in introducing the reformation of religion into Scotland, and settling the different forms or modes of ecclesiastical government attempted to be established there from the beginning to the end of that period, namely from about the year 1560 to 1650, when the printed history of the sufferings commences. Had it pleased God to continue his useful life till this larger work was finished, public curiosity would have been much gratified; for it contains the lives, not only of John Knox, George Buchanan, and others already well known, but the lives of a great number more, very learned, ingenious, respectable, and worthy men, scarce-
WOD

Wodrow, ly at all known to the literary world; besides a variety
of anecdotes naturally entering into such a work, illustra-
tive of the history and the living manners of that
age. Happily these manuscript lives are still preserved,
all written with his own pen, and some of the longest of
them copied, probably during his last long illness, in a
more legible hand. Whatever important or curious in-
formation they may contain, they are not fit for the
press in their present state. They are now deposited
in the library of the university of Glasgow.

Besides writing the history and the biography, both
extended by himself for publication, and two days every
week regularly appropriated to his preparation for the
pulpit, much of his time must have been occasional-
ly spent in writing letters, some of them like disserta-
tions, on theological and other literary subjects; for he
never corresponded with a very wide circle of acquaintances
and friends in Scotland, England, and Ireland, and
with a few on the continent and in North America.

His constitution in the first part of life was robust and
strong, his health in general good; but his studious
habit constant reading, and especially incessant writing,
it is supposed, may have brought on the bodily com-
plaint which occasioned his death. In the latter end of
the year 1734, a swelling about the size of a small
chestnut appeared on his breast, near the collar bone.
It was on the same place where a spark of fire had fallen
when he was a child, and had then left a little lump
and hardness like a large pea. About a month after the
swelling began, it had increased to the size of a plumb, and
in April 1732 was as large as a man's fist. It was
attempted to be removed by cautious; the attempt failed.
His body became greatly emaciated, and he gradually
declined till his death, which happened on the 21st of
March 1734. Supported by the testimony of a good
conscience, joined with the strong consolation and
well-founded hope of the gospel, he bore this long continued
severe distress with admirable fortitude, unbeholden piety
and resignation; never uttering a murmur, but behaving
to his friends who came to see him, and to all about him,
with much ease and afflection; thus leaving, both in the
active exertions of a useful life, and in his patient suf-
ferras at the close of it, a very edifying example to his
family and his flock. The day before his death, he
gathered his children around his bed, gave each of them
his dying blessing, with counsels suitable to their ages
and circumstances; last of all two boys, neither of them
four years old, too young to understand and feel these
marks of his affection, yet, after the example of the
venerable patriarch, Gen. xxxviii. 15. even them he drew
to him, laid his hands upon their heads, and devoutly
prayed, that the God of his fathers, the angel who had
redeemed him from all evil, would bless the kids.

Mr. Wodrow was married in the end of 1708, to
Margaret Warner, grand-daughter of the reverend Mr.
William Guthrie of Fenwick, well known in Scotland by
his writings, and daughter of the reverend Patrick
Warner, then living on his estate of Ardeer in Ayrshire.
Mr. Warner, in the early part of his life, had been chap-
return home, he was driven from his ministry and from
but returned in consequence of King James's indulgence,
and became minister of Irvine. He had a personal in-
terview on his last return with the prince of Orange at
the Hague, a short time before the Revolution, an ac-
count of which appears in the history, vol. ii. p. 244.

Mr. Wodrow had a family of 16 children, nine of whom,
with his widow, survived him in decent circumstances,
without any breach among them for above 25 years.
Three of his sons were clergymen of the church of Scot-
land; one was minister of the parish of Combeth, son-
other of Tarbolton; and the third, the late Dr. John
Wodrow, author of the life of Dr. Leechman of Glas-
gow, was minister of Stevenson in Ayrshire.

Besides his collection of fossils, and a few Roman
British medals, Mr. Wodrow left a valuable library of
books, many volumes of pamphlets and also of manu-
scripts written by others, sent to him in presents, con-
pied by his orders. The most valuable part of this is
now in the advocates library, and in the possession of
the church at Edinburgh. His own manuscript bio-
ography, as has been already said, is in the library of
the university of Glasgow.

WOLAK, a town in Germany, in Prussia, Silesia,
and capital of a duchy of the same name. It is
surrounded with strong walls and a moat, and most of
the houses are built with stone. The castle is also
encircled with deep ditches, and the greatest part
of the inhabitants are employed in a woolen manufac-
tory. In 1709 a Protestant church was allowed to
be built here. It is seated on the river Oder, 20 mls.
west of Breslau, and 32 south-east of Glogau.

TANY INDEX, and DYEING.

WOLF. See CANIS, MAMMALIA INDEX.
WOLF-Fish, or Sea-Wolf. See ANTHROPIC, IST.
WOLFE, Major-General James, was born at
Westerham in the county of Kent, about the beginning
of the year 1726. His father was Lieutenant-general
Edward Wolfe. He went into the army when very
young; and applying himself with unwearying assiduity
to the study of his profession, soon became remarkable
for his knowledge and his genius. He distinguished
himself at the battle of Lauffeld when little more than
20, and received the highest encomiums from the com-
mander in chief. After the peace he still continued to
cultivate the art of war. He contrived to introduce
the greatest regularity and the exactest discipline into
his corps, and at the same time to preserve the affection
of every soldier. In 1739 he was present as a brigadier-
general at the siege of Louisbourg. He landed first on
the island at the head of a division; and in spite of the
violence of the surf, and the force and well directed
fire of the enemy, drove them from their post with great
precipitation. The surrender of the town which hap-
sued after, was in a great measure owing to his
activity, bravery, and skill. The fame which he ac-
quired during this siege pointed him out to Mr. Pitt,
who was then minister, as the proper person to com-
mand the army destined to attack Quebec.

This was the most difficult and the most arduous undertaking
of the whole war. Quebec was the capital of the French
dominions in North America; it was well fortified,
situated in the midst of a large country, and defended
by an army of 20,000 men, regulars and militia, besides
a considerable number of Indian allies. The troops
destined for this expedition consisted of ten battalions,
making up altogether about 7000 men. Such was the
army...
army destined to oppose three times their own number, defended by fortifications, in a country altogether unknown, and in a late season in that climate for military operations. But this little army, says an officer who was present at that expedition, and who has been so obliging as to communicate all the information we desired, was always sanguine of success; for they were commanded by General Wolfe, who, by a very uncommon magnanimity and nobleness of behaviour, had attached the troops so much to his person, and inspired them with such resolution and steadiness in the execution of their duty, that nothing seemed too difficult for them to accomplish. The admirable skill with which his measures were pursued, and the prudence and vigour with which they were executed, are well known. He landed his army on the northern shore of the river St Lawrence in spite of the enemy, and forced them to a battle, in which they were completely defeated. The consequence of this battle was the reduction of Quebec, and the conquest of Canada. In the beginning of the battle General Wolfe was wounded in the wrist by a musket-ball: he wrapt his handkerchief round it, continued to give his orders with his usual calmness and pertinacity, and informed the soldiers that the advanced parties on the front had his orders to retire, and that they need not be surprised when it happened. Towards the end of the battle he received a new wound in the breast; he immediately retired behind the rear-rank supported by a grenadier, and laid himself down on the ground. Soon after a shout was heard; and one of the officers who stood by him exclaimed, "See bow they run!" The dying hero asked with some emotion, "Who run?" "The enemy (replied the officer); they give way every where." The general then said, "Pray, do one of you run to Colonel Burton, and tell him to march Webb's regiment with all speed down to Charles river, to cut off the retreat of the fugitives from the bridge. Now, God be praised, I shall die happy!" He then turned on his side, closed his eyes, and expired.

The death of General Wolfe was a national loss universally lamented. He inherited from nature an animating fervour of sentiment, an intuitive perception, an extensive capacity, and a passion for glory, which stimulated him to acquire every species of military knowledge that study could comprehend, that actual service could illustrate and confirm. This noble warmth of disposition seldom fails to call forth and unfold all the liberal virtues of the soul. Brave above all estimation of danger; generous, gentle, complacent, and humane; the pattern of the officer, the darling of the soldier. There was a sublimity in his genius which soared above the pitch of ordinary minds; and had his faculties been exercised to their full extent by opportunity and action, had his judgment been fully matured by age and experience, he would, without doubt, have rivalled in reputation the most celebrated captains of antiquity. His body was brought to England, and buried with military honours in Westminster abbey, where a magnificent monument is erected to his memory.

Wolfe, Christian, a celebrated German philosopher, was born at Breslau in 1679. After having been well instructed in the rudiments of learning and science in his own country, Wolfe prosecuted his studies successively in the universities of Jena, Hamburg, and Leipzig. At the age of 26 he had acquired so much distinction, that he was appointed professor of mathematics, and soon afterwards of philosophy in general, in the university of Heidelberg. After Leibnitz had published his Theodicea, Wolfe, struck with the novelty of the edifice which that philosopher had raised, assiduously laboured in the investigation of new metaphysical truths. He also digested the Elements of Mathematics in a new method, and attempted an improvement of the art of reasoning, in a treatise On the Powers of the Human Understanding. Upon the foundation of Leibnitz's doctrine of Monads, he formed a new system of Cosmology and Pneumatology, digested and demonstrated in a mathematical method. His work, entitled Theses de Deo, De Mundo, et de Anima, was published in the year 1719; to which were added, in a subsequent edition, Heads of Ethics and Policy.

Wolfe was now rising towards the summit of philosophical reputation, when the opinion which he entertained on the doctrine of necessity being deemed by his colleagues inimical to religion, and an opinion which he delivered in praise of the morality of the Chinese having given much offence, an accusation of heresy was publicly brought against him; and, though he attempted to justify himself in a treatise which he wrote to the subject of fatality, a royal mandate was issued in November 1723, requiring him to leave the Prussian dominions. Having been formerly invited by the landgrave of Hesse-Cassel to fill a professor's chair in the university of Cassel, Wolfe now put himself under the patronage of that prince, who had the liberality to afford him a secure asylum, and appointed him professor of mathematics and philosophy. The question concerning the grounds of the censure which had been passed upon Wolfe was now canvassed, and every German university was inflamed with disputes on the subject of liberty and necessity; and the names of Wolfians and Anti-Wolfians were every where heard. After an interval of nine years, the king of Prussia reversed his sentence of exile, and appointed him vice-chancellor of the university of Halle; where his return was welcomed with every expression of triumph. From this time he was employed in completing his Institutes of Philosophy, which he lived to accomplish in every branch except policy. In 1745 he was created a baron by the emperor of Bavaria, and succeeded Ludovig in the office of chancellor of the university. He continued to enjoy these honours till the year 1754, when he expired. He possessed a clear and methodical understanding; which, by long exercise in mathematical investigations, was particularly fitted for the employment of digesting the several branches of knowledge into regular systems; and his fertile powers of invention enabled him to teach almost every field of science in which he laboured, with some valuable additions. The lucid order which appears in all his writings enables his reader to follow his conceptions with ease and certainty, through the longest trains of reasoning.

Wolfenbuttle, a considerable town of Germany, in the circle of Lower Saxony, and duchy of Brunswick, with a castle, where the duke of Brunswick Wolfenbuttle resides. It is one of the strongest places in Germany, though the fortifications want repairing in several places. There is an excellent library, kept in a building lately erected for that purpose, consisting of 116,000 printed books, and 2000 uncommon books, with
WOL [734] WOO

with a cabinet of curiosities, relating to natural history.

It is seated on the river Ocker, five miles south of Brunswick, and 50 west of Halberstadt. E. Long. 10.
25. N. Lat. 52. 10.

WOLFRAM, or TUNGSTEN. See TUNGSTEN.

WOLFSBERG, a town of Germany, in Lower Carinthia, with a castle, on which the district about it depends, which is 20 miles in length, and 10 in breadth. It is seated on the river Lavant, at the foot of a mountain covered with wood, and full of wolves, from whence the town took its name. It is 36 miles east of Clagenfurt. E. Long. 15. 0. N. Lat. 46. 36.

WOLGST, a considerable town of Germany, in the circle of Upper Saxony, and in Pomerania, capital of a territory of the same name, with a castle, and one of the best and largest harbours on the Baltic sea. It is a well built place, subject to Prussia, and seated on the river Pein. E. Long. 13. 42. N. Lat. 54. 4.

WOLLASTON, WILLIAM, descended of an ancient family in Staffordshire, was born in 1639. He was in 1674 admitted a pensioner in Sidney college, Cambridge, where, notwithstanding several disadvantages, he acquired a great degree of reputation. In 1682, seeing no prospect of preferment, he became assistant to the head master of Birmingham school. Some time after, he got a small lecture about two miles distant, but did not the whole Sunday; which, together with the business of a great free-school for about four years, began to break his constitution. During this space he likewise underwent a great deal of trouble and uneasiness, in order to extricate two of his brothers from some incoherencies, to which their own imprudence had subjected them. In 1688 affairs took a new turn. He found himself by a cousin's will entitled to a very ample estate; and came to London that same year, where he settled; choosing a private, retired, and studious life. Not long before his death, he published his treatise, entitled The Religion of Nature Delineated; a work for which so great a demand was made, that more than 10,000 were sold in a very few years. He had scarcely completed the publication of it, when he unfortunately broke an arm; and this adding strength to distempers that had been growing upon him for some time, accelerated his death; which happened upon the 29th of October 1724. He was a tender, humane, and in all respects worthy man; but it is represented to have had something of the irascible in his constitution and temper.

His Religion of Nature Delineated exposed him to some censure, as if he had put a slight upon Christianity, by laying so much stress, as he does in this work upon the obligations of truth, reason, and virtue; and by making no mention of revealed religion. But this censure must have been the offspring of ignorance or envy, since it appears from the introduction to his work, that he intended to treat of revealed religion in a second part, which he lived not to finish.

WOLSEY, THOMAS, a famous cardinal and archbishop of York, is said to have been the son of a butcher at Ipswich. He studied at Magdalen college, Oxford, where he became acquainted with the learned Erasmus; and in the year 1500 became rector of Lymington in Hampshire: he was afterwards made chaplain to King Henry VIII. and obtained several preferments. Having gradually acquired an entire ascendency over

the mind of Henry VIII. he successively obtained the bishopric of York, lord high-chancellor of England, and prime minister; and for several years the arbiter of Rome. Pope Leo X. created him cardinal in 1515, and made him legate a latere; and the emperor Charles V. at the French king Francis I. loaded him with favours, in order to gain him over to their interest; but after having first aided with the emperor, he deserted him and espoused the interest of France. As his revenues were immense, his pride and ostentation were carried to the greatest height. He had 500 servants; among whom were 9 or 10 lords, 15 knights, and 40 esquires. His ambition to be pope, his pride, his exactions, and the political delay of Henry's divorce, occasioned his disgrace. In the earlier part of his life he seems to have been licentious in his manners; it was reported, that soon after his preferment to the living of Lymington in Hampshire, he was put into the stocks by Sir Ana Puylet, a neighbouring justice of the peace, for being drunk and making a riot at a fair. This treatment Wolsey did not forget when he arrived at the high station of lord-chancellor of England; but denounced in a message to the pope and warning him of the consequences of his course.

Whatever may have been his faults, there can be no doubt of their having been aggravated both by the zealous reformation and by the creatures of Henry VIII. who was himself neither Papist nor Protestant; for there is every reason to believe that the cardinal was sincere in his religious and sincerity, or at least consistency, was then an error. Wolsey was the patron of learned men; a judge and munificent encourager of the polite arts; and ought to be considered as the founder of Christ's college, Oxford; where, as well as in other places, many remains of his magnificent ideas in architecture still exist. He died in 1530.

WOOD, ANTHONY, an eminent biographer and antiquarian, was the son of Thomas Wood, bachelor of arts and of the civil law, and was born at Oxford in 1632. He studied at Merton college, and in 1651 took the degree of master of arts. He wrote, 1. The History and Antiquities of the University of Oxford; which was afterwards translated into Latin by Mr. Waller; and Mr. Peires, under the title of Historia et Antiquitates Universitatis Oxoniensis, 2 vols. folio. 2. Athenae Oxonienses; or an exact Account of all the Writers and Bishops who have had their education in the University of Oxford, from the Year 1500 to 1600, 2 vols. folio, which was greatly enlarged in a second edition published in 1721 by Bishop Tanner. Upon the first publication of this work the author was attacked by the university, in defence of Edward earl of Clarendon, lord high chancellor of England, and chancellor of the university, and was likewise animadverted upon by Bishop Burnet; upon which he published a Vindication of the Historiographer of the University of Oxford. He died at Oxford in 1695.
WOOD, a substance whereof the trunks and branches of trees consists. It is composed of a number of concentric circles or zones, one of which is formed every year; consequently their number corresponds to the age of the tree. These zones vary in thickness according to the degree of vegetation that took place the year of their formation. They are also of different degrees of thickness in different parts, that part of the tree which is most exposed to the sun and best sheltered growing fastest; hence in this country that part of the zone which looked towards the south while the tree was growing is generally thicker. The innermost zone is the one which was first formed, the outermost was formed the year before the tree was cut down. These zones are at first very soft and tender, and harden by degrees as the tree becomes older: this is the reason that the middle of a tree is so often much better wood than the outside of it.

The proper ligneous part of the wood consists of longitudinal fibres, disposed in fasciculi, and possessed of considerable hardness. It is this longitudinal direction of the fibres that renders it so much easier to cleave wood lengthwise, than across the tree, or in any other direction. See Plant and Vegetable Physiology.

For an account of the ingredients which enter into the composition of wood, see Chemistry Index.

For the Method of Staining or Dying Wood, see TURNING.

For more complete information concerning wood, see also TREE, and Strength of Materials.

Fossil Wood. Fossil wood, or whole trees, or parts of them, are very frequently found buried in the earth, and in different strata, some of which are stone, but more usually in earth; and sometimes in small pieces loose among the gravel. These, according to the time they have lain in the earth, or the matter they have lain among, are found differently altered from their original state; some of them having suffered very little change; and others being so highly impregnated with crystalline, spar, pyritic, or other extraneous matter, as to appear mere masses of stone, or lumps of the common matter of the pyrites, &c. of the dimensions, and, more or less, of the internal figure of the vegetable bodies into the pores of which they have made their way.

The fossil woods have been arranged by Dr Hill into three kinds: 1. The less altered; 2. The pyritic; and, 3. The petrified.

Of the trees, or parts of them, less altered from their original state, the greatest store is found in digging to small depths in bogs, and among what is called peat or turf earth, a substance used in many parts of the kingdom for fuel. In digging among this, usually very near the surface, immense quantities of vegetable matter of various kinds are found buried; in some places there are whole trees scarce altered, except in colour; the oaks in particular being usually turned to a jetty black, the pines and firs, which are also very frequent, are less altered, and are as inflammable as ever, and often contain between the bark and wood a black resin. Large parts of trees have also been not unfrequently met with unaltered in beds of another kind, and at much greater depths, as in strata of clay and loam, among gravel, and sometimes even in solid stone.

Besides these harder parts of trees, there are frequently found also in the peat earth vast quantities of the leaves and fruit and catkins of the hazel and similar trees; these are usually mixed with sedge and roots of grass, and are scarce at all altered from their usual texture. The most common of these are hazel nuts; but there are frequently found also the twigs and leaves of the white poplar, and a little deeper usually there lies a cracked and shattered wood, the crevices of which are full of a bituminous black matter; and among the stones of plums and other stone-fruits are sometimes found, but more rarely.

In this state the fruits and smaller parts of trees are usually found: what we find of them more altered, are sometimes large and long, sometimes smaller and shorter branches of trees; sometimes small fragments of branches, and more frequently small shapeless pieces of wood. The larger and longer branches are usually found bedded in the strata of stone, and are more or less altered into the nature of the stratum they lie in. The shorter and smaller branches are found in vast variety in the strata of blue clay used for making tiles in the neighbourhood of London. These are prodigiously plentiful in all the clay-pits of this kind, and usually carry the whole external resemblance of what they once were, but nothing of the inner structure; their pores being wholly filled, and undistinguishably closed, by the matter of the common pyrites, so as to appear mere simple masses of that matter. These fall to pieces on being long exposed to moisture; and are so impregnated with vitriol that they are what is principally used for making the green vitriol or copperas at Deptford and other places.

The irregular masses or fragments of petrified wood are principally of oak, and are usually found among gravel; though sometimes in other strata. These are variously altered by the inscription of crystalline and stony particles; and make a very beautiful figure when cut and polished, as they usually keep the regular grain of the wood, and show exactly the several circles which mark the different years growth. These, according to the different matter which has filled their pores, assume various colours, and the appearance of the various fossils that have impregnated them; some are perfectly white, and but moderately hard; others of a brownish black, or perfectly black, and much harder; others of a reddish black, others yellowish, and others greyish, and some of a ferruginous colour. They are of different weights also and hardnesses, according to the nature and quantity of the stony particles they contain: of these some pieces have been found with every pore filled with pure pellucid crystal; and others in large masses, part of which is wholly petrified and seems mere stone, while the rest is crumbly and is unaltered wood. That this alteration is made in wood, even at this time, is also abundantly proved by the instances of wood being put into the hollows of mines, as props and supports to the roofs, which is found after a number of years as truly petrified, as that which is dug up from the natural strata of the earth. In the pieces of petrified wood found in Germany, there are frequently veins of spar or of pure crystal, sometimes of earthly substances, and often of the matter of the common pebbles: these fragments of wood sometimes have the appearance of parts of the branches of trees in their natural state, but more frequently they resemble pieces of broken boards; these are usually capable of a high and elegant polish.
Wood.

Many substances, it is certain, have been preserved in the cabinets of collectors, under the title of petrified wood, which have very little right to that name. But where the whole outer figure of the wood, the exact incisions of the bark, or the fibrous and fistular texture of the stric, and the vestiges of the uriculi and trachea or air-vessels, are yet remaining, and the several circles still visible which denoted the several years growth of the tree, none can deny these substances to be real fossil wood. See Petrification.

Dr Parry of Bath has recently investigated the causes of the decay of wood, and the means of preventing it. For this purpose he recommends the application of a preparation of the resinous kind, mixed with a certain portion of bees-wax. The proportion of the ingredients and the mode of mixing them are as follows: Take 12 ounces of resin and 8 ounces of roll brimstone, each coarsely powdered, and 3 gallons of train oil; beat them slowly, gradually adding 4 ounces of bees-wax, cut into small bits. Frequently stir the liquor, which, as soon as the solid ingredients are dissolved, will be fit for use. It is recommended to dress every part of the wood-work with this composition twice over before the parts are put together, and once afterwards; and a higher state of preservation is promised from its use than has yet been attained. It should be observed, that in preparing this varnish, it is advisable, in order to prevent accidents, to use an earthen vessel, and to make the fire in the open air.

Wood (strychna), in Ancient Geography, a multitude of trees extended over a large continued tract of land, and propagated without culture. The generality of woods only consist of trees of one kind.—The ancient Saxons had such a veneration for woods, that they made them sanctuaries.—It is ordained, that none shall destroy any wood, by turning it into tillage or pasture, &c. where there are two acres or more in quantity, on pain of forfeiting 40s. an acre, by 35 Henry VIII. c. 17. All woods that are felled at 14 years growth, are to be preserved from destruction for eight years; and no cattle put into the ground till five years after the felling thereof, &c. 13 Eliz. c. 25. The burning of woods or underwood is declared to be felony; also those persons that maliciously cut or spoil timber-trees, or any fruit-trees, &c. shall be sent to the house of correction, there to be kept three months, and whipt once a month.

Wood, Engraving on, is commonly executed on box; and in many cases, engravings of this kind are used with advantage instead of copperplates. The art of cutting or engraving on wood is of very high antiquity; for Chinese printing is a specimen of it. Even in Europe, if credit be due to Papillon, this art was practised at a very remote period; for he mentions eight engravings on wood, entitled, "A representation of the warlike actions of the great and magnanimous Macedonian king, the bold and valiant Alexander; dedicated, presented, and humbly offered, to the most holy father, Pope Honorius IV. by Alexander Arberic Cunio Chevalier, and Isabella Cunio, &c." This anecdote, if true, carries the art of cutting in wood back to 1284 or 1285; for Honorius occupied the papal throne only during these two years. But this is not the remotest period to which some have carried the art in Europe: for the use of seals or signets being of very high antiquity, they imagine that the invention of wood-cuts must be coeval with them. The supposition is certainly plausible, but it is not supported by proof. The earliest impressions of a wooden-cut, of which there is any certain account, is that of St Christopher carrying an infant Jesus through the sea, in which a hermit is seen holding up a linden to show him the way; and a peasant, with a scythe on his back, climbing a hill, is exhibited in the hill ground. The date of this impression is 1432. In the year 1430 was printed at Haelern, "The history of John the evangelist and his revelation, represented in figures in wood, by Lowrett Janson Cotter;" and in 1438, Jorg Schopp of Augsburg cut in wood the history of the Apocalypse, and what was called The man's bible.

A folio chronicle, published 1493, is adorned with a great number of wood-cuts by William Plydenwurff and Michael Wolgemut, whose engravings were greatly superior to any thing of the kind which had appeared before them. The latter was the preceptor of Albert Durer, whose admirable performances in this department of art are justly held in the highest esteem even at the present day.

About this period it became the practice of almost all the German engravers on copper to engrave likenesses on wood; and many of their wood cuts surpass in beauty the impressions of their copperplates. Such are the wood-cuts of Albert Altdorfer, Hibel Peu, Virgil Soles, Lucas Van Cranach, and Lucas Van Leyden, the friend and imitator of Albert Durer, with several others.

The Germans carried this art to a great degree of perfection. Hans or John Holbein, who flourished in 1500, engraved the Dance of Death, in a series of wooden-cuts, which, for the freedom and delicacy of execution, have scarcely been equalled, and never surpassed. Italy, France, and Holland, have produced capital artists of this kind. Joan Terniisim printed his bible at Leyden, in 1554, with wooden-cuts of excellent workmanship. Christopher Jegher of Antwerp, from his eminence in the art, was employed by Ruben to work under his inspection, and he executed several pieces which are held in much estimation; they are particularly distinguished for boldness and spirit.

The next attempt in improvement in this art was by Hugo du Carpi, to whom is attributed the invention of the chiaro scuro. Carpi was an Italian, and of the 16th century; but the Germans claim the invention also, and produce in evidence several engravings by Mair, a disciple of Martin Schoen, of date 1490. His mode of performing this was very simple. He first engraved the subject upon copper, and finished it as much as the artists of his time usually did. He then prepared a block of wood upon which he cut out the extreme lights, and then impressed it upon the print; by which means a faint tint was added to all the rest of the piece, excepting only in those parts where the lights were meant to predominate, which appear on the specimen extant to be coloured with white paint. The drawings for this species of engraving were made on tinted paper with pen, and the lights were drawn upon the paper with white paint. But there is a material difference between the chiaro scuro of the old German masters and that of the Italians. Mair and Cranach engraved the outlines and deep
deep shadows upon copper. The impression taken in this state was tinted over by means of a single block of wood, with those parts hollowed out which were designed to be left white upon the print. On the contrary, the mode of engraving by Hugo da Carpi was, to cut the outline on one block of wood, the dark shadows upon a second, and the light shadows, or half-tint, upon a third. The first being impressed upon the paper, the outlines only appeared; this block being taken away, the second was put in its place, and being also impressed on the paper, the dark shadows were added to the outlines; and the third block being put in the same place upon the removal of the second, and also impressed upon the paper, made the dim tints, when the print was completed. In some instances, the number of blocks was increased, but the operation was still the same, the print receiving an impression from every block.

In 1698, John Baptist Michael Papillon practised engraving on wood with much success, particularly in ornamental foliage and flowers, shells, &c. In the opinion, however, of some of the most eminent artists, his performances are stiff and cramped. From that period the art of engraving on wood gradually degenerated, and may be said to have been wholly lost, when it was lately re-invented by Mr Bewick of Newcastle. This eminent artist was apprentice to Mr Bieby, a respectable engraver on metal. Mr Bieby, who was accustomed to employ his apprentices in engraving on wood, was much gratified with the performances of Thomas Bewick, and therefore advised him to prosecute engraving in that line. The advice was followed; and young Bewick inventing tools, even making them with his own hands, and saving the wood on which he was to work into the requisite thickness, proceeded to improve upon his own discoveries, without assistance or instruction of any kind. When his apprenticeship expired, he went to London, where the obscure wood engravers of the time wished to avail themselves of his abilities, while they were determined to give him no insight into their art. During his apprenticeship, he received from the Society for the Encouragement of Arts, &c. a premium of considerable value for the best engraving on wood.

The cut which obtained the premium was one of a series for an edition of Gay's Fables. Having remained some years in London, he returned to Newcastle, and entered into copartnership with his old master; and established his reputation as an artist by the publication of his admirable History of Quadrupeds. This was followed by his History of Birds, in 2 vols. The greater part of the volume on Quadrupeds, and the whole of the first volume of the work on Birds, was composed by Mr Bieby.

John Bewick, brother to Thomas, learned the art of him, and practised it for several years in London with great applause. His abilities, however, though respectable, were not, by the best judges, deemed so brilliant as his brother's; and one of the chief men, he was not to had health, and the nature of his connection with the booksellers and others, he seems not to have advanced the art beyond the stage at which he received it. He died, some years ago, at Newcastle.

Mr Nesbit, who executed the admirable cuts from designs by Thornton, for an edition of Hudibras, as well as the cuts for editions of Shakespeare and Thomson's Seasons, and Mr Anderson, whose beautiful cuts

adorn the poem entitled Grove Hill, have been the most successful of Thomas Bewick's pupils, who have appeared before the public as artists. It appears, that the method practised by the ancient engravers on wood, whose works are still admired, must have been different from that of Bewick and his pupils. What that method was seems to be altogether unknown. Papillon, who writes the best history extant of the art, guesses indeed in what manner the old engravers proceeded, so as to give to their works the spirit and freedom for which they are famed; but that his guesses are erroneous seems evident from the stiffness of his own works. The principal characteristic in the mechanical department of the production of the ancient masters is the crossing of the black lines, which Papillon has attempted with the greatest awkwardness, though it seems to have been accomplished by them with so much ease, that they introduced it at random, even where it could add nothing to the beauty of the piece. In Bewick's method of working, this cross hatching is so difficult and unnatural, that it may be considered as impracticable. Mr Nesbit has indeed introduced something of it into two or three of his pieces; but so great was the labour, and so little the advantage of this improvement, if such it can be called, that probably it will not be attempted again.

The engravers of Bewick's school work on the end of the wood, which is cut across the trunk of the tree, in pieces of the proper thickness. As wood cuts are generally employed in the printer's press amidst a form of types, this thickness must be regulated by the height of the types with which they are to be used. The tools employed are nearly the same with those used in copperplate engraving, being only a little more deep, or lozenge, as engravers call it. They must have points of various degrees of fineness for the different purposes to which they are applied, some of them being so much rounded off at the bottom as to approach to the nature of a goodle, whilst others are in fact little chisels of various sizes. These chisels and goodles, to which every artist gives the shape which he deems most convenient, are held in the hand in a manner somewhat different from the tool of the engraver on copper, it being necessary to have the power of lifting the chips upwards with ease. To attempt a description of this in writing would be in vain; but it is easily acquired, we are told, by practice.

The pupils of the school of Bewick consider it as quite improper to speak of his invention as a revival of the ancient art. Some old prints, it is true, have the appearance of being executed in the same way with his; but others have certainly been done by a method very different. It is therefore not fair to appreciate the present art by what has been done, but by what may be done; and that remains yet to be shown. The art is in its infancy; and those who are disposed to compare it with the art of engraving on copper, ought to look back to the period when copperplate engraving was of as recent invention as Bewick's method of engraving on wood. Marc Antonio, who engraved under the direction of the great painter Raphael, thought it no mean proof of his proficiency in his art, that he was able to imitate on copperplates the wood-cuts of Albert Durer; and Papillon is highly indignant that there should have been persons so very blind as to mistake the copies for the originals. If copper has its advantages
Wood

Wood is a material derived from the trunk and branches of trees, and it is a key component in the construction of many structures and objects. The properties of wood vary depending on the type of tree and the method of processing. Wood can be used in a variety of ways, including as a building material, furniture, and various other products.

Before the advent of modern chemistry, wood was a natural resource that was widely used for various purposes. The ability of wood to absorb and retain moisture made it a popular choice for building materials. However, the properties of wood can change over time, and it is important to understand how wood interacts with its environment.

Wood can be affected by moisture, temperature, and other environmental factors. For example, wood that is exposed to moisture can expand and contract, which can cause it to warp or crack. Similarly, wood that is exposed to high temperatures can be damaged or even burned.

In conclusion, wood is a versatile material that has been used throughout history for a variety of purposes. Understanding the properties of wood is important for anyone who works with this material, whether they are a carpenter, architect, or simply someone who values the beauty and functionality of wood.

Wood has been used for centuries in the construction of buildings, furniture, and other objects. It is a renewable resource that can be sustainably harvested and used for many different purposes. The properties of wood can be affected by moisture, temperature, and other environmental factors, and it is important to understand how these factors can impact the performance of wood in different applications.

Wood is also a material that is highly valued for its aesthetic qualities. The natural beauty of wood can add a sense of warmth and elegance to any space, and it is a popular choice for use in interior design and decoration.

In conclusion, wood is a versatile and valuable material that has many different applications. By understanding the properties of wood and how it can be used effectively, we can continue to appreciate and utilize this natural resource in new and innovative ways.
WOOD-PECKER. See PICUS. ORNITHOLOGY Index.

WOODMOTE. See FOREST COURTS.

WOODSTOCK, a town of Oxfordshire, in England, pleasantly seated on a rising ground, and on a rivulet; a well-compacted borough-town, and sends two members to parliament; but is chiefly noted for Blenheim-house, a fine palace, built in memory of the victory obtained by the duke of Marlborough over the French and Bavarians in August 1704. It was erected at the public expense, and is one of the noblest seats in Europe. One of the passages to it is over a bridge with one arch, 120 feet in diameter, resembling the Rialto at Venice. The gardens take up 100 acres of ground; and the offices, which are very grand, have room enough to accommodate 500 people. The apartments of the palace are magnificently furnished; and the staircases, statues, paintings, and tapestry, surprisingly fine. The town is about half a mile from the palace, having several good inns; and a manufacture of steel chains for watches, and excellent gloves. A steel chain has been made at this place which sold for 170l. — The population in 1811 was 1,419 persons. It is eight miles north of Oxford, and 60 west-north-west of London. W. Long. 1° 30'. N. Lat. 52° 52'.

With this brief, Dr. John was born in 1665, and educated at a country school, where he learned the Latin and Greek languages, and was afterwards sent to London, where he is said to have been put apprentice to a linen-draper. He was not long in that station, till he became acquainted with Dr. Peter Warvick, an eminent physician, who took him under his tuition and into his family. Here he prosecuted with great vigour and success the study of philosophy, anatomy, and physic. In 1692, Dr. Stricklen, of Gresham College, our author was chosen to succeed him, and the year following was elected F. R. S. In 1695, he obtained the degree of M. D. by patent from Archbishop Tenison; and the same year he published his Essay towards a Natural History of the Earth. He afterwards wrote many other pieces, which have been well received by the learned world. He founded a lectureship in the University of Cambridge, to be read there upon his Essay, &c. and handsomely endowed it. He died in 1728.

WOOF, among manufacturers, the threads which the weavers shoot across with an instrument called the shuttle. See CLOTH.

WOOKY or OKY HOLE, a remarkable cavern two miles from the city of Wells in Somersetshire; for an account of which, see the article GROTTO.

WOOL, the covering of sheep. See OVIS and SHEEP.

Wool resembles hair in a great many particulars; but besides its fineness, which constitutes an obvious difference, there are other particulars which may serve also to distinguish them from one another. Wool, like the hair of horses, cattle, and other animals, completes its growth in a year, and then falls off as hair does, and is succeeded by a fresh crop. It differs from hair, however, in the uniformity of its growth, and the regularity of its shedding. Every filament of wool seems to keep exact pace with another in the same part of the body of the animal; the whole crop springs up at once; the whole advances uniformly together; the whole loosens from the skin nearly at the same period, and thus falls off, if not previously shorn, leaving the animal covered with a short coat of young wool, which in its turn undergoes the same regular mutations.

Hairs are commonly of the same thickness in every part; but wool constantly varies in thickness in different parts, being generally thicker at the points than at the roots. That part of the fleece of sheep which grows during the winter is finer than what grows in summer. This was first observed by Dr. Anderson, the editor of the Bee, and published in his Observations on the Means of exciting a Spirit of National Industry.

While the wool remains in the state it was first shorn off the sheep's back, and not sorted into its different kinds, it is called fleece. Each fleece consists of wool of divers qualities and degrees of fineness, which the dealers therein take care to separate. The French and English usually separate each fleece into three sorts, viz. 1. Mother-wool, which is that of the back and neck. 2. The wool of the tails and legs. 3. That of the breast and under the belly. The Spaniards make the like division into three sorts, which they call prime, second, and third; and for the greater ease, mark each bale or pack with a capital letter, denoting the sort. If the tripe or separation be well made, in 15 bales there will be 12 marked A, that is, refine, or prime; two marked F, for fine, or second; and one S, for thirds.

The wools most esteemed are the English, chiefly those about Leominster, Cotswold, and the Isle of Wight; the Spanish, principally those about Segovia; and the French, about Berry: which last are said to have this peculiar property, that they will knot or bind with any other sort; whereas the rest will only knot with their own kind.

Among the ancients, the wools of Attica, Megara, Larissa, Apulia, and especially those of Tarentum, Parma, and Altino, were most valued. Varro assures us, that the people there used to clothe their sheep with skins, to secure the wool from being damaged.

Of late a great deal of attention has been paid to wool in this country, as well as several others. Several very spirited attempts have been made to improve it, by introducing superior breeds of sheep, and better methods of managing them. For this purpose has been formed the British Wool Society, an association formed for the purpose of obtaining the best breeds of fine-wooled sheep, with a view of ascertaining, by actual experiments, how far each species or variety is calculated for the climate of Great Britain; the qualities of their wool respectively; the uses to which each kind of wool could be most profitably employed in different manufactures; and the comparative value of each species of sheep, so far as the same can be determined.

Attention had for some time been paid by the Highland Society to a famous breed of fine-wooled sheep in Scotland; but it occurred to Sir John Sinclair, of Ulster, baronet, and to Dr. James Anderson, who are among the author of many useful publications, that the improvement of British wool was a matter of too much importance to be entrusted to a society which is obliged to devote its attention to such a variety of objects as the general improvement of the Highlands of Scotland. The latter of these gentlemen, therefore, in an Appendix to the Report of the Committee of the Highland Society...
Wool. Society of Scotland, for the year 1790, proposed the plan of a patriotic association for the improvement of British wool; and the former, who was convener of the committee to whom the subject of Shetland wool had been referred, wrote circular letters, recommending the plan. The consequence of which was, that on the 31st of January 1791, several noblemen and gentlemen of the highest respectability met in Edinburgh, and constituted themselves into a Society for the Improvement of British Wool. Of this society Sir John Sinclair was elected president; after which, in an excellent speech, he pointed out to the members the objects of the institution, the means by which those objects could be attained, and the advantages which would result from their united labours. This address was afterwards printed by order of the society.

The particular breeds of sheep to which the society proposed to direct its attention, were sheep for the hilly parts of Scotland; sheep for the plains, or the Lowland breed; and sheep for the islands. They were to try experiments also with sheep from foreign countries, distinguished by any particular property.

The principal objects which the members had in view, during the first year of their association, were: 1. To collect specimens of the best breeds which Great Britain at that period afforded, in order to ascertain the degree of perfection to which sheep had already been brought in this kingdom. 2. To procure from every country, distinguished for the quality of its sheep and wool, specimens of the different breeds it possessed, in order to ascertain how far the original breed, or a mixed breed from it and the native sheep of the country, could thrive in Scotland. 3. To disperse as much as possible all these breeds, both foreign and domestic, over the whole kingdom, wherever proper persons could be found to take charge of them, in order to try experiments on a more extensive scale than the society itself could do, to spread information, and to excite a spirit for the improvement of sheep and wool in every part of the country.

Sir John Sinclair had previously collected a flock, consisting of sheep of the Spanish, Herefordshire, Southdown, Cheviot, Lomond hills, and Shetland breeds, and of a mixed breed from these different sheep. This flock amounted to 110 rams, ewes, and lambs. M. d'Aubenton, in consequence of a correspondence with Sir John Sinclair, sent over to the society ten rams and five ewes, of real Spanish breed, which had been originally entrusted to his care by the late king of France: these, after encountering a number of obstacles, and after being stopped and threatened to be slaughtered at the customhouse of Brighthelmstone for the use of the poor, arrived safe at Leith. Lord Sheffield, at the same time, sent to the society four rams and six ewes of the Southdown and Spanish breeds. Mr. Bilton of Kiltsall, in Shropshire, presented them with three Hereford rams, reckoned by many the best breed in England; the society at the same time ordered 150 ewes of the same breed, and two ewes of the Long Mountain breed, reckoned the best in Wales, to be sent along with them. They purchased 57 rams and 173 ewes of the Cheviot breed, the best in Scotland, for the hilly parts excellent breed, which existed at Mochrum in Galway. The late earl of Oxford sent them in a present three rams of the Norfolk crossed by the Cape of Good Hope breed. Mr. Isaac Grant, junior of Leaton, in conjunction with Mr. Sibbald, merchant at Leith, presented them an Apulian ram and ewe; the ram armed in saftly, but the ewe unfortunately died on the passage. Mr. Baron Seton of Preston, in Linlithgowshire, sent them a ram and two ewes of a Spanish breed, which had been for some time kept in Sweden among any other. They purchased 100 ewes of a small breed existing in the parish of Leuchars in Fife, much resembling the Shetland. The Right Honourable William Conynghame of Ireland sent them 11 Spanish, seven Spanish ewes, 15 three-fourth breed and 16 half-breed Spanish and Irish ewes. Lord Sheffield sent them eight rams and 18 ewes; and his majesty took a present of two rams.

Thus, in the course of one year, the society, by donation or purchase about 500 sheep of different sorts and ages, and many of them from foreign countries: about 150 of these were distributed over different parts of Scotland, the greater number of which were sold to gentlemen anxious to promote the views of the society, and well qualified to make experiments on different breeds which they had obtained. The greatest part of the remainder were taken by different pottlers, who kept them for the society, and according to their directions, without any expense.

It is impossible to produce an instance of Mr. Kerr, a very intelligent sheep-farmer on the borders of England, was sent, at the expense of the society, to examine the state of sheep-farming along the east coast of Scotland and the interior parts of the Highlands. His tour was printed by order of the society, and contains the first intimation of the possibility of the Cheviot breed thriving in the north of Scotland.

In the year 1792, Messrs. Redhead, Laing, and Marshall were sent by the society, to make a survey of the state of sheep-farming through some of the principal counties of England; the result of which was also published by the society, and contains more information on the subject of the different breeds of England that any work hitherto published; and in 1794, Mr. John Nisam, who was sent on a tour through the southern districts of Scotland, which completed the circuit of almost the whole kingdom.

Thus a few private individuals, unaided by the public purse, had boldness enough to undertake ascertaining the comparative value of the different kinds of sheep in their own country, and to introduce some of the most celebrated breeds of other countries, and succeed in the spirited attempt. It is impossible in this place state more minutely the various other transactions of the society; to enter into any detail of the premiums given by this respectable institution for the improvement of the celebrated Shetland breed; to explain how, as if it were by magic, in a country where the manufacture of wool was little known, articles manufactured of that material were made, rivaling, and in some cases surpassing, the most celebrated fabrics of other countries. A war having unfortunately arisen, it became impossible to pay the same attention, or to carry on with the same success, novel enterprises; yet
old establishments often fall a sacrifice amid the horrors of war. The utmost that the British Wool Society could expect to do was to preserve the institution in such a state, that when peace shall be happily restored it may revive with double energy and spirit.

It is a curious fact that the Romans, during their residence in Britain, established a manufactory of woollen cloth at Winchester, which was so extensive as to supply their army; and there is reason to believe that the trade which they introduced into Britain, was not neglected by the native inhabitants, for the first 900 years of the Christian era. The long Spanish wool was imported into this country so early as the 12th century, and we find that since the days of Edward III. British fleeces were admirably adapted to the kind of cloth which was in greatest request, though now they are generally unequal to the production of that which is sought after.

Wool-combing, a well known operation, which when performed by the hand, is laborious, tedious, and expensive. The expense of it through all England has been calculated at no less a sum than 800,000; and to lessen this expense, the Rev. Edmund Cartwright of Doncaster in Yorkshire bethought himself, some years ago, of carding wool by machinery. After repeated attempts and improvements, for which he took out three patents, he found that wool can be combed in perfection by machinery, of which he gives the following description.

Fig. 1. is the crank lasher. A is a tube through which the material, being formed into a sliver, and slightly twisted, is drawn forward by the delivering rollers; B, a wheel fast upon the cross bar of the crank; C, a wheel, on the opposite end of whose axis is a pinion working in a wheel upon the axis of one of the delivering rollers.

Note. When two or more slivers are required, the cans or baskets, in which they are contained, are placed upon a table under the lasher (as represented at D), which, by having a slow motion, twist them together as they go up.

Fig. 2. is the circular clearing comb, for giving work in the head, carried in a frame by two cranks. Fig. 3. the comb-table, having the teeth pointing towards the centre, moved by cogs upon the rim, and carried round upon trucks like the head of a windmill. a, b, The drawing rollers. c, d, Callendar, or conducting rollers.

Note. Underneath the table is another pair of rollers, for drawing out the backings.

In the above specification, we have omitted the frame in which the machine stands, the wheels, shafts, &c. Had these been introduced, the drawing would have been crowded and confused; besides, as matters of information, they would have been unnecessary, every mechanical, when he knows the principles of a machine, being competent to apply the movements to it.

The wool, if particularly nice work, goes through three operations, otherwise two are sufficient: the first operation opens the wool, and makes it connect together into a rough sliver, but does not clear it. The clearing is performed by the second, and, if necessary, a third operation. A set of machinery, consisting of three machines, will require the attendance of an overlooker and ten children, and will comb a pack, or 240lb. in twelve hours. As neither fire nor oil is necessary for machine-combing, the saving of those articles, even the fire alone, will, in general, pay the wages of the overlooker and children; so that the actual saving to the manufacturer is the whole of what the combing costs, by the old imperfect mode of hand-combing. Machine-combed wool is better, especially for machine-spinning, by at least 12 per cent. being all equally mixed, and the slivers uniform, and of any required length.

WOOLSTON, Thomas, an English divine, was born at Northampton in 1669, and educated at Cambridge. His first appearance in the learned world was in 1704, in a work entitled, the Old Apology for the Truth of the Christian Religion, against the Jews and Gentiles, revived. He afterwards wrote many pieces: but what made the most noise, were six Discourses on the Miracles of Christ; which occasioned a great number of books and pamphlets upon the subject, and raised a prosecution against him. At his trial in Guildhall, before the lord chief justice Raymond, he spoke several times himself; and urged, that "he thought it very hard that he should be tried by a set of men who, though otherwise very learned and worthy persons, were no more judges of the subjects on which he wrote, than himself was a judge of the most crabbed points of the law." He was sentenced to a year's imprisonment, an at present. He purchased the liberty of the King's bench, where he continued after the expiration of the year, being unable to pay the fine. The greatest obstruction to his deliverance from confinement was, the obligation of giving security not to offend by any future writings, he being resolved to write again as freely as before. Whilst some supposed that this author wrote with the settled intention of subverting Christianity under the pretence of defending it, others believed him disordered in his mind; and many circumstances concurred which gave countenance to this opinion. He died, January 27, 1732-3, after an illness of four days; and, a few minutes before his death, uttered these words: "This is a struggle which all men must go through, and which I have borne only patiently, but with willingness." His body was interred in St George's church-yard, Southwark.

WOOLWICH, a town in Kent, with a market on Fridays. It is seated on the river Thames, and of great note for its fine docks and yards, where men of war are built; as also for its vast magazines of great guns, mortars, bombs, cannon-balls, powder, and other warlike stores. It has likewise an academy, where young officers are instructed in the military arts; the population in 1801 exceeded 9000. It is nine miles east of London. E. Long. 0° 10. N. Lat. 51° 30'.

WORCESTER, in Latin Wigornia, the capital of a county of England of the same name, stands on the river Severn, but so low that it can hardly be seen till one is close upon it. It is supposed to be the Branonium of Antoninus, the Brangoneminium of Ptolemy, and to have been built by the Romans to awe the Britons on the other side of the Severn. It was made an episcopal see about the year 680 by Sexulfius bishop of the Mercians; but the present cathedral was begun by Wulstan in the year 1084. The town hath been several times burnt down; first, in 1041, by Hardicanute, who also massacred the citizens; secondly, not long after William Rufus's time; and a third time, when King Stephen besieged and took it. Here, in latter times,
Worcester was fought that battle, in which Charles II, with his Scots army, was defeated by Cromwell. In a garden near the south gate of the city, where the action was hottest, the bones of the slain are often dug up. It had formerly strong walls and a castle; but these have been demolished long ago. It is now a large city, the streets broad and well paved, and some of them very regular and well built, particularly Foregate-street; so that in general, it is a very agreeable place. The cathedral is a stately edifice, and among other monuments in it are those of King John, of Arthur, elder brother to Henry VIII, and of the countess of Salisbury, who gave occasion to the institution of the order of the Garter. There are seven or eight hospitals in and about the city; of which that built and endowed by Robert Berkeley of Speckley, Esq, is a very noble one. There is a school founded by Henry VIII, three other schools, and six charity-schools. The churches, St Nicholas and All Saints, have been lately rebuilt, and are handsome edifices. The city carries on a great trade; for which it is chiefly indebted to its situation upon the Severn. The population in 1801 was estimated at 11,000, a large proportion of which is employed in the manufacture of broad cloth and gloves. The Welsh inhabit a part of it, and speak their own language. Its market is well supplied with provisions and cattle, and its quay is much frequented by ships. By a charter from James I, it is governed by a mayor, six aldermen who are justices of the peace, and chosen out of 24 capital citizens; a sheriff, the city being a county of itself; a common council, consisting of 48 other citizens, out of which two chamberlains are yearly chosen; a recorder, town-clerk, two coroners, a sword-bearer, 13 constables and four sergeants at mace. Of the bishops of this see, there have been, it is said, one pope, four saints, seven lord high chancellors, 11 archbishops, two lord treasurers, one chancellor to the queen, one lord president of Wales, and one vice-president. The city at present gives title of earl and marquis to the duke of Beaufort.

W. Long. 1. 55. N. Lat. 52. 10.

Worcester, Edward Somerset, Marquis of, was a distinguished political character in the time of Charles I, by whom he was created earl of Glamorgan, while heir apparent to the marquis of Worcester. This nobleman flourished chiefly in the reign of Charles I, and seems to have been a most zealous adherent to the cause of the unfortunate monarch, on whose account it is said that he and his father wasted an immense sum. Of this the king was so sensible, that he granted to the earl a most extraordinary patent, the chief powers of which were, to make him generalissimo of three armies, and admiral with nomination of his officers; to enable him to raise money by selling his majesty's woods, wardships, customs, and prerogatives; and to create by blank patents, to be filled up at Glamorgan's pleasure, from the rank of marquis to baronet. If any thing, says Lord Orford, could justify the delegation of such authority, besides his majesty having lost all authority, when he conferred it, it was the promise with which the king concluded, som. This patent was given up by the marquis to the after that era, in 1667; after he had published what Lord Orford calls the following amazing piece of folly.

"A century of the names and scannings of such inventions, as at present I can call to mind to have had and perfected, which (my former notes being lost) I have, at the instance of a powerful friend, endeavoured now in the year 1655, to set down in such a way as may sufficiently instruct me to put any of them in practice."

Some of the inventions referred to in this work are the following. A ship-destroying engine, a couch-piping engine, a balance water-work, a bucket cistern, an ebbing and flowing castle clock, a tinder-box piot, a pocket ladder, a most admirable way to raise weight, a stupendous water-work. For the last contributing the marquis procured an act of parliament in 1665, by which the sole benefit arising from it, one-third of it being appropriated to Charles II. and his successors.

In a manuscript addition to a copy of the Century of Inventions, the stupendous or water-commanding engine is described as boundless for height or quantity, raising no external, or even additional help or force in a set or continued in motion, but what intrinsically is afforded from its own operation, nor yet the twofold part thereof, and the engine consisteth of the following particulars. 1. A perfect counterpoise for what quantity soever of water. 2. A perfect counterpoise, for the height soever it is to be brought unto. 3. A piston mobile, commanding both height and quantity, regulat-er-wise. 4. A viscerger or counterval, supplying the place, and performing the full force of man, beast, or mill. 5. A helm or stern, with hole and ears, whereby any child may guide, order, and control the whole operation. 6. A particular magazine for water, according to the intended quantity or height of water. 7. A place for the original fountain, or an river to run into, and naturally of its own accord incor-porate itself with the rising water and at the very bottom of the same aqueduct, though never so big or high.

Various and very opposite opinions have been held with regard to the title of this nobleman to be consid-ered as a mechanical genius. Lord Orford has pronouced his work an amazing piece of folly; and Mr Hume, speaking of his political conduct, says, "That the king judged aright of this nobleman's character, speaking from his Century of Arts, or Scantling of inventions, which is a ridiculous compound of impossibilities, and shows what might be expected from such a man." Hist. of England. It may be fairly presumed from the quotations now made, that neither Lord Orford nor Mr Hume was qualified to judge of the marquis's work, otherwise a more temperate or a more modified opinion would have been given. By others, the author of the inventions has been regard-ed as one of the greatest mechanical geniuses, and is to be considered as the inventor of the steam-engine, which he denominates a stupendous water-work. That seems to be no reason to suppose that any steam-engine was erected by the marquis himself, but it is said the Captain Savary, after reading the marquis's book, tried many experiments upon the power and force of steam, and at last fell upon a method of applying it to raise water; and having built it up and destroyed all the marquis's books that could be got, claimed the honour of the invention to himself, and obtained a pa-tent for it.
Worcester The marquis of Worcester is sometimes confounded with John Tiptofi, earl of Worcester, a very accomplished literary character, who lived in the times of Henry VI. and Edward IV. Being attached to Edward, he absconded during the short restoration of Henry, and being taken concealed in a tree in Way Bridge forest in Huntingdonshire, he was brought to London, accused of cruelty in his administration of Ireland, and condemned and beheaded at the Tower in the year 1470.

This nobleman translated Cicero de Amicitia, some parts of Caesar's Commentaries, and was the author of several other works.

Worcestershire, a county of England, bounded by Warwickshire on the east, by Gloucestershire on the south, by the counties of Hereford and Salop on the west, and on the north by Staffordshire. According to Templeman, it is 36 miles in length, 28 in breadth, and about 150 in circumference, within which it contains seven hundred, and a part of two others, 11 market towns, of which three are boroughs, one city, namely Worcester, 152 parishes, about 540,000 acres, and in 1811, 160,546 inhabitants.

This being an inland county, well cultivated, and free from lakes, marshes, or stagnant waters, the air is very sweet and wholesome all over it. The soil in general is very rich, producing corn, fruit, especially pears, of which they make a great deal of perry, peas, and pasture. The hills are covered with sheep, and the meadows with cattle. Hence they have wool, cloth, stuffs, butter, and cheese in abundance. They are also well supplied with fuel, either wood or coal, and salt from their brine pits and salt springs. Of the last they have not enough for themselves, but export large quantities by the Severn; which noble river, to the great convenience and emolument of the inhabitants, runs from north to south through the very middle of the county, enriching the soil, and yielding it plenty of fish, and an easy expedient conveyance of goods to and from it. It is also watered by the Stour, Avon, Teme, &c. It sends nine members to parliament, viz. two for the town, two for the county, two for the city of Worcester, two for Droitwich, two for Evesham, and one for Bewdley; and lies in the diocese of Worcester, and Oxford circuit.

See Worcestershire, Supplement.

Word, in language, an articulate sound designed to represent some idea or notion. See Grammar and Language. See also Logic, Part I. chap. I.

Word, or Watch-word, in military affairs, is some peculiar word or sentence, by which the soldiers know and distinguish one another in the night, &c. and by which spies and designing persons are discovered. It is used also to prevent surprises. The word is given out in an army every night to the lieutenant or major-general of the day, who gives it to the majors of the brigades, and they to the adjutants; who give it first to the field-officers, and afterwards to a sergeant of each company, who carry it to the subalterns. In garrisons it is given after the gate is shut to the town-major, who gives it to the adjutants, and they to the sergeants.

Signals by the Drum, made use of in exercising of the Army, instead of the Word of Command, viz.

Signals by the drum. Operations.
A short roll, To caution.
A flam, To perform any distinct thing.
To arms, To form the line or battalion.
The march, To advance, except when intended for a salute.
The quick march, To advance quick.
The point of war, To march and charge.
The retreat, To retreat.
Drum ceasing, To halt.
Two short rolls, To perform the flank firing.
The dragoon march, To open the battalion.
The grenadier march, To form the column.
The troop, To double divisions.
The long roll, To form the square.
The grenadier march, To reduce the square to the column.
The preparative, To make ready and fire.
The general, To cease firing.
Two long rolls, To bring or lodge the colours.

Work, in the manage. To work a horse, is to exercise him at pace, trot, or gallop, and ride him at the manage. To work a horse upon voits, or head and haunches in or between two heels, is to passage him, or make him go sideways upon parallel lines.

To work, in sea language, is to direct the movements of a ship, by adapting the sails to the force and direction of the wind. See Seamanship.

Work, Carpenters, Clock, Crown, Field, Fire, Fret, Grotesque, Horn, Mosaic. See the several articles, together with Fortification and Pyrotechny.

Work-house, a place where indigent, vagrant, and idle people, are set to work, and supplied with food and clothing.

Work-houses are of two kinds, or at least are employed for two different purposes. Some are used as prisons for vagrants or sturdy beggars, who are there confined and compelled to labour for the benefit of the society which maintains them; whilst others, sometimes called poor-houses, are charitable asylums for such indigent persons as through age or infirmity are unable to support themselves by their own labour. The former kind of work-house, when under proper management, may be made to serve the best of purposes; of the latter we are acquainted with none which entirely commands our approbation.

To make confinement in a work-house operate to the correction of vagrants and disorderly persons (and if it produce not this effect it can hardly be considered as a beneficial institution), the prisoners should be shut up in separate cells, and compelled to labour for their own subsistence. A crew of thieves and vagabonds associating with each other is a hell upon earth, in which every individual is hardened in his crimes by the countenance and conversation of his companions; and wretches who, when at liberty, choose to beg or steal rather than to earn a comfortable livelihood by honest industry, will submit to any punishment which a humane overseer can inflict rather than work for the benefit of others. No punishment indeed will compel a vagrant to labour. He may assume the appearance of it, but he will make no progress; and the pretext of sickness or weakness is ever at hand for an excuse. Hence it is that thieves and strumpets.
Work-houses erected as charitable asylums appear to us, in every view that we can take of them, in situations which can serve no good purpose. Examples of the great motive which inclines people to this mode of providing for the poor. There is comparatively but a very small number of mankind in any country so apt and innfirm as not to be able to contribute, in some degree, to their subsistence by their own labour; and a such houses it is thought that proper work may be provided for them, so that the public shall have nothing to give in charity but what the poor are absolutely made to procure for themselves. It is imagined likewise, that numbers collected at a common table, can be maintained at less expense than in separate houses; and if soldiers are given for an example, who could not live their pay if they did not meet together. But these are not parallel. "Soldiers having the management of their pay, can club for a bit of meat; but as the inhabitants of the poor-house are maintained by the public, the same quantity of provisions must be allotted to each. The consequence is what might be expected: the bulk of them reserve part of their victuals for purchase or spirits. It is vain to expect work from them; poor wretches void of shame will never work seriously when the profit accrues to the public, not to themselves. Hunger is the only effectual means for compelling such persons to work."

The poor, therefore should be supported in their own houses; and to support them properly, the first thing to be done is, to estimate what each can earn by his own labour; for as far only as that falls short of maintenance, is there room for charity. In repining those evils which society did not or could not prevent, it ought to be careful not to counteract the wise purposes of nature, nor to do more than to give the poor a fair chance to work for themselves. The present distress must be relieved, the sick and the aged provided for; but the children must be instructed and labor. not aim, offered to those who have some ability to work, however small that ability may be. They will be as industrious as possible, because they work for themselves; and a weekly sum of charity under their own management will turn to better account than in a poor-house under the direction of mercenaries. Not a penny of it will be laid out on fermented liquors, unless perhaps as medicine in sickness. Nor does such low fare call for pity to those who can afford no better. All makes no part of the maintenance of those who, in many parts of Scotland, live by the sweat of their brows; and yet the person who should banish ale from a charity work-house, would be exclaimed against as hard-hearted, and even void of humanity.

That such a mode of supporting the poor in their own houses is practicable, will hardly admit of a dispute; for it has been actually put in practice in the city of Hamburg ever since the year 1788. At that period such revenues as had till then been expended in alms by the several church-warden, and those of which the administration had been connected with the work-house, were united under one administration with such sums as were collected from private benevolence. The city was divided into sixty districts, containing each an equal
equal number of poor; and over these 180 overseers were appointed. Actual relief was the first object; but at the very moment that this provision was secured, measures were taken to prevent any man from receiving a shilling which he could have been able to earn for himself. By these methods, which our limits will not permit us to state, the overseers were able to make a calculation tolerably exact of what each pauper wanted for bare subsistence, in addition to the fruits of his own labour. A flax-yarn-spinning manufacture was established, in which the yarn is paid for, not by its weight, but by its measure. The clean flax is sold to the poor at a low price, and a certain measure of yarn again bought from them at 30 per cent. above the usual price; so that the overseers are sure that all the yarn spun by the poor will be brought into their office. Every pauper brings with him a book in which the quantity delivered is carefully noted down, which furnishes the overseers with a continual average of the state of industry among the poor.

As soon as this institution was established, the overseers went through their districts, and asked, in all such mansions as could be supposed to harbour want, if the inhabitants stood in need of support? The question to all such poor as wished for relief, and were able to spin, was, Whether they did earn by their work 1s. 6d. a week? for experience had taught the inhabitants of Hamburg, that many poor live upon that sum; and they knew enough of their poor to suppose, that 1s. 6d. avowed earning was equal to something more. If the answer was affirmative, the pauper stood not in need of weekly assistance. If it was negative, work was given him, which, by being paid 30 per cent. above its value, afforded him 1s. 6d. a week easily, if he was ever so indifferent hand. The far more frequent cases were partial inability by age, or weakness, or want of skill. For poor of the latter description a school was opened, and in three months time the business was easily learnt. During that time, the pauper got first 2s. a week, and every week afterward 2d. less, till in the twelfth week he got nothing at all but his earnings, and was dismissed, with a wheel and a pound of flax gratis.

The quantity of work which disabled paupers were capable of doing in a week was easily and accurately ascertained by a week's trial in the spinning-school. The result was produced weekly before appointed members of the committee, and the sum which the poor could earn was noted down in their small books. The overseer was directed to pay them weekly what their earnings fell short of 1s. 6d. in every such week, when it appeared from their books that they had earned to the known extent of their abilities. From that moment applications became less frequent; and the committee had an infallible standard for distinguishing real want; whenever the pauper, if in health (if not, he was peculiarly provided for), had not earned what he could, then he had either been lazy, or had found more lucrative work; in either case, he was not entitled to a relief for that week, whatever he might be for the following.

This mode of providing for the poor, which attracted the notice and obtained the eulogium of the minister and the British house of commons, has for six years been in Hamburg attended with the happiest consequences. In the streets of that city a beggar is rarely to be seen, whilst those who stand in need of the charitable contributions of the rich, are much more comfortably, as well as at much less expense, maintained at home, with their children about them, than they could be in work-houses, under the management of mercenary overseers. For a fuller account of this judicious institution, we must refer our readers to Voght's Account of the Management of the Poor in Hamburg, since the year 1788, in a Letter to some Friends of the Poor in Great Britain.

WORLD, the assemblage of parts which compose the globe of the earth. See GEOGRAPHY and ASTROLOGY.

WORM, in Gunner's, a screw of iron, to be fixed on the end of a rammer, to pull out the wood of a firelock, carabine, or pistol, being the same with the wad-book, only the one is proper for small arms, and the other for cannon.

Worm, in Chemistry, is a long winding pipe, placed in a tub of water, to cool and condense the vapours in the distillation of spirits.

Blind-Worm, or Slow-Worm. See ANGUILL, ERPETOLOGY INDEX. Earth-Worm. See LUMBRICUS, HELMINTHLOGY INDEX.

Glow-Worm. See LAMPRUS, ENTOMOLOGY INDEX. Silk Worm. See SILK, No. 5.

WORMS, VERMES. See HELMINTHLOGY and CONCHOLOGY.

Worms, in the human body. See MEDICINE, No. 407.

Worms, in horses. See FARRIER.

Worms, in dogs. See FISHING.

Worms, an ancient and famous city of Germany, with a bishop's see, whose bishop was formerly a sovereign and prince of the empire. It is a free and imperial city, and the inhabitants are Protestants. It is famous for a diet held here in 1521, at which Luther assisted in person, in memory of which the Protestants built a handsome church, where Luther is represented as appearing at the diet. It is noted for the excellent wine that grows in the neighbourhood, which they call our Lady's milk. In the campaign of 1743, King George took up his quarters in this city, and lodged at the bishop's palace after the battle of Dettingen. Worms fell into the hands of the French in 1794, and was included in the department of Mont Tonnerre. It continued in their possession till 1814, when it was united to the territories of the duke of Hesse Darmstadt. It is seated on the western bank of the Rhine, 20 miles south-east of Mentz, and 32 south-west of Frankfort. E. Long. 8. 15. N. Lat. 49. 32.

WORMING OF DOGS. All dogs have certain strings under their tongues, by most called a worm; this must be taken out when they are about two months old, with the help of a sharp knife to slit it, and a shoemaker'sawl to raise it up; you must be careful to take all out, or else your pains is to little purpose; for till then he will be hardly ever fat and right, in regard the worm or string will grow foul and troublesome, and hinder his rest and eating. This cruel operation is generally recommended as a preventive of madness in dogs, or at least as disabling them, if mad, from biting in that condition.

In this operation, of which the vulgar account is given,
WORSHIP

Worshipping, which we have justly denominated a cruel one, it is not a string that is removed, but the duty by which the saliva is conveyed from the gland in which it is secreted to the mouth, for the purpose of mixing with the food and promoting its digestion and digestion. Nor this operation by means prevents the animal from biting, nor can it, in our opinion, obstruct the flow of the saliva by which the dreadful disease hydrophobia is communicated.

WORMUS, Olau, a learned Danish physician, born in 1388 at Arnhusen in Jutland. After beginning his studies at home, he studied at several foreign universities, and travelled to various parts of Europe for improvement. He returned to his native country in 1613, and was made professor of the belles lettres in the university of Copenhagen. In 1615, he was translated to the chair of the Greek professor; and in 1624 to the professorship of physic, which he held to his death. These occupations did not hinder his from practising in his profession, and from being the fashionable physician: the king and court of Denmark always employed him; and Christian IV. as a recompense for his services, conferred on him a canonry of Lunden. He published some pieces on subjects relating to his profession, several works in defence of Aristotle's philosophy, and several concerning the antiquities of Denmark and Norway; for which latter he is principally regarded, as they are very learned, and contain many curious particulars. He died in 1614.

WORMWOOD. See ARTEMISIA, BOTANY INDEX.

WORSHIP OF GOD (cultus Dei) amounts to the same with what we otherwise call religion. This worship consists in paying a due respect, veneration, and homage to the Deity, under a certain expectation of reward. And this internal respect, &c. is to be shown and testified by external acts: as prayers, sacrifices, thanksgivings, &c.

The Querists, and some other mystic divines, set aside not only all use of external worship, but even the consideration of rewards and punishments. Yet even the heathens had a notion that God did not require us to serve him for nought: "Dix quamobrem colendi sunt (saya Cicero), non intelligo, nullo nce accepto ab illis nec sperato bono."

The school-divines divide worship into divers kinds, viz. latristia, that rendered to God; and idolatristia, that rendered to idols or images. To which the Romanists add, dalia, that rendered to saints; and hyperdulina, that to the Virgin. Some theological writers have observed, that the Greek word, πράσινος, to worship, is not descriptive only of the honour which is appropriated to God, but is indifferently used to signify the honour and respect which are paid to superiors of all kinds in heaven or on earth. Accordingly, they have distinguished between civil and religious worship.

That it is the duty of man to worship his Maker, has been sufficiently proved under other articles (see PRAYER, and THEOLOGY, NO 40–45). It is not indeed justly to be conceived how any one who has tolerably well, can possibly neglect the duty of private worship; and referred to, that public worship does not seem to be enjoined in that system which is called the religion of nature, yet it is most expressly commanded by the majesty of Christ, and will be regularly performed by every one who reflects on its great utility.

As the illiterate vulgar cannot form to themselves correct notions of the divine providence and attributes, it is obvious, that without the institution of public worship, they would never think of worshipping God, unless perhaps occasionally, when under the present some severe calamity; but occasional worship, the spring of compulsion, could have little of the inward spirit of true devotion. Ignorant, however, as the least of the vulgar are, and necessarily must be, it cannot be denied, that in most Christian countries, perhaps all, they are more accurately acquainted with the first principles of religion, and the laws of morality, than the; leaders of barbarous nations. This superiority is doubtless owing in some measure to their access to Sacred Scriptures, but much more, we are persuaded, to the instruction which they receive in the assemblies which they frequent for public worship. If this is admitted, public worship may be easily proved to be the duty of every individual of the community: for those who may be supposed to stand in need of the contagion of society to kindle their own devotion, or of the preaching of a clergyman to instruct them in the doctrines and precepts of the gospel, "to foster, on these accounts, the assembling together, as the manner of some is," religious assemblies and public worship would very quickly fall into universal disuse. Man is an animal prone to imitation; and every order in society is ambitious of treading in the footsteps of its order immediately above it. Were the wise and the good, therefore, permitted to absent themselves from assemblies instituted for the public worship of the Saviour and Redeemer of the world, others would quickly follow their example; impelled to it not only by the universal propensity, but by the additional motive of wishing to appear both to the world and to themselves as wise and as good as their privileged neighbours. The consequence is obvious: one man would stay from church with the serious intention perhaps of employing the Lord's day in private devotion and religious study; another, following his example, would absent himself upon the same pretence, but would in reality waste the day in dozing indolence or in secret sensuality. For these and other reasons which might be easily assigned, no sincere Christian will think himself at liberty to do a practice enjoined by the inspired preachers of his religion, coeval with the institution, and retained by every sect into which it has since been unhappily divided.

As Christian worship consists of prayers and praises, it has been a matter of some debate whether it is not properly performed by preconceived forms or liturgies, or by extemporaneous addresses to the Almighty. But these modes have their advantages and disadvantages: and by the sacred writers neither of them is prescribed in opposition to the other. The advantages of a liturgy are, that it prevents absurd, extravagant, or impious addresses to God, sthich the folly or enthusiasm of individuals must always be danger of producing; it gives the congregation an opportunity of joining in the prayers which are put up for them, which they cannot possibly do in a series of extemporaneous petitions, since before they can assent to
WORT, any one of these and make it their own, their attention is necessarily called away to that which succeeded it; and it relieves the clergyman from the labour of composition, which seems incompatible with that fervour which constitutes the spirit of devotion.

The disadvantages of a fixed liturgy, which are the recommendations of extemporary prayer, are principally two. The forms composed in one age must, by the unavoidable change of language, circumstances, and opinions, become in some degree unfit for another; and the perpetual repetition of the same form of words is very apt to produce inattentive spirit in the congregation. It could not be expected that the clergy of the church of England take that liberty which is allowed them in the bidding prayer before sermon, perhaps the service of that church would unite in itself all the advantages both of liturgic and extemporary worship. We have only to add on this subject, that public prayers, whether precomposed or not, ought to be componable; that they ought to express just conceptions of the Divine attributes; recite such facts which the congregation are likely to feel, and no other; that they ought to contain as few contrived propositions as possible; and that, if it can be done without offence, the pompous style of the state should be laid aside in our prayers for the king, and all that are in authority; because in every act which carries the mind to God, human greatness must be annihilated.

WORT, the infusion of malt, of which beer is made. See BREWING. The use of this infusion in common affairs are well known. By Dr. Mc Bride it has lately been found to have a strong antiseptic virtue, and to be useful in preventing the scourvy and other diseases to which sailors are liable; this was confirmed by Captain Cook in his voyages. See MEANS OF PRESERVING THE HEALTH OF SEAMEN.

It is of great importance to the manufacturer to be able to ascertain with facility and precision the real strength of worts, or the quantity of saccharine matter contained in the infusion. This is accomplished by determining the specific gravity by means of instruments, which, from the purpose to which they are applied, have obtained the name of saccharometers. But as these instruments, from the very nature of the material with which they are filled, are liable to error, and the results which they afford cannot always be depended on. With the view of obviating these inconveniences, the patent araeometrical beads have been invented by Mrs. Lovi of Edinburgh. We have already noticed these beads on account of their accuracy, simplicity, and facility of application for ascertaining the specific gravity, or the real strength and value of spirituous liquors. See vol. x. p. 359.; and we now recommend them with greater confidence, from having had opportunities of knowing that they are capable of a more extended application, as in the manufacture of acids, and salts of different kinds; to ascertain the strength of acids, or that of saline solutions in bleaching; to determine the strength of liquids employed in the different processes of calcio printing and dyeing, and not only for the purpose of examining the strength of the acids employed, but also particularly to ascertain the density or specific gravity of the colouring matters which are used in these arts, so that the same degree of shade required may be always obtained. It has been suggested, that these beads might be conveniently employed in determining the strength of mineral waters, which, it is well known, vary considerably at different seasons of the year.

As the patent beads are constructed on the same principle from 8000, the specific gravity of alcohol, to 20000, which is double the specific gravity of water; and as they are divided into different series, each of which includes a range of specific gravities applicable to the particular fluids, the density or strength of which is required, we have no hesitation in asserting that they will be found extremely convenient and useful to all manufacturers and dealers, who wish to ascertain with accuracy the real strength and value of liquids.

It has been objected to this use, that they require a longer time than other instruments in using them. The same objection has been made to the introduction of other new instruments, the application of which frequent use has afterwards rendered familiar and easy. We have had opportunities of knowing that this objection is completely obviated by those who have been accustomed to use the beads. They find that they can determine the specific gravity of a liquid by means of the beads with the same facility, and in as short a time, as with any other instrument.

WOTTON, Sir Harry, an eminent writer, was the son of Thomas Wotton, Esq. and was born in 1568. He studied for some time at New College, Oxford, whence he removed to Queen's-college, where he made a great progress in logic and philosophy; wrote a tragedy for the use of that college, called Tancred; and afterwards received the degree of master of arts. After this, leaving the university, he travelled in France, Germany, and Italy; and having spent about nine years abroad, he returned to England, and became secretary to Robert Earl of Essex, with whom he continued till that earl was apprehended for high treason. He then retired to Florence, where he became known to the grand duke of Tuscany, who sent him privately with letters to James VI. king of Scotland, under the name of Octavio Baldi, to inform that king of a design against his life. Some months after he went back to Florence; but King James coming to the possession of the crown of England, Mr. Wotton returned home, was knighted by his majesty, and sent ambassador to the republic of Venice; and afterwards was employed in many other embassies to that and other courts; but the only reward he obtained for these services was his having the provostship of Eton conferred upon him about the year 1623, which he kept till his death, which happened in 1639. After his decease some of his manuscripts and printed tracts were published together in a volume, intitled Reliquiae Wottonianae.

WOTTON, Dr. William, a learned divine and writer, was the son of Mr. Henry Wotton, B. D. rector of Wrentham in Suffolk, where he was born in 1665. He was educated by his father, a gentleman well skilled in the learned languages; under whom he made such amazing proficiency, that at five years of age it is said he could render several chapters of the gospels out of Latin and Greek, and many psalms in Hebrew, into his mother tongue. When he was very young, he remembered the whole of almost every discourse he had heard; and often surprised a preacher by repeating his sermon to him. He was admitted into Catharine-hall in Cambridge some months before he was ten years old; when the progress he made in learning in that university en-
2. Those which entirely cut off the passage of the nervous influence through the body. Such are wounds of the brain, cerebellum, medulla oblongata, and spinal marrow. Wounds likewise of the small blood-vessels within the brain are attended with great danger, for the effused fluids pressing upon the brain. Nor is there less danger where the nerves which tend to the heart are wounded, or entirely divided; for, after this, it is impossible for the heart to continue its motion.

3. All wounds which entirely deprive the mind of the faculty of breathing.

4. Those wounds which interrupt the course of the chyle to the heart; such are wounds of the receptacles of the chyle, thoracic duct, and larger lacteals, &c.

5. There are other wounds which prove fatal if neglected and left to nature: such are wounds of the larger external blood-vessels, which might be remedied by ligature. Wounds of such parts generally prove fatal, and though a few instances may have occurred when people have recovered after them, yet they are always to be considered as extremely dangerous. Injuries of the brain have been destroyed, and wounds have been made into it, and the patients have lived. It is possible, too, that the thoracic duct might be wounded and the patient live; Mr. A. Cooper having shown, in a very ingenious paper in the Medical Records and Researches, that it may become obstructed, and the chyle conveyed into the system by anastomosing lymphatics.

In examining wounds, the next consideration is, whether the parts injured are such as may be supposed to induce dangerous symptoms, either immediately or at some period during the course of the cure. In order to proceed with any degree of certainty, it is necessary to be acquainted with those symptoms which attend injuries of the different parts of the body. If the skin and part of the cellular substance are only divided, the first effects are an effusion of blood; the lips of the wound retract, become tumefied, red and inflamed, leaving a gap of considerable wideness according to the length and depth of the wound. If a very considerable portion of skin and cellular substance is divided, a slight fever seizes the patient; the effusion of blood stops, the mean time stops, and the wound is partly filled with a cake of coagulated blood. Below this cake, the small vessels pour forth a clear liquor, which in a short time is converted into pus (see the articles Pou and Mucus). Below this pus granulations of new flesh arise, the cake of coagulated blood loosens, a new skin covers the place where the wound was, and the whole is healed up; and there only remains a mark, called a cicatrix or scar, showing where the injury had been received.

All wounds are accompanied with a considerable degree of pain, especially when the inflammation commences, when the division reaches no farther than the skin and cellular substance. If the muscular fibres are divided, the pain is much greater, because the part of the muscle is stretched by the contraction of the divided part and the action of the antagonist muscle, which is now less fitted to bear. The wound also gapes much more than where the cellular substance is also
alone divided, insomuch that, if left to itself, the skin will cover the muscular fibres, without any intervention of cellular substance; and not only a very unsightly cicatrix remains, but the use of the muscle is in some measure lost. — If the muscle happens to be totally divided, its fibres retract to a very considerable distance; and unless proper methods be taken to bring them into contact, the use of it is ever afterwards lost.

If a wound any considerable artery happens to be divided, the blood flows out with great velocity, and by starts; the patient soon becomes faint with loss of blood; nor does the haemorrhagy stop until he faints away altogether; and if as much vires still remains as is sufficient to renew the operations of life, he recovers after some time, and the wound heals up as usual. The part of the artery which is below the wound in the mean time becomes useless, so that all the inferior part of the limb would be deprived of blood, were it not that the small branches sent off from the artery above the wounded place become enlarged, and capable of carrying on the circulation. Nature also, after a wonderful manner, often produces new vessels from the superior extremity of the divided artery, by which the circulation is carried on as formerly. The consequences of such a profuse haemorrhagy may be, however, very dangerous to the patient, by inducing extreme debility, or universal dropsy. This great haemorrhagy happens especially where the artery is partially divided; because then the vessel cannot contract in such a manner as to close the orifice; however, if the wound is but small, the blood gets into the cellular substance, swelling up the member to an extreme degree, forming what is called a diffused aneurism. Thus the haemorrhagy soon stops externally, but great mischief is apt to flow from the confinement of the extravasated blood, from bringing on exterior suppuration among the muscles and bones, and thus not only the use of the limb is entirely lost, but the patient is brought into great danger of his life.

Wounds of the ligaments, nerves, and tendons, are likewise attended with bad consequences. When a nerve is entirely divided, the pain is but trifling, though the consequences are often dangerous. If the nerve be large, all the parts to which it is distributed below the wound immediately lose the power of motion and sensation. This, however, takes place only when all or the greatest part of the nerves belonging to a particular part are divided. If the spinal marrow, for instance, be divided near the head, the parts below soon lose their sensation irrecoverably; or if the bundle of nerves passing out of the axilla be divided, or tied, sensation in the greatest part of the arm below will be lost. But though a nerve should be divided, and a temporary palsy be produced, it may reunite, and perform its former functions. If a nerve be wounded only, instead of being divided, the worst symptoms frequently ensue.

Wounds which penetrate the cavities of the thorax are always exceedingly dangerous, because there is a scarce a possibility of all the viscer a escaping unharmed. A wound is known to have penetrated the cavity of the thorax principally by the discharge of air from it at each inspiration, by an extreme difficulty of breathing, and by coughing up blood. Such wounds, however, are not always mortal; the lungs have frequently been wounded, and yet the patient has recovered. — Wounds of the diaphragm are almost always mortal, either by inducing fatal convulsions immediately, or by the ascent of the stomach, which the pressure of the abdominal muscles forces up through the wound into the cavity of the thorax; of this Van Swieten gives several instances.

Even though the wound do not penetrate into the cavity of the thorax, the very worst symptoms may follow. For if the wound descends deeply among the external muscles, and its orifice lies higher, the extravasated blood will be therein collected, stagnate, and form various sinuses; which after having eroded the pleura, may at length pass into the cavity of the thorax. The matter having once found a vent into this cavity, will be continually augmenting from the discharge of the sinuous ulcer, and the lungs will at last suffer by the surrounding matter. If, in cases of wounds in the thorax, the rib or sternum happen to become carious, the cure will be extremely tedious and difficult. Galen relates the case of a lad who received a blow upon his sternum in the field of exercise: it was first neglected, and afterwards badly healed; but four months afterwards, matter appeared at the place which had received the blow. A physician made an incision into the part, and it was soon after cicatrizied; but in a short time a new collection made its appearance, and upon a second incision the wound refused to heal well. Galen found the sternum carious; and having cut off the diseased part, the pericardium itself was observed to be corroded, so that the heart could be seen quite naked; notwithstanding which, the wound was cured in not very long time.

There is sometimes difficulty in determining whether the wound has really penetrated into the thorax or into the abdomen; for the former descends much farther towards the sides than at the middle. But as the lungs are almost always wounded when the cavity of the thorax is penetrated, the symptoms arising from thence can scarcely be mistaken. — Another symptom which frequently, though not always, attends wounds of the thorax, is an emphysema. This is occasioned by the air escaping from the wounded lungs, and insinuating itself into the cellular substance; which being pervious to it over the whole body, the tumor passes from one part to another, till at last every part is inflated to a surprising degree. An instance is given in the Memoirs of the Royal Academy, of a tumour of this kind, which on the thorax was eleven inches thick, on the abdomen nine, on the neck six, and on the rest of the body four; the eyes were in a great measure thrust out of their orbits by the inflation of the cellular substance; and the patient died the fifth day. This was occasioned by a stab with a sword.

Wounds of the abdomen are not less dangerous than those of the thorax, on account of the importance of the viscera which it contains. When the wound does not penetrate the cavity, there is some danger of a hernia being formed by the protrusion of the peritoneum through the weakened integuments, and the danger is greater the larger the wound is. Those wounds which run obliquely betwixt the intestines of the muscles often produce sinuous ulcers of a bad kind. For as there is a large quantity of fat interposed everywhere betwixt the muscles of the abdomen, if a wound happens to run between them, the matter there collected, not meeting with free egress through the mouth of the wound, often makes its way in a surprising manner through the cellular...
WOUNDS

Wounds. A far substance, and forms deep sinusities between the muscles; in which case the cure is always difficult, and sometimes impossible.

If a large wound penetrate the cavity of the abdomen, some of the viscera will certainly be protruded through it; or if the wound be small, and closed up with fat so that none of the intestines can be protruded, we may know that the cavity of the abdomen is pierced, and probably some of the viscera wounded, by the acute pain and fever, paleness, anxiety, faintings, hiccough, cold sweats, and weakened pulse, all of which accompany injuries of the internal parts. The mischiefs which attend wounds of this kind proceed not only from the injury done to the viscerza themselves, but from the extravasation of blood and the discharge of the contents of the intestines into the cavity of the abdomen; which, being of a very putrescent nature, soon bring on the most violent disorders. Hence wounds of the abdominal viscera are very often mortal. This, however, is not always the case, for the small intestines have been totally divided, and yet the patient has recovered. Wounds both of the small and large intestines have healed spontaneously, even when they were of such magnitude that the contents of the intestines were freely dischargé through the wound into the abdomen, and after part of the intestines itself has been protruded through the wound of the intestines.

When the mesentry is injured, the danger is extreme, on account of its numerous vessels and nerves. Wounds of the liver, spleen, and pancreas, are also exceedingly dangerous, although there are some instances of the spleen being cut out of living animals without any considerable injury.

From the preceding account of the symptoms attending wounds in the different parts of the body, the surgeon may be enabled to judge in some measure of the event; though it must always be remembered, that wounds, even those which seemed at first to be of the slightest nature, have, contrary to all expectation, proved mortal, chiefly by inducing convulsions, or a locked jaw; so that no certain prognostic can be drawn on sight of recent wounds. We shall now, however, proceed to consider their treatment.

For the care of wounds, it has been already observed, that the ancients imitated balsams, the juice of herbs, &c. to be specifics. In after-ages, and in countries where balsams are not easily to be procured, salves were substituted in their place; and even at this day there are many who reckon a salve or ointment essentially necessary for healing the slightest cut. It is certain, however, that the care of wounds cannot be effected, nay, not even forwarded in the least, by ointments, unless in particular cases. That power which the human frame has of repairing the injuries done to itself, which by physicians is called vis medicae nature, is the sole agent in curing external injuries; and without this the most celebrated balsams would prove inefficacious.

When a wound has been made with a sharp instrument, and the extravasated blood sucked (A) out or washed away, it will almost always heal by adhesion. When a wound does not heal by this process, there are three stages to be observed in its cure; the first, called suppuration, which takes place when the ends of the wound contract themselves, and pour out the liquid which is converted into pus. As soon as this appears, the wound, or granulating stage, in which the flesh begins to grow up, takes place; and as this proceeds, the edges of the wound acquire a fine bluish pearl color, which is that of the new skin beginning to cover the wound as far as the granulations have filled it up. This press continues, and the skin advances from all sides towards the centre, which is called the cicatrising of the wound. For the promoting of each of these processes, certain ointments were formerly much in vogue. But it is now found, that no ointment whatever is capable of promoting them; and that it is only necessary to keep the wound clean, and to prevent it from being allowed to access to it. This, indeed, nature takes care to do by covering the wound with a cake of coagulated blood, but if a wound of any considerable magnitude should be left entire to nature, the pus would form before the crust of coagulated blood in such a quantity that it would most probably corrupt, and the wound degenerate to a corroding ulcer. It is necessary, therefore, to clean the wound frequently; for this purpose it will be proper to apply a little ointment spread on soft flannel. And, in a healthy body, the wound will heal without farther trouble. As to the ointment employed, it is almost indifferent what it be, provided it has no acid or stimulating ingredient in its composition; hog's lip or the simple ointment of the Pharmacopoeia will answer perfectly.

But though, in general, wounds thus easily admit of a cure, there are several circumstances which require different treatment, even in simple divisions of the body parts, when neither the membranous nor tenacious parts are injured. These are, 1. Where the wound is large, and gapes very much, so that, if allowed to heal in a natural way, the patient might be greatly disfigured by the scar. It is proper to bring the lips of the wound near to each other, and to join them either by adhesive plaster or by suture, according as the wound is superficial, or deep. 2. When foreign bodies are lodged in the wound, as when a cut is given by glass, &c. it is necessary to extract them, before the wound is dressed, for it will never heal until they are discharged. Where these bodies are situated in such a manner as not to be capable of being extracted without lacerating the adjacent parts, which would occasion violent pain and other bad symptoms, it is necessary to enlarge the wound, so that these offending bodies may be easily removed. This treatment, however, is chiefly necessary in gunshot wounds, of which we shall afterwards speak. 3. When the wound is made in such a manner that it runs for some length below the skin, and the bottom is much lower than the orifice, the matter collected from all parts of the wound will be lodging in the bottom of it, where, corrupting by the heat, it will degenerate into a fistulous ulcer. To prevent this, we must

(A) See an account of the method of sucking wounds, in Mr John Bell's Discourse on Wounds, Part I. discourse v. p. 215.
WOUNDS.

must use compresses, applied so that the bottom of the wound may suffer a more considerable pressure than the upper part of it. Thus the matter formed at the bottom will be gradually forced upwards, and that formed at the upper part will be incapable of descending by its weight; the divided parts, in the mean time, easily uniting when brought close together. Indeed, the power which nature has of uniting different parts of the human body is very surprising; for, according to authors of credit, even if a piece of flesh be totally cut out, and applied in a short time afterwards to the place from whence it was cut, it will unite. That a part cut out of a living body does not entirely die, but does the vital power for some time, is evident from the modern practice of transplanting teeth; and from an experiment of Mr. John Hunter’s, where he put the testicle of a cock into the belly of a living hen, and the testicle adhered to the liver, and became connected to it by means of blood vessels. We have therefore the greatest reason to hope, that the divided parts of the human body; when closely applied to each other, will cohere without leaving any sinus or cavity between them. However, if this method should fail, and matter be collected in the depending part of the wound, it will be necessary to make an opening in that part in order to let it out; after which the wound may be cured in the common way. During the course of the cure, it sometimes happens that the wound, instead of filling up with granulations of a florid colour, shoots up into a glassy-like substance which rises above the level of the surrounding skin, while, at the same time, instead of laudable pus, a thin ill-coloured and fetid ichor is discharged. In this case the lips of the wound lose their beautiful pearl colour, and become callous and white, and does the vitrifying of the wound at all advance. When this happens in a healthy patient, it generally proceeds from some improper management, especially the making use of too many emollient and relaxing medicines, an immoderate use of balsams and ointments. Frequently nothing more is requisite for taking down this fungus than dressing with dry lint: at other times desiccative powders, such as calamine, tooty, calcined alum, &c. will be necessary; and sometimes red precipitate mercuric nitrate must be used. There is last balsam, in some cases, a great pain, if sprinkled in its dry state upon the wound; it is therefore most proper to grind it with some yellow basilicon ointment, which makes a much more gentle, though at the same time an efficacious erasor. Touching the overgrown parts with blue vitriol is also found very effectual.

Hitherto we have considered the wounded patient as otherwise in a state of perfect health; but it must be observed, that a large wound is capable of disordering the system to a great degree. If the patient is strong and vigorous, and the pain and inflammation of the wound great, considerable degree of fever may arise, which will be necessary to check by bleeding, low diet, and other parts of the antiphlogistic regimen, at the same time the inflamed lips of the wound and parts adjacent are to be treated with emollient fomentations or cataplasmis till the pain and swelling abate. On the other hand, it may happen, when the patient is of a weak and lax habit, that the vitriol may not be sufficient to exert such an inflammation in the wound as is absolutely necessary for its cure. In this case, the edges of the wound look pale and soft; the wound itself ichorous and bloody, without any signs or granulations; or if any granulations shoot up, they are of the fungus glassy kind above mentioned. To such wounds all external applications are vain; it is necessary to strengthen the patient by proper internal remedies, among which thistle has a principal place, until the wound begins to alter its appearance. In such persons, too, there is some danger of a hectic fever by the absorption of matter; and this will take place during the course of the cure, even when the appearances have been at first as favourable as could be wished. This happens generally when the wound is large, and a great quantity of matter formed; but by this discharge the patient is weakened; so that the pus is no sooner formed, than it is conveyed into the body by the absorbent vessels, and immediately affects the patient with feverish heat. When this takes place, the best remedy is to exhibit the thistle copiously, at the same time to support the patient by proper cordials and nourishing diet. Indeed, in general, it will be found, that, in the case of wounds of any considerable magnitude, a more full and nourishing regimen is required than the patient, even in health, has been accustomed to; for the discharge of pus, from the quantity is considerable, proves very debilitating. And it is constantly found, that the cure of such sores goes on much more easily when the patient is kept in his usual habit of body, than when his system is much emaciated by a very low allowance; and, for the same reason, purgatives, taken more freely than is necessary to keep the bowels open, and whatever else tends to weaken the constitution, are improper in the cure of wounds.

Hemorrhages very frequently happen in wounds. Of hemorrhages either from a division of a large artery, or of a number of small ones. In this case, the first step to be taken by the surgeon is to effect a temporary stoppage of the blood by means of compression, and he is then to tie up all the larger vessels according to the methods usually directed.

When the principal arteries of a wound have been tied, and a little blood continues to be discharged, which appears to come from sundry small vessels only, an experienced surgeon is induced to think that the compression of the bandages will in all probability effect a total stoppage of the hemorrhage. In a general oozing from the whole surface of a sore, and when no particular vessel can be distinguished, there is a necessity for trusting to the bandage or compression; but whenever an artery can be discovered, of whatever size it may be, it ought to be secured by a ligature. But it frequently happens, that considerable quantities of blood are discharged, not from any particular vessel, but from all the small arteries over the surface of the wound; and in wounds of great extent, particularly after the extirpation of cancerous breasts, and in other operations where extensive sores are left, this species of hemorrhage often proves very troublesome by being exceedingly difficult to suppress.

In constitutions perfectly healthy, on the occurrence of wounds even of the most extensive nature, as soon as the larger arteries are secured, all the small vessels which have been divided are diminished, not only in their diameters, but also in their length; in consequence of which, they recede considerably within the surface of the
the surrounding parts. This cause of itself would probably, in the greatest number of instances, prove sufficient for restraining all loss of blood from the smaller arteries. Another very powerful agent however is provided by nature for producing the same effect. From the extremities of the divided vessels which at first discharged red blood, there now, in their contracted state, oozes out a more thin, though viscid, fluid, containing a great proportion of the coagulable parts of the blood; and this being equally distributed over the surface of the wound, by its agglutinating powers has a very considerable influence in restraining all such hemorrhages.

When a tedious oozing occurs in a patient young and vigorous, and where the tone of the muscular fibres is evidently great, the most effectual means of putting a stop to the discharge is to relax the vascular system, either by opening a vein in some other part, or, what gives still more immediate relief, by uniting the ligation on one of the principal arteries of the part, so as to allow it to bleed freely: those violent spasmodic twitches too, so frequent after operations in any of the extremities, when they do not depend on a nerve being included in the ligation with the artery, are in this manner more effectually relieved than by any other means.

By the same means the patient, from being in a feverish heat and much confused, soon becomes very tranquil: the violent pulsation of the heart and larger arteries abates, and the blood not being propelled with such impetuosity into the smaller vessels of the part, they are left at more liberty to retract.

The patient ought to be kept exceedingly cool; wine and other cordials should be rigidly avoided; cold water, acidulated either with the mineral or vegetable acids, ought to be the only drink; motion of every kind, particularly of the part affected, should be guarded against; and the lip of the wound being drawn together by adhesive plaster, and gently covered with soft charpia, it ought to be tied up with a bandage so as to produce a moderate degree of pressure on the extremities of the divided parts.

As soon as a sufficient quantity of blood has been discharged, the wound dressed, and the patient laid to rest, a dose of opium proportioned to the violence of the symptoms ought to be immediately exhibited. It ought to be remarked, however, that in all such circumstances, much larger doses of this medicine are necessary than in ordinary cases requiring the use of opiates. Small doses, instead of answering any good purpose, seem frequently rather to aggravate the various symptoms; so that whenever they are had recourse to in such cases, they ought always to be given in quantities sufficient for the intended effect.

But hemorrhages of this nature happen much more frequently in relaxed enfeebled habits, where the solids have lost part of their natural firmness, and the fluids have acquired a morbid tenuity. In this case a moderate use of generous wine ought to be immediately prescribed; for nothing tends so much, in such circumstances, to restrain hemorrhages, as a well directed use of proper cordials. By tending to invigorate and bracce the solids, they enable the arterial system to give a due resistance to the contained fluids; and have also a considerable influence in restoring to the fluids that viscidity of texture, of which in all such instances we suspect them to be deprived.

A nourishing diet also becomes proper; the patient ought to be kept cool; and the mineral acids, finding utility in every species of hemorrhage, ought also to be prescribed. Rest of body is here the proper; and opiates, when indicated either by pain or spasmodic affections of the muscles, ought never to be omitted.

Together with these remedies adapted to the gummy system, particular dressings, appropriated to the parts to which they are to be applied, have been found very beneficial. In healthy constitutions, ten minutes after the discharge of blood is over, the parts are covered with a viscid coagulable effusion from the mouths of the now retracted arteries; but in constitutions of a opposite nature, where the solids are much relaxed, the blood in general is found in such an attenuated state as to afford no secretion of this nature.

To supply as much as possible the deficiency of the natural balsam, different artificial applications have been invented. Dusting the part with starch or wheat-flour has sometimes been found of use, and gum arabic in powder has been known to answer when these failed.

Applications of this kind, indeed, have been made with success in all such hemorrhages, with whatever habit of body they happen to be connected; but they have always proved more particularly serviceable in laxed constitutions, attended with an attenuated state of the blood and an enfeebled muscular system. Alcohol, or any other ardent spirits, impregnated with a great quantity as they can dissolve of myrrh, or any other of the heating viscid gums, may be here used with freedom, though in constitutions of an opposite turn they ought never to be employed. The bland antimoniac, a remedy of this nature, has long been famous for its influence in such cases: but that indiscriminate use of this and similar applications which has long prevailed with some practitioners, is undoubtedly done much harm; for as they are all possessed of very stimulating powers, they of course tend to aggravate every symptom in wounds connected with a tense state of fibres, or much pain, especially when spasmodic muscular affections prevail.

By a due perseverance in one or other of the plans here pointed out, it will seldom happen that hemorrhages are not at last put a stop to: but when the contrary does occur, when notwithstanding the use of the remedies recommended, a discharge of blood still continues; in addition to the means already advised, an equal moderate pressure ought to be applied over the whole surface of the sore, to be continued as long as the necessity of the case seems to indicate.

In finishing the dressings of such wounds, after the adhesive plaster and compresses have been applied, a bandage properly adapted to the part ought to be employed, and in such a manner as to produce an equal degree of pressure over the surface of the wound sensible. But it now and then happens that no bandage can be applied so as to produce the desired effect; and in such cases the hand of an assistant is the only resource: which being firmly pressed over the dressing will commonly succeed when no other means is found to have much influence.
Wounds of the nerves, tendons, and ligaments, are attended with much more violent symptoms than those where even considerable arteries are divided, and they frequently resist every method of cure proposed by the most skilful practitioners. In the simple process of blood-letting, it frequently happens that the tendinous expansion called the *aponeurosis* of the biceps muscle is wounded, or even the tenden of that muscle itself is punctured, by the point of the lancet; or sometimes a nerve which happens to lie in the neighbourhood is partially divided. Any one of these wounds, though they are the smallest we can well suppose to be given, are frequently very dangerous and difficult of cure. It sometimes immediately happens on the introduction of the lancet, that the patient complains of a most exquisite degree of pain; and when this occurs, we may rest assured that either a tendon or a nerve has been wounded. On some occasions, by proper management, such as evacuating a considerable quantity of blood at the orifice newly made, by keeping the part at perfect rest, and preserving the patient in as cool a state as possible, the pain at first complained of will gradually abate, and at last go off entirely without any bad consequence. At other times, however, this pain which occurs instantaneously on the introduction of the lancet, instead of abating, begins soon to increase; a fullness, or small degree of swelling, takes place in the parts contiguous to the wound; the lips of the sore become somewhat hard and inflamed; and, in the course of about 24 hours from the operation, a thin watery serum begins to be discharged at the orifice.

If, by the means employed, relief is not soon obtained, these symptoms generally continue in nearly the same state for two or perhaps three days longer. At this time the violent pain which at first took place becomes still more distressing; but instead of being sharp and acute as before, it is now attended with the sensation of a burning heat, which goes on to increase, and proves, during the whole course of the ailment, a source of constant distress to the patient. The fullness and hardness in the lips of the wound begin to increase, and the swelling in the neighbouring parts gradually extends over the whole members. The parts at last become exceedingly tense and hard; an erysipelatous inflammation appears over the whole member; the pulse by this time is generally very hard and quick; the pain is now intense, the patient exceedingly restless; twichings of the tendons occur to a greater or less degree; on some occasions, a locked jaw and other convulsive affections supervene; and all these symptoms continuing to increase, it most frequently happens that the torture under which the patient has been groaning is at last terminated by death.

Different opinions have prevailed respecting the cause of these symptoms. By some they have been imputed to wounds of the tendons. By others the tendons are supposed to be so entirely destitute of sensibility, as to be quite inappreciable of producing so much distress; so that wounds of the nerves they consider, on all such occasions, as the true cause of the various symptoms we have mentioned.

One or other of these ideas continued to be the only source for explaining the various phenomena found to occur in this malady, till a different opinion was suggested by the late ingenious Mr John Hunter of London.
Wounds.

In order to prevent as much as possible the consequent inflammation and other symptoms which usually ensue, a considerable quantity of blood should be immediately discharged at the orifice just made: the limb, for several days at least, ought to be kept in a state of perfect rest, care being at the same time taken to keep the muscles of the part in as relaxed a state as possible: the patient should be also kept cool, on a low diet; and, if necessary, gentle laxatives ought to be administered.

When, notwithstanding these means, the symptoms, instead of diminishing, rather become more violent; if the lips of the orifice turn hard and more inflamed, if the pain become more considerable, and especially if the swelling begin to spread, other remedies come to be indicated. In this state of the complaint, topical blood-letting, by means of leeches applied as near as possible to the lips of the wound, frequently affords much relief; and when the pulse is full and quick, it even becomes necessary to evacuate large quantities of blood by opening a vein in some other part.

The external applications usually employed in this state of the complaint are warm emollient fomentations and poultices. In similar affections of other parts no remedies with which we are acquainted would probably be found more successful; but in the complaint now under consideration, all such applications, instead of being productive of any advantage, rather do harm. The heat of the part is here one of the most distressing symptoms; and warm emollient applications rather tend to augment this source of uneasiness. The lips of the wound also are rendered still more hard, swollen, and of course more painful; and the swelling of the contiguous parts is increased. The best external remedies are cooling astrignents, especially the saturnine applications. The parts chiefly affected being alternately covered over with cloths wet with a solution of saccharum saturni, and pledgelets spread with Guillard's cerate, are kept more cool and easy than by any other remedy hitherto used. The febrile symptoms which occur must at the same time be attended to, by keeping the patient cool, on a low diet, preserving a lax state of the bowels; and, if necessary, farther quantities of blood ought to be evacuated.

On account of the violence of the pain, which is sometimes so excessive as to destroy entirely the patient's rest, opiates ought to be freely exhibited; and when twingeings of the tendons and other convulsive symptoms supervene, medicines of this kind become still more necessary. In order, however, to have a proper influence in this state of the complaint, opiates ought to be given in very full doses; otherwise, instead of answering any good purpose, they constantly tend to aggravate the different symptoms, not only by increasing the heat and restlessness, but by having an evident influence in rendering the system more susceptible than it was before of the pain and other distressing effects produced upon it by the wound.

It often happens, however, either from neglecting the dying or from improper treatment, that all these remedies are had recourse to without any advantage whatever: the fever, pain, and swelling of the parts continue, and convulsive affections of the muscles at last occur, all tending to indicate the most imminent danger.

In this situation of matters, if we have not immediate recourse to some effectual means, the patient will not fail a victim to the disorder; and the only remedy by which much real advantage is to be expected, is a joint and extensive division of the parts in which the evil producing all the mischief was at first made. When well, from the experience of ages, that much more pain and distress of every kind are commonly produced by a partial division either of a nerve or of a tendon, than from any of these parts being at once cut entirely. Now the intention of the operation here recommended, is to produce a complete division of the nerve or tendon we suppose to have been wounded by the point of the lance, and which we consider as the sole cause of all the subsequent distress.

This operation being attended with a good deal of pain, and being put in practice for the removal of symp toms from which it is perhaps difficult to persuade the patient that much danger can occur, all the remedies we have mentioned should be made trial of before it is proposed: but at the same time, care ought to be taken that the disorder is not allowed to proceed for far before we have recourse to it; for if the patient should previously much weakened by the feverish symptoms have continued violent for any length of time, neither the remedy nor any other with which we are acquainted would probably have much influence. As soon, therefore, as the course already prescribed has been fairly tried, and is found to be inadequate to the effects expected from it, we ought immediately to have recourse to a free division of the parts affected.

Whatever a wounded or ruptured tendon may be situated, the limb should be placed in such a manner that it will most readily admit of the ruptured end of the tendon being brought together; and when in this situation the muscles of the whole limb in which the injury has happened must be tied down with a roller, so as to prevent them from all kinds of exertion during the cure, endeavouring at the same time to keep the parts easy and relaxed. Thus, in a wound or rupture of the tendon of the rectus muscle of the thigh, the patient's leg should be kept as much as possible stretched out during the cure, while the thigh should be in some degree bent, to rest the muscle itself as far as possible.

In similar affections of the tendo Achillis, the leg should be kept constantly bent to relax the muscles of the leg, and the foot should be stretched out to admit of the ends of the ruptured tendon being brought into contact. A roller should be applied with a firmness quite sufficient for securing the muscles and tendons in the situation; but care must be taken to prevent it from impeding the circulation. With this view, soft fine loans should be preferred either to linen or cotton; for being more elastic, it more readily yields to any swelling which the limb may be attacked.

The late Dr Monro was the first who gave any accurate directions for the treatment of rupture in the leg tendons; and it is perhaps given with more precision, from his having himself experienced the effects of the misfortune in the tendo Achillis. He used a foot-sock or slipper, made of double quilted ticking, and left open at the toe; from the heel of which a strap went up above the calf of the leg.
strong piece of the same materials went round the calf, and was fastened with a lace. On the back part of this was a buckle, through which the strap of the foot-sock was passed, by which the calf could be brought down, and the foot extended at pleasure. Besides there was a piece of tin applied to the fore part of the leg, to prevent the foot from getting into any improper posture during sleep. After proposing to walk, he put on a shoe with a heel two inches deep; and it was not till the expiration of five months that he ventured to lay aside the tin-plate; and he continued the use of the high-heeled shoe for two years.

From this treatment a knowledge may be formed of the treatment necessary to be followed in the laceration of tendons of other parts of the body.

Wounds of the thorax, even though none of the viscera should be wounded, we may yet reasonably expect that a considerable quantity of blood will be extravasated; and this, if very large, must be evacuated if possible. However, it ought to be particularly observed, that this extravasated blood should not be discharged before we are assured that the wounded vessels have done bleeding. When the pulse appears sufficiently strong and equal, the extremities warm, no hiccup or convulsion, and the patient's strength continues, we may then know that the internal hemorrhage has ceased, and that the means for discharging the blood may now be safely used. Matter, water, and blood have sometimes vanished from the cavities of the thorax, and been afterwards discharged by sweat, urine, &c. Yet this but seldom happens; and if we were to trust to nature alone in these cases, it is certain that many would perish from a destruction of the vital viscera by the extravasated blood, who by an artificial extraction of the same blood might have been saved.

Wounds of the abdomen must be closed as soon as possible, and then treated as simple wounds; only they ought to be dressed as seldom and expeditiously as possible. Copious bleeding and a spare diet, with other parts of the antiphlogistic regimen, are here absolutely necessary.

It sometimes happens, that, through a large wound of the abdominal integuments, the intestine comes out without being injured. The most certain method, in all such cases, is to return the protruded part as soon as possible; for although writers in general formerly recommended warm fomentations, &c., to be previously applied, the latest authors upon this subject consider the most natural and proper fomentation to be that which is produced by the heat and moisture of the patient's belly, and that therefore the intestines, if no mortification has taken place, are to be cleared from extraneous matter, and immediately returned.

When the wound of the abdomen is large, the intestines easily prolapse, and they are as easily returned. But when part of an intestine has been forced through a narrow wound, it is much more dangerous. For the prolapsed intestine being distended by flatus, or the ingested aliment driven thither by the peristaltic motion, it will become inflamed, tunnelled, and incapable of being returned through the stricture of the wound; whence gangrene will soon follow. In this case the utmost care is to be taken to reduce the intestine to its natural size. When this cannot be accomplished by other means, some practitioners of great eminence have even advised the puncturing of the intestine in different places in order to discharge the flatus. This practice has also been recommended in an incarcerated hernia, but is exceedingly disapproved of by Mr. Pott and later writers; and it seems to be very dubious whether any good can possibly arise from it. To puncture any part that is already inflamed, must undoubtedly add to the inflammation; and it is very improbable that the discharge of flatus procured by the punctures would be at all a recompense for the bad consequences produced by the increased inflammation. The method of Celsus is much more eligible: It is to dilate the wound so as to reduce the intestine with ease.

Sometimes part of the intestine is lost either by suppuration or gangrene. In this case, all that can be done is to put a single stitch through the wounded bowels, to fix it to the external wound by passing the suture also through the sides of the wound. The ends of the intestine may perhaps adhere; or at any rate the wound will continue to perform the office of an anus, out of which the feces will continue to be discharged during life. The directions given by some surgeons about inserting the upper end of the gut into the lower, and stitching them together, are perfectly impracticable; and even if they were practicable, would certainly produce new mortification, which could not but be fatal.

When the omentum appears prolapsed, the same general treatment is to be observed; only that, when it is mortised, the dead part may be safely extirpated.—We shall conclude the article of abdominal wounds with a case from the memoirs of the academy of sciences for the year 1705, which shows that we ought not to despair, even though the most desperate symptoms should take place. A madman wounded himself in 18 different places of the abdomen. Eight of these penetrated the cavity, and injured the contained viscera; he had a diarrhea, nausea, and vomiting, tension of the abdomen, with difficult respiration and violent fever, so that his life was despaired of. During the first four days he was bled 7 times; and during the greatest part of the cure his diet consisted almost entirely of flesh-broths, with the addition of some mild vegetables. By these means he was not only cured of his wounds, but restored to his right senses. Seventeen months after, he went mad again, and threw himself over a precipice, by which he was instantly killed. On opening the body, the wounds were found to have penetrated the middle lobe of the liver, the intestinum jejunum, and the colon.

Such extraordinary cures are to be imputed, according to the satisfactory explanation of Mr. J. Bell, to the abdomen being perfectly full, and constantly subjected to strong pressure between the diaphragm and abdominal muscles; which keeps the parts contiguous to a wound closely applied to it, also in some measure prevents the discharge of feces or even of blood, and gives an opportunity for a very speedy adhesion between the parts.

In wounds of the head, where the cellular membrane of only is affected, and the aponeurosis and pericranium the head are untouched, phlebotomy, lenient purges, and the use of the common febrifuge medicines, particularly those of the neutral kind, generally remove all the threatening symptoms. When the inflammation is gone off, it leaves on the skin a yellowish tint and a dry scurf, which continue until perspiration takes them away; and upon the removal...
Wounds

removal of the disease, the wound immediately recovers
healthy aspect, and soon heals without further trouble.
But in the worst kind of these wounds, that is, when
small wound passes through the tela cellula and apo-
neurosis to the pericranium, the patient will admit of
more free evacuations by phlebotomy than in the former.
In both, the use of warm fomentations is required; but
an emollient cataplasm, which is generally forbid in the
crysotelatus swellings, may in this latter case be used to
great advantage. Where the symptoms are not very
pressing, nor the habit very inflammable, this method
will prove sufficient; but it sometimes happens that the
scab is so tense, the pain so great, and the symptomatic
fever so high, that by waiting for the slow effect of such
means the patient runs a risk from the continuance of
the fever; or else the injured aponeurosis and pericra-
nium become sloughy, produce an abscess, and render
the case both tedious and troublesome. A division of
the wounded part, by a simple incision down to the bone,
almost half an inch or an inch in length, will most com-
monly remove all the bad symptoms; and if it be done in
time, will render every thing else unnecessary.
The wounds penetrating into the cavities of the joints
do not seem at first alarming; yet, by exposure to the
air, the lining membrane of such cavities acquires such a
degree of sensibility as to endanger life when they are
large. As soon therefore as any extraneous body, pushed
into the joint, is removed, the admission of the exter-

cal air is to be guarded against as much as possible.
If the wound be not too large, this may be done by
pulling the skin over the wound of the joint; and, to
prevent its retraction, rather adhesive plaster, with pro-
per bandaging, is to be used. But when inflammation
has come on, repeated and copious blood-letting, together
with fomentations, becomes necessary, and as the pain,
in these cases, is apt to be violent, opiates must be ad-
ministered; but should matter be formed in the cavity
of the joint, free vent must be given to it.

Of contused and lacerated Wounds.—When the small
vessels are ruptured by a blow with any hard instrument
without penetrating the skin, at the same time that
the solid fibres of the part are crushed, the injury is
termed a contusion: and when at the same time the
skin is broken, it is termed a contused and lacerated
wound.

Every contusion therefore, whether the skin is broken
or not, may be properly reckoned a wound; where the
injury is so slight that none of the contents of the small
vessels are extravasated, it scarcely deserves to be men-
tioned. The immediate consequence of a contusion,
therefore, is a swelling, by reason of the extravasation
just mentioned; and the skin becomes discoloured by
the blood stagnating under it; but as this fluid, even
though covered by the skin, cannot long remain in the
natural state, it thence happens, that the contused part
soon loses its florid red colour, and becomes blue or
black; the thinner parts being in the mean time gra-
dually taken up by the absorbent vessels. This at last
happens to the blood itself; the blue disappears, and is
succeeded by a yellowish colour, showing that the blood is
now dissolved; after which, the part recovers its former
appearance, and the ruptured vessels appear to have united as if no injury had happened.

These are the symptoms which attend the slightest
kind of contusions; but it is evident, that where the

blow is so violent as to rupture the blood-vessels, and
some of the large nerves, all the bad consequences
attend an open wound of those parts will ensue, and
will not be at all alleviated by the circumstance of the
skin remaining whole. Hence it is easy to see, that,
contusion may produce ulcer of the worst kind, pa-
grene, saphacera, carious bones, &c.; and if it comes
to be on a glandular part, a scarifier or cancer is
frequently found to ensue. Even the visceras them-
self, especially of the abdomen, may be injured by contu-
sion to such a degree as to produce an inflammation, pa-
grene, or saphacera, say instant death, without resorting
the skin.

Of Gun-shot Wounds.—Gun-shot wound are con-
sidered in no other light than contused wounds;
those made by a musket or pistol ball, the first thing
to be done are, to extract the ball, or any other ex-
traneous body which may have lodged in the wound
ed part; and to stop the hemorrhage, if there is a
situation of blood from the rupture of some coelidien
artery.

It is frequently necessary to enlarge the wound in
order to extract the ball; and if it has gone quite
through (provided the situation of the part wounds
will admit of its being done with safety), the wound
is to be laid freely open through its whole length, in
which means any extraneous body will be more easily
removed, and the cure facilitated.

In order to get at the ball, or any foreign matter, the
probe is to be used as sparingly as possible; and it
must appear evident to any one, who will only consider
the nature of the symptoms attendant on piercing
wounds of the breast or belly, either from a bullet or
sharp instrument; the thrusting in a probe to parts in-
der such circumstances being unavoidably a fresh
on every repetition. Wherever probing is necessary,
the finger is to be preferred as the best and most
practical, where it can be used.

If a ball, or any other foreign body, happens to be
lodged near the orifice, or can be perceived by the
finger to lie under the skin, though at some distance from
the mouth of the wound, we should cut open it and let it
out: but when it is sunk deep, and lies absolutely be-
yond the reach of the finger, it must appear evident on
the least reflection, that thrusting, first a long probe
in quest of the bullet and then, as has been here prac
tised, a long pair of forceps, either with or without
teeth, into a wound of that kind, though with some

certainty to extract it, must either contuse, or initia-

ize and inflame the parts to a great degree; and conse-
quentially do as much, or more, mischief as the ball did

first in forcing its passage to such a length. And should
they at the same time lay hold of any considerable
nerve or nerve along with the ball (which can scarcely
fail of being the case), what shocking consequences
would attend such a proceeding? Nor would attempts
of this sort be less injurious, as a bullet should happen
to be lodged in the cavity of the belly or breast. Such at-
ttempts are the less necessary, because a great number
instances have occurred, where balls have been quitly
lodged in several parts of the body, till after many days
they have worked themselves a passage through the

tissue, and were very easily extracted; and many persons
where balls have been entirely left behind.

In case the wound be occasioned by a musket or
tut shot, and of course be small, it will be necessary to
dilate the wound without delay, provided the nature of
the part will permit of this with safety: for in wounds
near a joint, or in very membranous or tendinous parts,
the knife, as well as forceps, should be put under some
restraint; nor should any more opening be made than
what is absolutely requisite for the free discharge of the
matter lodged within.

Where the wounded person has not suffered any great
loss of blood, and this is generally the case, it will be
advisable to open a vein immediately, and take from the
arm a large quantity; and to repeat bleeding as circum-
stances may require, the second, and even the third day.
Repeated bleedings in the beginning are followed by
many advantages. They prevent pain and a good deal of
inflammation, lessen any feverish surveys, and seldom
fail to obviate imposthunations, and a long train of com-
pliated symptoms which are wont otherwise to inter-
rupt the cure, miserably harass the poor patient, and
too often endanger his life. Even where the feverish
symptoms run high, and there is almost a certainty that
matter is forming, bleeding, in such a state, is very fre-
cently of great advantage.

For the first twelve days after the wound has been re-
ceived, it will be proper to observe a cooling regimen,
both in respect of the medicines that may be prescribed,
and the diet requisite for the support of the patient. It
is likewise absolutely necessary that the body be con-
stantly kept open. Unless, therefore, nature does this
office of herself, a stool should be every day procured,
either by emollient clysters, or some gentle laxative
taken at the mouth; and whenever there is much pain
in the wounded parts, immediate recourse must be had to
opium.

As to external applications, whatever is of a hot spiri-
tuous nature is remarkably injurious on these occasions,
and what no wounded part can in any degree bear. The
wound may be dressed with pledgets of any emollient
ointment; the whole being covered with a common poultice,
or, in some cases, the preparations of lead may
be used. An opiate should now be administered; and
the part affected being placed in the easiest and most
convenient posture, the patient should be laid to rest.
The formation of matter, in every contused wound, is
an object of the first importance; for, till this takes
place, there is often reason to suspect that gangrene may
happen. With a view to hasten suppuration, the warm
poultices should be frequently renewed, and they should
be continued till the tension and swelling, with which
wounds of this kind are usually attended, be removed,
and till the sore has acquired a red, healthy, granula-
ting appearance, and then it is to be treated like a com-
mon ulcer.

Gun-shot wounds are commonly covered from the
beginning with deep sloughs, and various remedies are
recommended for removing these. Every appearance,
however, of this kind with which they are attended pro-
cceeds entirely from contusion; and, excepting the injury
be extensive, the slough is not often perceptible, or it is
so thin as to come away along with the matter at the
first or second dressing. Although emollient poultices
be extremely useful, they ought to be no longer conti-
cued than till the effects already mentioned are produced;
otherwise they will not only relax the parts, but also
produce too copious a discharge of matter, which is
sometimes attended with great danger. A too copious
flow of matter may proceed from different causes; but
in whatever way it may have been produced, the prac-
tice to be adopted must be nearly the same. Every col-
lection which appears must have a free outlet, and the
limb laid in that posture which will most readily admit
of its running off. In such circumstances, nourishing
diet and Peruvian bark in considerable quantities are
highly useful. When the discharge continues copious,
in spite of every effort to check it, detached pieces of
bone or some extraneous matter are probably the cause.
In such a situation nothing will lessen the quantity of
matter till such substances be removed. The wound
ought therefore again to be examined, and any loose
bodies taken away. Pieces of cloth have been known
to be removed by setons, when that method was practi-
cable, after every other method had failed. Opium is
frequently used in checking an excessive discharge
when it happens to be kept up by irritation.

Although no considerable hemorrhage may happen
on first receiving a gun-shot wound; yet after the sloughs
commonly produced upon such occasions have come off,
some considerable arteries may be exposed, and then a
dangerous hemorrhage may ensue. The hemorrhage
is often preceded by a great heat in the injured parts,
and with a throbbing pulmonary pain. At this period it
may frequently be prevented by plentiful blood-letting,
particularly local. But if the hemorrhage has fairly
taken place, and from arteries of considerable size, no-
thing will restrain it but the proper application of lig-
tures. As the discharge in these cases would often
prove dangerous before the surgeon could be procured,
the attendants should be furnished with a tourniquet,
with directions to apply it, upon the first appearance of
blood.

Till of late years the sacrifying of gun-shot wounds Sacrifying
was a practice which prevailed very universally among improper
surgeons; and it was expected by this, that the sloughs
with which wounds are sometimes covered would sooner
separate, and that the cure would thereby be more rea-
dily performed. It is now, however, known, that this
practice, instead of being useful, very generally does
harm by increasing the inflammation. It should there-
fore be laid entirely aside.

When a gun shot wound cannot easily or safely be laid
open from one end to the other, perhaps it may be pro-
per to introduce a cord through the sinus. This, how-
ever, should not be attempted till the first or inflam-
natory state of the wound is over: but when a cord cannot
be properly introduced, on account of the situation or
direction of the wound, compression may prove equally
useful here as in cases of punctured wounds.

Mortification happening after gun-shot wounds is to Mortification
be treated in the same manner as if it had arisen from
in any other cause, only bark is not to be promiscuously used;
as, in phlegmatic habits, it may prove hurtful,
though in debilitated relaxed habits it will be extreme-
ly useful; but even in such it should never be given
while much pain and tension continue.

OF WOUNDS and Injuries of the Head producing Frac-
tures and Depressions.—When the brain is compressed by the
set of symptoms ensue, extremely dangerous, though with the
sometimes they do not make their appearance till
after a considerable interval. But at whatever time
they appear, they are uniformly of the same kind, and

Symptoms.
Wounds are in general as follows: drowsiness, giddiness, and stupor, with diminution of sight, dilatation of the pupil, and where the injury done to the head is great, there is commonly a discharge of blood from the eyes, nose, or ears. Sometimes the fractured bone can be discovered through the integuments, at other times it cannot. There is an irregular and oppressed pulse, and snoring or apoplectic stertor in breathing. There is likewise nausea and vomiting, with an involuntary discharge of feces and urine. Among the muscles of the extremities and other parts, there is loss of voluntary motion, convulsive tremors is some parts of the body, and palsy in others, especially in that side of the body which is opposite to the injured part of the head.

Some of the milder of these symptoms, as vertigo, stupor, and a temporary loss of sensibility, are frequently induced by slight blows upon the head, but commonly soon disappear, either by rest alone, or by the means to be afterwards pointed out. But when any other symptoms ensue, such as dilatation of the pupils, and especially when much blood is discharged from the eyes, nose, and ears, and that there is an involuntary discharge of feces and urine, it may be reasonably concluded that compression of the brain is induced.

The cavity of the cranium, in the healthy and natural state, is everywhere completely filled by the brain; whatever therefore diminishes that cavity, will produce a compression of the brain. The causes producing such a diminution may be of various kinds, as fracture and depression of the bones of the cranium; the forcible introduction of any extraneous body into the cavity of the cranium; effusion of blood, serum, pus, or any other fluid; the thickness and irregularity of the bones of the cranium in certain diseases, as in lues venerae, rickets, or spina ventosa; or water collected in hydrocephalus cases. The first set of causes shall be considered in their order. The four last mentioned belong to the province of the physician, and have been considered in a former part of this work.

Fractures of the cranium have been differently distinguished by different authors; but it seems sufficient to divide them into those attended with depression, and those which are not.

In fracture and depression of the cranium, the treatment ought to be, to discover the situation and extent of the fracture; and to obviate the effects of the injury done to the brain, by raising or removing all the depressed parts of the bone.

When the teguments corresponding to the injury done to the bone are cut or lacerated, and as is sometimes the case, entirely removed, the state of the fracture is immediately discovered; but when the integuments of the skull remain entire, even though the general symptoms of fracture be present, there is sometimes much difficulty in ascertaining it. When, however, any external injury appears, particularly a tumor from a recent contusion, attended by the symptoms already described, there can be no doubt of the existence of a fracture. But it sometimes happens that compression exists without the smallest appearance of tumor. In such cases, the whole head ought to be shaved, when an inflammatory spot may frequently be observed. Sometimes the place of the fracture has been discovered by the patient applying the hand frequently on or near some particular part of the head.

When the symptoms of a compressed brain are evidently marked, no time ought to be lost in making an examination of the state of the cranium, whenever appearances point out, or even lead to the inference, in what part a fracture may be situated. To this purpose an incision is to be made upon the face through the integuments to the surface of the bone, which must be sufficiently exposed to admit of an examination.

Some authors have recommended a crucial incision; others one in form of the letter T; while many make a considerable part of the integuments to be entirely removed. But as it is more agreeable to the present mode of practice to save as much of the skin as possible, a simple incision is generally preferred, unless the fracture run in different directions, and then the incision must vary accordingly. It will frequently happen, that a considerable part of the integuments must be separated from the skull, in order to obtain a distinct view of the full extent of the fracture; but no part of the integuments is to be entirely removed.

When blood vessels of any considerable size are divided, either before or in time of the examination, the ophthalmic vein, is certainly the amount by which the patient may lose a sufficient quantity, the vessels ought to be secured.

After the integuments have been divided, if the skull be found to be fractured and depressed, the nature of the case is rendered evident; but even when there is no external appearance of fracture, tumor, discoloration, or other injury, if the patient continue to labor under symptoms of a compressed brain, if the pericranium has been separated from the bone, and especially if the bone has lost its natural appearance, and has acquired a purplish or dusky yellow hue, the trepan ought to be applied without hesitation at the place where these appearances mark the principal seat of the injury.

Again, although no mark either of fracture or of any diseases underneath should appear on the outer surface of the bone, yet there is a possibility that the inner part may be fractured and depressed. This indeed is not a common occurrence, but it happens probably more frequently than surgeons have been aware of; and where it does happen, the injury done to the brain is in great, and attended with as much danger, as where the whole thickness of the bone is best in. The application of the trepan is therefore necessary.

But if, after the application of the trepan, it happens that no mark of injury appears either in the outer or inner table of that part, or in the dura mater below it, and that the symptoms of a compressed brain still continue, a fracture in some other part is to be suspected; or that kind of fracture termed by practitioners counterfeit fracture, where the skull is fractured and sometimes depressed on the opposite side to, or at a distance from, the part where the injury was received. This is fortunately not a very frequent occurrence, and has even been doubted by some; but different instances of it have been beyond all question, been found. If therefore the operation of the trepan has been performed, and no fracture
WOUNDED

is discovered, no extravasation appears on the surface of the brain; and if blood-letting and other means usually employed do not remove the symptoms of compression, the operator is to search for a fracture on some other part. The whole head should again be examined with much accuracy; and, by pressing deliberately but firmly on the whole, if the smallest indicates the existence of the portion affected, the patient the bone examined. In this way fractures have been frequently detected, which might otherwise have been concealed.

Having now considered every preparatory to the operation of the trepan, we shall next point out the means best adapted for the removal or elevation of a depressed portion of the bone.

The first thing to be done is, after shaving the head, to make an incision as deep as the bone, and directly upon the course of the fracture.

The patient ought to be lain on a table, with a mattress under him, with his head placed upon a pillow, and secured by an assistant. When the extent of the fracture has been determined, and the bleaching from the incision stopped, the depressed bone is now to be elevated; but previous to this it is necessary to search for detached pieces. Should any be found, they ought to be removed by a pair of forceps adapted to this purpose. By the same instrument any splinters of bone which may have been left in may be removed; but when a part of the bone is broken beyond the level of the rest of the cranium, as much of the periosteum is then to be removed by a raspatory, as will allow the trephine to be applied; or, if the operator incline, for the sake of dispatch, he may use the trepan; or the operation may be begun and finished with the trephine, while the trepan may perform the middle and principal part of the work. This part of the work is begun by making a hole with the perforator, deep enough to fix the central pin of the trephine, in order to prevent the saw from slipping out of its central course, till it has formed a groove sufficiently deep to be worked steadily in; and then the pin is to be removed. If the bone be thick, the teeth of the saw must be cleaned now and then by the brush during the perforation, and dipped in oil as often as it is cleaned, which will considerably facilitate the motion, and render it more expeditious: making it at the same time much less disagreeable to the patient, if he possess his senses. That no time may be lost, the operator ought to be provided with two instruments of the same size, or at least to have two heads which can be readily fitted to the same handle.

After having made some progress in the operation, the groove ought to be frequently examined with a pick-tooth, or some such instrument, in order to discover its depth; and if one side happen to be deeper than the other, the operator ought to press more on that side which is shallowest. Precautions are more particularly necessary when the operation is performed upon a part of the skull which is of an unequal thickness, especially after the instrument has passed the diploe. And though it be said by writers in general that the instrument may be worked boldly till it comes at the diploe (which is generally known by the appearance of blood), yet the operator should be upon his guard in this point, examining from time to time if the piece be loose, lest through inadvertence the dura mater be wounded; for in some parts of the skull there is naturally very little diploe, and in old subjects scarcely any. It ought likewise to be remembered, that the skulls of children are very thin. When the piece begins to vibrate, it ought to be snapped off with the forceps or lever; for the sawing ought by no means to be continued till the bone be cut quite through, otherwise the instrument may plunge in upon the brain; or at least injure the dura mater (b).

If the inner edge of the perforation be left ragged, it is to be smoothed with the lenticular, to prevent it from irritating the dura mater. Particular care is to be taken in using the instrument, lest it should press too much upon the brain.

The next step is to raise the depressed part of the bone with the lever, or to extract the fragments of the bone, grumous blood, or any extraneous body. After this, if there appear reason to apprehend that blood, lymph, or matter, is contained under the dura mater, it ought to be cautiously opened with a lancet, endeavouring to avoid the blood-vessels running upon it, or lying immediately under it.

When the trepan is to be used on account of a fissure in which the bone will not yield, the instrument should be applied so as to include part of it, if not directly over it, as it is most probable that the extravasated fluid will be found directly under it. And when the fissure is of great extent, it may be proper to make a perforation at each end, if the whole can be conveniently brought into view; and in some cases several perforations may become necessary.

When it is proposed to make several perforations to remove depressed fragments of the bone which are firmly fixed, and having the internal surface larger than the external, or to raise them sufficiently, it is necessary to apply the trepan as near the fractured parts as possible; making the perforations join each other, to prevent the trouble of cutting the intermediate spaces.

When the skull is injured over a suture, and it is not thought advisable to use the trepan, a perforation ought to be made on each side of the suture, especially in young subjects, in which the dura mater adheres more strongly than in adults; because there cannot be a free communication between the one side and the other, on account of the attachment of that membrane to the suture.

After the elevation of the depressed pieces, or the removal of those which are quite loose, the extraction of the extraneous bodies, and the evacuation of extravasated fluids, &c. the sore is to be dressed in the lightest and easiest manner; all that is necessary being to apply a pledget of fine scraped lint, covered with simple ointment, to that part of the dura mater which is laid bare by

(b) A trepanning instrument has been invented by Mr Rodman, surgeon, Painley, which has no central pin, and it is so contrived that any given thickness of bone may be cut, so that the danger from other instruments is by the use of this entirely avoided. See a more detailed account of this instrument under Apæastinon.
Wounds, by the trepan, or otherwise; after which the edges of the scalp are to be brought together or nearly so, and another pledge laid along the whole course of the wound; a piece of fine soft linen is to be laid over all, and the dressings may be retained in their place by a common night-cap applied close to the head, and properly fixed.

The patient is to be placed in as easy a position in bed as possible, with his head and shoulders elevated a little more than ordinary. If the operation be attended with success, the patient will soon begin to show favourable symptoms; he will soon show signs of increasing sensibility, and the original bad symptoms will gradually disappear. After this he ought to be kept as quiet as possible; proper laxatives are to be administered, and such as may be least of a nauseating nature. His food ought to be simple and easy of digestion, and his drink of the most diluted kind. If he complain of the wound being uneasy, an emollient poultice should be immediately applied, and renewed three or four times in the twenty-four hours. By these means there will commonly be a free suppuration from the whole surface of the sore.

Every time the wound is dressed, the purulent matter ought to be wiped off from it with a fine warm sponge; and if any degree of sloughiness take place on the dura mater or parts adjacent, it will then be completely separated. Granulations will begin to form, which will continue to increase till the whole arise to a level with the surface of the cranium. The edges of the sore are now to be dressed with cerate strappo, and the rest of it covered with fine soft lint, kept gently pressed on by the nightcap properly tied. In this way the cure will go on favourably; luxuriance of granulations will commonly be prevented; the parts will cicatrice kindly; and as the skin has been preserved in making the first incision, the cicatrix will be but little observed.

But things do not always proceed in this favourable manner. Sometimes in a few hours after the operation the patient is seized with a kind of restlessness, tossing his arms, and endeavouring to move himself in bed, while the symptoms of a compressed brain remain nearly the same as formerly. In this case, especially if the pulse be quick and strong, the patient ought to be bled freely, as there will be reason to suspect some tendency to inflammation in the brain. Sometimes, though the trepan has been properly applied, the symptoms are not relieved, on account of extravasated fluids collected internally under the dura mater, or between the pia mater and brain, or in the cavity of the ventricles. The danger in these cases will be in proportion to the depth of the collection. Particular attention therefore ought always to be paid to the state of the dura mater after the perforation has been made. If blood be collected below the dura mater, this membrane will be found tense, dark coloured, elastic, and even livid; in which case, an opening becomes absolutely necessary to discharge the extravasated fluid. Gentle scratches are to be made with a scalpel, till a probe or directory can be introduced; upon which the membrane is to be sufficiently divided in a longitudinal, and sometimes even in a cruciate direction, till an outlet to the fluid be given.

After the dura mater has been cut in this manner, there is some danger of the brain protruding it in opening; but the danger from this is not equal to the bad effects arising from effused fluids compressing the brain.

A troublesome and an alarming appearance now follows the operation of the trepan; namely, is excrescences called fungii, formerly supposed to spring immediately from the surface of the brain, but which, in general, originate from the surface of the dura mater cut edge of the bone granulating too luxuriously.

It often happens that they possess little sensibility; and then the best method to prevent their rising to a great height is to touch them frequently with a cautery: but some cases occur where their sensibility is so great that they cannot be touched, unless they be by a small neck; and then a ligature may be put round them, and tightened from time to time till they be off, which will commonly be in the course of a few days. It seldom happens, however, that there is an occasion for applying such means for the removal of these tumours, for they generally fall off as the perforations of the bone fill up the sore.

If they do not, as the connection between the brain be then in a great measure intercepted, they may be with more safety removed, either by excision, or cautery, or by ligature.

The cure being thus far completed, only some cicatrix will remain, and in general the parts will be nearly as firm as at first: but when much of the instruments have been separated or destroyed, as they may never regenerated, the bone will be left covered only by a thin cuticle, with some small quantity of a yellow substance. When this is the case, the person ought to wear a piece of lead or tin, properly fitted and laid with flannel, to protect it from the cold and other external injuries.

This is the method now commonly practised in cases of compression; but it frequently happens, that indeed of compression, such a degree of concussion takes place that no assistance from the trepan can be attended with any advantage; for the effects of concussion are totally different from those of compression, and therefore to be removed in a different manner.

WOUNDS, in Farriery. See Farriery Index.
WRASSE, or OLD WIFE. See LARIES, Ichthyology Index.
WREATH, in Heraldry, a roll of fine linen or silk (like that of a Turkish turban), consisting of the colours borne in the escutcheon, placed in an achievement between the helmet and the crest, and immediately supporting the crest.

WRECK, or SHIPWRECK, the destruction of a ship by rocks or shallows at sea.

By the ancient common law, where any ship was lost at sea, and the goods or cargo were thrown upon the land, these goods, so wrecked, were judged to belong to the king: for it was held, that, by the loss of the ship, all property was gone out of the original owner. But this was undoubtedly unjust, owing to the owner, and was consonant neither to reason nor humanity. Wherefore it was first ordained by King Henry I, that if any person escaped alive out of the ship, it should be no wreck; and afterwards King Henry II, by his charters, declared, that if on the coasts of either England, Pic-}

ou, Oleron, or Gascony, any ship should be destroyed,
and either man or beast should escape or be found there-
in alive, the goods should remain to the owners, if they
claimed them within three months; but otherwise should
be esteemed a wreck, and should belong to the king, or
other lord of the franchise. This was again confirmed
with improvements by King Richard I.; who, in the
second year of his reign, not only established these con-
cessions, by ordaining that the king should be the
warder of the wrecks, but also that if he perished, his children, or, in
default of them, his brethren and sisters, should retain the
property: and in default of brother or sister, then the
goods should remain to the king (a). And the
law, as laid down by Bracton in the reign of Henry III.,
seems still to have improved in its equity. For then, if
not only a dog (for instance) escaped, by which the
owner might be discovered, but if any certain mark
were set on the goods, by which they might be known
again, it was held to be 30 years. And this is cer-
tainly most agreeable to reason; the rational claim of
the king being only founded upon this, that the true
owner cannot be ascertained. Afterwards, in the first
statute of Westminster, the time of limitation of claims,
given by the charter of Henry II., is extended to a year
and a day, according to the usage of Normandy: and
it enacted, that if any man, a dog, or a cat, escape alive,
the vessel shall not be adjudged a wreck. These an-
imals, as in Bracton, are only put for examples; for it is
now held, that not only if any live thing escape, but
if proof can be made of the property of any of the goods
or lading which come to shore, they shall not be for-
feited as wreck. The statute further ordains, that the
sheriff of the county shall be bound to keep the goods a
year and a day (as in France for one year, agreeable to
the maritime laws of Oleron, and in Holland for a year
and a half), that if any man can prove a property in
them, either in his own right or by right of representa-
tion, they shall be restored to him without delay; but
if no such property be proved within that time, they
shall be the king's. If the goods are of a perma-
nable nature, the sheriff may sell them, and the money
shall be liable in their stead. This revenue of wrecks
is frequently granted out to lords of manors as a royal
franchise; and if any one be thus intitled to wrecks in
his own land, and the king's goods are wrecked there-
on, the king may claim them at any time, even after
the year and day.

It is to be observed, that, in order to constitute a le-
gal wreck, the goods must come to land. If they con-
tinue at sea, the law distinguishes them by the barbarous
and uncouth appellations of jettam, flotsam, and ligan.
Jettam is where goods are cast into the sea, and there
sink and remain under water: flotsam is where they
continue swimming on the surface of the waves: ligan
is where they are sunk in the sea, but tied to a cork or
buoy, in order to be found again. These are also the
king's, if no owner appears to claim them; but if any
owner appears, he is intitled to recover the possession.

For even if they be cast overboard, without any mark
or buoy, in order to lighten the ship, the owner is not
by this act of necessity construed to have renounced his
property: much less can things ligan be supposed to be
abandoned, since the owner has done all in his power to
assert and retain his property. These three are there-
fore accounted so far a distinct thing from the former,
which are cast and escapes, omnes res suas liberas et quietas
haberet, but also, that if he perished, his children, or, in
default of them, his brethren and sisters, should retain the
property: and in default of brother or sister, then the
goods should remain to the king (a).

Wrecks, in their legal acceptation, are at present not
very frequent; for if any goods come to land, it rarely
happens, since the improvement of commerce, naviga-
tion, and correspondence, that the owner is not able to
assert his property within the year and day limited by
law. And in order to preserve this property entire for
him, and if possible to prevent wrecks at all, our laws
have made many very humane regulations; in a spirit
quite opposite to these savage laws which formerly pre-
vailed in all the northern regions of Europe, and a few
years ago were still said to subsist on the coasts of the
Baltic sea, permitting the inhabitants to seize on whatever
they could get as lawful prize; or, as an author of their own expresses it, "in navislegemisericordia et calamitate tantum Victores admixture." For
by the statute 27 Edw. III. c. 13. if any ship be lost on
the shore, and the goods come to land (which cannot,
says the statute, be called wreack), they shall be pre-
rently delivered to the merchants, paying only a reason-
able reward to those that saved and preserved them,
which is intitled salvage. Also by the common law, or
persons (other than the sheriff) take any goods so
cast on shore, which are not legal wreck, the owners
might have a commission to inquire and find them out,
and compel them to make restitution. And by 12 Ann.
stat. 2. c. 18. confirmed by 4 Geo. I. c. 12. in order to
assist the distressed, and prevent the scandalous illegal
practices on some of our sea-coasts (too similar to those
on the Baltic), it is enacted, that all head-officers and
others of towns near the sea, shall, upon application
made to them, summon as many hands as are necessary,
and send them to the relief of any ship in distress, on
forfeit of 100l.; and in case of assistance given, sal-
vage shall be paid by the owners, to be assessed by three
neighbouring justices. All persons that secrete any
goods shall forfeit their treble value; and if they will-
fully do any act whereby the ship is lost or destroyed,
by making holes in her, stealing her pumps, or oth-
erwise, they are guilty of felony without benefit of clergy.
Lastly, by the statute of 26 Geo. II. c. 19. plundering
any vessel, either in distress or wrecked, and whether
any living creature be on board or not (for whether
wreck or otherwise, it is clearly not the property of the
populace), such plundering or preventing the escape of
any person that endeavours to save his life, or wounding
him with intent to destroy him, or putting out false
lights in order to bring any vessel into danger, are all
declared to be capital felonies; in like manner as the
destroying of trees, steeples, or other stated sea-marks,

(a) In like manner Constantine the Great, finding that by the imperial law the revenue of wrecks was given
to the prince's treasury or fiscus, restrained it by an edict (Col. 1 1. 5 1.) and ordered them to remain to the
owners; adding this humane exposition: "Quod enim jus habet fiscus in aliena calamitate, ut de re tam
luctuosa compendium sectetur."

Vol. XX. Part II.
Wreck is punished by the statute 8 Eliz. c. 13, with a forfeiture of 100l. or outlawry. Moreover, by the statute of Geo. II. pillaging any goods cast ashore is declared to be petty larceny; and many other salutary regulations are made, for the more effectually preserving ships of any nation in distress.

By the civil law, to destroy persons shipwrecked, or prevent their saving the ship, is capital. And to steal even a plank from a vessel in distress or wrecked, makes the party liable to answer for the whole ship and cargo. The laws also of the Wisigoths, and the most early Neapolitan constitutions, punished with the utmost severity all those who neglected to assist any ship in distress, or plundered any goods cast on shore.

WREN. See Motacilla, Ornithology Index.

WREN, Sir Christopher, a great philosopher, and one of the most learned and most eminent architects of his age, was the son of Christopher Wren, dean of Windsor, and was born in 1632. He studied at Wadham college in Oxford, where he took the degree of master of arts in 1653, and was chosen fellow of All-Souls college.

When very young he discovered a surprising genius for the mathematics, in which science he made great advances before he was sixteen years old. In 1657, he was made professor of astronomy at Gresham college, London, which he resigned in 1660, on his being chosen to the Savilian professorship of astronomy in Oxford: he was next year created doctor of laws, and in 1663 was elected fellow of the Royal Society. He was one of the commissioners for the reparation of St Paul's; and in 1665 travelled into France, to examine the most beautiful edifices there, when he made many curious observations. At his return to England, he drew a noble plan for rebuilding the city of London after the fire, which he presented to parliament; and upon the decease of Sir John Denham in 1668, was made surveyor-general of his majesty's works; and from that time had the direction of a great number of public edifices, by which he acquired the highest reputation. He built the magnificent theatre at Oxford, St Paul's cathedral, the churches of St Stephen Walbrook, and St Mary-le-Bow, the Monument, the modern part of the palace of Hampton Court, Chelsea college, one of the wings of Greenwich hospital, and many other beautiful edifices. He was president of the Royal Society, one of the commissioners of Chelsea college, and twice member of parliament; first for Plymouth in Devonshire, and then for Melcomb Regis in the same county; but in 1718 was removed from his place of surveyor-general. He died in 1723, and was interred in the vault under St Paul's.

This great man also distinguished himself by many curious inventions and discoveries in natural philosophy; and, among many others, contrived an instrument for measuring the quantity of rain that falls on any space of land for a year; he invented many ways of making astronomical observations more accurate and easy; and injecting liquors into the veins of animals, &c. He translated into Latin Mr. Oughtred's Horologicon, the church of Salisbury, and other pieces. After his death, his posthumous works and draughts were published by his son.

WRESTLING, a kind of combat or engagement between two persons unarmed, body to body, to prove their strength and dexterity, and try which can throw his opponent to the ground.

Wrestling is an exercise of very great antiquity and fame. It was in use in the heroic age; witness Hercules, who wrestled with Antaeus.

It continued a long time in the highest repute, and had considerable rewards and honours assigned to it in the Olympic games. It was the custom for the victor to anoint their bodies with oil, to give the kens to their antagonists.

Lucyrgus ordered the Spartan maidens to wrestle in public quite naked, in order, as it is observed, to less them of their too much delicacy and niceness, to make them appear more robust, and to familiarize the popl, &c. to such nuditities.

WRIST, in Anatomy. See there, No. 33.

WRIT, in Law, signifies, in general, the king's except in writing under seal, issuing out of some court, directed to the sheriff or other officer, and commanding something to be done in relation to a suit or suit, a giving commission to have the same done. And, according to Fitzherbert, a writ is said to be a formal letter the king in parchment, sealed with his seal, and directed to some judge, officer, or minister, &c. at the mast of a subject, for the cause briefly expressed, which is to be determined in the proper court according to law.

WRITS, in civil actions, are either original or judicia: original, are such as are issued out of the court of chancery for the summoning of a defendant to appear; and are granted before the suit is commenced, in order to begin the same; and judicial writs issue out of the court where the original is returned, after the suit is begun. See Process.

The original writ is the foundation of the suit. See Suits.

When a person hath received an injury, and thinks it worth his while to demand a satisfaction for it, he is to consider with himself, or take advice, what the redress of the law has given for that injury; and thereupon to make application or suit to the court, the fountain of all justice, for that particular specific remedy which he is determined or advised to pursue. As for money due or bond, an action of debt; for goods detained without force, an action of detinue or trover; or, if taken with force, an action of trespass vi et armis; or, to try the title of lands, a writ of entry or action of trespass in ejectment; or for any consequential injury received, a special action on the case. To this end he is to sue out, or purchase by paying the stated fees, an original or original writ from the court of chancery, which is the officia iustitiae, the shop or mint of justice, wherein all the king's writs are framed. It is a mandatory letter from the king in parchment, sealed with his great seal, and directed to the sheriff of the county wherein the injury is committed, or supposed so to be, requiring him to command the wrong-doer, or party accused, either to do justice to the complainant, or else to appear at court, and answer the accusations against him. Whatever the sheriff does in pursuance of this writ, he must return or certify to the court of common pleas, together with the writ itself: which is the foundation of the jurisdiction of that court, being the king's warrant for the judge to proceed to the determination of the cause. For it was a maxim introduced by the Normans, that there should be
be no proceedings in common-pleas before the king’s justices without his original writ; because they held it unprofitable that those justices, being only the substitutes of the crown, should take cognizance of any thing but what was thus expressly referred to their judgment. However, in small actions, below the value of forty shillings, which are brought in the court-baron or county-court, no royal writ is necessary; but the foundation of such suits continue to be (as in the times of the Saxons) not by original writ, but by plaint; that is, by a private memorial tendered in open court to the judge, wherein the party injured sets forth his cause of action: and the judge is bound of common right to administer justice therein, without any special mandate from the king. Now indeed even the royal writs are held to be demandable of common right, on paying the usual fees: for any delay in granting them, or setting an unusual or exorbitant price upon them, would be a breach of magna charta, c. 29. "nulli vendemus, nulli negabimus, aut differimus justitiam vel rectum."

Original writs are either optional or peremptory; or, in the language of our law, they are either a precept or a si te fecerit securus. The precept is in the alternative, commanding the defendant to do the thing required, or show the reason wherefore he has not done it. The use of this writ is where something certain is demanded by the plaintiff, which is in the power of the defendant himself to perform; as, to restore the possession of land, to pay a certain liquidated debt, to perform a specific covenant, to render an account, and the like; in all which cases the writ is drawn up in the form of a precept or command, to do thus, or show cause to the contrary; giving the defendant his choice to redress the injury or stand the suit. The other species of original writs is called a si fecerit te securus, from the heads of the writ; which directs the sheriff to cause the defendant to appear in court, without any option given him, provided the plaintiff gives the sheriff security effectually to prosecute his claim. This writ is in use where nothing is specifically demanded, but only a satisfaction in general; to obtain which, and minister complete redress, the intervention of some judicature is necessary. Such are writs of trespass, or on the case, wherein no debt or other specific thing is sued for in certain, but only damages to be assessed by a jury. For this end the defendant is immediately called upon to appear in court, provided the plaintiff gives good security of prosecuting his claim. Both species of writs are tested or witnessed, in the king’s own name; “witness ourself at Westminster”, or wherever the chancellor may be held.

The security here spoken of, to be given by the plaintiff for prosecuting his claim is common to both writs, though it gives denomination only to the latter. The whole of it is at present become a mere matter of form; and John Doe and Richard Roe are always returned as the standing pledges for this purpose. The ancient use of them was to answer for the plaintiff, who in case he brought an action without cause, or failed in the prosecution of it when brought, was liable to an amercement from the crown for raising a false accusation; and so the form of the judgment still is. In like manner, as by the Gothic constitutions no person was permitted to lay a complaint against another nisi sub scriptura aut specificatione trium testium, quod actionem vollet sequi; and, as by the laws of Sancho I. king of Portugal, damages were given against a plaintiff who prosecuted a groundless action.

The day on which the defendant is ordered to appear in court, and on which the sheriff is to bring in the writ, and report how far he has obeyed it, is called the return of the writ; it being then returned by him to the king’s justices at Westminster. And it is also, as made returnable at the distance of at least 15 days from the date or testum, that the defendant may have time to come up to Westminster, even from the most remote parts of the kingdom; and upon some day in one of the four terms, in which the court sits for the dispatch of business.

WRITING, the art or act of signifying and conveying our ideas to others, by letters or characters visible to the eye. See COMPOSITION, GRAMMAR, and LANGUAGE.

The most ancient remains of writing, which have been transmitted to us, are upon hard substances, such as stones and metals, which were used by the ancients for edicts and matters of public notoriety; the decalogue was written on two tables of stone; but this practice was not peculiar to the Jews, for it was used by most of the eastern nations, as well as by the Greeks and Romans; and therefore the ridicule which Voltaire attempts to cast upon that part of the book of Genesis, where the people are commanded to write the law on stones, is absurd; for what is there said by no means implies, that other materials might not be used on common occasions. The laws penal, civil, and ceremonial, among the Greeks, were engraved on tablets of brass which were called clydes.

We find that wood was also used for writing on in different countries. In the Slovian library (No. 4852) are six specimens of Kufic writings, on boards about two feet in length, and six inches in depth. The Chinese, before the invention of paper, wrote or engraved with an iron tool upon thin boards or on bamboo. Pliny says, that table books of wood were in use before the time of Homer. These table books were called by the Romans pugilares. The wood was cut into thin slices, and finely planed and polished. The writing was at first upon the bare wood, with an iron instrument called a stylus. In latter times these tables were usually waxed over, and written upon with that instrument. The matter written upon the tables which were thus waxed over was easily effaced, and by smoothing the wax new matter might be substituted in the place of what had been written before. The Greeks and Romans continued the use of waxed table-books long after the use of papyrus, leaves, and skins, became common, because they were so convenient for correcting extemporary compositions.

Table books of ivory are still used for memorandums, but they are common: written upon with black lead pencils. The practice of writing on table-books covered with wax was not entirely laid aside till the commencement of the 14th century.

The bark of trees was also used for writing by the ancients, and is still in several parts of Asia. The same thing may be said of the leaves of trees. It is needless to observe the use of parchment and vellum, papyrus and paper, for writing; it is too well known.
The method of fabricating these substances has been already described as they occurred in the order of the alphabet. It is obvious, that when men wrote, or rather engraved, on hard substances, instruments of metal were necessary, such as the chisel and the stylus; but the latter was chiefly used for writing upon boards, waxed tablets, or on bark.

When the ancients wrote on softer materials than wood or metal, other instruments were used for writing with, of which reeds and canes seem to have been the first. Reeds and canes are still used as instruments for writing with by the Tartars, the Indians, the Persians, the Turks, and the Greeks. Pencils made of hair are used by the Chinese for their writing; they first liquefy their ink, and dip their pencils into it. Hair-pencils have likewise been used for writing in Europe. Large capital letters were made with them from the time of the Roman emperors till the 16th century. After the invention of printing they were drawn by the illuminators. Quills of geese, swans, peacocks, crows, and other birds, have been used in these western parts for writing with, but how long is not easy to ascertain. St Isidore of Seville, who lived about the middle of the 7th century, describes a pen made of a quill as used in his time.

Method of restoring decayed Writings. In the 77th volume of the Phil. Trans. there is a paper on this subject by Sir Charles Blagden. One of the best methods he found upon experiment to be, covering the letters with phlegistocratic or prussic alkali, with the addition of a diluted mineral acid; upon the application of which, the letters changed very speedily to a deep blue colour, of great beauty and intensity. To prevent the spreading of the colour, which, by blotting the parchment, detracts greatly from the legibility, the alkali should be put on first, and the diluted acid added upon it. The alkali thin with a feather over the traces of the letters, and then to touch it gently, as nearly upon or over the letters as can be done with the diluted acid, by means of a feather or a bit of stick cut to a blunt point. Though the alkali should occasion no sensible change of colour, yet the moment the acid comes upon it, every trace of a letter turns at once to a fine blue, which soon acquires its full intensity, and is beyond comparison stronger than the colour of the original trace had been. If, then, the corner of a bit of blotting paper be carefully and dexterously applied near the letters, so as to imbibe the superfluous liquor, the staining of the parchment may be in a great measure avoided; for it is this superfluous liquor which, absorbing part of the colouring matter from the letters, becomes a dye to whatever it touches. Care must be taken not to bring the blotting paper in contact with the letters, because the colouring matter is soft whilst wet, and may easily be rubbed off. The acid chiefly employed was the mane; but both the vitriolic and nitrous succeed very well. They should be so far diluted as not to be in danger of corroding the parchment, after which the degree of strength does not seem to be a matter of much nicety.

WRITEN MOUNTAINS. See MOUNTAINS.

WRY-NECK. See JYNX, ORNITHOLOGY INDEX.

WURTEMBERG, or WIRTZEMBERG, formerly a duchy, now a kingdom in Germany. It is surrounded on all sides by the territories of Baden and Böingen, except at the point where it touches the lake of Constance. It consists chiefly of the basin or valley of the Neckar, but a small part of it extends across the Rhine. Its greatest length from south to north is 115 miles, its breadth from east to west 90, and its area amounts to 8,200 square English miles. Wurtzberg is one of the most populous countries in Germany, in number of inhabitants in 1812 being 1,991,840, or 17 on an average to each square mile.

Great numbers of emigrants leave this state annually for America or Russia. The country is hilly to the south, where it embraces part of a low range of mountains called the Black-forest, and some scattered branches of the Alps, but presents generally an undulating surface in the north. It is, upon the whole, one of the most fertile districts of Germany. Besides wheat, oats, barley, maize, rye, hemp, and potatoes, it produces tobacco, fruits of many kinds, and vines, which are cultivated to a great extent, and yield a wine of fine quality. A considerable number of sheep, and still greater proportion of black cattle are fed in the Black forest, and other hilly districts. These districts furnish abundance of wood. There are mines of iron, copper, cobalt and iron, but not so productive as to supply the internal consumption. There are also manufactures of linens and woolens; a few of cotton, with some of leather and iron.

The inhabitants are Lutherans, with a small intermixture of Catholics. They are said to be distinguished from the other Germans by a greater share of vivacity, frankness, and good humour, but not by great sobriety or industry. Their dialect is tamed with roughness, but they can boast of having produced many writers of acknowledged merit. There is no part of Germany so well supplied with schools, not only for elementary instruction, but also for the learned languages. The people are in short extremely well informed; and the effects of their superior intelligence have been seen in the many struggles they maintained, since the year 1815, for the restoration of their ancient privileges, which were abolished during the ascendency of Bonaparte. Under their ancient constitution, the diet consisted of a house of prelates (for there were no seculars) representing certain abbeys, provostships, and Lutheran convents; and a house of deputies chosen by the towns. This diet met only on extraordinary occasions, but it appointed a great and a little committee, which held two or three sessions in the year; and through these committees it not only decided upon all taxes proposed, but controlled every branch of the administration, and even nominated one-third of the judges. The king offered his subjects a new constitution in 1816, but this was considered less liberal than their old one, and it experienced so much opposition that he was obliged to withdraw it. During the present year (1819) the differences between the contending parties have been adjusted by another constitution proposed by the king and accepted by the people; and which may therefore be presumed to be more favourable to popular rights, though they have not seen the specific articles of which it consists.

Wurtzberg has been greatly enlarged during the recent changes in Germany. In 1796 its surface was estimated at 3,200 square English miles, and its inhabitants at 608,697; which is less than one half of its present...
present extent and population. It was indebted for the greater part of its acquisitions to Bonaparte; who also bestowed the title of king upon the duke in 1806. Stuttgart is the chief town.

WURTSBURG, a large bishopric in Germany, situated on the Main, erected into a dukedom in 1806, and given to Bavaria in 1814 as a compensation for Salzburg.

WURZBURG, a large and handsome city of Germany, containing about 21,000 inhabitants. It is defended with good fortifications, and has a magnificent palace. There is a handsome hospital, in which are the court and town, and the chief town is at a small distance from the city, and commands it, as it stands upon an eminence. It communicates with the city by a stone bridge, on which are 12 statues, representing many saints. There are manufactures of woolens, glass, leather, chemical substances, &c. There is also an university, founded in 1403. It is seated on the river Maine, in E. Long. 9° 48'. Lat. 49° 40'.

WYCHERLEY, William, an eminent English comedian, was born about 1640. A little before the restoration of King Charles II, he became a gentleman-commoner of Queen's college Oxford, where he was reconciled to Dr Barlow to the Protestant religion, which he had a little before abandoned in his travels. He afterwards entered himself in the Middle-temple, but soon quit the study of the law for pursuits more agreeable to his own genius, as well as to the taste of the age. Upon writing his first play, entitled, Love in a Wood, or St James's Park, which was acted in 1672, he became acquainted with several of the celebrated wits both of the court and town, and liked womankind. The theater of Cleveland. Some time after appeared his comedies, called The Gentleman Dancing Master, the Plain Dealer, and the Country Wife; all which were acted with applause. George duke of Buckingham had a very high esteem for him, and bestowed on him several advantageous posts. King Charles also showed him signal marks of favour; and once gave him a proof of his esteem, which perhaps never any sovereign prince before had given to a private gentleman. Mr Wycherley being ill of a fever, at his lodgings in Bond-street, the king did him the honour of a visit. Finding him extremely weakened, he commanded him to take a journey to the south of France, and assured him, at the same time, that he would order him 500l. to defray the charges of the journey. Mr Wycherley accordingly went into France; and having spent the winter there, returned to England entirely restored to his former vigour. The king, shortly after his arrival, told him, that he had a son, who he was resolved should be educated like the son of a king, and that he could not choose a more proper man for his governor than Mr Wycherley; for which service 1500l. per annum should be settled upon him.

Immediately after this offer he went to Tunbridge, where walking one day upon the Well's walk with his friend Mr Fairhead of Gray's Inn, just as he came up to the bookseller's shop, the countess of Drogheads, a young widow, rich, noble, and beautiful, came thence to inquire for the Plain Dealer; "Madam," says Mr Fairhead, "since you are for the Plain Dealer, there is for you." But pushing Mr Wycherley towards her. "Yes," says Mr Wycherley; "this lady can bear plain dealing; for she appears to be so accomplished, that what would be a compliment to others, would be plain dealing to her." "No, truly, Sir," said the countess. "I am not without my faults, any more than the rest of my sex; and yet notwithstanding, I love plain dealing, and am never more fond of it than when it tells me of them." "Then, madam," says Mr Fairhead, "you and the Plain Dealer seem designed by Heaven for each other." —In short, Mr Wycherley walked a turn or two with the countess, waited upon her home, visited her daily while she staid at Tunbridge, and married her soon after without acquainting the king. By this step, which was looked upon as a contempt of his majesty's orders, he forfeited the royal favour. The ceremony of marriage was settled her whole fortune upon him; but his title being disputed after her death, he was so reduced by the exigencies of the law and other incumbrances, as to be unable to satisfy the impositions of his creditors, who threw him into prison; and the bookseller who printed his Plain Dealer, by which he got almost as much money as the other gained reputation, was so ungrateful as to refuse to lend him 200l. in his extreme necessity. In that confinement he languished seven years; but at length King James going to see the above play, was so charmed with it, that he gave immediate orders for the payment of his debts, and even granted him a pension of 200l. per annum. But the prince's bountiful intentions were in a great measure defeated merely through Mr Wycherley's modesty; he being ashamed to tell the earl of Mulgrave, whom the king had sent to demand it, a true state of his debts. He laboured under the weight of these difficulties till his father died, who left him 600l. a-year. But this estate was under limitations, he being only a tenant for life, and not being allowed to raise any money for the payment of his debts. However, he took a method of doing it which few suspected to be his choice; and this was making a jointure. He had often declared, that he was resolved to die married, though he could not bear the thoughts of living in that state again: accordingly, just at the eve of his death, he married a young gentleman with 1500l. fortune, part of which he applied to the uses he wanted it for. Eleven days after the celebration of these mutials, in December 1715, he died, and was interred in the vault of Gentz-garden church.

Besides his plays above mentioned, he published a volume of poems in folio. In 1728 his posthumous works in prose and verse were published by Mr Theobald.

WYNDHAM, Sir William, descended of an ancient family, was born about the year 1687, and succeeded young to the title and estate of his father. On his return from his travels, he was chosen member for the county of Somerset; in which station he served in the three last parliaments of Queen Anne, and as long as he lived: after the change of the ministry in 1722, he was appointed secretary at war; and in 1715 was raised to be chancellor of the exchequer. Upon the breach between the lord of Oxford and Lord Bolingbroke, he adhered to the interests of the latter. He was removed from his employment on the accession of George I. and falling under suspicion on the breaking out of the rebellion in 1715, was apprehended. He made his escape; a reward was published for apprehending him; he surrendered, was committed to the Tower, but never brought to a trial. After he regained his liberty, he continued in opposition to the several administrations under which he lived; and died in 1740.
Whilst the water is conveyed through the grating to the scuppers.

The xebecs, which are generally armed as vessels of war by the Algerines, mount from 16 to 24 carraús, and carry from 300 to 450 men, two-thirds of whom are generally soldiers.

By the very complicated and inconvenient method of working these vessels, what one of their captainsAllier told Mr Falconer will be readily believed, that every xebec requires at least the labour of two square-rigged ships, wherein the standing sails are calculated to answer every situation of the wind.

XENOCRATES, a celebrated ancient Greek philosopher, was born at Chalcedon in the 9th Olympiad. At first he attached himself to Euxitheus, but afterwards became a disciple of Plato, who took most pains in cultivating his genius, which was naturally heavy. His temperament was gloomy, his aspect severe, and his manners little tinctured with urbanity. These faults his master took great pains to correct; frequently advising him to sacrifice to the Graces; and the pupil was patient of instruction, and knew how to value the kindness of his preceptor. As long as Plato lived, Xenocrates was one of his most esteemed disciples; after his death he closely adhered to his doctrine; and in the second year of the 110th Olympiad, he took the chair in the academy, as the successor of Speusippus.

Xenocrates was celebrated among the Athenians, not only for his wisdom, but for his virtues. So eminent was his reputation for integrity, that when he was called upon to give evidence in a judicial transaction, in which an oath was usually required, the judges unanimously agreed, that his simple asseveration should be taken, as public testimony to his merit. Even Philip of Macedon found it impossible to corrupt him. So abstenious was he with respect to food, that his provision was frequently spoiled before it was consumed. He chastity was irresistible. Phryne, a celebrated Athenian contessa, attempted without success to seduce him. Of his humanity the following pathetic incident is a sufficient proof: A Sparrow, which was pursued by a hawk, flew into his bosom; he afforded it protection till its enemy was out of sight, and then let it go, saying, that he would not betray a suppliant. He was fond of retirement, and was seldom seen in the city. He was discreet in the use of his time, and carefully allotted a certain portion of each.
who had fallen in battle. In this command he acquired great glory by the prudence and firmness with which he conducted them back, through the midst of innumerable dangers, into their own country. The particulars of this memorable adventure are related by Xenophon himself in his "Retreat of the Ten Thousand." After his return into Greece, he joined Agesilaus, king of Sparta, and fought with him against the Thebans in the celebrated battle of Cheronaea. The Athenians, displeased at this alliance, brought a public accusation against him for his former conduct in engaging in the service of Cyrus, and condemned him to exile. The Spartans, upon this, took Xenophon, as an injured man, under their protection, and provided him a comfortable retreat at Stellinthe in Elea. Here, with his wife and two children, he remained several years, and passed his time in the society of his friends, and in writing those historical works which have rendered his name immortal. A war at length arose between the Spartans and Eleans; and Xenophon was obliged to retire to Lepreus, where his eldest son had settled. He afterwards removed, with his whole family, to Corinth, where, in the first year of the hundred and fifth Olympiad, he finished his days.

XENOPHON the Younger, a Greek writer, so called to distinguish him from the celebrated Xenophon, was born at Ephesus, and lived, according to some authors, before Heliodorus, that is, about the beginning of the 4th century. He is only known by his "Ephesicae," a Greek romance in five books, which is esteemed, and contains the amours or adventures of Abracomes and Anthia. This romance was printed at London, in Greek and Latin, in 1724, 4to.

XERXES I. the fifth king of Persia, memorable for the vast army he is said to have carried into the field against Leonidas king of Sparta; consisting, according to some historians, of 800,000 men, while others make it amount to 3,000,000, exclusive of attendants. The amount that attended this prodigious land force is likewise made to consist of 2000 sail; and all the success they met with was the taking and burning of the city of Athens; for the army was shamefully repulsed near the straits of Thermopylae by Leonidas, and the fleet was dispersed and partly destroyed by Themistocles at the straits of Salamis, who had only 380 sail under his command. Xerxes was assassinated by Artabanes, chief captain of his guards, and his distinguished favourite. See SPARTA.

XIMENES, FRANCIS, a justly celebrated cardinal, bishop of Toledo, and prime minister of Spain, was born at Torrelaguna, in Old Castile, in 1433, and studied at Alcala and Salamanca. He then went to Rome; and being robbed on the road, brought nothing back but a bull for obtaining the first vacant prebend: but the archbishop of Toledo refused it him, and threw him into prison. Being at length restored to liberty, he obtained a benefice in the diocese of Siguenza, where Cardinal Gonzales de Mendoza, who was the bishop, made him his grand vicar. Ximenes some time after entered among the Franciscans of Toledo; but being there troubled with visits, he retired to a solitude named Castellar, and applied himself to the study of divinity and the oriental tongues. At his return to Toledo, Queen Isabella of Castile chose him for her confessor, and afterwards nominated him archbishop of Toledo; which, next to the papacy, is the richest dignity in the church of Rome. This honour (says Dr Robertson) he declined with a firmness
Ximenes' firmness which nothing but the authoritative injunction of the pope was able to overcome. Nor did this height of promotion change his manners. Though obliged to display in public that magnificence which became his station, he himself retained his monastic severity. Under his pontifical robes he constantly wore the coarse frock of St. Francis, the rents of which he used to patch with his own hands. He at no time used linen, but was commonly clad in hair-cloth. He slept always in his habit; most frequently on the floor or on boards, and rarely in a bed. He did not taste any of the delicacies which appeared at his table, but satisfied himself with that simple diet which the rule of his order prescribed. Notwithstanding these peculiarities, so opposite to the manner of the world, he possessed a thorough knowledge of its affairs, and discovered talents for business which rendered the fame of his wisdom equal to that of his sanctity. His first care was to provide for the necessities of the poor; to visit the churches and hospitals; to purge his diocese of usurers and places of debauchery; to degrade corrupt judges, and place in their room persons whom he knew to be distinguished by their probity and disinterestedness. He erected a famous university at Alcala; and in 1499 founded the college of St. Ildefonso. Three years after he undertook the Polyglot Bible; and for that purpose sent for many learned men to come to him at Toledo, purchased seven copies in Hebrew for 4,000 crowns; and gave a great price for Latin and Greek manuscripts. At this Bible they laboured above 12 years. It contains the Hebrew text of the Bible; the version of the Septuagint, with a literal translation; that of St. Jerome, and the Chaldee paraphrases of Onkelos; and Ximenes added to it a dictionary of the Hebrew and Chaldee words contained in the Bible. This work is called Ximenes' Polyglot. In 1507 Pope Julius II. gave him the cardinal's hat, and King Ferdinand the Catholic entrusted him with the administration of affairs. Cardinal Ximenes was from this moment the soul of every thing that passed in Spain. He distinguished himself at the beginning of his ministry by discharging the people from the burdensome tax called aracule, which had been continued on account of the war against Granada; and laboured with such zeal and success in the conversion of the Mahometans, that he made 3,000 converts, among whom was a prince of the blood of the kings of Grenada. In 1509 Cardinal Ximenes extended the dominions of Ferdinand, by taking the city of Oran in the kingdom of Algiers. He undertook this conquest at his own expense, and marched in person at the head of the Spanish army clothed in his pontifical ornaments, and accompanied by a great number of ecclesiastics and monks. Some time after, foreseeing an extraordinary scarcity, he erected public granaries at Toledo, Alcala, and Torrelaguna, and had them filled with corn at his own expense; which gained the people's hearts to such a degree, that to preserve the memory of this noble action they had an eulogium upon it cut on marble, in the hall of the senate-house at Toledo, and in the marketplace. King Ferdinand dying in 1516, left Cardinal Ximenes regent of his dominions; and the archduke Charles, who was afterwards the emperor Charles V., confirmed that nomination. The cardinal immediately made a reform of the officers of the supreme council and of the court, and put a stop to the oppression of the gran-
cold and formal expressions of regard, he was allowed to retire to his diocese; and he expired a few hours after reading it in 1517, in the 1st year of his age.

This famous cardinal ought not to be confounded with Roderic Ximenes, archbishop of Toledo, in the 15th century, who wrote a History of Spain in nine books; nor with several other Spanish writers of the name of Ximenes.

XIPHIAS, the Sword-Fish; a genus of fishes belonging to the order of Apodes. See Ichthyology Index. This fish is common in the Mediterranean sea, especially in that part which separates Italy from Sicily, and which has been long celebrated for it: the promontory Pelorus, now Capo di Faro, was a place noted for the resort of the xiphias, and possibly the station of the speculator, or the persons who watched and gave notice of the approach of the fish.

The ancient method of taking them is particularly described by Strabo, and agrees exactly with that practised by the moderns. A man ascends one of the cliffs that overhang the sea: as soon as he spies the fish, he gives notice, either by his voice or by signs, of the course it takes. Another that is stationed in a boat, climbs up the mast, and on seeing the sword-fish, directs the rowers towards it. As soon as he thinks they are got within reach, he descends, and taking a spear in his hand, strikes it into the fish; which, after weakening itself with its agitation, is seized and drawn into the boat. It is much esteemed by the Sicilians, who buy it up eagerly, and at its first coming into season give for it about sixpence English per pound. The season lasts from May till August. The ancients used to cut this fish into pieces and salt it; whence it was called Thamus Thurierus, from Thurii, a town in the bay of Tarantum, where it was taken and cured.

The sword-fish is said to be very voracious, and that it is a great enemy to the tunny, which (according to Belon) are as much terrified at it as sheep are at the sight of a wolf. It is a great enemy to whales, and frequently destroys them.

XYLO-ALOES, or Alo Wood, in the Matera Medica, is a product of the tree growing in China and some of the Indian islands. See Excelsaria.

This drug is distinguished into three sorts; the calambar, or tambac, the common lignum aloes, and calambarum.

The calambar, or finest aloe wood, called by authors lignum aloes praeestissimum, and by the Chineses subkiang, is the most resinous of all the woods we are acquainted with: it is of a light spongy texture, very porous, and its pores so filled up with a soft and fragrant resin, that the whole may be pressed and dried by the fingers like wax, or moulded about by chewing in the mouth in the manner of mastich. This kind, laid on the fire, melts in great part like resin, and burns away in a few moments with a bright flame and perfumed smell. Its scent, while in the mass, is very fragrant and agreeable; and its taste acid and bitterish, but very aromatic and agreeable. It is so variable in its colour, that some have divided it into three kinds; the one variegated with black and purple; the second, with the same black, but with yellowish instead of purple; and the third, yellow alone like the yolk of an egg: this last is the least scented of the three. The variation, however, is owing to the trunk of the tree being itself of three different colours; and the heart of it is the valuable sort first described. The two following are supposed to be the outer parts of the trunk; though this seems doubtful, especially in regard to the last sort, from the circumstance mentioned of its being found in large logs entire, and sometimes only the heart, which, as above noticed, constitutes the calambar.

The lignum aloes vulgare is the second in value. This is of a more dense and compact texture, and consequently less resinous than the other; there is some of it, however, that is spongy, and has the holes filled up with the right resinous matter; and all of it, when good, has veins of the same resin in it. We meet with it in small fragments, which have been cut and split from larger: these are of a tolerably dense texture in the more solid pieces, and of a dusky brown colour, variegated with resinous black veins. It is in this state very heavy, and less fragrant than in those pieces which show a multitude of little holes, filled up with the same blackish matter that forms the veins in others. The woody part of these last pieces is somewhat darker than the other, and is not unfrequently purplish, or even blackish. The smell of the common aloe wood is very agreeable, but not so strongly perfumed as the former. Its taste is somewhat bitter and acrid, but very aromatic.

The calambar, called also ocybuxum sylvestre, and lignum aloes mexicanum, is light and friable, of a dusky and often mottled colour, between a dusky green black and a deep brown. Its smell is fragrant and agreeable, but much less sweet than that of either of the others; and its taste bitterish, but not so much acrid or aromatic as either of the two former. This is said to be met with very frequently, and in large logs; and these sometimes entire, sometimes only the heart of the tree. This is the aloe wood used by the cabinet-makers and joiners.

This drug is esteemed a cordial taken inwardly; and is sometimes given in disorders of the stomach and bowels, and to destroy the worms. A very fragrant oil may be procured from it by distillation; which is recommended in paralytic cases from five to fifteen drops. It is at present, however, but little used; and would scarce be met with anywhere in the shops, but that it is an ingredient in some of the old compositions.

XYNOECLA, in Grecian antiquity, an anniversary feast observed by the Athenians in honour of Minerva, upon the sixteenth of Hecatombole, to commemorate their leaving, by the persuasion of Theseus, their country seats, in which they lay dispersed here and there in Attica, and uniting together in one body.

XYSTARCHA, in antiquity, the master or director of the stystus. In the Greek gymnasium the xystarcha was the second officer, and the gymnasiarcha the first; the former was his lieutenant, and presided over the two xystus, and all exercises of the athlete therein.

XYSUS, among the Greeks, was a long portico, open or covered at the top, where the athletes practised wrestling and running: the gladiators, who practised therein, were called xystici. Among the Romans, the xystus was only an alley, or double row of trees, meeting like an arbour, and forming a shade to walk under.
Y, or γ, the 23d letter of our alphabet: its sound is
formed by expressing the breath with a sudden
expansion of the lips from that configuration by
which we express the vowel u. It is one of the ambigial
guishes, being a consonant in the beginning of words,
and placed before all vowels, as in yard, yield, young,
&c. but before no consonant. At the end of words it
is a vowel, and is substituted for the sound of i, as in
ty, decency, &c. In the middle of words it is not used
so frequently as i is, unless in words derived from
the Greek, as in style, empyreal, &c. though it is admitted
into the middle of some pure English words, as in dying,
lying, &c. The Romans had no capital of this letter,
but used the small one in the middle and last syllables of
words, as in corvamby, ons, martyr. γ is also a num-
meral, signifying 150, or, according to Baronius, 159;
and with a dash a top, as γ, it signified 150,000.

YACHT, or YATCH, a vessel of state, usually em-
ployed to convey princes, ambassadors, or other great
personages, from one kingdom to another.
As the principal design of a yacht is to accommodate
the passengers, it is usually fitted with a variety of con-
venient apartments, with suitable furniture, according
to the quality or number of the persons contained therin.
The royal yachts are commonly rigged as ketches,
except the principal one reserved for the sovereign,
which is equipped with three masts like a ship. They
are in general elegantly furnished, and richly ornament-
ed with sculpture; and always commanded by captains
in his majesty's navy.

Besides these, there are many other yachts of a small-
er kind, employed by the commissioners of the excise,
navy, and customs; or used as pleasure-boats by private
gentlemen.

YAMS. See DIOSSCREA,

YAMBOO. See Eugenia,

BOTANY INDEX.

YARD of a SHIP, a long piece of timber suspended
upon the masts of a ship, to extend the sails to the wind.
See Mast and sail.

All yards are either square or lateen; the former of
which are suspended across the masts at right angles,
and the latter obliquely.
The square yards are nearly of a cylindrical surface.
They taper from the middle, which is called the slings,
towards the extremities, which are termed the yard-
arms; and the distance between the slings and the yard-
arms on each side is by the artificers divided into quar-
ters, and yard arms. The middle quarters are
formed into eight squares, and each of the end parts is
figured like the frustum of a cone. All the yards of a
ship are square except that of the mizen.
The proportions for the length of yards, according to
the different classes of ships in the British navy, are as
follows:

1000: gun-deck:
560: main-yard, fig. 1...100
559: Pl. ccclXXVIII...90
570: Note, the figure...70
576: represents the...60
575: yard and sails of...50
561: a ship of 74 guns...45
380: fore-yard...100
874: all the rest...

To apply this rule to practice, suppose the gun-deck
144 feet. The proportion for this length is, 1000:
to 375, so is 144 to 83: which will be the length
of the main-yard in feet, and so of all the rest.

Cross jack and spriet-sail yards equal to the fore top-
sail-yard.

Sprit-topsail-yard equal to the fore top-sail-gallant-yard.
The diameters of yards are in the following propor-
tions to their length.
The main and fore yards five-sevenths of an inch to
one yard. The topsail, cross-jack, and spriet-sail yard,
nine-fourteenths of an inch to one yard. The top-
gallant, mizen topsail, and spriet-topsail yards, eight-
three-tenths of an inch to one yard.
The mizen-yard five ninths of an inch to one yard.
All studding-sail booms and yards half an inch to one
yard in length.
The lifts of the main-yard are exhibited in the above
figure by g, g; the horses and their stirrups by h, h; the
reef-tackles and their pendents by k, k; and the brace
and brace-pendents by m, m.
The lateen-yards evidently derive their names from
having been peculiar to the ancient Romans. They are
usually composed of several pieces fastened together by
wooldings, which also serve as steps whereby the sailors
climb to the peak or upper extremity, in order to fur-
or cast loose the sail.
The mizen-yard of a ship, and the main-yard of a
bilander, are hung obliquely on the mast, almost in the
same manner as the lateen-yard of a xebec, setter, or
polacre.

YARD, a measure of length used in Britain and
Spain, consisting of three feet, chiefly to measure cloth,
stuff, &c.
YARD-Arm is that half of the yard that is on either side of the mast, when it lies athwart the ship. Yards also denote places belonging to the navy, where the ships of war, &c. are laid up in harbour.

Sanctorius observes, that a great deal is insensibly discharged, when nature endeavours to get rid of the retained perspirable matter, by yawning and stretching of the limbs. To these a person is most inclined just after sleep, because a greater quantity going off by the pores of the skin than at other times, whenever a person wakes, the increasing contraction that then happens closes a great deal of the perspirable matter in the cutaneous passages, which will continually give such irritations as excite yawning and stretching: and such motions, by shaking the membranes of the whole body, and shifting the contact of the fibres, and the inclosed matter, by degrees throw it off. Hence we see the reason why bountiful strong people are most inclined to such motions, because they perspire most in time of sleep, and therefore have more of the perspirable matter to lodge in the pores, and greater irritations thereunto.

The advantages of some little exercise just after waking in a morning are considerable, as it tosses off all the perspirable matter that is ready for its exit out of the body. When yawning is troublesome, Hippocrates says that long deep respiration or drawing in the air at long intervals cures it.

YEAR, in Astronomy and Chronology. See Astronomy and Kalendār.

The ancient Roman year was the lunar year, which, as first settled by Romulus, consisted of only 10 months; viz. 1. March, containing 31 days. 2. April. 3. May. 4. June. 5. Quintilis. 6. Sextilis. 7. September. 8. October. 31. 10. December. 30. In all 304 days; which came short of the true lunar year by 30 days, and of the solar by 51 days. Numa Pompilius corrected this irregular constitution of the year, and composed two new months, January and February, of the days that were used to be added to the former year.

The ancient Egyptian year, called also the year of Nabonassar, on account of the epoch of Nabonassar, is the solar year of 365 days, divided into 12 months, of 30 days each, besides five intercalary days added at the end. The names, &c. of the months are as follows: 1. Thoth. 2. Paophi. 3. Athyr. 4. Choja. 5. Tybi. 6. Meheir. 7. Phamenoth. 8. Pharumeth. 9. Pachon. 10. Baunet. 11. Epiphi. 12. Mesori; beside the 4th.

The ancient Greek year was lunar; consisting of 12 months, which at first had 30 days a-piece, then alternately 30 and 29 days, computed from the first appearance of the new moon; with the addition of an embolimic month of 30 days, every 3d, 5th, 8th, 11th, 14th, 16th, and 19th year of a cycle of 19 years; in order to keep the new and full moons to the same term or seasons of the year. Their year commenced with that new moon, the full moon of which comes next after the summer solstice. The order, &c. of their months was thus: 1. Ewtrionth, containing 29 days. 2. Me-mi-nanth, 30. 3. Ba-ni-tron, 29. 4. Manpianth, 30. 5. Pani-tron, 29. 6. Phianth, 30. 7. Gi-mi-th, 29. 8. Ti-phonth, 30. 9. Elbtonth, 30. 10. Minith, 30. 11. Phionth, 29. 12. Ewtrionth, 30.

The ancient Jewish year is a lunar year, consisting 5 E 2 commonly
commonly of 11 months, which alternately contain 30 and 29 days. It was made to agree with the solar year, either by the adding of 11, and sometimes 12 days, at the end of the year, or by an embolistic month. The names and quantities of the months stand thus: 1. Nisan, or Abib, 30 days. 2. Jiar, or Zius, 29. 3. Sibab, or Sivan, 30. 4. Thammuz, or Tam-muz, 29. 5. Ah, 30. 6. Elul, 29. 7. Tsir, or E-thanim, 32. 8. Marcheswam, or Bul, 30. 9. Cisleu, 30. 10. Tisbe, 29. 11. Sabat, or Schelbeith, 30. 12. Adar, in the embolistic year, 30. Adar, in the common year, was but 29. Note, in the defective year, Cisleu was only 29 days; and in the redundant year, Marcheswam was 30.

The Persian year is a solar year of about 365 days; consisting of 12 months of 30 days each, with five interscalary days added at the end.

The Arabic, Mahometan, and Turkish year, called also the year of the Hefiga, is a lunar year, equal to 354 days eight hours and 43 minutes, and consists of 12 months, which contain alternately 30 and 29 days.

The Hindu year, which is of course a lunar year, differs from these, and is indeed different in different provinces of India. The best account that we have of it is by Mr. Cavendish, in the Phil. Trans. of the Royal Society of London for the year 1792. Before I speak of the civil year of the Hindoos (says this eminent philosopher), it will be proper to say a few words of the astronomical year, by which it is regulated.

The astronomical year begins at the instant when the sun comes to the first point of the Hengoo zodiac. In the year 1792, it began on April 9th, at 22h. 14' after midnight of their first meridian, which is about 41' of time west of Calcutta; but, according to Mr. Gentle's account of the Indian astronomy, it began 2h. 23' earlier. As this year, however, is longer than ours, its commencement falls continually later, in respect of the Julian year, by 50' 26' in four years. This year is divided into 12 months, each of which corresponds to the time of the sun's stay in some sign; so that they are of different lengths, and seldom begin at the beginning of a day.

The civil day in all parts of India begins at sunrise, and is divided into 60 parts called dandias, which are again divided into 60 pallas. In those parts of India in which the Benares almanac, or as it is there called jurna, is used, the civil year is lunar solar, consisting of 12 lunar months, with an intercalary month inserted between them occasionally. It begins at the day after the new moon next before the beginning of the solar year. The lunar month is divided into 30 parts called teeths; these are not strictly of the same length, but are equal to the time in which the moon's true motion from the sun is 12°. From the new moon till the moon arrives at 12° distance from the sun is called the first teethe; from thence till it comes to 24°, is called the second teethe; and so on till the full moon, after which the teethe return in the same order as before.

The civil day is constantly called by the number of that teethe which expires during the course of the day; and as the teethe is sometimes longer than one day, a day sometimes occurs in which no teethe ends. When this is the case, the day is called by the same number as the following day; so that two successive days go by the same name. It often happens, however, that two teethe ends on the same day; in which case the number of the first of them gives name to the day, not that there is no day called by the number of the last, but that a gap is made in the order of the days. In the last part of the month the days are counted from the full moon, in the same manner as in the former part they are counted from the new moon; only the last day, or that on which the new moon happens, is called the 30th, instead of the 1st. It appears, therefore, that each half of the month constantly begins on the day after that on which the new or full moon falls; only sometimes the half month begins with the second day, the first being wanting.

This manner of counting the days is sufficiently intricate; but that of counting the months is still more so.

The civil year, as was before said, begins at the day after the new moon; and, moreover, in the year which has an intercalary month, this month begins the day after the new moon; but, notwithstanding this, the ordinary civil month begins at the day after the full moon. To make their method more intelligible, the first day of the month is called the first month of the natural month. The civil month Visaka, the first in Hindoo kalender, which extends from the 9th of April to the 10th of May, begins at the day after the full moon which is nearest to the instant at which the sun enters Mecha, the first in order of the Indian sign, whether before or after; however, it is not always accurately the nearest.

A consequence of this way of counting the months is, that the first half of Chitra, the last month in the Hindoo kalender, extending from March the 29th to April the 9th, falls in one year, and the latter half is the following year; and whenever the sun enters a sign during a natural month, this month is intercalary. The number of days in the month varies from 29 to 32. Indeed the Hindoo months, both solar and lunar, consist neither of a determinate number of days, nor are regulated by any cycle, but depend solely on the motions of the sun and moon; so that a Hindoo has no way of knowing what day of the month it is, but consulting his almanac; and what is more, the month ought sometimes to begin on different days, in different places, on account of the difference in latitude and longitude, not to mention the differences which may arise from errors in computation. This mode of computing time must be attended with many inconveniences; but in the transactions of civil life the Hindoos do not regard it. A disagreement, however, in the computation of the teethe, which sometimes also happens, occasions no small perplexity; because the teeths of the lunar days are regulated most of their religious festivals. Every Brahmmin in charge of a temple, or whose duty is to announce the times for the observance of religious ceremonies, is therefore furnished with one of their almanacs; and if he be an astronomer, he makes such corrections in it as the difference of latitude and longitude renders necessary.

New Year's Gift. See GIFT.

YEAST, or YEAST, a head or scum rising upon beer or ale while working or fermenting in the vat. See BREWING.

It is used for a leaven or ferment in the baking of bread, as serving to swell or puff it up very considerably.
Mr. Henry has published a method of preparing artificial yeast, by which good bread may be made without the assistance of any other ferment. The method is this: Boil flour and water together to the consistency of treacle, and when the mixture is cold saturate it with fixed air. Pour the mixture thus saturated into one or more large bottles or narrow-mouthed jars; cover it over loosely with paper, and upon that lay a slate or board with a weight to keep it steady. Place the vessel in a situation where the thermometer will stand from 70° to 80°, and stir up the mixture two or three times in 24 hours. In about two days such a degree of fermentation will have taken place, as to give the mixture the appearance of yeast. With the yeast in this state, and before it has acquired a thoroughly vinous smell, mix the quantity of flour intended for bread, in the proportion of six pounds of flour to a quart of yeast, and a sufficient portion of warm water. Knead them well together in a proper vessel, and covering it with a cloth, let the dough stand for 12 hours, or till it appears to be sufficiently fermented in the fore-mentioned degree of warmth. It is then to be formed into loaves and baked.

Mr Henry adds, that perhaps the yeast would be more perfect, if a decoction of malt were used instead of simple water.

It has lately been discovered, that a decoction of malt alone, without any addition, will produce a yeast proper enough for the purpose of brewing. This discovery was made by Joseph Senyor, servant of the reverend Mr Mason of Aston near Roberham; and he received for it a subscription of 20l. from the Society for promoting Arts, Manufactures, and Commerce. The process is as follows: Procure three earthen or wooden vessels of different sizes and apertures, one capable of holding two quarts, the other three or four, and the third five or six; boil a quart of a peck of malt for about eight or ten minutes in three pints of water; and when a quart is poured off from the grains, let it stand in the first or smaller vessel in a cool place till not quite cold, but retaining that degree of heat which the brewers usually find to be proper when they begin to work their liquor. Then remove the vessel into some warm situation near a fire, where the thermometer stands between 70° and 80° degrees Fahrenheit, and there let it remain till the fermentation begins, which will be plainly perceived within 30 hours: add then two quarts more of a like decoction of malt, when cool, as the first was; and mix the whole in the second or larger vessel, and stir it well in, which must be repeated in the usual way, as it rises in a common vat: then add a still greater quantity of the same decoction, to be worked in the largest vessel, which will produce yeast enough for a brewing of 40 gallons.

Common ale yeast may be kept fresh and fit for use several months by the following method: Put a quantity of it into a close canvas bag, and gently squeeze out the moisture in a screw-press till the remaining matter be as firm and stiff as clay. In this state it may be close packed up in a tight cask for securing it from the air; and will keep fresh, sound, and fit for use, for a long time. This is a secret that might be of great use to the brewers and distillers, who, though they employ very large quantities of yeast, seem to know no method of preserving it, or raising nurseries of it; for want of which they sustain a very considerable loss: whereas the brewers in Flanders make a very great advantage of supplying the malt distillers of Holland with yeast, which is rendered lasting and fit for carriage by this easy expedient.

YELLOW, one of the islands of Shetland, lying northeast from the Mainland, and divided from it by an arm of the sea, called Tell Sound. By some it is thought to have been the Thule of the ancients. In the old descriptions it is said to be 20 miles long and 8 broad. It is very mountainous and full of moss; but there are pretty considerable pastures in which they feed a great many sheep; and it also affords plenty of peat. It has eight large harbours, which would not be thought despicable in other countries. Anciently it seems to have been pretty populous, since there are in it three churches, twenty chapels, and many barges or Pittish forts.

YELLOW, one of the original colours of light. Yellow-Colour for House-painting. See Colour-Making.

Note: Yellow, a beautiful colour much used by painters, formerly thought to be prepared from arsenic, but now discovered to have lead for its basis.

YELLOW-Hammer. See Fringilla, Ornithology Index.

YELLOW-Fever. See Medicine, N° 168.

YEMEN, a province of Arabia, stretching along the Red sea and Indian ocean, and forming a part of the country once known by the name of Arabia Felix. YEOMAN, the first or highest degree among the plebeians of England, next in order to the gentry.

The yeomen are properly freeholders, who having land of their own, live on good husbandry. YEOMAN, or Yeoman, is also a title of office in the king's household, of a middle place or rank between an officer and a groom.

YEOMEN of the Guard were anciently 250 men of the best rank under gentry, and of larger stature than ordinary, each being required to be six feet high. At present there are but 100 yeomen in constant duty, and 70 more not in duty; and as any of the 100 dies, his place is supplied out of the 70. They go dressed after the manner of King Henry VIII.'s time. They formerly had diet as well as wages when in waiting; but this was taken off in the reign of Queen Anne.

YEST, or Yeast. See Yeast.

YEY. See Taxus, Botany Index.

Yew trees are remarkable for their duration. There are now growing within 300 yards of the old Gothic ruins of Fountain's abbey, near Rippon, in Yorkshire, seven very large yew trees, commonly called the Seven Sisters, whose exact ages cannot be accurately ascertained, though tradition says that they were standing in the year 1088. It is said also, that when the great Fountaın's abbey was building, which is 900 feet long, and was finished in 1283, the masons used to work their stones, during the hot summers, under the shade of these trees. The circumference of the Seven Sisters, when measured by a curious traveller, were of the following sizes:—the smallest tree, round its body, 5 yards 1 foot; fours others are from 5½ to 7½ yards; the sixth is 9½ yards; and the seventh is 11 yards 1 foot 7 inches in circumference, being 2 yards 10 inches larger than the great...
YOR

great yew tree now growing in the churchyard at Greystoke, in North Wales, which is 9 yards 9 inches. These trees are the largest and oldest in the British dominions.

YONCA, an appellation anciently given to the kings of Peru, and the princes of their blood; the word literally signifying lord, king, emperor, and royal blood.

YOAK, or YOKE, in Agriculture, a frame of wood fitted over the necks of oxen, whereby they are coupled together and harnessed to the plough.

Yoxall of Land, anciently was the space which a yoke of oxen, that is, two oxen, may plough in one day.

YOLK, the yellow part in the middle of an egg (see EGGS).

YONNE, a department in the central part of France, lying along both sides of the river Yonne. The soil is fertile, and produces grain of all kinds, hemp, legumes, fruits, and vines. Wine is a principal article of commerce in this department. Wood and pastureage also abound. The manufactures, which consist of woolens, cottons, briers, leather, paper, glass, ironwork, &c., are not of great importance. The extent of this department is 7,292,225 hectares, and the population in 1817 amounted to 3,359,994. Auverro is the chief town.

YORK, in Latin Eboracum, the capital of Yorkshire in England. This city is so ancient that the origin of it is uncertain. In the time of the Romans a legion was stationed here, it being then the capital of the Britons, and here died the emperor Severus, and Flavius Valerius Constantius Chlorus, father of Constantine the Great. There was then also a temple of Saturna here, and no less than three military ways went from hence. In the time of the Saxons it was erected into an archbishopric by Pope Honorius, to which are now subject the bishoprics of Chester, Durham, Carlisle, and the Isle of Man; though anciently 12 bishoprics in England, and all Scotland, were. A horn is still kept in the minster, by which Ulphius, one of the Saxon princes, bestowed all his lands and revenues upon the church. This city suffered very much during the ravages of the Danes; but, after the Conquest, it began to flourish again. The cathedral, which cost a long time and a great deal of money in building, is a most stately Gothic pile. Its chapter-house is particularly admired for its painted glass, its fine marble stalls, its pillars of alabaster, and curious contrivance. In it is the following inscription:

Ut Rosa, flos florum, sic est Domus ista Domorum.

The choir is remarkable for its fine carvings, particularly the statues of all the English monarchs; and the windows are excellently painted with the history of the Bible. The lantern steeple is 70 feet square, and 188 high, and the windows are 45. At the south end is a circular lighted, called the marigold window from the colour of its glass; and at the north end is a very large one, whose painting represents embroidery.

This city was formerly reckoned the second city in England; but though it stands upon more ground, it is inferior in trade, wealth, and population, to Manchester, Liverpool, and several other cities. The inhabitants amounted to 18,217 in 1811. It is situated in a fine plain, on both sides the Ouse, walled and divided into four wards, containing 28 parishes. It enjoys large privileges and immunities, conferred upon it by a succession of kings from Henry II. and its chief magistrate has the title of lord mayor, which is in some respects peculiar to it and London. Richard II. made it a county of itself. The conservancy of most of the rivers, within certain limits, belongs to the lord mayor and aldermen. The middle arch of the bridge over the Ouse is thought to equal that of the Bridge at Venice in architecture, height, and breadth, the diameter being 81 feet, and the height 57. Though the city is 60 miles distant from the sea, yet ships of 7 tons burden come up the river to it. The town-hall or guild-hall stands upon the bridge, and is superior in all respects to that of London. In the Popish times there were nine abbeys here, and a vast number of churches; but of the latter there are only 17 now. To a steeple of that of Allhalls is reckoned the finest in England. The archbishop has a fine palace, and an assembly-room, designed by the earl of Burlington, a very noble. Here are plays, assemblies, concerts, &c., the like entertainments, at some house or other, almost every night in the week. In the old castle, built originally by William the Conqueror, in the time of the assizes are kept. It serves also for the county gaol, which is the nearest and pleasantest in England, with an area larger than that of the king's-bench, and it has a handsome chapel in it, with a good allowance for a preacher. This city has long given the title of their some branch of the royal family.

The plenty and cheapness of provisions induce many persons of small fortune, or that would live frugally, to take up their abode here; and the noisome remains of Roman antiquities, and those of a later date, as shafts, churches, and castles, procure this city a visit from every curious traveller. Many Roman altars, urns, coins, inscriptions, &c., have been found; and Saxon coins are still extant that have been struck here. The market, being two in number, for this city, have precedence of all others, except those of London, in the house of commons. An infirmary, after the manner of those of Bath, Bristol, &c., has been erected in it; and a cotton manufacture established and brought to great perfection. Besides four weekly markets, it has a great many fairs, one, in particular, every other Thursday for cattle and sheep. W. Long. 1. N. Lat. 53° 59'.

YORKSHIRE, the largest county of England, bounded on the south by Derbyshire, Nottinghamshire, and Lincolnshire; on the north by Durham and Westmorland; on the east by the German ocean; and on the west by Lancashire and a part of Cheshire. It is upwards of 80 miles in length from east to west, nearly as much in breadth, and about 560 in circumference, containing, in the whole, 26 hundreds or wapentakes, 49 market-towns, 563 parishes, 242 vicarages, with many chapels of ease, and 2330 villages. It is divided into three parts or ridings, viz. the West, East, and North; so denominated from their situation, in respect of the city of York. Each of these is as large, if not larger, than any ordinary county. There are other divisions, as Richmondshire, Allertonsire, Holderness, Hallamshire, Craven, Cleveland, Mammehall, Holdens, &c.

As the soil and face of the country vary greatly,
Y O R

[ 775 ]

Y O R

does the air. In the hilly parts the air is good, but the soil very indifferent; of the lower some are marshy, others dryer, and the soil of both rich; but the air of the former is more foggy and unhealthy than that of the latter. The manufactures of this county are cutlery and hard-ware, particularly knives, bits, and spurs; but the principal are stockings and woolen cloth, with which it supplies in a great measure Germany and the North. As to the produce, it abounds in corn, cattle, horses, lead and iron, coal, wood, lime, liquorice, alum, jet, &c. It lies wholly in the northern circuit, and much the greater part of it in the diocese of York; that only which is called Richmondshire belonging to the diocese of Chester. The members it sends to parliament are 30; of which two are for the shire and 28 for the towns.

New-York, one of the United States of America, is bounded towards the south-east by the Atlantic ocean; east by Connecticut, Massachusetts, and Vermont; north by the 45th degree of latitude, which divides it from Canada; north-westwardly by the river Iroquois or St Lawrence, and the lakes Ontario and Erie; south-west and south by Pennsylvania and New Jersey. The whose state contains about 44,000 square miles, equal to 28,160,000 acres.

The state, to speak generally, abounds with lakes, some of salt and others of fresh water. It is intersected by ridges of mountains running in a north-east and south-west direction. Beyond the Alleghan mountains, however, the country is a dead level, of a fine rich soil, covered in its natural state, with maple, beech, birch, cherry, black-walnut, locust, hickory, and some mulberry trees. On the banks of Lake Erie, are a few chesnut and oak swamps. Back of Lake Erie the plains extend thinly through the country. All the creeks that empty into Lake Erie have falls, which afford many excellent mill seats. East of the Alleghan mountains, the country is broken into hills with rich intervening valleys. The hills are clothed thick with timber, and when cleared afford fine pastures; the valleys, when cultivated, produce wheat, hemp, flax, peas, grass, oats, Indian corn.

The principal rivers are the Hudson, and the Mohawk, which is a branch of the former. The Hudson is navigable for sloops 150 miles from its mouth, and by the Mohawk boats ascend about 70 miles farther. A canal is now in progress to extend the inland navigation from the head waters of the Mohawk to Lake Erie, a distance of 200 miles. In the north-eastern ports, Lake Champlain affords a navigable communication for 100 miles; and the St Lawrence, with lakes Ontario and Erie, for many hundred miles more, on the north-western frontier.

Iron abounds in the state of New York, and lead is wrought at some places, but the other metals are scarce. Roofing slate, lime-stone, marble, and coal are found in some situations. Gypsum and salt (from springs) are abundant in the western parts. The mineral waters of Balston and Saratoga are celebrated for their medicinal virtues.

The wild animals are now becoming rare in this state. The wolf, formerly common, is seldom seen. The bears, which are still found in considerable numbers, often carry off the hogs from new settlements. The couguar seldom appears; the deer, fox, marten, beaver, and squirtle are found occasionally. Snakes of a large size are met with in the uncultivated parts.

The population of this state in 1790 was estimated at 100,000; in 1800 it amounted to 1,188,070; and in 1810, to 1,953,049, including 15,017 slaves. At the last mentioned period New York was the second state in the union for population; but it is probably now the first.

The legislative power is vested in a senate and house of assembly. The latter is elected annually by ballot, by electors who must be freeholders to the value of fifty dollars, or residents renting tenements of five dollars yearly value. The senate is elected for four years, one fourth being renewed every year. The permanent number of senators is 32, of members of the lower house 150. The executive power resides in a governor elected for three years by the freeholders, with a council of four senators, chosen annually by the legislature. The judges, who are appointed by the governor and council, hold their offices during good behaviour till the age of sixty.

There is no state religion, but the clergymen of each persuasion are supported by the voluntary contributions of their congregations. The Presbyterians are the most numerous sect, the Baptists, Methodists, Quakers, and Roman Catholics are also pretty numerous. In 1815, there were 2621 primary schools in the state, at which 140,720 scholars were educated. It is rare to meet with any person in this state who cannot read and write. There is also a considerable number of academies, and three colleges,—Columbia College founded in 1754, Union College founded in 1794; and Hamilton College in 1812. The number of scientific and humane societies is also considerable. Above seventy newspapers are printed in the state.

The manufactures of this state consist of iron, glass, gunpowder, woollens, linens and cottons, cordage, spirits, leather, hats, &c. Though several large works are established, about one third of the articles produced are made in families. The whole value of manufactures in 1810 was thirty-three millions of dollars; but during the war with England in 1814, the amount was supposed not to fall short of fifty millions. So rapid has been the accumulation of capital in this state, that the value of lands and houses, which was found by a fiscal survey in 1799 to be 100,825,700 dollars, amounted according to a new survey in 1814 to 269,370,000 dollars. The exports of this state, in 1817, amounted to 18,707,433 dollars; being one half greater than those of any other state in the union.

Though New York is the first commercial state in North America, the bulk of the inhabitants live by agriculture. They are generally industrious, sober, and well informed. There are still some small societies of Dutch and Germans, who preserve both the language and manners of their country. In general the inhabitants of this state are neither infected with the hypocritical austerity, pride, and selfishness of the New Englanders, nor with the lax morality and ostentatious habits of the people of the southern states. In times of difficulty they have generally held a moderate course.

New-York, a city of North America, capital of the state of the same name. It is situated at the south-west point.
an act constituting 21 gentlemen (of whom the governor and lieutenant-governor for the time being, are ex officio) a body corporate and politic by the name of "The Regents of the University of the State of New-York." They are entrusted with the care and management of the same in general, and have power to grant charters for erecting colleges and academies through the state. It is now denominated Columbia college. It consists of a faculty of arts, and one of medicine, containing the first four presidents and seven professors, and the second a don, and the same number of professors.

The government of this city is at present in the hands of a mayor, aldermen, and common council; and the city is divided into seven wards, in each of which two aldermen and assistant are annually chosen by the people. A court of session is held for the trial of criminal cases. There were eight banks in the city in 1814; and there is a great number of literary, scientific, and benevolent institutions. The shipping belonging to the port in 1815 amounted to 278,689 tons. New-York is 95 miles N. E. of Philadelphia, 197 N. E. of Baltimore, and 913 from Charleston. W. Long. 74° 9' 45" N. Lat. 40° 42' 8".

YOUNG, Dr EDWARD, was the son of a clergyman of the same name, and was born about the year 1699. When sufficiently qualified, he was matriculated at All-Souls college, Oxford; and designing to follow the civil law, he took a degree in that profession. In this situation he wrote his poem called The Last Dr, published in 1724; which coming from a layman, was universal satisfaction: this was soon after followed by another, entitled The Fire of Religion, or Vanquished Love. These productions gained him a respectable acquaintance; he was intimate with Addison, and became one of the writers of the Spectator: but the turn of his mind leading him to the church, he took orders, was made one of the king's chaplains, and obtained the living of Welwyn in Hertfordshire, worth about 500l. per annum, but he never rose to higher preferment. For some years before the death of the late prince of Wales, Dr Young attended his court pretty constantly; but upon his decease all his hopes of church preferment vanished; however, upon the death of Dr Hales, he was taken into the service of the princess dowager of Wales, and succeeded him as her private chaplain. When pretty far advanced in life, he married the lady Elizabeth Lee, daughter of the late earl of Litchfield. This lady was a widow, and had an able son and daughter, who both died young. What he felt for their loss, as well as for that of his wife, is finely expressed in his Night Thoughts, in which the young lady is characterized under the name of Narcissa; her brother by that of Plfindler; and his wife, though nameless, is frequently mentioned; and in thus, in an apostrophe to death, he establishes the loss of all the three.

Inarticulate archer, could not once suffice! Thine shaft flew thrice, and thrice my peace was slain. And thrice ere thrice thou monstred her heart.

He wrote three tragedies, The Revenge, Bunnis, and The Brothers. His satires, called Love of Force in universal Passion, are by many esteemed his principal performance; though Swift said the poet should have
Z

Z, or z, the 24th and last letter, and the 10th consonant of our alphabet; the sound of which is formed by a motion of the tongue from the palate downwards and upwards to it again, with a shutting and opening of the teeth at the same time. This letter has been reputed a double consonant, having the sound *dz*, but some think with very little reason: and, as if we thought otherwise, we often double it, as in *private, murzzle,* &c. Among the ancients, *ζ* was a numeral letter, signifying 2000; and with a dash added a-top, *ζ* signified 2000 times 2000, or 40,000,000.

In abbreviations this letter formerly stood as a mark for several sorts of weights; sometimes it signified an ounce and a half; and very frequently it stood for half an ounce; sometimes for the eighth part of an ounce, or a dram troy weight; and it has in earlier times been used to express the third part of an ounce or eight scruples. *ZZ* were used by some of the ancient physicians to express myrrh, and at present they are often used to signify zinc zinc or ginger.

*Zaara, Zapha, Saharah, or the Desert*, a vast country of Africa, bounded on the north by Barbary, on the east by Fezzan and Cashma, on the south by Tombuctoo, and on the west by the Atlantic ocean. Zaara contains a variety of wandering nations, all proceeding from Arabs, Moors, and fugitive Portuguese, who took refuge there when the family of the Sheriffs made themselves masters of the three kingdoms of Bar.
ZAF

ZAM

barry. All these people bear indiscriminately the names of Nara, Moors, or Arabs. They are subdivided into various nations, of which the most considerable are the Mongearts, Trarsars, and Bracnars. The Mongearts lead a wandering life, and live chiefly on the milk of their flocks, with a little barley-meal, and some dates. The poorer sort go naked, except the females, who commonly wrap a clout about their middle, and wear a kind of bonnet on their head; but the wealthier sort have a kind of loose gown, made of blue calico, with large sleeves, that is brought them from Nérogland. When they move from one place to another for fresh pasture, water, or prey, most of them ride on camels, which have generally a sort of saddle between the bunch and the neck, with a string or strap run through their nostrils, which serves for a bridle; and instead of spurs they use a sharp bodkin. Their tents or huts are covered with a coarse stuff, made of camel’s hair, and a kind of wool or moss that grows on the palm trees. These Arabs live here under the government of their sheikhs or sheiks; as in Arabia, Egypt, and other places. The other two tribes are rather more civilized. They are all Mahometans.

ZABULON, in Ancient Geography, one of the twelve tribes; bounded on the north by the tribes of Asher and Naphthali; on the east by the sea of Galilee; on the south by the tribe of Issachar or the brook Cislon, which ran between both; on the west by the Mediterranean; so that it touched two seas, or was bimarsus.

ZABULON, in Ancient Geography, a very strong town in the tribe of that name, on the Mediterranean, surnamed of men, near Ptolemais: its vicinity to which makes it probable that it was also Chabulon, unless either name is a faulty reading in Josephus; distant about 60 stadia from Ptolemais.

ZACYNTHUS, in Ancient Geography, an island to the south of Cephalenia 60 stadia, but nearer to Peloponnesus, in the Ionian sea, formerly subject to Ulysses, in compass above 160 stadia, woody and fruitful, with a considerable cognominal town and a port. The island lies over against Elis, having a colony of Achaeans from Peloponnesus, over against the Corinthian gulf. Both island and town are now called Zante.

ZAFFRE, is the oxide of cobalt, employed for painting pottery ware and porcelain of a blue colour. The method of preparing it is as follows: The cobalt taken out of the mine is broken with hammers into pieces about the size of a hen’s egg; and the stone involucrum, with such other heterogeneous matters as are distinguishable by the eye, are separated as much as possible. The chosen mineral is then pounded in stamping mills, and sifted through brass wire sieves. The lighter parts are washed off by water, and it is afterwards put into a large flat-bottomed arched furnace, resembling a baking oven, where the flame of the wood reverberates upon the ore; which is occasionally stirred and turned with long handled iron hooks or rakes; and the process is continued till it ceases to emit any fumes. The oven or furnace is terminated by a long horizontal pallery, which serves for a chimney; in which the ore contains a little bismuth, as this semimetal is very fusible, it is collected at the bottom of the furnace. The cobalt remains in the state of a dark grey oxide, and is called saffire. One hundred pounds of the cobalt ore lose 20 and even 30 per cent during this operation, which is continued 4 or even 9 hours, according to the quality of the ore. The roasted ore being taken out from the furnace, such parts as are corroded into lungs are pounded and sifted afresh. Zaffre, in commerce, is never pure, being mixed with two or rather three parts of powdered flints. A proper quantity of the best set of these, after being ignited in a furnace, is thrown into water to render it friable, and more easily reduced to powder; which, being sifted, is mixed with the saffire, according to the before-mentioned dose; and the mixture is put into casks, after being moistened with water. This oxide, fused with three parts of sand and one of potash, forms a blue glass; which, when pounded, sifted, and afterwards ground in mills, included in large casks, forms smalt.

The blue of zaffre is the most solid and fixed of all the colours that can be employed in vitrification. It suffers no change from the most violent fire. It successfully employed to give shades of blue to enamel, and to the crystal glasses made in imitation of some opaque and transparent precious stones, as the lapis lazuli, the turquois, the sapphire, and others of the kind.

ZALFUCUS, a famous legislator of the Locians, and the disciple of Pythagoras, flourished 500 B.C. He made a law, by which he punished adulterers with the loss of both their eyes; and his son sleeping, was not absolved from this punishment: yea, to show the father as well as the just lawyer, he put out his own right, and his son’s left eye. This example of justice and severity made so strong an impression on the minds of his subjects, that no instance was found of the commission of that vice during the reign of that legislator. It is added, that Zaleucus forbade any wine being given to the sick on pain of death, unless it was prescribed by the physicians; and that he was so jealous of his laws, that he ordered, that whoever was desirous of changing them, should be obliged, when he made the proposal, to have a cord about his neck, in order that he might be immediately strangled, if those alterations were esteemed no better than the laws already established. Diodorus Siculus attributes the same thing to Cleonidas legislator of the Sybarites.

ZAMA, in Ancient Geography, a town of Numidia, a district of Cappadocia, of unknown situation. Another Zama, of Mesopotamia, is on the Soconus, to the south of Nisibis. A third, of Numidia, distant five days journey to the west of Carthage: it was the other royal residence of the kings of Numidia, hence called Zama Regia. It stood in a plain; was stronger by art than nature; richly supplied with every necessary; not abounding in men, and every weapon both of defense and annoyance. The last of these is remarkable for the decisive battle fought between the two greatest commanders in the world, Hannibal the Carthaginian and Scipio Africanus. Of this engagement, the most important perhaps that ever was fought, Mr Hooke gives the following account.

As Scipio drew up his army after the Roman manner, except that he placed the cohorts of the Principes directly behind those of the Hastati, so as to leave sufficient space for the enemy’s elephants to pass through from
C. Lælius was posted on the left wing with the Italian horse, and Masinissa with his Numidians on the right. The intervals of the first line Scipio filled up with his Velites, or light-armed troops, ordering them, upon a signal given, to begin the battle; and, in case they were repulsed, or broke by the elephants, to run back through the lanes before mentioned, and continue on their flight till they were got behind the Triarìi. Those that were wounded, or in danger of being overtaken, were to turn off to the right and left through the spaces between the lines, and that way escape to the rear.

The army thus drawn up, Scipio went from rank to rank, urging his soldiers to consider the consequences of a defeat and the rewards of victory: on the one hand, certain death or slavery (for they had no town in Africa strong enough to protect them); on the other, not only a lasting superiority over Carthage, but the empire of the rest of the world.

Hannibal ranged all his elephants, to the number of above 80, in one front. Behind these he placed his mercenaries, consisting of 12,000 men, Ligurians, Gauls, Balearics, and Mauritanians.

The new levies of Carthaginians and other Africans, together with 4000 Macedonians, under a general named Spoeter, composed the second line. And in the midst of the distance was about a furlong he posted his Italian troops, in whom he chiefly confided. The Carthaginian horse formed his right wing, the Numidians his left.

He ordered his several leaders to exhort their troops not to be discouraged by their own weakness, but to place the hope of victory in him and his Italian army; and particularly directed the captains of the Carthaginians to represent to them what would be the fate of their wives and children if the event of this battle should not prove successful. The general term, walking through the ranks of his Italian troops, called upon them to be mindful of the 17 campaigns in which they had been fellow-soldiers with him; and of that constant series of victories by which they had extinguished in the Romans all hope of ever being conquerors. He urged them to remember, above all, the battles of Trebia, Thrasymenus, and Cannae; with any of which the approaching battle was in no wise to be compared, either with respect to the bravery or the number of the enemy. The Romans were yet unfooled, and in the height of their strength, when you first met them in the field; nevertheless you vanquished them. The soldiers now before us are either the children of the vanquished, or the remains of those whom you have often put to flight in Italy. Maintain therefore your general's glory and your own, and establish to yourselves the name of invincible, by which you are become famous throughout the world.

When the Numidians of the two armies had skirmished a while, Hannibal ordered the managers of the elephants to drive them upon the enemy. Some of the beasts, frightened at the noise of the trumpets and other instruments of war which sounded on all sides, immediately ran back amongst the Numidians of the Carthaginian left wing, and put them into confusion; which Masinissa taking advantage of, entirely routed them. Great destruction was made of the Velites by the rest of the elephants, till these also being terrified, some of them ran through the void spaces of the Roman army which Scipio had left for that purpose; others falling among the cavalry of the enemy's right wing, gave Lælius the same opportunity against the Carthaginian horse as had been given to Masinissa against the Numidian, and of which the Roman hast did not fail to make the same use. After this the infantry of the foremost lines joined battle. Hannibal's mercenaries had the advantage in the beginning of the conflict; but the Roman hastati, followed and encouraged by the Principes, who exhorted them to fight manfully, and showed themselves ready to assist them, bravely sustained the attack, and at length gained ground upon the enemy. The mercenaries not being seasonably supported by their second line, and therefore thinking themselves betrayed, they in their retreat fell furiously upon the Africans; so that these, the Hastati coming up, were obliged to fight for some time both against their own mercenaries and the enemy. When the two Carthaginian lines had ceased their mutual rage, they joined their strength; and though now but a mere throng of men, broke the Hastati: but then the Principes advancing to the assistance of the latter, restored the battle; and most of the Africans and mercenaries were here cut off. Hannibal did not advance to their relief, the Roman Triarìi not having yet engaged, and the Principes being still in good order; and lest the routed Africans and mercenaries should break the ranks of his Italian soldiers, he commanded these to present their spears at those who fled to them for protection, which obliged the runaways to move off to the right and left.

The ground over which the Romans must march before they could attack Hannibal being strewed with heaps of dead bodies and weapons, and being slippery with blood, Scipio feared that the order of his battalions would be broke, should he pass it hastily. To avoid this mischief, he commanded the Hastati to give over the pursuit, and halt where they were, opposite to the enemy's centre: after which, having sent all his wounded to the rear, he advanced leisurely with the Principes and Triarìi, and placed them on the wings of the Hastati. Then followed a sharp engagement, in which victory was long and eagerly disputed. It would seem that the Romans, though superior in number, were once upon the point of losing the day; for Polybius tells us, that Masinissa and Lælius came very seasonably, and as if sent from heaven, to their assistance. These generals being returned from the pursuit of the enemy's flight, suddenly upon the rear of Hannibal's men, most of whom were cut off in their ranks; and of those that fled, very few escaped the horse, the country all round being a plain.

There died of the Carthaginians in the fight above 20,000, and almost the like number were taken prisoners. The loss on the side of the Romans amounted to about 2000 men. Hannibal escaped with a few horse to Adrumetum, having performed every thing in the engagement which could be expected from a great general. His army (say Polybius) could not have been more skilfully drawn up. For as the order of the Roman battalions makes it extremely difficult to break them, the Carthaginian wisely placed his elephants in the front, that they might put the enemy in confusion before the armies should engage. In his first line he placed the mercenaries; men bold and active, but not well
well disciplined, that by their impetuosity he might give
a check to the ardour of the Romans. The Africans
and Carthaginians, whose courage he doubted, he pos-
ed in the middle between the mercenaries and his Ita-
ilian soldiers, that they might be forced to fight; or at
least that the Romans, by slaughtering them, might fat-
tigue themselves and blunt their weapons. Last of all,
he drew up the troops he had disciplined himself, and
in whom he chiefly confided, at a good distance from
the second line, that they might not be broken by the
route of the Africans and mercenaries, and kept them
in reserve for a vigorous attack upon a tired and weak-
ened enemy."

ZANGUEBAR, a country in Africa, lying on the
eastern coast, between three degrees of north latitude,
and 18 south. It includes several petty kingdoms, in
which the Portuguese have various settlements. The
inhabitants, except those converted by the Portuguese,
are all Mahometans or idolaters; and the latter much
the more numerous. The names of the principal terri-
tories are Mombasa, Lamu, Melinda, Quioila, and Mo-
sambiqui. The Portuguese have built several forts in
Mombaza and Mosambique, and have settled several
colonies there. They trade with the negroes for slaves,
ivory, gold, ostrich-feathers, wax and drugs. The
productions are much the same as in other parts of
Africa between the tropics.

ZANONIA, a genus of plants of the class pentan-
dria. See Botany Index.

ZANTE, an island of the Mediterranean, near the
coast of the Morea, 19 miles south east of the island of
Cephalea, belonging to the Ionian republic. It is
about 24 miles in length and 12 in breadth, and very
pleasant and fertile; but its principal riches consist in
currents, with which it greatly abounds. They are cul-
tivated in a very large plain, under the shelter of moun-
tains on the shore of this island; for which reason the
sun has greater power to bring them to perfect ma-
turity. The town called Zante may contain near
20,000 inhabitants; the whole island contains about
40,000. The houses are low, on account of the fre-
quent earthquakes, for scarce a year passes without one;
however, they do no great damage. The natives speak
both Greek and Italian. There are very few Roman
Catholics among them; but they have a bishop as well
as the Greeks. This place has no fortifications, but
there is a fortress upon an eminence planted with cannon.
In one part of this island is a place which shaks when
the wind blows, like a quagmire; and a spring which throws
out a great deal of bitumen, especially at the time of
an earthquake. It serves instead of pitch to pay the
bottoms of the ships, and about 100 barrels in a year
are used for this purpose. There are about 50 villages
in the island; but no other large town beside Zante.
It is seated on the eastern side of the island, and has
a good harbour. This and the other Ionian islands are
now under the protection of Britain. E. Long. 21. 3
N. Lat. 27. 73.

ZANTHOXYLUM, the Toothache-tree, a gen-
us of plants of the class dioecia; and in the natural
system arranged under the 46th order, Hederacer. See
Botany Index.

ZAPATA, a kind of feast or ceremony held in
Italy in the courts of certain princes, on St Nicholas's
day; wherein people hide presents in the shoes or slip-
pers of those they would do honour to, in such wise
as may surprise them on the morrow when they rise
to dress; being done in imitation of the practice of
St. Nicholas, who used in the night-time to throw noted
money in at the windows to marry poor maid maids.

ZEA, INDIAN CORN; a genus of plants of the
monocot. See Botany Index. There is only one spe-
cies, the Maize, maize. The Indians in New England,
and many other parts of America, had no other vege-
table but maize or Indian corn for making their food.
They call it wacaciah; and in the United States of
America there is a great proportion of the bread of the
country made of this grain. In Italy and Germany
there is also a species of maize which is the food of the
poor inhabitants. The ear of the maize yields a much greater
quantity of grain than any of our corn ears. There are
commonly about eight rows of grain in the ear, often ten,
if the ground be good. Each of these rows contains
least 30 grains, and each of these gives much more
flour than a grain of any of our corn. The grain is
usually either white or yellowish; but sometimes they
are red, bluish, greenish, or olive-coloured, and some-
times striped and variegated. This sort of grain, though
so essentially necessary to the natives of the place, is yet
liable to many accidents. It does not ripen till the end
of September; so that the rains often fall heavy upon
it while on the stalk, and the birds in general pick it
when it is soft and unripe. Nature has, to defend it
from these accidents, covered it with a thick husk,
which keeps off slight rains very well; but the birds
if not frightened away, often eat through it, and devor
a great quantity of the grain.

There are three or four varieties of maize in different
parts of America. That of Virginia is very tall and
robust, growing to seven or eight feet high; that of
New England is shorter and lower. And the Indians
further up in the country have a yet smaller kind in
common use. The stalk of the maize is jointed like the
sugar-cane; it is very soft and juicy, and the juice is
sweet and saccharine, that a syrup, as sweet as that of
sugar, has been often made of it; and things sweetened
with it have been found not distinguishable from those
done with sugar. It has not been tried yet whether it
will crystallise into sugar; but in all probability it will.

The Americans plant this corn any time from the
beginning of March to the beginning of June; but the
best season is the middle of April. The savage Indians,
who knew nothing of our account of months, used to
guide themselves in the seed-time of this useful plant by
the budding of some particular trees of that country,
and by the coming up of a sort of fish into their rivers
which they call the aurobes. These things were so
regular, that they were in no danger of missing the
time.

The manner of planting maize is in rows, at equal
distances, every way about five or six feet. They open
the earth with a hoe, taking away the surface to three
or four inches deep, and of the breadth of the los
they then throw in a little of the finest earth, so as to
leave the hole four inches deep or thereabouts, and in
each of these holes they place four or five grains at a
little distance from one another. If two or three of
these grow up, it is very well; some of them are com-
pletely destroyed either by the birds or other animals.
When the young plants appear, they hoar up the weeds from time to time; and when the stalk gathers some strength, they raise the earth a little about it, and continue this at every hoeing till it begins to put forth the ears; then they enlarge the hill of earth, round the root, to the size of a hop-hill, and after this they leave it till the time of harvest, without any farther care. When they gather the ears, they either immediately strip off the corn, or else hang up the ears, tied in traces at distances from one another; for if they are laid near together, they will heat and rot, or else sprout and grow; but kept cool and separate, they will remain good all the winter. The best method is to thrash out the corn as soon as the harvest is over, to dry it well on mats in the sun, and then lay it up in holes of the ground, well lined with mats, grass, or the like, and afterwards covered at top with more earth. The most careful among the Indians use this method, and this sort of subterranean granary always proves good.

The uses of this plant among the Indians are very many. The great article is the making their bread of it; but besides this, the stalks, when cut up before they are too much dried, are an excellent winter food for cattle; but they usually leave them on the ground for the cattle to feed on. The husks about the ear are usually separated from the rest, and make a particular sort of fodder, not inferior to our hay. The Indian women have a way of slitting them into narrow parts, and they then weave them artificially into baskets and many other toys. The original way of eating the grain among the Indians was this: they boiled it whole in water till it swelled and became tender, and then they fed on it either alone, or ate it with their fish and venison instead of bread. After this, they found the way of boiling it into a sort of pudding, after bruising it in a mortar; but the way of reducing it to flour is the best of all. They do this by parching it carefully in the fire, without burning, and then beating it in mortars and sifting it. This flour they lay up in bags as their constant provision, and take it out with them when they go to war, eating it either dry or with water. The English have contrived, by mixing it into a stiff paste, either by itself or with rye or wheat-meal, fermenting it with leaven or yeast, and baking it in a hot oven, to make good bread of it. They have likewise found out a method of making good beer, either of the bread or by malting the grain.

ZEA, passionate ardour for any person or cause. It is most frequently used to denote a strong and warm attachment to the distinguishing doctrines or worship of some particular sect of Christians. Thus we say, a zealous Calvinist, Arminian, or Papist; though we may likewise with the greatest propriety say of an upright and benevolent man, that he is zealous of good works.

ZEA, from which they are separated by a narrow channel, on the north; by Brabant on the east; by Flanders, from which they are separated by one of the branches of the Scheldt, on the south; and by the German ocean on the west.

New Zealand, a country of Asia, in the South Pacific ocean, first discovered by Tasman, the Dutch navigator, in the year 1642, who gave it the name of Staten Land, though it has been generally distinguished in our maps and charts by the name of New Zealand, and was supposed to be part of a southern continent: but it is now known, from the late discoveries of Captain Cook, who sailed round it, to consist of two large islands, divided from each other by a strait four or five leagues broad. They are situated between the latitudes of 34 and 48 degrees south, and between the longitudes of 166 and 180 degrees east from Greenwich. One of these islands is for the most part mountainous, rather barren, and but thinly inhabited; but the other is much more fertile, and of a better appearance. In the opinion of Sir Joseph Banks and Dr Solander, every kind of European fruits, grain, and plants, would flourish here in the utmost luxuriance. From the vegetables found here, it is supposed that the winters are milder than those in England, and the summers not hotter, though more equally warm; so that it is imagined, that if this country were settled by people from Europe, they would, with moderate industry, be soon supplied, not only with the necessaries, but the luxuries of life, in great abundance. Here are forests of vast extent, filled with very large timber trees; and near 4000 plants were found here that had not been described by the naturalists. The inhabitants of New Zealand are stout and robust, and equal in stature to the largest Europeans. Their colour in general is brown, but in few deeper than that of the Spaniard who has been exposed to the sun, and in many not so deep; and both sexes have good features. Their dress is very uncouth, and they mark their bodies in a manner similar to the inhabitants of Otaheite, and which is called tattooing. Their principal weapons are lances, darts, and a kind of battle-axes; and they have generally shown themselves very hostile to the Europeans who have visited them.

ZEALOTS, an ancient sect of the Jews, so called from their pretended zeal for God's law and the honour of religion.

ZEBA. See Equus, Mammalia Index.

ZEBU, a name given by M. de Buffon to the bos indicus of Linnæus. See Mammalia Index.

ZECHIN, or ZECCHINO. See Sequin.

ZEDOARY, in the Materia Medica. See Kempferia.

ZELL, a city of Germany in the circle of Lower Saxony, capital of the duchies of Zell and Lounenburg, situated at the confluence of the rivers Aller and Fuhe, 30 miles north of Hannover, and 40 south of Lounenburg.

ZEMBLA, Novia, a very large island lying in the Northern ocean, to the north of Russia, from which it is separated by the strait of Wajgata. It has no inhabitants except wild beasts, particularly white foxes and bears. In 1595 a Dutch vessel was cast away on the coast, and the ship's company were obliged to winter here;
ZEMINDAR, in its original meaning, signifies a great landholder of Bengal; but it is now more strictly applicable to those who have their title constituted or confirmed by a patent or charter from government, by which they hold their lands or zemindaries upon certain conditions. It appears from history, that, in times prior to the irruption of the Mahomedans, the rajahs who held their residence at Delhi, and possessed the sovereignty of Hindostan, deputed officers to collect their revenues. The word zemindar is Persian, and that language can have had no currency in the countries of India, until it was introduced by the people of Persia. When the emperor Shcabul-Dien Ghory conquered the empire of Hindostan at the end of the 12th century, he left Sultan Cutub-ul-Dien to be his vicerey at Delhi, and administer the government of Hindostan. From that time the customs and practices of the Mahomedans began gradually to be established in India: their armies were sent into the countries of the reduced rajahs, under the command of omrals, in order to preserve the conquest; and lands were allotted to them to defray the expense. From hence arose the system of Jaghiradarry in Hindostan. But when these omrals Jaghiradars had established their own strength, several of them rebelled against the imperial authority, and aspired at the crown. Thus circumstanced, the emperors, in order to obviate these mischiefs, thought it would be more politic to commit the management of the country to the native Hindoos, who had most distinguished themselves by the readiness and constancy of their obedience to the sovereign power.

In pursuance of this plan, districts were allotted to numbers of them under a reasonable revenue (Jumma Mahal), which they were required to pay in money to the governors of the provinces, deputed from the emperor. And in case any one of the omrals or provincial governors should swerve from his allegiance, the zemindars of that country were to exert themselves in such a manner as should check rebellion, and restore good government. For this purpose, grants of zemindary were severally conferred upon such of the Hindoos as were obedient; describing their apposition under the authority of the crown and every person who had received a grant under the authority of the crown was thereby fully invested with the functions of a zemindar.

The functions of a zemindar are, 1st. The preservation and defence of their respective boundaries from traitors and insurgents. 2dly. The tranquillity of the subjects, the abundance of cultivators, and increase of his revenue. 3dly. The punishment of thieves and robbers, the prevention of crimes, and the destruction of highwaymen. The accomplishment of these objects is considered in the royal grant as the discharge of office to the sovereign; and on that account the word office (khidmut) is employed in the Dewanny Suntud for a zemindary.

It was a rule in the times of the ancient emperors, that when any of the zemindars died, their effects and which, in consideration of the rights of long service, which is incumbent on sovereigns, and elevates the dignity of the employer, sunnuds for the office of zemindary were granted to the children of the deceased zemindar; and no other person was accepted, because the inhabitants could never feel for any stranger the attachment and affection which they naturally entertained in the family of their zemindar, and would have been excessive if any other had been put over them. For this reason, the emperors, considering it as a means of facilitating the minds of the people, graciously fixed that confirmed the children of the deceased zemindar to the office of their fathers and grandfathers, by issuing, or sunnudas to transfer the possession to them. By this means zemindaries became truly heritable property, which, however, could be transferred by gift or sale to the family to another. They could likewise be forfeited to the sovereign, by the zemindar's deviation from allegiance, neglecting to pay his tribute, or to disobey the duties of his station.

It is universally known, says Sir Charles Romes Bough, that, when the three provinces of Bengi, Bahar, and Orissa, were ceded to the British East India Company, the country was distributed among the zemindars and talookdars or holders of land, who paid stipulated revenue, by twelve installments, to the sovereign power or its delegates. They assembled at the capital in the beginning of every Bengali year (commencing in April), in order to complete their final payments, and make up their annual accounts; to settle the discount to be charged upon their several remittances of various coins for the purpose of reducing them to one standard, or adjust their concerns with their bankers; to petition for remissions on account of storms, droughts, inundations, disturbances, and such like; to make their representations of the state and occurrences of their districts; after all which they entered upon the collections of the new year; of which, however, they were not permitted to begin receiving the rents from their own farmers, till they had completely closed the accounts of the preceding year, so that they might not encroach upon the new rents, to make up the deficiency of the past. Our authors prove, we think completely, the right of the zemindars to transfer their possessions, either by inheritance to their children, or, with the consent of the sovereign, to other families; and he argues strenuously and successfully against the bad policy, as well as injustice of interfering with these rights, as long as the zemindars discharge the duties of their several stations.

ZEND, or ZENDAVESTA, a book ascribed to Zar-aster, and containing his pretended revelations; which the ancient Magians and modern Persians, called also Gauzy, observe and reverence in the same manner as the Christians do the Bible, and the Mahometans the Koran, making it the sole rule both of their faith and manners. The word, it is said, originally signifies any instrument for kindling fire, and is applied to this book to denote its aptitude for kindling the flame of religion in the hearts of those who read it. The Zend contains a reformed system of Magianism; teaching that there is a Supreme Being, eternal, self-existent, and independent, who created both light and darkness, out of which he made all other things; that these are in a state of conflict, which will continue till the end of the world; that there shall be a general resurrection and judgment; and that just retribution shall
shall be rendered unto men according to their works; that the angel of darkness with his followers shall be consigned to a place of everlasting darkness and punishment, and the angel of light with his disciples introduced into a state of everlasting light and happiness; after which light and darkness shall no more interfere with each other. The Zend also enjoins the constant maintenance of sacred fires and fire temples for religious worship; the distinction of clean and unclean beasts; the payment of tithes to priests, which are to be of one family or tribe; a multitude of washings and purifications, resembling those of the Jewish law; and a variety of rules and exhortations for the exercise of benevolence and charity.

In this book there are many passages evidently taken out of the Scriptures of the Old Testament, particularly out of the Psalms of David: The author represents Adam and Eve as the first parents of all mankind, gives in substance the same account of the creation and deluge with Moses, differing indeed with regard to the former, by converting the six days of the Mosaic account into six times, comprehending in the whole 365 days; and speaks also of Abraham, Joseph, Moses, and Solomon. Moreover, Dr. Baumgarten asserts, that this work contains doctrines, opinions, and facts, actually borrowed from the Jews, Christians, and Mahometans; whence, and from other circumstances, he concludes that both the history and writings of this prophet were probably invented in the later ages, when the fire-worshippers under the Mahometan government thought fit to vindicate their religion from the suspicion of idolatry.

At whatever period the Zend may have been written, we are assured by Dr. Hyde, that it is in the pure old Persian language, and in the character called Peplari. Some parts of it contain the original text, and others Zoroaster’s second thoughts subjoined, for explaining more fully his doctrine. These were occasioned by the opposition of adversaries, and unforeseen circumstances which occurred during the fabrication of the imposture. About 300 years ago, when the old Persian language had become antiquated and little understood, one of the destitute or high-priests among the Persians composed the Sadda, which is a compendium in the vulgar or modern Persian tongue, of those parts of the Zend that relate to religion, or a kind of code of canons and precepts, drawn from the theological writings of Zoroaster, serving as an authoritative rule of faith and practice for his followers. This Sadda is written in a low kind of Persian verse, and as Dr. Hyde informs us, it is bonorum et malorum farago, having many good and pious things, and others very superstitious and trifling. See Persians and Zoroaster.

ZENITH, in Astronomy, the vertical point, or a point in the heavens directly over our heads.

ZENO ELEATES, an eminent Grecian philosopher, was born at Elea about 504 years before Christ. He was a zealous friend of civil liberty, and is celebrated for his courageous and successful opposition to tyrants; but the inconsistency of the stories related by different writers concerning him in a great measure destroys their credit. He chose to reside in his small native city of Elea rather than at Athens, because it afforded a freer scope to his independent and generous spirit, which could not easily submit to the restraints of authority. It is related, that he vindicated the warmth with which he re
esented reproach, by saying, “If I were indifferent to censure, I should also be indifferent to praise.” The invention of the dialectic art has been improperly ascribed to Zeno; but there can be no doubt that this philosopher, and other metaphysical disputants in the Eleatic sect, employed much ingenuity and subtility in exhibiting examples of most of the logical arts, which were afterwards reduced to rule by Aristotle and others.

According to Aristotle, he taught, that nothing can be produced either from that which is similar or dissimilar; that there is only one being, God; who is eternal, homogeneous, and spherical, neither finite nor infinite, neither quiescent nor moveable; that there are many worlds; that there is in nature no vacuum; that all bodies are composed of four elements, heat and moisture, cold and dryness; and that the body of man is from the earth, and his soul an equal mixture of these four elements. He argued with great subtility against the possibility of motion. If Seneca’s account of this philosopher deserves credit, he reached the highest point of scepticism, and denied the real existence of external objects. The truth is, that after all that has been advanced by different writers, it is impossible to determine whether Zeno understood the term one, metaphysically, logically, or physically; or whether he admitted or denied a nature properly divine.

Zeno, the founder of the sect of the Stoics, was born about 300 years before Christ at Citium, in the island of Cyprus. This place having been originally peopled by a colony of Phenicians, Zeno is sometimes called a Phenician. His father was by profession a merchant, but discovering in the youth a strong propensity towards learning, he early devoted him to philosophy. In his mercantile capacity he had frequent occasion to visit Athens, where he purchased for his son several of the writings of the most eminent Socratic philosophers. These he read with great avidity; and when he was about 30 years of age, he determined to take a voyage to a city which was so celebrated both as a mart of trade and of science. If it be true, as some writers relate, that he brought with him a valuable cargo of Phenician purple, which was lost by shipwreck upon the coast of Piraeus, this circumstance will account for the facility with which he at first attached himself to a sect whose leading principle was the contempt of riches. Upon his first arrival in Athens, going accidentally into the shop of a book-seller, he took up a volume of the Commentaries of Xenophon; and after reading a few passages, was so much delighted with the work, and formed so high an idea of the author, that he asked the book-seller where he might meet with such men. Crates the Cynic philosopher happening at that instant to be passing by, the bookseller pointed to him, and said, “Follow that man.” Zeno attended upon the instructions of Crates, and was so well pleased with his doctrine that he became one of his disciples. But though he admired the general principles of the Cynic school, he could not easily reconcile himself to their peculiar manners. Besides, his inquisitive turn of mind would not allow him to adopt that indifference to every scientific inquiry which was one of the characteristic distinctions of the sect. He therefore attended upon other masters, who professed to instruct their disciples in the nature and causes of things. When Crates, displeased at his following other philosophers, attempted to drag him by force out of the school of Stilpo, Zeno said
said to him, "You may seize my body, but Stilpo has held of my mind." After continuing to attend upon the lectures of Stilpo several years, he passed over to other schools, particularly to those of Xenocrates and Diodorus Cronus. By the latter he was instructed in dialectics. He was so much delighted with this branch of study, that he presented to his master a large pecuniary gratuity, in return for his free communication of some of his ingenious subtleties. At last, after attending almost every other master, he offered himself as a disciple of Polemo. This philosopher appears to have been Zeno's intention in thus removing from one school to another, was to collect materials from various quarters for a new system of his own; for, when he came into Polemo's school, he said to him, "I am no stranger, Zeno, to your Phcenician arts; I perceive that your design is to creep slily into my garden, and steal away my fruit." Polemo was not mistaken in his opinion. Having made himself master of the tenets of others, Zeno determined to become the founder of a new sect. The place which he made choice of for his school was a public portico in Athens, adorned with the pictures of Polygnotus, and other eminent painters. It was the most famous portico in Athens, and called, by way of eminence, Zethe, "the Porch." It was from this circumstance that the followers of Zeno were called Stoics.

In his person Zeno was tall and slender; his aspect was severe, and his brow contracted. His constitution was feeble, but he preserved his health by great abstinence. The supplies of his table consisted of figs, bread, and honey; notwithstanding which, he was frequently honoured with the company of great men. In public company, to avoid every appearance of an assuming temper, he commonly took the lowest place. Indeed so great was his modesty, that he seldom chose to mingle with a crowd, or wished for the company of more than two or three friends at once. He paid more attention to neatness and decorum in external appearance than the Cynic philosophers. In his dress indeed he was plain, and in all his expenses frugal; but this is not to be imputed to avarice, but a contempt of external magnificence. He showed as much respect to the poor as to the rich; and conversed freely with persons of the meanest occupations. He had only one servant, or, according to Seneca, none.

Zeno lived to the extreme age of 98; and at last, in consequence of an accident, voluntarily put an end to his life. As he was walking out of his school he fell down, and in the fall broke one of his fingers; upon which he was so affected with a consciousness of infirmity, that, striking the earth, he said, "Why am I thus imperturbed? I obey thy summons;" and immediately went home and strangled himself. He died in the first year of the 12th Olympiad. The Athenians, at the request of Antigonus, erected a monument to his memory in the Ceramicum.

We ought not to confound the two Zenos already mentioned with Zeno, a celebrated Epicurean philosopher, born at Sidon, who had Cicero and Pomponius Atticus for his disciples, and who wrote a book against the mathematics of it, is lost; nor with several other Zenos mentioned in history.

ZENOBIA, queen of Palmyra. See Palmyra.
inhabitants of Crotona to be hung up in the temple of Juno: this last he painted from five beautiful girls of that city, copying from each her greatest excellencies. Many observers, that this admirable painter, disputing for the prize of painting with Parrhasius, painted some grapes so naturally, that the birds flew down to peck them. Parrhasius, on the other hand, painted a curtain so very artfully, that Zeuxis, mistaking it for a real one that hid his rival's work, ordered the curtain to be drawn aside, to show what Parrhasius had done; but having found his mistake, he indignantly confessed himself vanquished, since he had only imposed upon birds, while Parrhasius had deceived even a master of the art. Ammon then painted a boy loaded with grapes; when the birds also flew to this picture, at which he was vexed; and confessed, that his work was not sufficiently finished, since, had he painted the boy as perfectly as the grapes, the birds would have been afraid of him. Archelaus, king of Macedon, made use of Zeuxis's pencil for the embellishment of his palace. One of this painter's finest pieces was a Hecules strangling some serpents in his cradle, in the presence of his affrighted mother; but he himself chiefly esteemed his Athlete, or Champion, under which he placed a Greek verse that afterwards became very famous, and in which he says, "That it was easier to criticize than to imitate the picture." He made a present of his Alemena to the Argigentines. Zeuxis did not value himself on speedily finishing his pictures; but knowing that Agatharchus glorièd in his being able to paint with ease and in a little time, he said, "That for his part he, on the contrary, gloried in his slowness; and, if he was long in painting, it was because he painted for eternity." Various Placaeus says, that Zeuxis having painted an old woman so very heartily at the sight of this picture, that he died: but as no one, at the time, was mentioned this particular, there is the greatest reason to believe it fabulous. Carlo Dati has composed in Italian the Life of Zeuxis, with those of Parrhasius, Apelles, and Protagenes. This work was printed at Florence in 1667.

ZICLAG, or ZIKLAG, in Ancient Geography, a town of the tribe of Simeon, on the borders of the Philistines (Joshua xxv. and xxi.), but in the hands of the Philistines till David's time (1 Sam. xviii. and xxx.).

ZIMENT-WATER, COPPER-WATER, the name by which some have called water found in places where there are copper-mines, which is impregnated with particles of that metal.

The most famous spring of this kind is about a mile distant from Newohl in Hungary, in the great copper-mine called by the Germans Herrngrund. The water in this mine is found at different depths, and is received into basins, for the purpose of separating the copper from it: in some of these it is much more set with this metal than in others, and will make the supposed change of iron into that metal much sooner. The most common pieces of iron used in the experiments are horse-shoes, nails, and the like; and they are found very little altered in shape, after the operation, except that their surfaces are more raised. The water appears greenish in the basin, where it stands; but if a glass of it be taken up, it looks clear as crystal; it has no smell, but a strong vitriolic astrin gente taste, insomuch that the lips and tongue are blistered and scorched upon tasting it.

ZIN, in Ancient Geography, a wilderness encompassing Idumea, at least on the south and west, as far as Palestine or Canaan; but according to Wells, on the east of Edom, to the north of Ezion-geber.

ZINC, a metallic substance, formerly considered as one of the brittle metals; or, according to the distinction of the older chemists, a semi-metal or an imperfect metal, because it was found to be destitute of some of the properties of other metals which were considered as perfect. For an account of the properties and combinations of zinc, as they were then known, see CHEMISTRY INDEX; and for the history of its ores, see MINERALOGY INDEX.

But in the progress of chemical discovery it has been found that zinc is not a less perfect metal than others; for in the year 1825, it was announced that a patent was granted to Messrs Hobson and Sylvester of Sheffield for a method of manufacturing zinc. From their discovery it appears, that zinc raised to a temperature of about 210° and 320° of Fahrenheit, is not only very malleable, but may be passed through rollers, or drawn into wire. After the metal has been treated in this manner, it does not return to its former brittleness, but continues soft, flexible, and extensible, and may be applied to many uses for which this metal was before thought unfit.

We must, however, notice, that a prior claim to the discovery of rend-ring zinc ductile and malleable, has been made by Mr Lowry, in favour of a Mr Sheffield of Somers-town. Twenty years before the time of Messrs Hobson and Sylvester's patent being announced, Mr Sheffield, in making away of some blende, was impatient to examine the metal, struck an ingot for the purpose of breaking it while it was yet hot, but was much surprised to find that instead of being brittle, and breaking with the usual fracture of zinc, it was extremely tough, and when he succeeded in breaking it, after many bendings backward and forward, it exhibited a steel-grained fibrous texture. At first he doubted of the metal being zinc, but he repeated the experiment on what he knew to be pure metal, and obtained the same result; and from this he concluded that zinc at a certain temperature is equally malleable and ductile with other metals. This he found to be the case by drawing it into wire, and laminating it between rollers, by which he produced plates not exceeding the 8-\text{th} of an inch, and possessing the strength and tenacity of silver.

Since the time that our article CHEMISTRY was printed, the decomposition of potash, soda, the alkaline earths, and some other bodies which were formerly considered as simple, or were only conjectured from analogy to be compound, has been effected by Mr Davy; and as we were disposed to entertain hopes that something new might be added to the unexpected and brilliant discoveries of that celebrated chemist, we had deferred, till near the close of our work, giving any account of them. This is the reason that the fact was merely announced under the words Potash and Soda, and a reference made to Galvani Trottii, under which it was intended to give a short description of the apparatus employed in the experiments which led to the discoveries alluded to. For the same reason we were induced to make a farther reference to this place, because zinc is...
one of the metallic substances usually employed in the construction of galvanic apparatus. We shall therefore here employ a few pages, 1st, In a description of the improvements which have been made in the construction of galvanic apparatus; and, 2d, We shall lay before our readers a view of the discoveries in galvanic electricity since the treatises on **Chemistry** and **Galvanism** in this work were printed.

**Galvanic Apparatus.** — A very considerable improvement has been made on the construction of galvanic batteries, by which they are rendered, not only more convenient and manageable, but far more powerful. Under the article Galvanism, we have described particularly the construction of the galvanic trough, and we have noticed that the soldering of the plates of zinc and copper employed for this purpose was attended with considerable difficulty. In the new method of construction the plates are not soldered together, but are merely connected by means of a metallic arc. In this way each pair of plates can be removed from the trough at pleasure, for the purpose of examining and cleaning them. The new apparatus is constructed precisely on the same principle as the *couronne de Tasseau*, proposed by Volta, and described at p. 333 of Galvanism. The trough employed in this apparatus is prepared in the same way as when the plates of zinc and copper soldered together were fixed in it by means of cement; but in place of the metallic plates, plates of glass, or some other non-conducting substance, are introduced and secured by cement, so that there shall be no communication between the different cells into which the liquid is introduced. The plates of zinc and copper connected by means of the metallic arc, at the distance of about half an inch, are placed in different cells, having a plate of glass between each pair of plates. Each cell then contains a plate of each of the metals, which are unconnected, excepting through the medium of the liquid which is to be the conductor of the electricity. It is scarcely necessary to mention, that the proper order of arrangement shall be observed, so that throughout the whole trough or battery there shall be a series of zinc, copper, and liquid.

Beside the convenience and simplicity of this mode of constructing galvanic troughs, it possesses this further advantage of being more powerful, because instead of one surface of the plates, as in the former construction of this apparatus, both surfaces are exposed to the action of electricity, and therefore the power is greatly increased. A farther improvement, it is said, has been made in constructing batteries of this kind, which consists in employing troughs of Wedgewood's ware, with partitions of the same material, instead of wooden troughs with partitions of glass. This improvement was first suggested by Dr. Babington.

The following is the account of the construction of galvanic apparatus, with the view of ascertaining in what way the greatest effect might be produced, with the least waste of power and expense. The experiments which we are now to mention were made by Mr. Children. For this purpose a battery was constructed, connected by leaden straps, soldered on the top of each pair of plates. Twenty pairs of plates were employed, and each plate was four feet high by two feet wide. The whole extent of surface exposed amounted to 92,160 square inches; the trough was made of wood, with wooden partitions, covered with cement, to resist the action of the acid employed. The battery was charged with a mixture of three parts of running nitric, and one of sulphuric acid, diluted with thirty of water; the quantity employed was 252 gallons. With this apparatus the following experiments were made.

**Exper. 1.** Eighteen inches of platinum wire, of an eighth of an inch diameter, were completely fused about twenty seconds. **Exper. 2.** Three feet of the same wire were heated to a bright red, visible by day and night. **Exper. 3.** Four feet of the same wire were rendered very hot, but not perceptibly red by daylight. **Exper. 4.** Charcoal burnt with intense brilliancy.

**Exper. 5.** Ten inches of iron wire of 1/16 of an inch diameter, were barely fused; three feet of the wire were not ignited. **Exper. 6.** No effect was produced on imperfect conductors. **Exper. 7.** The piles of the electrometer were not affected. **Exper. 8.** When the cuticle was dry, no shock was given by battery, and it was scarcely perceptible when the wire was wet.

To contrast the effects of this apparatus with those differing in the size and number of plates, the latter employed 200 pairs of plates, each about two inches square, placed in half pint pots of common queen's wine. The same liquid was employed, with the addition of a fresh portion of sulphuric acid, in the proportion of about a quarter of a pint to a gallon. The experiments with this apparatus gave the following results.

**Exper. 1.** Potash and barytes were readily decomposed. **Exper. 2.** The metalization of ammonia was produced with great facility. **Exper. 3.** Charcoal was vividly ignited. **Exper. 4.** The gold leaves of the electrometer diverged considerably. **Exper. 5.** After the battery was in action three hours, it gave a vivid spark; at the end of 24 hours it metalized ammonia; at the end of 41 hours it was nearly exhausted. From these results of these experiments, Mr. Children concludes, that the theory of the mode of action of the voltaic battery proposed by Mr. Davy is confirmed, namely, that the intensity increases with the number, and the quantity with the extent of the series. The point is proved by the effects produced on the platinum and iron wires, in the 1st and 3rd experiments with the large battery, as well as by the experiments on imperfect conductors in the small apparatus; for as the platinum wire is a perfect conductor, and not liable to oxidation, it allows the electricity to be freely transmitted, and from the immense quantity given out from a surface of such extent, they evolve, on their mutual annihilation, heat sufficient to raise the temperature of the platinum to the point of fusion. But a very small portion of the electricity passes through the iron wire, in consequence of its easy oxidation, and the thin film of oxide formed on its surface. This arises from the low state of the intensity of the electricity, as it appears from its want of power on the gold leaves of the electrometer. From the same deficient intensity, the decomposition of barytes could not be effected by the large battery, and the same battery exhibited a very weak action on imperfect conductors; but the small battery exerted great power on that class of bodies, and decomposed them readily, although its surface was 30 times less than the surface of the great battery; but the num-
taining the positive wire, was reddened; paper coloured by turmeric placed in the other tube, had its colour deepened; the acid matter produced a slight turbidity in a solution of nitrate of silver; the fluid from the negative tube retained the property of affecting the turmeric after being boiled, and indeed became more vivid as the quantity was diminished by evaporation. Carbonate of ammonia was added, and the whole being dried, and exposed to a strong heat, a minute quantity of white matter remained, which had all the properties of carbonate of soda.

The same experiment was repeated with glass tubes, and the result was, that the quantity of alkali obtained was 20 times greater, but no traces of muriatic acid could be perceived. Mr Davy suspecting that the agate might contain a minute portion of saline matter, repeated the experiment four times. The quantity of alkaline matter diminished in every operation, and in the last process, although the battery had been kept in great activity for three days, the fluid possessed in a slight degree only the power of acting on paper tinged with turmeric; but its alkaline property was very sensible to litmus paper slightly reddened. The acid matter in the other tube was abundant; it had a sour taste, and produced no effect on solution of muriate of barytes, but left a black stain from a drop on a polished plate of silver. Thus it appeared to be extremely diluted nitrous acid.

For the purpose of making the experiment with greater accuracy, two hollow cones of pure gold (fig. 2) were employed, each containing about 25 grains of water. They were filled with distilled water, connected by moistened amianthus, as before, and exposed to the action of a battery of 100 pairs of plates of six inches square. The liquid used was a solution of alum, and diluted sulphuric acid. In ten minutes the water in the negative tube changed litmus paper to a slight blue, and the water in the positive tube produced a red tint. The process having continued for 14 hours, the acid was found to increase in quantity during the whole time, but the alkaline fluid in the other tube did not affect the tests more than in the first trial. The acid seemed to be the pure nitrous, with an excess of nitrous gas. The experiment was repeated, and carried on for three days, and similar results were obtained. From these experiments it was concluded, that the distilled water contained a minute portion of saline matter, but so minute indeed, that it was insensible to the most delicate chemical tests. This appeared to be the case by evaporating a quantity of the distilled water that was used very slowly, at a heat below 140° Fahrenheit, in a silver still. A quantity of solid matter equal to seven-tenths of a grain, of a saline but metallic taste, was obtained. It seemed to be a mixture of nitrate of soda and nitrate of lead. Mr Davy then employed some of the water collected in the second process of slow distillation, in another experiment with the gold tubes and connecting amianthus. At the end of two hours the water in the negative tube had no effect on turmeric paper; litmus, it could just be perceived, was changed; but by heating the water strongly for two or three minutes, it was deprived even of this power, and from this he supposes that it was owing to a small quantity of ammonia. A similar experiment was made with a portion of the same water in the agate tube, and precisely the same results were obtained. From these experiments...
experiments Mr. Davy fairly concludes, that the fixed alkali is not generated during the process, but merely evolved, either from the solid materials employed, or some saline matter in the water.

Many experiments were made in vessels composed of different substances, with the water procured by slow distillation; and in almost every instance some fixed alkali appeared. When tubes of wax were employed, the alkaline matter was a mixture of soda and potash, and the acid matter, a mixture of sulphuric, muriatic, and nitric acids. A tube of resin afforded alkaline matter, which was principally potash. A cube of Carrara marble of about an inch, having an aperture in its centre, was placed in a platinum crucible, which was filled as high as the upper surface of the cube, with the purified water. The aperture was filled with the same liquid, and the crucible was positively electrified by a powerful battery, and the negatively electrified wire introduced into the aperture. Fixed alkali and lime were obtained in this experiment; the quantity of alkali diminishing as the experiment was repeated, and after 11 processes, each continued for two or three hours, disappeared altogether. The quantity of lime-water obtained was uniform.

When 500 grains of this marble were analyzed, they afforded about three-fourths of a grain of fixed saline matter, having soda for its base. Suspecting that the Carrara marble might have been recently exposed to sea water, Mr. Davy subjected to a similar experiment a piece of granular marble from the mountains of Donnegal, and by means of negative electricity he obtained fixed alkali. Argillaceous schistus from Cornwall gave the same result, and serpentine and gray wacken both afforded soda.

In other experiments Mr. Davy subjected other bodies to the action of the same power, with the view of effecting a decomposition. Thus, two cups of compact sulphate of lime, each containing about 14 grains of water, were connected by fibrous sulphate of lime moistened with pure water. The cups were filled with the same fluid, and they were introduced into the circuit of a galvanic battery with 100 pairs of plates of six inches. In five minutes the water in the positive cup became acid, while that in the opposite cup tinged tannic acid. An hour after, a saturation solution of lime was formed in the negative cup, and the other contained a solution of sulphuric acid of moderate strength.

Two cubic pieces of crystallized sulphate of strontium of about an inch, with a hole drilled in each, capable of receiving eight grains of water, were plunged in pure water, in a platinum crucible, and the level of the fluid was kept a few lines below the surface of the cubes. The holes in the earthy mineral were filled with pure water, and two platinum wires were introduced into them. At the end of thirty hours the fluid in the cavity of the negative side precipitated solution of sulphate of potash and sulphuric acid appeared in the other.

Two pieces of fluorspar of lime, having each a cavity, and connected by moist asbestus, were subjected to a similar experiment. The decomposition was slow; but in two days a solution of lime appeared in the one tube, and an acid in the other, which precipitated acetate of lead, and left a spot upon the glass, from which it was evaporated, so that it must have been fluoric acid.

Compact zeolite being prepared in the same way, and electrostatically electrified in the same manner as the cube of Carrara marble, afforded soda and lime. Lepidolite, by similar treatment, gave potash; and an alkaline matter, which seemed to be a mixture of soda, potash and lime, was extracted from a piece of vitraceous lava from Mount Etna.

The decomposition of saline bodies, which are soluble in water, was more rapid. A diluted solution of sulphate of potash introduced into the agate cup connected by amiantus moistened with pure water, being electrified by a battery with 50 pairs of plates, produced in four hours a weak solution of potash in the negative cup, and a solution of sulphuric acid in the positive cup. Similar phenomena were observed when sulphate of soda, nitrate of potash, nitrate of barytes, sulphate of ammonia, phosphate of soda, succinate, oxalate, and benziate of ammonia and alum, were employed. To acids in a certain time collected in the tube containing the positive wire, and the alkalies and earths in the negative tube. Solutions of the muriatic salts, subject to decomposition by the same process, uniformly afforded oxyhydratic acid on the positive side.

Saturated saline solutions were most rapidly decomposed, but the smallest proportion was also acted on. Thus, if a piece of paper tinged with tannic acid is plunged into pure water, in a proper circuit, in contact with the negative point, the minute quantity of amiantus compound contained in the paper, produces instantly a brown tint near its point of contact. Acid appears from limosus paper at the positive surface.

Experiments were made with the view of ascertaining whether in these processes the separation of the constituent parts was complete, from the last portion of the compound. The following experiment shows this to be the case. "A very weak solution of sulphate of potash, containing 20 parts of water, and one part of saturated solution at 64°, was electrified in the two agate cups, by the power of 50 pairs of plates for three days; the connecting amiantus which had been moistened with pure water, was removed, washed with pure water, and again applied twice every day. By this precaution the presence of any neutral salt that might adhere to it, and disturb the results, was prevented. The alkali obtained in this process in the solution had the properties of pure potash, and when it had been saturated with nitric acid, it gave no turbidity by mixture with solution of muriate of barytes; the acid matter exposed to a strong heat, evaporated, without losing any residue."

Mr. Davy then made experiments on the transfer of certain of the constituent parts of bodies, and also on the passage of acids, alkalis, and other substances, through various attracting chemical menstrua, by means of electricity, and in these experiments he obtained many curious and interesting results; but for an account of them, as well as of his observations on the different phenomena, and on the mode of decomposition and transition, we must refer to the memoir itself.

After the investigations in which Mr. Davy had been occupied, and the singular and unexpected results which he obtained, he ventured to conclude, from the general principles on which the phenomena might be explained, that the new methods of proceeding would lead to a more intimate knowledge concerning the true elements of
ZIN [ 789 ] ZIN

Decomposition of the Alkalis.

In the first attempts that were made on the decomposition of potash, Mr. Davy employed an aqueous solution, saturated at a common temperature. It was exposed to the action of a powerful galvanic battery, composed of 24 plates of copper and zinc of 12 inches square, 100 plates of six inches, and 150 plates of four inches square, charged with solutions of alum and nitrous acid. The action was very intense; a great deal of heat and violent effervescence were produced, but the water only of the solution was evolved, and its hydrogen and oxygen were disengaged. Potash in the state of igneous fusion, in a spoon of platina, was next exposed to the action of a battery of 100 plates of six inches, highly charged. The spoon was connected with the positive side. In this experiment some brilliant phenomena were produced. The potash appeared to be a good conductor; and, while the communication was preserved, a most intense light was emitted from the negative side, and a column of flame, seemingly owing to the development of combustible matter, arose from the point of contact. When the order was reversed, and the platina spoon was connected with the negative side, a vivid and constant light appeared at the opposite point. There was no inflammation round it; but aeriform globules, which inflamed in the atmosphere, rose through the potash. The platina was considerably acted on.

Although potash, when perfectly dry, be a non-conductor, it acquires a conducting power by being slightly moistened. A small piece of pure potash exposed for a few seconds to the atmosphere, was placed on a disc of platina connected with the negative side of a battery of 250 plates of six and four inches, in a state of intense activity. A platina wire from the opposite side was brought in contact with the upper surface of the alkali. A vivid action soon took place. The potash fused at both points of electrification; a violent effervescence appeared at the upper surface; but at the lower or negative surface no elastic fluid was emitted, but small globules like quick-silver were produced, some of which burnt with explosion and bright flame as they were formed, and others remained and were only tarnished, and finally covered by a white film formed on their surfaces. These globules were the basis of potash. The same results were obtained, when gold and other metals, plumbo, or charcoal, were employed; and the effects were the same when the process was conducted in an exhausted receiver.

Mr. Davy also obtained the same substance from potash, fused by means of a lamp, and placed in glass tubes confined by mercury, and furnished with hermetically inserted platina wires, to transmit the electricity; but the glass was rapidly dissolved by the action of the alkali, so that the process could not be long carried on.

In these experiments on potash, the combustible base was produced from the negative surface, and oxygen was evolved from the positive surface. The same effects invariably followed, when the experiment was conducted above mercury. The same thing was proved synthetically. The combustible substance obtained from the potash had its metallic lustre destroyed in the atmosphere, and a white crust formed upon it. This crust was found, upon examination, to be pure potash; but this was still further confirmed by placing globules of the combustible matter in tubes containing common air, or oxygen gas, confined by mercury. An absorption of the oxygen took place, and a crust of alkali was formed upon the globule. When the combustible matter confined in given portions of oxygen, was strongly heated, a rapid combustion, with a brilliant white flame, was produced, and the metallic globules were converted into a white and solid mass, which was found to be pure potash.

To the combustible matter thus obtained from potash, Mr. Davy gave the name of potassium. From its strong affinity for oxygen, it was extremely difficult to preserve it unchanged, for the purpose of examining its properties. The substance which he found to be least affected, is newly distilled naphtha. In this fluid potassium may be kept for many days nearly unaltered, and its physical properties may be examined in the atmosphere, when covered by a thin film of it.

Potassium, at 60° Fahrenheit, is in the form of small globules, which have the metallic lustre and general appearance of mercury; at 70° it becomes more fluid, and at 100° different globules easily run into one. At 30° of Fahrenheit it is soft and malleable, and exhibits the lustre of polished silver. At 52° it becomes hard and brittle, and, when broken, presents a crystalline texture. To reduce it to vapour, it requires a red heat; and in proper circumstances, it may be subjected to distillation, without change. It is a good conductor of heat, and a perfect conductor of electricity.

In the properties now mentioned, potassium approaches nearly to the metals; but it is very different in its specific gravity. In naphtha of the specific gravity of 861 it rose to the surface; and it did not sink in double distilled naphtha, the specific gravity of which was about 770. From these and other experiments, Mr. Davy estimates the specific gravity of potassium at 6, so that it is the lightest fluid body known. In its solid form it is somewhat heavier; but, even in this state, when cooled to 40° Fahrenheit, it swins in double distilled naphtha.

With the view of ascertaining the proportions of the constituent parts of potash, Mr. Davy made two experiments, by subjecting the metallic base to combustion in oxygen gas. In the first experiment, 1/2 of a grain of potassium were employed; the combustion was made upon platina, and was rapid and complete, and the basis appeared to be perfectly saturated. The result of this experiment indicates 86.7 of basis, and 13.3 of oxygen, in the 100 parts of potash. In another experiment, the result he obtained was 85.5 of basis, and 14.5 of oxygen. The mean of these two experiments is 86.1 of basis, and 13.9 of oxygen, in 100 parts of potash.

The results of the decomposition of water by the basis of the alkalis, which were more readily and perfectly obtained than those of their combustion, exhibited the proportion of base to be 84, and that of oxygen 16; but the mean of 86.1 of base, and 13.9 of oxygen, and 84 base and 16 oxygen, is 85 of potassium and 15 of oxygen, which may be taken as the proportions of the elements of potash.

Mr. Davy’s discoveries have been confirmed by the ingenious
ingenious experiments of Thenard and Gay-Lussac. These distinguished chemists have decomposed potash by a different process. They introduced iron filings into a bent gun barrel, which was placed across a furnace. A tube with a stopcock, containing a quantity of solid potash, is connected with one extremity of the gun barrel; to the other extremity there is attached a tube of safety, containing mercury, for the purpose of excluding the atmosphere, and allowing any gaseous matter formed during the process to escape. The potash in the tube is to be kept cold by means of a freezing mixture, till that part of the barrel containing the iron filings has been raised to a white heat. The potash is then fused by applying heat, by means of a portable furnace, and it is allowed to pass through a small opening, to come in contact with the iron filings, where it is decomposed, the oxygen of the potash entering into combination with the iron, and the base passing on to the other extremity of the tube in a state of sublimation. At that extremity the metallic base is condensed by the application of excessive cold, and in this way the potassium may be obtained at less expense, and in greater quantity, than by means of galvanism. During this progress, hydrogen gas is evolved, which, it is supposed, is owing to the decomposition of the water contained in the alkali. The potassium thus obtained is in the form of brilliant laminae, which adhere to the sides of the gun barrel. An alloy of the same metal with iron is also found in that part of the barrel containing the filings. Mr. Davy has repeated this experiment, and he finds that the base obtained in this manner is heavier, and its melting point higher, than what is procured by means of galvanism. This, it is supposed, may arise from its being combined with a small proportion of iron. The metallic base of soda was obtained by a similar process.

But, according to the view which the French chemists have taken of these discoveries, and the results of their own experiments, they conclude, that the metallic substances derived from the alcalies are not simple, but are compounds of the several bases with hydrogen.

Another method of decomposing potash, and obtaining its base, which is still simpler, has been followed by Curaudau. In this process the decomposition is effected by charcoal. A mixture of carbonate of potash is made with flour or charcoal and linseed oil. This mixture is introduced into an iron or earthen tube or retort, and calcined, by gradually raising the heat, till a bluish light be seen in the inside of the vessel. Soon after an abundant evolution of vapour takes place, which, at the base of the alkali, to be collected by introducing a clean iron rod, on which it condenses. Care must be taken to withdraw the rod before it is too hot, and to plunge it in oil of turpentine, under the surface of which the metallic crust on the rod may be separated. In this way a quantity of potassium may be procured. The base of soda is obtained by a similar process.

Fig. 3. is a representation of the apparatus employed by the French chemists in decomposing potash. A B C E is the gun barrel laid across the furnace, with its apparatus; D is the furnace, and F is the pipe of the bellows.

Fig. 4. is a section of the tube containing the potash.

But the chemical relations of potassium are not less extraordinary than its physical properties. It combines slowly with oxygen, and without flame, at all temperatures below that of its vaporization. At this point combustion takes place, with a brilliant white light, and intense heat. When it is heated slowly in a quantity of oxygen gas, which is not sufficient for its complete combustion, and at a temperature below that of inflammation, as for instance 40° of Fahrenheit, it changes in a red brown colour, and the solid form, consisting partly of potash, and partly of its base, is of a grey colour. When exposed to water, or again heated to the quantities of air, the whole is converted into potash.

When dry potash and potassium are fused together under proper circumstances, the base is deprived of its metallic splendour, and the two substances unite into a compound of a red brown colour when fluid, and of a dark gray when solid. This compound, when exposed to the air, soon absorbs its full proportion of oxygen, and is wholly converted into potash. The substance thus formed seems to be in a lower state of oxidation, so that it is to be considered as an oxide of potassium with a smaller proportion of oxygen.

When potash is introduced into oxyhydrogen acid gas, it burns spontaneously with a bright red light, and a white salt is formed, which is muriate of potash. When a globule of potassium is heated in hydrogen gas, at a degree below its point of vaporization, it seems to dissolve in it, for the globule is diminished in volume, and the gas explodes with alkaline fumes, and bright light, when brought into the air; but, by cooling, the potassium is wholly or principally deposited, for the gas is deprived of its property of spontaneous combustion.

When potassium is thrown into water, it decomposes it with great violence; an instantaneous explosion, with brilliant flame, is produced, and a solution of pure potash is obtained. In these experiments, a white ring of smoke, gradually extending as it rises in the air, is produced, similar to the phenomenon of the combustion of phosphorated hydrogen. When a globule of the base of potash is placed upon ice, it instantly burns with a bright flame; part of the ice is melted, and in the cavity there is found a solution of potash.

By placing a globule of potassium upon moistened paper, tinged with turmeric, the moment it comes in contact with the water, it burns, and, moving rapidly upon the paper, leaves behind it a deep reddish brown trace, thus demonstrating, in a very simple manner, the production of the alkali by the decomposition of water.

Potassium readily decomposes the small quantities of water contained in alcohol and ether, even in their purest state. As potash is insoluble in ether, when the base is thrown into it, oxygen is furnished to it, and hydrogen gas evolved, and, as the alkali is formed, the ether becomes white and turbid. It is observed, that the energy of action of potassium in ether and alcohol, is proportional to the quantity of water which they contain, and hydrogen and potash are always produced.

When potassium is thrown into solutions of mineral acids, it inflames and burns on the surface, and when plunged, by proper means, beneath the surface, is expelled in potash, surrounded by naphtha, it acts upon the oxygen with great intensity. In sulphuric acid, a white waxy substance, covered with a yellow coating, which is supposed to be sulphate of potash surrounded with sulphur, and a gas, having the smell of sulphurous acid, and
Zinc

and which is probably a mixture of that substance with hydrogen gas, are formed. When potassium is thrown into nitric acid, nitrate of potash is formed, and nitrous gas is dissolved.

Potassium readily combines with phosphorus and sulphur. When pressed upon a piece of phosphorus, they both become fluid, enter into combustion, and produce phosphorus of potash. When the experiment is made upon naphtha, no gaseous substance is given out; the compound has the appearance of a metallic phosphorus, is of the colour of lead, and has the lustre of polished lead. Exposed to the air at common temperatures, it combines slowly with oxygen, and is converted into phosphorus of potash. When heated upon a plate of platinum, it gives out fumes, but does not burn till it reaches the temperature of the rapid combustion of potassium.

When potassium is brought into contact with sulphur in fusion, in tubes filled with the vapour of naphtha, they combine rapidly, with the evolution of heat and light. A grey substance is thus formed, which has the appearance of artificial sulphuret of iron; if it be kept in fusion, it rapidly dissolves the glass. When this experiment is made in a glass tube, hermetically sealed, no gas is disengaged, if the tube be opened under mercury; but when it is made in a tube connected with a mercurial apparatus, a small quantity of sulphurated hydrogen is evolved. When the combination is effected in the atmosphere, a great inflammation takes place, and sulphuret of potash is formed, and by farther exposure to the air, it is at last converted into sulphate of potash.

When one part of potassium is added to eight or ten of mercury, in bulk, at 65° of Fahrenheit, they instantly unite, and form a substance like mercury in colour, but less coherent. When a globule is made, to touch a globule of mercury about twice as large, they combine with considerable heat. The compound is fluid at the temperature of its formation, but, when cool, it becomes solid, with the appearance of silver. With the 17th part of potassium to the weight of mercury, the amalgam is hard and brittle; but with one part of potassium, and 70 of mercury, it is soft and malleable. Exposed to the air, these compounds absorb oxygen, and deliquescent potash is formed; and in a few minutes the mercury is revived. A globule of the amalgam, thrown into water, decomposes it rapidly with a hissing noise; potash is formed; pure hydrogen is disengaged, and the mercury remains free. This amalgam dissolves all the metals, and even acts on iron and platinum.

When potassium is heated with gold, silver, or copper, in a close vessel of pure glass, a rapid action is produced, and the compound thrown into water effects its decomposition; potash is formed, and the metals are revived. Potassium forms an alloy with fusible metal, which has a higher point of fusion than the fusible metal itself.

Potassium has little effect on colourless and recently distilled naphtha: but, in naphtha, exposed to the air, it is soon oxidized, and an alkali which unites with the naphtha into a brown soap that collects around the globule, is formed. Potassium acts slowly on the concrete oils, as tallow, spermaceti, and wax, even when heated; coaly matter is deposited, a little gas is evolved, and a soap is formed. On the fluid fixed oils the effects are similar, but take place more slowly. With the assistance of heat, volatile oils are rapidly decomposed by potassium; gas is evolved, and charcoal deposited.

The metallic oxides, when heated in contact with potassium, are readily reduced. When a small quantity of oxide of iron was heated with it, to a temperature approaching its point of distillation, a vivid action took place. Alkali, in gray metallic particles, which effervesced in muriatic acid, appeared. The oxides of lead and tin were revived more rapidly, and with potassium in excess, an alloy was formed with the revived metal.

Potassium readily decomposes flint glass and green glass, by a gentle heat. The metallic oxides are reduced, and the alkali formed decomposes the glass. At a red heat, even the purest glass is acted on by potassium; the oxygen in the alkali of the glass seems to be divided between the potassium employed, and the potassium which is the base of the alkali in the glass, and thus effects an oxidation in the first degree.

Soda.—When pure soda was subjected in similar circumstances to the action of galvanism, similar results were obtained as from potash; but the decomposition required a more intense action in the battery, or it was necessary to have the alkali in thinner and smaller pieces. Potassium remained fluid at the temperature of the atmosphere, at the time of its production; but the base obtained from soda, which was fluid in the degree of heat of the alkali during its formation, became solid on cooling, and exhibited the lustre of silver. With a battery of 100 pairs of plates of six inches, in full activity, the decomposition of pieces of soda of about 15 to 20 grains in weight only could be effected; and it was necessary also that the distance between the wires should not exceed one-eighth or one-tenth of an inch. But when 250 pairs of plates were employed, highly charged for the decomposition of soda, the globules often burst at the moment of their formation, and sometimes exploded and separated into smaller globules, which darted rapidly through the air, in a state of vivid combustion, producing a beautiful effect of continued jets of fire.

When the metallic base which is obtained from soda, and which Mr Davy has denominated sodium, was exposed to oxygen, it was converted into soda; and when this process was conducted by strongly heating the base in a given portion of oxygen, a rapid combustion with a brilliant white flame was produced, and the metallic globule was converted into a white solid mass, which was found to be soda. The oxygen gas was absorbed during the operation, and nothing was given out which affected the purity of the residual air.

The theory of the decomposition of the alkalies is stated by Mr Davy in the following words. "As in all decompositions of compound substances which I had previously examined, at the same time that combustible bases were developed at the negative surface in the electrical circuit, oxygen was produced, and evolved or carried into combination at the positive surface, it was reasonable to conclude, that this substance was generated in a similar manner by the electrical action of the alkali; and a number of experiments made above mercury, with the apparatus for excluding external air, proved that this was the case. When solid potash or soda, in its conducting state, was included in glass tubes, furnished with electrified platinum wires, the new substances..."
were generated at the negative surfaces; the gas given out at the other surface proved, by the most delicate examination, to be pure oxygen; and, unless when excess of water was present, no gas was evolved from the negative surface.

For the purpose of determining the proportions of the elements of soda, Mr. Davy made experiments similar to those by which he ascertained the proportions of the base and oxygen of potash. By subjecting sodium to combustion in oxygen gas, it appeared that 100 parts of soda are composed of 80 of metallic base, and 20 of oxygen; but the results of its oxidation by the decomposition of water, indicated the proportions to be 23 of oxygen, and 77 of base. By taking the mean proportions, obtained from the results of the two sets of experiments, the elements of soda may be estimated at 78.5 of metallic base, and 21.5 of oxygen.

Sodium, which remains solid at common temperatures, is white and opaque; and examined under a film of naphtha, has the lustre and appearance of silver. It is very malleable, and softer than common metallic substances. With a slight pressure it spreads into thin leaves, and a globule of one-tenth or one-twelfth of an inch in diameter, is easily spread over a surface of one-fourth of an inch; and different globules are easily made to adhere, and form one mass by strong pressure. This property of welding which belongs to iron and platina at a white heat only, is not diminished when sodium is cooled to 32° Fahrenheit.

Sodium, like potassun, is a conductor of electricity and heat, and small globules subjected to galvanism inflame and burn with bright explosions. Sodium sinks in naphtha of specific gravity .862; but by mixing perfectly about 12 parts of naphtha, and five of oil of sassafras, the sodium remains at rest in any part of the fluid. This makes its specific gravity = about .9348, water being taken as 1. The particles of sodium lose their cohesion at 120° Fahrenheit. It becomes quite fluid at 180°, so that it readily fuses under boiling naphtha. The temperature at which it is volatilized is not ascertained, but it remains fixed in a state of ignition at the point of fusion of plate glass.

The chemical relations of sodium are analogous to those of potassium, but with some characteristic differences. Exposed to the atmosphere, it is immediately tarnished, and is gradually covered with a white crust, which is pure soda. It combines slowly with oxygen, and without any luminous appearance at common temperatures. When heated, the combination is more rapid, but no light is emitted till it acquire a temperature near that of ignition. The flame in oxygen gas is white, and it sends forth bright sparks, producing a very beautiful effect; in common air, the colour of the light is like that of the combustion of charcoal, but brighter. When sodium was heated in hydrogen gas, it seemed to have no action on it.

Sodium burns vividly in oxymuriatic acid gas, giving out numerous sparks of a bright red colour; a saline matter is produced, which is muriate of soda. When sodium is thrown into water, it produces a violent effervescence with a loud hissing noise; it combines with the oxygen of the water to form soda, which is dissolved, and its hydrogen is disengaged. During the process there is no luminous appearance; but when sodium is thrown into hot water, a more violent decomposition takes place. A few scintillations are observed at the surface of the water, which is owing to small particles of the basis which are thrown out of the water, heated to such a degree as to burn in passing through the atmosphere. But when a globule of sodium is brought into contact with a small particle of water, or with moistened paper, the heat produced is usually sufficient for its combustion, as in this case there is no medium to carry off the heat rapidly.

Sodium produces similar effects with potassium as when brought into contact with alcohol and ether. In soda with great energy on the strong acids; with nitrous acid it produces a vivid inflammation, and with nitric and sulphuric acids, great heat, but no light, is generated. The effects of sodium and potassium on the fixed and volatile oils, and naphtha, are quite analogous; but the appearances of the saponaceous compounds are somewhat different, the combinations with sodium being of a darker colour, and apparently less soluble.

Sodium also exhibits two degrees of combination with oxygen; the first is of a deep brown colour, which is fluid when produced, and becomes a dark grey solid on cooling. By attracting oxygen from the air, or by the decomposition of the water, it is converted into soda.

Sodium forms compounds with sulphur and phosphorus. In close vessels filled with the vapour of naphtha, it enters into combination with sulphur, giving out during the process a vivid light and heat, and often attended with explosion, from the vaporization of a portion of sulphur, and the disengagement of sulphated hydrogen gas. The sulphuret of sodium is of a deep grey colour. In its combination with phosphorus, the compound obtained has the appearance of lead, and by exposure to the air, or by being subjected to combustion, the phosphuret of sodium is converted into phosphated soda.

Sodium forms compounds with the metals. In the proportion of one-fourth with mercury, a compound is obtained, which is of the colour of silver, and remains solid; the combination is accompanied with considerable heat. Sodium forms an alloy with tin, without producing any change of colour, and it has some action upon lead and gold when heated; but in its state of alloy it is soon converted into soda, by exposure to the air, or by the action of water, which it decomposes with disengagement of hydrogen. The amalgam of mercury and sodium seems to be capable of forming triple compounds with some other metals; and it would appear that iron and platina remain in combination with the mercury, after they are deprived of the sodium by exposure to the air. The same amalgam of sodium and mercury likewise forms compounds with sulphur; the triple compound thus obtained is of a dark grey colour.

Ammonia.—The chemical composition of ammonia has been many years considered as fully established; but in the course of Mr. Davy's experiments on the decomposition of the fixed alkalies, it occurred to him that oxygen might also form one of the constituents of ammonia, and this he also proved by experiment. Charcoal carefully burnt, and deprived of moisture was ignited by a galvanic battery of 250 pairs of plates of six and four inches square, in a small quantity of pure ammoniacal gas, confined over mercury. A great expansion of the gaseous matter took place, and the white substance...
into water it forms ammonia, with the evolution of hydrogen, and the re-appearance of the mercury in its metallic state. Mr Davy repeated this experiment, and he found that to produce an amalgam from 50 or 60 grains of mercury, in contact with a saturated solution of ammonia, required a considerable time, and that this amalgam changed considerably, even in the short period that was necessary for removing it from the solution. Conceiving that the de-oxidation and combination with mercury might be more easily effected in its nascent state, he placed 50 grains of mercury in a cavity in muriate of ammonia. The muriate slightly moistened was placed on a plate of platina, and connected with the positive side of a large galvanic battery. The mercury was made negative by means of a platina wire; a strong effervescence, with much heat, immediately took place; the globule of mercury in a few minutes enlarged to five times its former dimensions. It had the appearance of amalgam of zinc. Metallic crystallizations shot from it as a centre round the body of salt. They had an arborecent appearance, often became coloured at their points of contact with the muriate, and when the connection was broken, rapidly disappeared, while ammoniacal fumes were given off, and the mercury was reproduced. With a piece of carbonate of ammonia, similar phenomena were exhibited. The amalgam was formed very rapidly; but when the galvanic action was powerful in this last case, a black matter appeared in the cavity, which was probably carbon, from the decomposition of the carbonic acid. 

Mr Davy considering the strong attraction of potassium and sodium for oxygen, was led to examine whether they produced any effect in the amalgamation of ammonia independent of electricity. With this view he united small portions of potassium and sodium with mercury, and brought them into contact with moistened muriate of ammonia. An amalgam was formed, which rapidly increased to six or seven times its volume, and the compound seemed to contain a larger proportion of ammoniacal base than that obtained by electricity. It appears, too, that a portion of the metallic base employed to effect the de-oxidation always remained in combination with the compound, so that it was not a pure amalgam. The following are the properties of the amalgam from ammonia, obtained by means of galvanism.

When this amalgam is formed at the temperature of 70° or 80°, it is in the state of a soft solid, of the consistence of butter; at 32° it becomes firmer, and assumes a crystallized form, in which small facets appear, which seem to be cubical. The amalgam of potassium crystallizes in cubes, as beautiful, and in some cases as large, as those of bismuth. The specific gravity of the amalgam is less than three, water being one. When the amalgam is thrown into water, a quantity of hydrogen equal to half its bulk, is evolved, and the water becomes a weak solution of ammonia. The amalgam being confined in a given portion of air, the air increases in bulk, and the mercury is revived. Ammoniacal gas equal to 1/4 or 1/8th of the volume of the amalgam, is produced, and oxygen equal to one-seventh or one-eighth of the ammonia, disappears. When the amalgam is thrown into muriatic acid gas, it becomes instantly coated with muriate of ammonia, and a small portion of hydrogen is evolved. In sulphuric acid it becomes...
ZIN [ 794 ] ZIN

It has been observed that the proportion of oxygen, which loses its elastic form, varies according to the proportion employed contains more or less moisture. Thus, ammonia saturated with water at 65° Fahrenheit, potassium caused the expansion of twelve and a half cubic inches of air; but in ammonia deprived of moisture, by exposure for two days to a tempest that had been ignited, the same quantity of potassium occasioned the expansion of sixteen cubic inches; but without the degrees of moisture of the gas, the quantity of hydrogen generated always appeared equal for equal quantities of metal; and according to the French chemists, the proportions are stated to have been the same as well as have resulted from the action of water upon potassium.

In Mr. Davy's experiments, the proportions were rather less. In one, conducted with great care, eight grains of potassium generated, by their action upon water, eight and a half cubic inches of hydrogen; and eight grains of potassium from the same source, in their reaction upon ammonia, produced 5½ cubic inches of hydrogen gas. This difference, however, is not considerable, Mr. Davy found always to take place.

In Mr. Davy's experiments on the action of potassium on ammonia, he employed retorts of plate glass. The potassium was fastened upon trays of platinum wire, which were introduced into the glass retorts filled with stop-cocks. The retorts were exhausted by an air pump, then filled with hydrogen, exhausted a second time, and afterwards filled with ammonia. (See fig. 5.)

The following are the properties of the mixture formed from the action of ammonia on potassium. 1. It is crystallized, and presents irregular faces, which are extremely dark, and in colour and texture not unlike the green oxide of iron; it is opaque when examined in thin masses, but is semi-transparent in thin films, and imparted of a bright brown colour by transmitted light.

2. It is fusible at a heat a little above that of boiling water, and if heated much higher, emits globules of gas; 3. It appears to be considerably heavier than water, but sinks rapidly in oil of safflower. 4. It is a conductor of electricity. 5. When it is melted in oxygen gas, it burns with great vividness, emitting bright sparks. 6. Oxygen is absorbed, nitrogen is emitted, and pce., which from its great fluidity seems to contain water, is formed. The water thrown upon water, it acts upon it with much energy, produces heat, and often inflammation, and evolves ammonia. When thrown upon water, it appears with a hissing noise, and globules from it often move in a state of ignition upon the surface of the water. It rapidly effervesce and deliquesces in air, but can be preserved under naphtha, in which, however, it softens slowly, and in partial dissolution. When it is plunged under water filling an inverted jar, by means of a proper tube, it instantly disappears with effervescence, and the non-absorbable elastic fluid liberated is found to be hydrogen gas.

It is found that the weight of this substance is greater than that of the potassium from which it is formed; and from this it is concluded, that part of the ammonia, or of its elements, enters into its composition. When this substance is decomposed by heat, nitrogen and hydrogen gases, with a portion of ammonia, are given out. It appears, however, that the production of the ammonia...
is in proportion to the moisture admitted, and when the moisture is considerable, the whole product is ammonia.

When this substance is exposed to heat, a matter remains, which even by increasing the heat, is no farther changed. On this residuum water act violently, and with effervescence, from the evolution of hydrogen gas. Ammonia and potash are not the same time reproduced.

Mr. Davy's conclusion from these experiments is, that the substance formed by the action of ammonia on potassium is a compound of the latter with a small proportion of oxygen and nitrogen; and as it is found that the quantity of hydrogen given out during its formation is nearly equal to the hydrogen contained in the ammonia, it follows that neither hydrogen nor the ammonia itself can be supposed to enter into its composition.

In prosecuting this investigation, Mr. Davy made various experiments, and whether the substance was acted on by water, exposed to the action of oxygen, or decomposed by heat, it was found, contrary to expectation, that the quantity of nitrogen evolved during its decomposition was much less than in proportion to the quantity of ammonia which had disappeared in its formation.

In one experiment, in which the decomposition was effected by heat, the gaseous product was examined, and was found to be partly potash, partly potassium; but it afforded no traces of ammonia, when acted on by water, which is a proof that it retained no nitrogen. In another experiment, 11 cubic inches of ammonia, or 2.05 grains, were decomposed by potassium. The product was 3.6 cubic inches of nitrogen, equal to 1.06 grain; 16 cubic inches of hydrogen, equal to .382 grain; and there was added to the potassium a quantity of oxygen equal to .6 grain. These products taken together amount to 2.03 grains, which is nearly equal to the quantity of ammonia employed; but this quantity of ammonia, if the proportions of its elements be estimated, from its decomposition by electricity, would have yielded 5.4 cubic inches of nitrogen, equal to 1.6 grain, and only 14 cubic inches equal to .33; and allowing the separation of oxygen in this process in water, it cannot be estimated at more than .11 or .12; and hence, if the analysis of ammonia by electricity come near to accuracy, there is in this process a considerable loss of nitrogen, and the production of oxygen and hydrogen.

In a recent experiment, Mr. Davy, can these extraordinary results be explained? The decomposition and composition of nitrogen seem proved, and one of its elements appears to be oxygen; but what is the other element? Is the gas that appears to possess the properties of hydrogen a new species of inflammable aferiform substance? Or has nitrogen a metallic basis, which alloys with the iron or platinum? Or is water alike the ponderable manner of nitrogen, hydrogen, and oxygen? Or is nitrogen a compound of hydrogen, with a larger proportion of oxygen than exists in water? Of these important questions, Mr. Davy adds, the two first seem the least likely to be answered in the affirmative, from the correspondence between the weight of the ammonia decomposed, and the products, supposing them to be known substances.

In concluding this subject, we must observe, that it still remains in a considerable degree of obscurity. It seems, however, to be ascertained, that the base of ammonia is of a metallic nature, which must be derived, either from the nitrogen or the hydrogen, or from both, or perhaps these substances are only different forms of combination of the elementary base. Or if nitrogen be supposed to be an oxide of hydrogen, then hydrogen in its gaseous form is either a metallic substance, or has a metallic base, which latter enters into combination with the mercury employed in the decomposition of ammonia.

Decomposition of the Earths.

From the results of the experiments on potash and soda, which Mr. Davy obtained, he was led to entertain the strongest hopes of being able to effect the decomposition both of the alkaline and common earths; and the phenomena which took place in the imperfect trials made upon these bodies counseled the idea that had obtained since the earliest periods of chemistry of their being metallic in their nature.

The earths, like the fixed alkaies, are non-conductors of electricity; but the fixed alkaies become conductors by fusion: the insensible nature of the earths; however, rendered it impossible to operate upon them in this state: the strong affinity of their bases for oxygen, made it unavailing, to act upon them in solution in water; and the only methods that proved successful, were those of operating upon them by electricity in some of their combinations, or of combining them at the moment of their decomposition by electricity in metallic alloys, so as to obtain evidences of their nature and properties. To render the experiments upon the earths satisfactory, a more powerful battery will be required, than Mr. Davy has a prospect of seeing very soon constructed; he therefore prefers the imputation of having published unfinished labours, to that of having concealed any new facts.

Barites, strontites, and lime, slightly moistened, were electrified by iron wires under sulphur, by the same methods, and with the same powers, as those employed for the decomposition of the fixed alkaies. In these cases gas was copiously evolved, which was inflammable; and the earths, where in contact with the negative metallic wires, became dark coloured, and exhibited small points, having a metallic lustre, which, when exposed to air, gradually became white: they became white likewise when plunged under water; and when examined in this experiment with a magnet, a greenish powder seemed to separate from them, and small globules of gas were disengaged.

In these experiments there was great reason to believe that the earths had been decomposed; and that their bases had combined with the iron, so as to form alloys decomposable by the oxygen of the air or water; but the indistinctness of the effect, and the complicated circumstances required for producing it, were such as to compel Mr. Davy to form other plans of operation.

Mr. Davy bearing in mind the strong attraction of potassium for oxygen, was induced to try whether this body might not detach the oxygen from the earths, in the same manner as charcoal decomposes the common metallic oxides. He heated potassium in contact with dry pure lime, barites, strontites, and magnesia, in tubes of plate-glass; but as he was obliged to use very small quantities, and as he could not raise the heat to ignition without fusing the glass, he obtained no good results in this manner.
ZIN

manner. The potassium appeared to act upon the earths and on the glass, and dark brown substances were obtained, which evolved gas from water, but no distinct metallic globules could be procured: from these, and other like circumstances, it seemed probable, that though potassium may partially deoxidigenate the earths, yet its affinity for oxygen, at least at the temperature employed, is not sufficient to effect their decomposition. Mr. Davy, having made mixtures of dry potash in excess and dry barytes, lime, strontites, and magnesia, brought them into fusion, and acted upon them in the galvanic circuit in the same manner as he employed for obtaining the metals of the alkalies. He expected that the potassium and the metals of the earths might be deoxidigenated at the same time, and enter into combination in alloy.

In this way of operating, the results were more distinct than in the last: metallic substances appeared less fusible than potassium, which burned the instant after they had formed, and which by burning produced a mixture of potash and the earth employed. An attempt was made to form the metallic substances under naphtha, but without much success. To produce the result at all, required a charge by the action of nitric acid, which the state of the batteries would not often allow of; and the metal was generated only in very minute films, which could not be detached by fusion, and which were instantly destroyed by exposure to air.

Mr. Davy had found in his researches upon potassium, that when a mixture of potash and the oxide of mercury, tin, or lead, was electrified in the galvanic circuit, the decomposition was very rapid, and an amalgam, or an alloy of potassium, was obtained; the attraction between the common metals and potassium apparently accelerating the separation of the oxygen. The idea that a similar kind of action might assist the decomposition of the alkaline earths, induced him to electrify mixtures of these bodies and the oxide of tin, of iron, of lead, of silver, and of mercury; and these operations were far more satisfactory than any of the others.

A mixture of two-thirds of barytes, and one-third of oxide of silver very slightly moistened, was electrified by iron wires; an evanescece took place at both points of contact, and a minute quantity of a substance, possessing the whiteness of silver, formed at the negative point. When the iron wire to which this substance adhered, was plunged into water containing a little alum in solution, gas was disengaged, which proved to be hydrogen; and white clouds, which were found to be sulphate of barytes, descended from the point of the wire.

A mixture of barytes and red oxide of mercury, in the same proportions was electrified in the same manner. A small mass of solid amalgam adhered to the negative wire, which evidently contained a substance, that produced barytes by exposure to the air, with the absorption of oxygen; and which occasioned the evolution of hydrogen from water, leaving pure mercury, and producing a solution of barytes.

Mixtures of lime, strontites, magnesia, and red oxide of mercury, treated in the same manner, gave similar amalgams, from which the alkaline earths were regenerated by the action of air or water, with like phenomena; but the quantities of metallic substances obtained were exceedingly minute; they appeared as mere superficial formations surrounding the point of the wire, nor did they increase after the first few minutes of electrization, even when the process was carried on for two or three hours.

These experiments were at first made when the batteries were in bad order; but were afterwards repeated with a new and much more powerful apparatus, constructed in the laboratory of the Royal Institution, consisting of five hundred pairs of double plates of six inches square.

When Mr. Davy attempted to obtain amalgams with this apparatus, the transmitting wires being of platinum, of about 1/25 of an inch diameter, the heat generated was so great as to burn both the mercury and basis of the amalgam at the moment of its formation; and even, by extending the surface of the conductors, this power of ignition was modified, yet still the amalgam was only procured in thin films, and globules sufficiently large to submit to distillation could not be procured. When the transmitting wires were of iron of the same thickness, the iron acquired the temperature of ignition, and combined with the bases of the earths in preference to the mercury; and metallic alloys of a dark grey colour were obtained, which acted on water with the evolution of hydrogen, and were converted into oxide of iron and alkaline earths.

While Mr. Davy was engaged in these experiments, he received a letter from Professor Berzelius of Stockholm, who stated that in conjunction with Dr. Piotr, he had succeeded in decomposing barytes and lime, by negatively electrifying mercury in contact with them, and that in this way he had obtained amalgams of the metals of these earths.

Mr. Davy immediately repeated these operations with perfect success; a globule of mercury, electrified by the power of the battery of 300, weakly charged, was made to act upon a surface of slightly moistened barytes, fixed upon a plate of platinum. The mercury gradually became less fluid, and after a few minutes was found covered with a white film of barytes, and when the amalgam was thrown into water, hydrogen was disengaged, the mercury remained free, and a solution of barytes was formed.

The result with lime, as these gentlemen had stated, was precisely analogous. Strontites and magnesia were decomposed in the same manner.

From strontites the expected result soon took place; but from magnesia, in the first trials, no amalgam could be procured. By continuing the process, however, for a longer time, and keeping the earth continually moist, at last a combination of the basis with mercury was obtained, which slowly produced magnesia by absorbing oxygen from the air, or by the action of water.

Mr. Davy found that all these amalgams might be preserved for a considerable period under naphtha. In length of time, however, they became covered with a white crust under this fluid. In water, the amalgam of barytes was most rapidly decomposed; that of strontites and that of lime next in order: but the amalgam of magnesia, as might be expected from the weak affinity of the earth for water, very slowly changed. When a little sulphuric acid was added to the water, however, the evolution of hydrogen, and the production of solution of magnesia, were exceedingly rapid, and the mercury soon remained free.

Mr. Davy believed, that one reason why magnesia was less easy to metallize, than the other alkaline earths, was...
Zinc was owing to its insolubility in water, which would prevent it from being presented in the nascent state, detached from its solution at the negative surface.

He then made the experiment, using moistened sulphate of magnesia instead of the pure earth; and the amalgam was much sooner obtained. Here the magnesia was attracted from the sulphuric acid, and probably deoxygenated and combined with the quicksilver at the same instant.

The amalgams of the other bases of the alkaline earths could be obtained in the same manner from their saline compounds: muriate and sulphate of lime, the muriate of strontium and barytes, and nitrate of barytes, were decomposed by the same means as the other earths.

The earths, separated at the deoxygenating surface; these seemed instantly to undergo decomposition, and, seized upon by the mercury, were in some measure defended from the action of air, and from the contact of water, and preserved by their strong attraction for this metal.

In attempting to procure the metals of the alkaline earths, the latter were slightly moistened, and mixed with one-third of red oxide of mercury; the mixture was placed on a plate of platina; a cavity was made in the upper part of it to receive a globule of mercury, of from 50 to 60 grains in weight; the whole was covered by a film of naphtha, and the plate was made positive, and the mercury negative, by a proper communication with the battery of five hundred.

The amalgams obtained in this way were distilled in tubes of plate-glass, or in some cases in tubes of common glass. These tubes were bent in the middle, and the extremities were enlarged and rendered globular by blowing, so as to serve the purposes of a retort and receiver. The tube, after the amalgam had been introduced, was filled with naphtha, which was afterwards expelled, by boiling, through a small orifice in the end corresponding to the receiver, which was hermetically sealed when the tube contained nothing but the vapour of naphtha, and the amalgam. It was found immediately that the mercury rose pure by distillation from the amalgam, and it was very easy to separate a part of it; but to produce a complete decomposition was very difficult, as nearly a red heat was required for the purpose, and as at a red heat the bases of the earths instantly acted upon the glass, and became oxygenated. When the tube was large in proportion to the quantity of amalgam used, the vapour of the naphtha furnished oxygen sufficient to destroy part of the bases: and when a small tube was employed, it was difficult to heat the part used as a retort sufficient to drive off the whole of the mercury from the bases, without raising too highly the temperature of the part serving for the receiver, so as to burst the tube.

In consequence of these difficulties, in a multitude of trials, only a very few successful results were obtained; and in no case could our author be absolutely certain, that there was not a minute portion of mercury still in combination with the metals of the earths.

In the best result obtained from the distillation of the amalgam of barytes, the residuum appeared as a white metal, of the colour of silver. It was fixed at all common temperatures, but became fluid at a heat below redness, and did not rise in vapour when heated to redness, in a tube of plate-glass, but acted violently up on the glass, producing a black mass, which seemed to contain barytes, and a fixed alkaline basis, in the first degree of oxygenation. When exposed to air, it rapidly tarnished, and fell into a white powder, which was barytes. When this process was conducted in a small portion of air, the oxygen was absorbed and the nitrogen remained unaltered; when a portion of it was introduced into water, it acted upon it with great violence and sunk to the bottom, producing in it barytes; and hydrogen was generated. From the minuteness of the quantities obtained, neither its physical nor chemical qualities could be examined correctly. It sunk rapidly in water, and even in sulphuric acid, though surrounded by globules of hydrogen, equal to two or three times its volume; from which it seems probable, that it cannot be less than four or five times as heavy as water. It flattened by pressure, but required a considerable force to produce this effect.

The metals from strontites sunk in sulphuric acid, and exhibited the same characters as that from barytes, except in producing strontites by oxidation.

The metal from lime, Mr. Davy has never been able to examine, either when exposed to air, or when under naphtha. In the case in which he was able to distil the quicksilver from it to the greatest extent, the tube unfortunately broke, while warm, and at the moment that the air entered, the metal, which had the colour and lustre of silver, instantly took fire, and burned with an intense white light into quicklime.

The metal from magnesia seemed to act upon the glass, even before the whole of the quicksilver was distilled from it. In an experiment in which the process was stopped before the mercury was entirely driven off, it appeared as a solid; having the same whiteness and lustre as the metals of the other earths. It sunk rapidly in water, though surrounded by globules of gas, producing magnesia, and quickly changed in air, becoming covered with a white crust, and falling into a fine powder, which proved to be magnesia.

In several cases in which amalgams of the metals were obtained, containing only a small quantity of mercury, they were exposed to air on a delicate balance, and it was always found, that, during the conversion of the metal into earth, there was a considerable increase of weight.

Mr. Davy endeavoured to ascertain the proportions of oxygen and basis in barytes and strontites, by heating amalgams of them in tubes filled with oxygen, but without success. He satisfied himself, however, that when the metals of the earths were burned in a small quantity of air, they absorbed oxygen, gained weight in the process, and were in the highly caustic or unslaked state; for they produced strong heat by the contact of water, and did not effervescence during their solution in acids.

The evidence for the composition of the alkaline earths is then of the same kind as that for the composition of the common metallic oxides; and the principles of their decomposition are precisely similar, the inflammable matters in all cases separating at the negative surface in the galvanic circuit, and the oxygen at the positive surface.

Mr. Davy has denominated the metals obtained from the alkaline earths, barium, strontium, calcium, and magnesium.

In attempting the decomposition of the other earths,
Mr. Davy was less fortunate in obtaining distinct results; and he observes that the methods which have usually proved successful, as well as some others, failed. When alumina was subjected to the action of electricity, it was in a state of fusion with potash. In this process metallic globules were produced, but they consisted chiefly of the base of the alkali. Some appearances, however, showed that the alumina itself was decomposed; for when soda was employed, the metallic product obtained was less fusible than sodium itself, and when it was acted on by water, it produced soda and a white powder. When potash was fused with the alumina, and subjected to galvanic action, the metallic product decomposed water with great rapidity, and the solution obtained deposited alumina by the action of an acid. When potassium in the state of amalgam, with one-third of mercury, in contact with alumina, was negatively electrified under naphtha, and after the process had been continued for some time, the amalgam was added to water, a decomposition took place, and a solution was obtained, which produced a cloudiness on the addition of an acid; but all these results are to be considered as very imperfect evidence of the decomposition of alumina.

Mr. Davy was still less successful in attempting the decomposition of silica, partly from its insolubility, and partly from its being scarcely, if at all, affected with electricity, when diffused in water, and placed in the galvanic circuit; but by following the same processes as in his experiments on alumina, some indications of decomposition appeared. When silica was fused with six parts of potash, and was placed in fusion in the galvanic circuit, metallic matter was obtained, from which, by exposure to the air, or by dropping it into water, a minute quantity of silica was reproduced. When potassium, amalgamated with one-third of mercury, and in contact with silica, was negatively electrified, he obtained a similar result; but in none of the experiments could the product obtained be considered as the pure base of the earth.

The earths of zirconia and glauca were also subjected to the action of galvanism, by processes similar to those which have now been described, and in both there were some indications of decomposition; but the results were not so perfect as to lead to any certain conclusion respecting their nature.

Decomposition of Sulphur and Phosphorus.

Sulphur.—Sulphur, which had formerly been considered as a simple substance, appears, from the experiments of some of the French chemists, and particularly those of Berthollet junior, to be a compound of sulphur and hydrogen. The latter chemist, in his experiments to investigate the nature of this substance, caused sulphur to pass through a coated glass tube, which was heated to whiteness; some indications of sulphurized hydrogen were obtained. He then formed metallic sulphures, as of iron, copper, and mercury, and in these processes, which were performed in an earthen retort with great care, sulphurized hydrogen gas was also obtained. Water in the state of vapour being passed over sulphur in fusion, caused the evolution of sulphurized hydrogen; the water was not decomposed, for no trace of acid could be observed. It seemed only to have effected the disengagement of hydrogen from the sulphur.

Mr. Davy, in the course of his experiments in galvanism, subjected sulphur to the action of that power. The sulphur which he employed was sublimed in a retort filled with azotic gas, and it was kept hot till the commencement of the experiment. The reason of the preliminary process was, to avoid any unpleasant vapors which might arise from water absorbed by the sulphur. The sulphur introduced into a curved tube, fig. 7, which was furnished with wires of platina A and B, the upper A being hermetically sealed into the end of the tube, was then placed in the galvanic circuit of a battery of 30 pairs of plates of six inches, in a state of great intensity. A very intense action followed, accompanied by great heat and a brilliant light. The sulphur soon entered into ebullition, and gave out a great quantity of elastic gas, a good deal of which was permanent. The sulphur itself assumed a deep red brown colour. The gas emitted was sulphurated hydrogen. In another experiment made on 200 grains of sulphur, the amount of sulphurated hydrogen obtained was equal to more than five times the volume of the sulphur. A considerable scum was observed to have taken place on the wire of platina; and the sulphur, at its point of contact with the wires, reddened moist litmus paper. When sulphurated potassium are heated together, a very powerful scum takes place. Sulphurated hydrogen is discharged with very intense heat and light. From these experiments the conclusion seems fair and obvious, that hydrogen exists in sulphur, for a substance, as Mr. Davy shows, which can be produced from it in such abundance, is not to be considered merely as an accidental ingredient. But as it is admitted that sulphurated hydrogen contains oxygen, Mr. Davy contends that oxygen is to be regarded as one of the constituents of sulphur. In his opinion he is supported by experiment. He heated potassium in sulphurated hydrogen gas, from which carbon had been as much as possible abstracted, by means of lime. The potassium took fire, and burnt with a brilliant flame. When four grains of potassium were heated in 20 cubic inches of gas, the quantity of gas diminished only about 2½ cubic inches; but the properties of the gas were totally changed. A small portion only of it was absorbed by water, and the remainder was hydrogen, holding in solution a minute portion of sulphur. Some sulphur was observed on the sides of the retort, and a solid matter was formed, which on the surface was of a red colour, like sulphuret of potassa, but intensely dark grey, like sulphuret of potassium. By submerging this substance to the action of muriatic acid, sulphurated hydrogen gas was obtained, but the proportion was less than would have been given out, had the potassium been in combination with pure combustible matter. Even this Mr. Davy concludes, that there is a principle in sulphurated hydrogen which is capable of destroying partially the inflammability of potassium, and of producing upon it all the effects of oxygen. As sulphurated hydrogen is obtained by heating sulphur strongly in hydrogen gas, Mr. Davy introduced four grains of sulphur in a glass retort, containing about 20 cubic inches of hydrogen, and by means of a spirit lamp, he raised the heat nearly to a redness. No perceptible change took place in the volume of the gas after the process. The obtained sulphur was unchanged in its properties, and about three cubic inches of an elastic fluid, absorbable by water, reddening moist litmus, and having all the properties of sulphurated hydrogen gas, were formed.

The properties of boracic, fluoric, and muriatic acids.

The properties of boracic, fluoric, and muriatic acids, many of which are quite analogous to those of other acids whose elements have been discovered, have led chemists to conclude that oxygen is also the acidifying principle in the former; but the separate existence or nature of the base of these three acids was, till the late researches of galvanism were instituted, utterly unknown. The investigation of the nature of the substances has been prosecuted by Mr. Davy, and of the French chemists; and of their experiments we shall now give a very short account.

Boracic acid.—When boracic acid was moistened with water, and exposed between two surfaces of platinum, and then subjected to the battery of 300 plates, an olive brown matter formed on the negative surface, and, increasing in thickness, appeared at last almost black. This substance was permanent in water, but it dissolved and effervesced in warm nitrous acid. Heated to redness on the platinum, it burned slowly, and gave off white fumes, which reddened moistened limes paper. A black mass remained, which through a magnifier appeared vitreous, and seemed to contain a fixed acid. The inference drawn from this experiment is, that the acid was decomposed, and again by the latter process reproduced.

When equal weights of potassium and boracic acid were heated together in a green glass tube, which had been exhausted, after being twice filled with hydrogen gas, an intense ignition, with vivid inflammation, where the potassium was in contact with the boracic acid, took place, even before the temperature approached near a red heat. When the acid had been heated to whiteness, before being introduced into the tube, and powdered and used while yet warm, the quantity of gas which was hydrogen, given out in the operation, did not exceed twice the volume of the acid. In this mode of conducting the experiment, 12 or 14 grains of each of the two substances only could be employed, on account of the intense heat and consequent fusion of the glass tube with larger proportions. Mr. Davy found in several experiments, in which he employed equal parts of acid and potassium, that a great proportion of the former remained undecomposed, and he ascertained that twenty grains of potassium had their inflammability destroyed by eight grains of boracic acid.

To collect the substances formed in the process, metallic tubes with stop-cocks, and exhausted, after being filled with hydrogen, were employed. With tubes of brass or copper, a dull red heat only, but with iron tubes,
ZIN

Zine. A white heat was applied; and in all cases the acid was decomposed by the same results. The substance obtained from the iron tube was in some parts of a dark olive colour, and in others almost black. It did not effervesce with warm water, but was rapidly acted upon by it. The solutions obtained consisted of subbo-

rate of potash, and potash.

The following are the properties of the substance obtained in the decomposition of boracic acid by means of processes conducted in brass tubes, which afforded it in greatest proportion. To this substance Mr. Davy has given the name of boracium, which, as it is produced in the manner now described, is in the form of a pulverulent mass of the darkest shades of olive; it is opaque, very friable; the powder does not scratch glass, and is non-conductor of electricity. Dried at 100° or 120°, it gives off moisture, by decreasing the temperature; and when heated, the atmosphere, takes fire at a temperature below the boiling point of olive oil, emitting a red light, and sparks like charcoal. When exposed from air, and subjected to a white heat in a platina tube, exhausted after being filled with hydrogen, it remains unchanged, excepting in becoming a little darker, and acquiring a greater specific gravity.

Boracium introduced into a retort filled with oxygen gas, and heated by a spirit lamp, throws off vivid scin-
tillations like those of the combustion of the barb of charcoal, and the mass gives out a brilliant light. A sublimates, which is boracic acid; it becomes coated with a vitreous substance, which is also found to be the same acid. When this is washed off, the black residue requires a greater heat, but it is also inflamed, and converted into boracic acid. When boracium is brought into contact with oxygen acid gas, at common temperatures, it immediately takes fire, and burns with a brilliant white light, coating the inside of the vessel with a white substance, which is boracic acid. Boracium heated to redness with hydrogen or nitrogen, became of a darker colour, and gave out a little moisture, but remained otherwise unchanged. Thrown into concentrated nitric acid, it rendered it bright red; nitric acid was produced and absorbed, but no rapid solution took place till the acid was heated, when the boracium appeared with effervescence and the evolution of nitrous gas, and the fluid yielded boracic acid. The action of boracium on sulphuric and muriatic acids was not remarkable. It combined with the fixed alkalies, both by fusion and aqueous solution, and formed pale olive-coloured compounds, which, by muriatic acid were precipitated of a dark colour. When fused with sulphur, it dissolved slowly, and the sulphur became of an olive colour. Its action with phosphorus in the same circumstances was still feebleer, but it communicated a shade of pale green.

From the experiments now detailed, it appears that boracium obtained by means of potassium, is different from any other known species of matter, and seems to be the same as that obtained from boracic acid by electricity. According to the result of experiments made by Mr. Davy, boracic acid is composed of one part of dark residual substance to be an oxide, it consists of 4.7 of boracium, and 1.55 of oxygen.

For an account of the experiments of Gay Lussac and Achenard, in investigating the nature of boracic acid,

see Jour. de Physique, tom. lvii. or Nicol. Jour. xii. p. 260.

Fluric acid.-According to the experiments of Mr. Davy, potassium, when heated in fluric acid gas, undergoes combustion, and a great abstraction of the gases takes place. In other experiments, he found that when fluric acid gas, procured in contact with glass, is intro-

duced into a plate glass retort, exhausted after being filled with hydrogen gas, white fumes appear from the action of the potassium, which loses its splendour, and becomes coloured with a gray crust. The fumes in more copious when the bottom of the retort is gently heated. The volume of the gas examined at the time appears to be a little increased, with the addition of hydro-

gen; and when the temperature is raised nearly in the point of sublimation of the potassium, the metal then enters through the crust, becomes first of a copper colour, and then inflames and burns with a brilliant red light. After this combustion, the fluric acid is either wholly or partially destroyed, according as the quantity of potassium is great or small; and a mass of a chocolate color is found in the bottom of the retort; the sides of the top are lined with a sublimate, which is partly cholate, and partly of a yellow colour. When the raised gas is washed with water, mixed with oxygen gas, and exposed to the action of an electrical spark, it detains, and affords a diminution in the same way as hydrogen gas.

In one experiment with 19 cubic inches of fluric acid gas, and ten grains of potassium, 14 cubic inches of the gas disappeared, and about two and a quarter of hydrogen gas were produced. The gas had not been artificially dried; little sublimate was produced, but the whole of the bottom of the retort was covered with a brown crust. When this mass was exam-

ined with a magnifier, it seemed to consist of different kinds of matter. It did not conduct electricity; it ef-

fervesced violently in water, with the evolution of a inflammable gas, which had somewhat of the odor of phosphorated hydrogen. Part of the mass heated in the air, burnt slowly, and was converted into a white saline matter. It also burnt with difficulty in heated oxygen gas, but it absorbed a portion that required nearly a red heat. The light emitted resembled that from the combustion of liver of sulphur. Chocolate-coloured particles were found floating in the water, noted on a portion of the mass, and when the solid matter was separated by the filter, the fluid was found to contain fluote of potash and potash. The solid residue was heated in a small glass retort filled with oxygen gas; it burnt before reaching a red heat, and became white. Oxygen was absorbed, and acid matter produced. The remainder had the properties of the substance formed from fluric acid gas, holding siliceous earth in solution by the action of water.

The decomposition of the fluric acid, Mr. Davy observes, by potassium, seems analogous to that of the acids of sulphur and phosphorus. In neither of these cases are the pure bases, or even the bases in their com-

on form, evolved; but new compounds result, and in one case, sulphures and sulphites, and in the other, phos-

phurates and phosphites of potash, are generated.

In another experiment Mr. Davy attempted the decom-

position of fluric acid gas, which was perfectly dry, and free from siliceous earth, by mixing 100 g. of
of dry boracic acid, and 200 grains of flour spar. The mixture was introduced into the bottom of an iron tube, having a stop-cock and tube of safety attached. The tube was inserted horizontally in a forge, and 20 grains of potassium in an iron tray were placed in that part of it where the heat was only of a dull red. The bottom of the tube was raised to a white heat, and the acid, as it was generated, was acted upon by the heated potassium. The result obtained was a substance in some parts black, and in others of a dark brown colour. It did not effervesce with water, and when lixiviated, afforded a dark brown combustible mass which did not conduct electricity, and, when burnt in oxygen gas, afforded boracic and fluoric acids. This substance did not infuse spontaneously in oxy-muriatic acid gas; but it effervesced violently, and dissolved in nitric acid. Mr Davy thinks that this substance is a compound of the olive-coloured oxide of boracic acid, and an oxide of the base of fluoric acid; but he had not examined its properties particularly.

Muriatic acid—Many conjectures have been offered with regard to the nature and constitution of muriatic acid, and many attempts have been made to effect its decomposition. Mr Davy has extended his researches to this substance, and has prosecuted the investigation with his usual ardour. It is still, however, to be regretted, that his success has not been commensurate with his ingenuity and industry. Some have supposed, that the base of muriatic acid is hydrogen, while others contend that the base is a compound of hydrogen and nitrogen.

The result of Mr Davy's first experiments in this inquiry showed, that the water alone in combination with the muriatic acid is decomposed, and that this elastic fluid contains a larger proportion of water than is usually suspected; and from various experiments he concludes, that muriatic acid gas, in its common state, is combined with at least one-third of its weight of water. In the prosecution of his researches, therefore, his object was to obtain the muriatic acid free from water. With this view he heated dry muriate of lime, mixed both with phosphoric acid, and dry boracic acid, in tubes of porcelain and of iron, and employed the blast of an excellent forge; but by none of these methods was any gas obtained, till a little moisture was added to the mixture, and then muriatic acid was given out in such quantity as almost to produce explosions. In distilling the liquor of Libavius, or the fuming muriate of tin, which contains dry muriatic acid, with sulphur and with phosphorus, no separation of the acid took place; but with the addition of water, muriatic acid gas was evolved with great heat and violence. By distilling mixtures of corrosive sublimate and sulphur, and of calomel and sulphur in their common states, muriatic acid gas was evolved; but when these substances were dried by a gentle heat, the quantity of gas obtained was greatly diminished. Mr Davy, and also the French chemists, endeavoured to procure dry muriatic acid by the distillation of a mixture of calomel and phosphorus. The result obtained is considered as a compound of muriatic acid, phosphorus, and oxygen. In Mr Davy's experiments, the product was more copious when corrosive sublimate was employed. With the same view of procuring dry muriatic acid gas, he exposed phosphorus to the action of oxy-muriatic acid gas, in the hope that in the oxidation of the phosphorus, the whole of the moisture would be absorbed; but the examination of the result showed, that no muriatic acid gas had been evolved during the process, so that the muriatic acid which had disappeared, must exist, either in the white sublimate which had collected in the top of the retort, or in a limpid fluid which had formed in its neck. When the sublimate was exposed to the air, it emitted fumes of muriatic acid, and when brought into contact with water, muriatic acid gas was evolved, and phosphoric and muriatic acids remained in solution in the water. Mr Davy regards this white sublimate as a combination of phosphoric and muriatic acids in their dry states. The limpid fluid was of a pale greenish yellow colour; it rapidly disappeared on exposure to the air, emitting dense white fumes, which had a strong smell, differing a little from that of muriatic acid. Mr Davy thinks that this is a compound of phosphoric and muriatic acids, both free from water.

Mr Davy made other experiments for the purpose of procuring muriatic acid in its uncombined state, but with no better success. He then tried the effects of potassium introduced into the fluid generated by the action of phosphorus on corrosive sublimate; but such was the violent action of the substances operated upon, that the apparatus was generally destroyed, and he was thus precluded from examining the results. But for a particular detail of the experiments, we must refer to the memoir itself; and for the extended account of Mr Davy's investigations on this curious and interesting subject, of which we have given as comprehensive a view as our limits would permit, see Chemistry, Supplement.

ZINNIA, a genus of plants of the class ERYNGIUM, and in the natural system arranged under the 49th order, Compositae. See Botany Index.

ZINZENDORFF, NICHOLAS LEWIS, COUNT, was the noted founder of the German religious sect called Moravians or Herrnhueters, or, as they pretend, the restorer of that society. From his own narrative, it appears, that when he came of age in 1721, his thoughts were wholly bent on gathering together a little society of believers, among whom he might live, and who should entirely employ themselves in exercises of devotion under him. He accordingly purchased an estate at Bertholdsdorf in Upper Lusatia, where, being joined by some followers, he gave the curacy of the village to a person of his own complexion; and Bertholdsdorf soon became talked of for a new mode of piety. One Christian David, a carpenter, brought a few proselytes from Moravia: they began a new town about half a league from the village, where Count Zinzendorff fixed his residence among them, and whither greater numbers of Moravians flock and established themselves under his protection: so that in 1732 their number amounted to 600. An adjacent hill, called the Huthberg, gave occasion to these colonists to call their new settlement Huth des Herrn, and afterwards Herrnhuth; which may be interpreted the guard or protection of the Lord. The whole sect have taken their name. The count spared neither pains nor art to propagate his opinions; he went himself all over Europe, and at least twice to America; and sent missionaries throughout the world. Count Zinzendorff died in 1760. Those who wish to know more of the Moravian tenets may consult Rimmus's account. Zn.
ZION, or Zion College. See London, p. 76.

ZIPH, or Siph, in Ancient Geography, the name of a wilderness or desert in the tribe of Judah, where David was fugitive; lying to the south-east of Hebron; a Ziph or Siph, a twofold town in this tribe; the one more to the south towards Idumea, on the confines of Eleutheropolis, (Jerome); the other eight miles to the east of Hebron, towards the Dead sea, being southwards, because near Mount Carmel. Here was a mountain, mentioned 1 Sam. xxviii. 14., in which David abode, said by Jerome to be rugged, dismal, and always overcast. Ziphim, Ziphites or Ziphenses, the inhabitants of Ziph, ver. 10.

ZIRCHNITZEB, otherwise called the Lake of Cosirnkites, in Carniola, is about one German fur English miles in length, and half as much in breadth, contains three beautiful islands, and is encompassed by some distance with mountains and forests. But what is most remarkable is, that it disappears generally once a year, about St John's or St James's day, running off through holes or pits in the bottom; sometimes it disappears twice or thrice a year, and sometimes even in winter if the weather be dry. On the other hand, it has been known to continue two or three years without running off. Of the holes or pits, there are five much larger than the rest, each of which successively, when the water runs off, stands empty five days; so that the whole lake becomes dry in 25. As soon as the beginning of the ebb is observed, the fishing in the pits begins, which belongs to five seignories. The fish, which are carp, tench, pike, eels, and two other sorts called schlesien and ruffen, are caught by laying nets over the holes. Mr Keysler tells us, that upon the ringing of a bell at Zirknitz, when the waters begin to fall, the peasants, both men and women, run to the pools quite naked.

ZIRCON, a mineral substance containing a peculiar earth. See Mineralogy Index.

ZIRCONIA, a peculiar earth. See Chemistry Index.

ZIZANIA, a genus of plants of the class monocotyl, and in the natural system arranged under the 4th order, Gramina. See Botany Index.

ZODIAC, a broad circle, whose middle is the ecliptic, and its extremes two circles parallel thereto, at such a distance from it as to be bound or comprehended the revolutions of the sun and planets, (see Astronomy). It is a curious enough fact, that the solar division of the Indian zodiac is the same in substance with that of the Greeks, and yet that it has not been borrowed either from the Greeks or the Arabsians. The identity, or at least striking similarity, of the division, is universally known; and M. Montucut has endeavoured to prove, that the Bramins received it from the Arabs. His opinion, we believe, has been very generally admitted; but in the second volume of the Asiatic Researches, the accomplished president Sir William Jones has proved it an unanswerable, that neither of those nations borrowed that division from the other; that it had been among the

ZOI,
ZOOLOGY, [803]

the Hindoos from time immemorial; and that it was probably invented by the first progenitors of that race, whom he considers as the most ancient of mankind, before their dispersion. The question is not of importance sufficiently general; straitened as we are by the limits prescribed us, for our entering into the dispute; but we think it our duty to mention it, that our astronomical readers, if they think it worth their while, may have recourse to the original writers for further information.

ZOEGEA, a genus of plants of the class syneriesia.

See Botany Index.

ZONE, in Geography and Astronomy, a division of the terraqueous globe with respect to the different degrees of heat found in the different parts thereof. The zones are demarcated torrid, frigid, and temperate. The torrid zone is a band, surrounding the terraqueous globe, and terminated by the two tropics. Its breadth is $46^\circ 5^\prime$. The equator, running through the middle of it, divides it into two equal parts, each containing $23^\circ 26^\prime$. The ancients imagined the torrid zone uninhabitable. The temperate zones are contained between the tropics and the polar circles. The breadth of each is $43^\circ 2^\prime$. The frigid zones are segments of the surface of the earth, terminated, one by the antarctic, and the other by the arctic circle. The breadth of each is $46^\circ 5^\prime$.

ZOOLOGY, is that part of natural history which relates to animals. See Natural History.

ZOO PHY TES. The name Zoophytes, Zoophyta (i.e., animal plants, from ζωή, animal and φυτή, plant), has been long appropriated to a numerous assemblage of marine or aqueous productions, which have puzzled the ingenuity of naturalists to ascertain their place in the chain of nature's works, and which have been alternately ranked among vegetable and animal, and sometimes even among mineral substances. At length, however, they seem, by general consent, to have been considered over to the animal kingdom, and, with the addition of several tribes from the Linnaean orders of Intestina, Molusca, and Infusoria, have, by Cuvier and his colleagues of the French school, been elevated to the rank of a separate class. See Helminthology, No. 11.

In the Linnaean system, the zoophytes of earlier modern naturalists constitute the 4th order of the class Vermes, and as such have been enumerated under Helminthology; but as the circumscribed limits of that article did not admit of our describing or figuring many species, we shall now as far as possible supply that deficiency by selecting a few of the most curious or interesting species of the Linnaean zoophytes; and we shall take this opportunity of making a few observations on some of the genera to which they belong.

Fig. 1. and 2, represent the Tubifora musica, crimson tubipore, or organ coral; one of the most elegant of these singular productions. This species is distinguished from its congeners by having the tubes connected into fascicule or bundles, and separated from each other by transverse membranous partitions. The whole mass consists of upright parallel tubes, rising over each other by stages, something like the cells of a honeycomb. These tubes vary in height from half an inch to an inch; and are from one-tenth to one-eighth of an inch in diameter. Examined internally, they appear to contain a smaller tube divided at certain distances by radiated partitions (see fig. 2.), by means of which the transverse septa sometimes communicate with each other. These transverse septa are of unequal heights. The colour of the mass is a deep purple, or a rich crimson. The size of the mass varies considerably; but specimens have been obtained of from a foot to three feet in diameter.

It is found abundantly in the Pacific ocean, and on the shores of some of the islands in the Indian sea.

In its recent state it is covered with a mucous or gelatinous substance, which pervades the whole mass and enters within each tube. The inhabiting animal is not certainly ascertained, but seems to be allied to the neritid tribe.

Figs. 3. and 4. exhibit two views of the Madrepora fora fungites, or mushroom madrepor. This body so fungites, exactly resembles a mushroom that it has very common. Figs. 3. & 4. have been regarded as that vegetable in a state of petrifaction; but recent observations seem to prove that it is formed by small animals like medusae. The convex side of this madrepor is conical, sometimes obtusely pointed, and exhibits on its surface those stellated pores which form the distinguishing character of the genus, while the concave surface is divided into numerous radiated furrows so as to represent the gills of a mushroom.

When first obtained, it is of a delicate white colour, especially on the concave part, but it soon acquires a brown or yellowish tinge. It is found of various sizes, from an inch to six inches in diameter. It is met with chiefly in the Indian ocean and Red Sea.

At fig. 5. is represented that elegant coral called by Isis hippuris, the black and white jointed coral, of Ellis. The specific character of this coral is that it is composed of white striated joints united by black junctions; but that structure is not visible till after the coral has been freed from a whitish soft spongy part, with which the branches are covered in their natural state. See fig. 6. It is found chiefly in the Indian sea, and varies in height from a few inches to nearly two feet.

Fig. 7. represents the Antipathes myriophyllus, or Antipathes row antipathes, or sea-yarrow, of its natural size; while myriophyllus, fig. 8. shows one of the pinne considerably magnified.

This is one of those zoophytes which in their habitus, and appearance almost exactly resemble some of the vertebrate tribes, and hence have received the names of sea-hen, sea-cypress, sea-fennel, &c. From their colour they are usually denominatd black coral. This species, though one of the smallest, is not the least elegant of the tribe. It consists of numerous branches, composed of very slender pinne arranged in no certain order. The whole coral is seldom above a foot in height, and rough on its outer surface. This also is a native of the Indian ocean, being found more especially on the coasts of the Molucca islands, and is sometimes met with in the Great South sea.

Fig. 9. exhibits a specimen of red coral, the Isis naja, Gorgonia bista of Linnae, and Gorgonia nobilis of later naturalists. This substance, though now nearly exploded from the materia medica, will still retain a place in our cabinets for its intrinsic beauty and elegant appearance; but when examined on its native beds, or soon after being fished up, it shews a very different surface from that under which we usually see it. Fig. 9. represents it as prepared for sale by being deprived of its fleshy animal bark or coating, but retaining the striated appearance which marks its specific character; but fig. 10. exhibits a piece of it in its natural state, with polyves extruded from the fleshy coat, and showing still more distinctly at the extremities the striae below.
ZOO [804] ZOO

**Zoophytes.** Red coral is found in large beds or reefs in several parts of the Mediterranean Sea, and coral fisheries are established on the coasts and near the islands. A fishery of this kind in the straits of Messina is minutely described by Spallanzani in his *Travels in the two Sicilies*, vol. iv. To tear the coral from the rocks, they make use of a machine composed of two beams tied across each other, and furnished with a leaden weight to sink them, and a quantity of loose hemp and several strong nets to entangle the branches of the coral. To this machine is attached a strong rope, which is held by the fishers, and serves both to direct the net and to draw it up when the coral is entangled. Several boats go in company, each containing eight men, and the fishery lasts from April to July. The quantity collected every year amounts on an average to twelve Sicilian quintals, each equal to 250 pounds Troy, and each pound usually sells for about four shillings and sixpence. They do not fish on the same bank oftener than once in ten years, as this time is deemed necessary for the coral to acquire its full size and vigour.

Another beautiful species of gorgonia, the *Gorgonia ceratophylla*, is figured at fig. 11. This is distinguished by its dichotomous flatish stem, and ascending branches. The outer flesh is of a purplish colour, and the branches are furnished with two rows of scattered pores from which the polypi appear. It is found in the Mediterranean, and sometimes on the eastern coasts of America.

**Aclyonium gorgonides.** Nearly allied to the gorgonias is the species of alcyonidum represented at fig. 12. This is the *Alcyonium gorgonides* of Gmelin. It is of a cinereous colour, of a sandy fleshy consistence, having radiated warty cells. It is found on the northern coast of South America, especially near the island of Curacoa.

The zoophytes which naturalists distinguish by the generic name aclyonidum, sometimes form independent bodies of a rounded form, such as those called the *sea-orange*, *sea-fish*, &c.; or cover the surface of shells and other marine bodies like a kind of bark. Their internal part or base is friable, and, when dried, appears to be composed of fine fibres, which are either longitudinal, as in the present case, diverging, or circular. This base is covered with a soft crust, that in drying assumes a leathery consistence, and is pierced with numerous little cells, inhabited by the alcyonidum. In some species these cells are dispersed over the whole surface of the coral, while in others they are confined to particular spots or tubercles. They are all inhabitants of the ocean, where they are usually fixed to rocks or other solid bodies.

In the article *Helminthology* we have sufficiently treated of the nature and properties of the sponges, and have there mentioned particularly the common or official sponge. At fig. 13 is represented a more curious species, the *Sp. tubulosa* or *flustra*, the *tubular* or *pipey sponge*. This consists of simple upright, attenuated, rigid tubes, tuberculated on the outer surface, which is of a black colour. It is found in the seas that wash the coasts of America.

**Flustra arenosa.** The flustrae are a tribe of insignificant zoophytes, which seem scarcely entitled to the rank which they hold in the animal creation. They are formed of a congeries of superficial cells, placed close together, like those of a honeycomb, but generally occupying only a single surface. Sometimes this substance forms a coating to some other marine body, at others it is unattached and forms a floating foliaceous mass or mat. The species *Flustra arenosa* is one of the most curious, and is described by Ellis under the name of *Echinus arenatus*, called in the Linnean Transactions, vol. v. *Flustra arenosa*. It is composed of sandy particles agglutinated together with slime, and in shape resembles the fore part of a horse's hoof. It is very frangible, and so thin as to be easily broken. These flustrae are found abundantly on the coast of Kent, and about Holy-head on the Welsh coast.

Fig. 14. represents a specimen of *Sertularia crispula*, the small sea-bristle coralline of Ellis, of its natural size; and fig. 15, shows the same specimen considerably magnified. This species is distinguished by being simply pinnaed, with bent alternate pinnae, furnished with very remote processes growing only on one side, and oblong auxiliary ovaries. It is one of the smallest and most delicate of the tribe, seldom exceeding an inch and a half in height. It is very common, and is found on the British coasts.

None of the zoophytes bear a nearer resemblance to vegetables than the *sertularia*. Their creeping root, their branched stem, and tufts of seeming flowers (the polypi processes) give them all the air of plants. Hence they were long considered as sea-mosses, and described by botanists under that name. See Ruy's *Siphonae*, p. 38. and 39. When attentively examined, however, their animal nature will scarcely be disputed. Externally they are composed of a horny substance, perfectly transparent, and through this may be distinguished the animal substance traversing the centre of the stem and branches like the pith of a plant, and appearing externally as little knobs or protuberances in the form of tentaculated polypi. These extraneous polypi are considered by Cuvier (Tableau Elémentaire, p. 768) not as distinct animals, but only as parts of the same animal which constitutes the sole inhabitant of the sertularia. These zoophytes adhere to rocks, shells, &c., by creeping roots, and appear to propagate by means of eggs. They are among the most common of this class of animated beings.

The *Pennatula*, or *Sea-pens*, constitute a very curious tribe of zoophytes, which are completely locomotive, and swim in the manner of fishes. They consist of an internal bone or rather horny substance, covered with a sensitive fleshy coat. Their lower extremity is simple like the barrel of a quill, while the upper extremity is expanded into a flattened part, that is generally composed of pinnae like the barbs of a quill, though it is sometimes merely a simple expanded mass furnished with polypi processes.

Fig. 17. represents one of the most common *sea-pens* properly so called, the *Pennatula phosphorea*, phosphorescent *penatula*, of its natural size. It has a fleshy stem, a rough middle part, and imbricated pinnae. The pins are furnished on one side with lesser pinnae, at the extremities of which appear the polypi. See fig. 18, which shows one of the separate pinnae, a little magnified. This species is of a fine red or light scarlet colour, and when alive exhibits a strong phosphorescent light, so as to render distinctly visible objects that are near it. It is pretty common on the coasts of Britain, and is sometimes taken in the fishermen's nets, or adhering to the bights.

For figures of two other Linnean zoophytes, the *Tubularia magnifica*, and *Hydra viridis*, see Plate CLIII.
ZUG

Several of Cuvier's zoophytes are represented in Plates XXXIV, CCL. and CCLII, and some of the Infusoria in Plates XXXV. and XXXVI.

ZOOTOLOGY, the art of dissecting animals or living creatures, being the same with anatomy. See Anatomy.

ZORILLE, a species of wessel which inhabits Peru, and other parts of South America; and is said to be remarkable for its fetid odour.

ZORAOASTER, or ZERDUSHT, a celebrated ancient philosopher, said to have been the reformer or the founder of the religion of the magi. It is wholly uncertain to how many eminent men the name of Zoroaster belonged. Some have maintained that there was but one Zoroaster, and that he was a Persian; others have said that there were six eminent founders of philosophy of this name. Ham the son of Noah, Moses, Osiris, Mithras, and others, both gods and men, have by different writers been asserted to have been the same with Zoroaster. Many different opinions have also been advanced concerning the time in which he flourished. Aristotle and Pliny fix his date at 800 years before the death of Plato. According to Laertius, he flourished 600 years before the Trojan war; according to Suidas, 500. If, in the midst of so much uncertainty, any thing can be advanced with the appearance of probability, it seems to be this; that there was a Zoroaster, a Perso-Median, who flourished about the time of Darius Hystaspes; and that besides him there was another Zoroaster, who lived in a much more remote period among the Babylonians, and taught them astronomy. The Greek and Arabian writers are agreed concerning the existence of the Persian Zoroaster; and the ancients unanimously ascribe to a philosopher, whom they call Zoroaster, the origin of the Chaldaean astronomy, which is certainly of much earlier date than the time of Hystaspes: it seems, therefore, necessary to suppose a Chaldaean Zoroaster distinct from the Persian. Concerning this Zoroaster, however, nothing more is known, than that he flourished towards the beginning of the Babylonish empire, and was the father of the Chaldaean astrology and magic. All the writings that have been ascribed to Zoroaster are unquestionably spurious.

ZOSTERA, a genus of plants of the class gymnandria, and in the natural system arranged under the second order, Piperites. See Botany Index.

ZOSIMUS, an ancient historian who lived at the end of the fourth and beginning of the fifth century. There are six books of his history extant; in the first of which he runs over the Roman affairs in a very succinct manner from Augustus to Dioscorus; the other five are written more diffusely. Zosimus was a zealous Pagan; whence we find him frequently inveighing with great bitterness against the Christian princes, particularly against Constantine the Great, and the elder Theodosius. His history has been published with the Latin version of Leunclavius at Frankfort, 1692, with the other minor historians of Rome, in folio; and at Oxford in 8vo, 1679.

ZUG, a canton of Switzerland, bounded on the east and north by that of Zurich, on the south by Schweitz and Lucerne, and on the west by the canton of Lucerne and the Freye-Amt or Free Provinces. It is not above 12 miles either way; but very populous and fruitful, yielding wine, wheat, chestnuts, and other fruits, in its vales, and excellent pasture on its mountains. The inhabitants of this canton are staunch Roman Catholics. It lies in the diocese of Constance, and its government is democratic. There are two lakes in it abounding in fish, particularly large carps, pikes, and a species of trout called rotela; as well as several woods full of game. Zug, which gives name to it, and is its capital, stands on the east side of a lake of the same name, about seven miles long, and is a strong neat town, containing a priory and two convents.

ZUILA, a town in the territory of Fessan, in Africa, which stands on a space of about a mile in circuit, but was formerly of much greater extent. The environs are level, well supplied with water, and fertile, planted with groves of date-trees, and the inhabitants pay much attention to agriculture. N. Lat. 27. 29. E. Long. 16. 39.

ZUINGLIUS, ULRICUS, an able and zealous reformer, who laid the foundation of a separation from Rome in Switzerland, at the same time that Luther did the like in Saxony, was born at Wildehausen in 1487. While he officiated as preacher at Zurich, a Franciscan sent by Leo X. came to publish indulgences there; against which Zuingleius, after the example of Luther, declaimed powerfully. In the course of this opposition he started a new doctrine, which he called Evangelical Truth; and from the beginning of 1519 to 1523, he preached not only against indulgences, but against other articles of the Roman church. But though Zuingleius made no less progress than Luther, he conducted himself with more moderation and prudence; and wished to have the concurrence of the civil powers, procured two assemblies to be called at Zurich: by the first, he was authorised to proceed as he had begun; and by the second, the outward worship and ceremonies of the church of Rome were abolished. During these transactions, Zuingleius published several books in defence of his doctrines; but treating of the eucharist, and prescribing a form of celebrating the Lord's Supper different from Luther, he was involved in violent disputes with the rest of his reforming brethren. Respecting the divine decrees, the opinion of Zuingleius and his followers differ very little from that of the Pelagians: and instead of declaring with Calvin, that the church is a separate independent body, vested with the right of legislation for itself, Zuingleius ascribed to the civil magistrate an absolute and unbounded power in religious matters, allowing at the same time a certain subordination among the ministers of the church. This was abundantly agreeable to the magistrates of Zurich; but the rest of the Swiss cantons disallowing of their proceedings, other assemblies were called, and things tending to tumult, both sides had recourse to arms; when Zuingleius, who began as a preacher, died in arms as a soldier, in 1531. His works are in four volumes folio.

ZURICH, a canton of Switzerland, bounded to the north by Swabilia and the canton of Schaffhausen; to the south by the town and territory of Rapperschweil and the cantons of Schwitz and Zug; to the east by the Thurgau, Toggenburg, and Uritzach; and to the west by the free bailiwicks and county of Baden. It is about 60 miles from north to south, and 48 from east to west. With respect to its face, air, and soil, it is said to be an epitome of all Switzerland, as containing in it hills, valleys,
ZURICH [806]

valleys, plains, corn-lands, vineyards, lakes, and rivers. Their wines have a tartness at first, but the longer they are kept the more agreeable they are. The other products are excellent fruits, corn, pasture, fine clay, chalk, several coloured earths, pit-coal, turf, and sulphur. There are also some mineral springs in the canton, and some lakes; Zurich is the most considerable, it is 24 miles long, and two broad. The reformation was introduced here by Zuingleus in the year 1517. This canton is the first in rank, and inferior only to that of Bern in extent, power, and wealth; in consequence of which, its representatives preside in the general diet, when held in any place belonging in common to the cantons; and the affairs relating to the whole confederacy are transacted in its offices. Its quota, for the defence of the several members of the confederacy, is 1,400 men. Of one of the two armies raised on these occasions, it nominates one of the commanders in chief, as Lucerne does the other. Its revenue is said to be about 150,000 crowns a-year; of which, one year with another, two thirds are expended in the charges of government, and the rest laid up in the treasury. It can bring 50,000 fighting men into the field at a very short warning.

Zurich, the capital of a canton of the same name in Switzerland, stands in a pleasant country, near where the river Aa issues from the lake that takes its name from the town, 23 miles from Schaffhausen, and 144 from Geneva. After having been ruined by Attila the Hun, it is said to have been restored by Thumerus, son of Theodoric king of the Goths, from whom it took the name of Thuricum, corrupted afterwards into that of Zurich. It is fortified in the modern way, and has wide ditches, faced with stone. There are five arsenals in it, well stored with arms and artillery; an academy or college, having 15 professors; a museum, or chamber of rarities; a stately town-house, the pillars in the front of which are of black marble, streaked with white; and a town library. The sovereignty and administration of all affairs are lodged in the greater and lesser council, out of which are chosen the city-officers, as the councils are out of the 13 companies of burghers. There are several other councils or colleges, each of which has its particular department. Here are a great variety of silk, woollen, linen, cotton, and other manufactures; this being the place of the greatest trade in all Switzerland. The town is well supplied with provisions by and from its lake. The streets are neat, and houses well built, but not magnificent. In the town-library are several letters to Builinger from Lady Jane Gray, daughter to the duke of Suffolk. In one of the arsenals is the figure of William Tell, dressed and armed in the ancient Swiss manner, with the cross-bow whence he shot the arrow that struck the apple off his child's head.

Both men and women are so fond of music, that they are few of them that cannot play on some instrument. If a burgher goes out of town, or a peasant enters it, without a sword, they are liable to be fined. No persons, whatever their rank or office may be, are exempted from the sumptuary laws. The burgomasters, who are the same as the advoures at Bern, have the title of excellence. The hospitals here are neat and well endowed. The environs are pleasant and fruitful; for which it is not a little indebted to the lake. That part of it which is next Zurich is called the Lower Lake, and the other end the Upper. The cathedral, or great church, is collegiate. The present city is said to owe its origin to a nunnery, founded by the emperor Lewis I., near where the ancient Tigurum stood. E. Long. 9°. 30'. N. Lat. 47°. 20'.

ZUTPHEN, a strong and considerable town of the province of Guelderland, in the kingdom of the Netherlands, and capital of a county of the same name. It has a magnificent church, and is surrounded with walls. It was taken by the French in 1672, who in 1673 delivered it up to the States-General. It is seated at the confluence of the rivers Berkel and Yssel, nine miles south-east of Deventer, and 53 east by south of Amsterdam. E. Long. 6°. 10'. N. Lat. 52°. 10'.

ZUYDER-ZEE, a great gulf or bay of the German ocean, which extends from south to north in the United Provinces, between Friesland, Over-Yssel, Guelderland, and Holland. It is so called from its situation towards the south. It is said that the Zuyder-Zee was formerly a lake, and that the land is swallowed up which united North-Holland with Friesland.

ZYGOMATA, a bone of the head, or rather a coin or assemblage of two processes or eminences of bones. See Bones of the Head, under ANATOMY.

ZYGOMATICUS, a muscle of the head, arising from the Os Zygoma, whence its name, and terminating at the angle of the lips.

ZYGOPHYLLUM, Bean-Sapfer, a genus of plants of the class of decandria, and in the natural system arranged under the 14th order, Graines. See BOTANY INDEX.

ZYMOSIOMETER (formed from Zyma, fermentation, and metra, measure), an instrument proposed by Swammerdadam, in his book De Respiratio, with which to measure the degree of fermentation occasioned by the mixture of different matters, and the degree of heat which those matters acquire in fermenting; the same instrument is employed to ascertain the heat or temperament of the blood of animals.

FINIS.
