On the morning of the 6th, he ordered his artillery to be advanced and disposed along the front of the line. It was soon found, however, that little was to be done with artillery, and that the great object was, to entice the Austrian general from his strong position, and draw him to the plain. For this purpose, at noon of the 6th, the French infantry formed in columns, and advanced with the greatest spirit and rapidity to the Austrian intrenchments. The lower tier of redoubts was instantly carried; but, as the centre of the French became endangered, and the Austrian cavalry appeared descending from the heights, and preparing to enter the plain, with an evident intention of flanking the French columns, Dumourier despatched the duke of Orleans to lead those columns against the second tier of redoubts, while a detachment of chasseurs and hussars flew to check the progress of the Austrian cavalry. Some smart skirmishing between the cavalry on both sides now ensued, and while this diversion was taking place, the left division of the French army possessed themselves of the village of Jemappes, while its centre obtained entire possession of the second tier of redoubts. In the mean time the whole of the Austrian cavalry had quitted the heights, and engaged the French on the plain below Jemappes. This was the point to which Dumourier had wished to bring them, and now the superior numbers and activity of the French quickly decided the fortune of the day. The Austrians were routed at every point, and forced to abandon the field of battle, leaving 5000 of their dead, with the greater part of their artillery. The loss of the French, however, was considerably greater, and is, on good authority, estimated at 14,000; but this loss appeared trifling to Dumourier, as by this victory he acquired possession of the whole of the Austrian Netherlands.

The positions of the French and Austrian forces in this battle are represented in Plate DLIV. 1, The centre of the Austrian army, commanded by Clairfayt. 2, A part of this army commanded by General Lilien. 3, Another part under the command of General Beaulieu. 4, Redoubts on the heights of Jemappes. 5, Austrian intrenchments. 6, French columns advancing to attack the intrenchments. 7, A battery. 8, Columns of cavalry. 9, Columns attacking the eminences above Mons. 10, Battery on the height of Fremery. 11, The wood of Fresnee. 12, The plain on which the French and Austrian cavalry were engaged. 13, Austrian detachment.

The columns N° 9. were first engaged; and N° 6. having obtained some advantage, Dumourier ordered the battery, N° 7. to be erected, by which the redoubts, N° 4. were silenced. In the mean time the French advanced against the intrenchments, 5, and attacked in front. From the left of the French army, as far as the centre, the cavalry fought hand to band, in the plain, 12, with the Austrian horse, which was dreadfully cut up in the wood of Du Fresnee, 11. The right of the Austrians, being totally routed, gave way and fell back on Mons. The superiority of the French in numbers is evident from inspecting the columns in the plan.

After having dwelt so long on that part of military tactics which relates to operations in the field, we must be extremely brief with respect to the attack and defence of fortified towns. Indeed our principal object in this part will be to explain the nature of a siege, and the various circumstances that may occur, both on the part of the besiegers, and on that of the besieged, rather than to lay down a system of instructions for either party. With this view, we shall first enumerate the principal instruments and engines employed in the attack or defence of a fortress, and explain the nature and construction of the works constructed by the besiegers, either for the purpose of making their approaches to the place, or for undermining its walls or outworks.

43 Of sieges.

44 Instruments employed in sieges. Plate DLV. Fig. 1—20.

In Plate DLV. are represented the principal instruments employed in sieges. Fig. 1. is a fascine for the construction of redoubts or temporary defence of a detachment. Figs. 2. 3. and 4. exhibit various views of what are called *gabions*, or cylindrical cases of wicker work, open at both ends, for sticking into the ground, as seen at fig. 4. when they are filled with earth, and fascines, &c. laid on them. Fig. 2. is a section of the gabion; fig. 3. shews its hollow inside, and fig. 4. is its elevation. Fig. 5. and 6. represent bags for holding sand, the former empty, the latter full; and fig. 7. represents the manner in which they are usually disposed for the protection of the men. Fig. 8. is a saucisson, or very long close faggot, for laying over gabions. Fig. 9. is the outline of a blind, which is stuck into the earth by the sharp stakes at its extremity, and hides the workmen from the besieged. Fig. 10. represents what is called a chandelier, and fig. 11. two of these with fascines piled up across them. Fig. 12. is a cheval de frize; fig. 13. 14. 15. exhibit various views of a *mantlet*, or moveable blind placed on two wheels, used both to protect and conceal the workmen of the besiegers. Fig. 13. is a plan of the mantlet; fig. 14. a side view of it, and fig. 15. a view of its front next the enemy. Fig. 16. is a madrier or screen with two leaves, moveable on wheels; and fig. 17. represents a gate with orgues or lattice work on one side, and a portcullis on the other. Fig. 18. is a hook, and fig. 19. a fork used in sapping. Fig. 20 represents three caltrops or crows feet, used to scatter over the ground, to prevent the approach of cavalry, by laming their horses feet. For a fuller explanation of these instruments, see the several articles in the general alphabet.

45 Of investing.

When a town is about to be besieged, it is first *invested;* that is, a considerable body of troops, usually cavalry, encamp in its neighbourhood, and take possession of all the avenues till the army arrive, which is to carry on the regular operations of the siege.

46 Of lines of circumvallation.

When the army has *sat down* before the place, its first object is, to ascertain the lines or direction of the works to be thrown up for the attack of the place. These are called *lines of circumvallation*, and their direction is to be determined by the plan of the fortification about to be besieged. After ascertaining, in the manner explained under Fortification, the number of sides of which the polygon of the place consists, and the length of each, as well as the radius of a circle to be drawn round the place, concentric with its works, the polygon of the circumvallation is easily described. This being traced, the engineer takes on each of the extremities of its sides the lines BD and BE, fig. 21. each of 15 fathoms, and from the points D and E, Fig. 21.

taken

Military Tactics.

taken for the centre and distance of 25 fathoms, he describes two arcs cutting each other at F, whence are drawn the lines FD, FE, for the faces of the redans of the line of circumvallation; thus are formed the salient parts EFD of this line, which serve to flank it. The same operation is performed on every side of the circumvallation, and then the principal line is traced. The parapet within must be six or eight feet deep, and without is made a ditch parallel to all its parts, three or four fathoms in breadth. The parapet of the circumvallation will be $7\frac{1}{2}$ feet high, and the depth of the ditch equal to the height of the parapet.

Fig. 22. To make the profile of the circumvallation, let AB, fig. 22. be a line level with the country, and CD the scale of the profile. Let A be the side of the town, and B that of the country; take AE of six feet; from the point E, raise the perpendicular EF, of three feet, and draw the line AF, which will be the talus or slope of the banquette.

Draw FG parallel to AB, three feet from F to G, and the line FG will be the breadth of the banquette. On the point G raise the perpendicular GH, on the line FG, $4\frac{1}{2}$ feet. Draw from the point H, HK parallel to AB; make HK $7\frac{1}{2}$ feet, HI, $1\frac{1}{2}$ foot; draw GI, which will be the inside of the parapet of circumvallation.

From the point K, let fall on the line AB the perpendicular KM; take KL $1\frac{1}{2}$ foot, and draw IL, which will be the upper part of the parapet of the line of circumvallation. Take MN equal to five feet, and from the point N draw the perpendicular NO, and set off $7\frac{1}{2}$ feet from N to O. Draw OR parallel to AB, making the distance equal to 18 feet from O to R; draw LN, and produce it to P, and LP will be the scarp. From the point R raise RS, perpendicular to OR, or parallel to ON. Make QR=OP, and draw QS, which produce beyond S, three feet to V; then take SX equal to six feet, and draw VX, and the profile of the circumvallation is completed; VQ being the counterscarp, and VX the glacis.

At A and A (fig. 21.) are small half moons before the gates of the circumvallation in the middle of the curtains.

Plate DLVI. fig. 1. -- 3. In Plate DLVI. at fig. 1. is represented the manner in which the lines of circumvallation were drawn at the siege of Philipsburg in 1734. In these lines regular bastions were constructed, as seen in fig. 2.

Fig. 4. 5. Fig. 4. and 5. of the same plate represent another line of circumvallation drawn round the city of Arras, when it was besieged by the Spaniards in 1654. Before the circumvallation were dug a great number of holes, two feet in diameter, and $1\frac{1}{2}$ foot deep, in which were fastened stakes for obstructing the approach of cavalry.

47 Of the trenches and parallels.

While the lines of circumvallation, which are intended to protect the besiegers from the enemy without, are constructed, all materials necessary for the trenches are got ready, and the figure and direction of these are determined. If the place be regularly fortified, and stand on level ground, it is indifferent on which side the besiegers commence their attack. Suppose C, fig. 2. Plate DLVII. to be the place besieged, and A and B two bastions to be attacked. The besiegers begin with indefinitely producing towards the field the capitals of these two bastions; in like manner the capital of the half moon opposite the curtain between these two bastions is produced. Eight hundred fathoms are set off from the salient angles D and E of the covert-way of F and G. This done, the lines DH and DI are drawn, each equal to 300 fathoms, and about the centre C with the radius CH or CI, is described an arch produced beyond H and I, and on this arch HI is constructed the first parallel. Then on the same lines DF, EG, are taken the points M and N, each 140 fathoms distant from H and I; and through these points M and N, about the centre C, is described another arch, on which is constructed the second parallel. This second arch will cut the produced capital of the half-moon in the point L, which is to be observed, in order to begin from hence a trench which may extend to the salient angle of the covert-way before this half-moon. Lastly, through the points O and P, the distance of 20 or 25 fathoms from the angles D and E, a third arch is described from the centre C, on which the third parallel is constructed. The first parallel is terminated by producing the faces *a b*, *a b*, of the half-moons 1 and 2, collateral to the bastions A and B; but the parallel is extended 15 or 20 fathoms beyond the intersection of this prolongation. The second parallel will be less extended than the first, by about 30 fathoms on each side, and the third less than the second by the same distance.

Plate DLVII. fig. 2.

The trenches or approaches are now to be traced. For this purpose, the engineer takes a long ruler, and lays it on the point G, so that it may make with the produced capital EG of the bastion B, an angle EGS, whose side GS being produced, shall meet no part of the covert-way, and shall be distant about 10 or 12 fathoms from the angles to which it approaches nearest. GS is taken of any extent, and the ruler is put on the point S; so that it shall make with GS such an angle GST, as that the side ST produced shall not fall on any part of the covert-way, but be 10 or 12 fathoms distant from the most salient parts. This side is terminated in T; and now the angle STI is made, whose side TI should terminate at the point I, where it meets the first parallel. The same operation being performed on FH, the outline of the trenches is completed as far as the first parallel.

Fig. 1. of this plate illustrates the method of constructing what are called *lines of countervallation*. These are drawn nearer the town than the lines of circumvallation, but are constructed on the same principles. They are employed chiefly when the garrison of the place is so strong as to disturb the operations of the besieging army by sallies.

In sieges where the garrison is strong, it is often necessary to cut parts of trenches, as VV (fig. 2.) between the second and third parallels, so as to communicate with the main trench. These parts of parallels are denominated *half parallels*, or places of arms, and are constructed in the following manner. Let ABCDFGMQ (fig. 1. Plate DLVIII.) be a part of the trenches, and let AB be one of the sides opposite to the enemy; produce AB, so that BE shall be five or six fathoms, and in FG take also five or six fathoms from I to L, which will give the ends of the trench BFLI, the use of which is to cover the *boyace* or branch IOMG, whereby the enemy will not know the place where it falls into the trench AB, and to make room for withdrawing those who are in this part of the trench- Plate DLVIII. fig. 1.

es,

Military Tactics. es, and that the passage may be free at all the angles. In like manner produce the side GM from M to N, and the side IC from O to P, and this will give the end of the trench MNOP, which will cover the branch DCOQ. The same is to be done at all the angles of the trench. The parapet of the trench being made to cover it, ought to change sides alternately. If, for instance, AE, in the preceding figure, be towards the place, it is evident that the side GN will be towards it also, and likewise the side CD; and therefore the parapet of the trench is successively constructed from the right side to the left, and from the left to the right.

Figs. 2. 3. 4, of this plate represent profiles of the regular trenches and the places of arms, and require no particular explanation.

In tracing the trenches, it is of the greatest consequence to ascertain the distance of the extremity of the line of direction to the top of the salient angle of the covert-way. The following simple method of doing this is given by Vauban. Let A (fig. 5.) be the vertex of the salient angle of the covert-way, and AB the line of direction of the trench whose length is required. At the point B, draw BC perpendicular to AB, to which give any measure, and at the point C draw CD perpendicular to BC. In CD take any point E, and in the line of direction between it and the angle A place a picquet G in the line BC. Measure GC and CE, and say as GC : BG :: CE : AB.

Fig. 5

48 Of saps.

When in carrying on the trenches towards the town, the workmen begin to be much annoyed by the fire of the besieged, recourse is had to what is called *sapping*, which may be thus explained. Let ABC be the part of the trenches advanced to A (fig. 6. Plate DLVIII.), so near the town as to render it impossible, without evident danger, to work any longer at the approaches, unless the men have some cover against the fire of the place; and let the branch AD be traced by the engineer, not with a cord, as at the opening of the trenches, but with some pickets, which he has taken care to place in the direction this branch ought to have, to serve as a guide to the workmen. A cut is made in the parapet BA of the trenches, and then the men designed to work by sap, who are therefore called sappers, will move forward through the opening A successively, eight in number. Fig. 7. of Plate DLVIII. and fig. 1. of Plate DLIX. will illustrate the mode of operation. The first sapper rolls a mantlet before him, and places a gabion on the line AD, fig. 6. He then makes a small excavation about six inches from the gabion, of about one foot and a half in depth, and as much in breadth, emptying the earth which he digs up into the gabion. He then pushes forward his mantlet, fixes another gabion, and continues his trench as long as he is able. He is followed by a second, who widens the trench six inches in breadth away from the gabion, and six in depth. The rest follow this second, till the trench is made three feet wide, and as many deep, and as soon as the gabions are filled with earth, fascines or saucissons are placed on their top, and the superfluous earth is thrown over them, and on the opposite side, by way of parapet.

Plate DLVIII. fig. 6. 7. 8. Plate DLIX. fig. 1. 2.

49 Of batteries.

Cannon are made use of at a siege for two different purposes; the first to drive away the enemy from their defences, and the second to dismount their guns. To produce these two effects, the batteries should not be above the mean reach of cannon shot from the place; that is, above 300 fathoms. Therefore there is no possibility of constructing them till the first parallel be formed; and as the distance of this first parallel from the place is generally 300 fathoms, the batteries must be on this line, or beyond it, nearer the town. They must always be placed, when the ground will permit, on the produced faces of the works attacked. Let Z be the centre of the place attacked (fig. 3. Plate DLIX.), and the trenches as well as the parallels completed. To find a proper position for erecting batteries, produce the faces AD, AC, BE, BF, of the two bastions attacked, till their prolongation cuts the first parallel. Produce also the two faces OM and OL of the half-moon MOL of the front attacked, and the faces HG and IK of the two collateral half-moons 1 and 2, to the first parallel, and erect batteries on those produced faces, as is seen in P, Q, R, S, T, U, X, and Y. They are advanced beyond the first parallel 40 or 50 fathoms; and are parted from the trenches, that they may be used with greater ease and convenience, and less trouble to the workmen.

Plate DLIX. fig. 3.

50 Of traverses.

When the works of the besiegers approach the glacis, they are continued in a zig-zag direction, by short angular trenches, but from the foot of the glacis they are continued in the following manner. Two sets of sappers, protected by their mantlets, make a sap on each side of the ridge of the glacis, with a deeper ditch than usual, and a parapet on each side. This is called a double sap, and has across it traverses or banks three fathoms thick (see Plate DLX. fig. 1.), with small passages on one side (see fig. 4.) to preserve the communication. These traverses are constructed so near to each other, as to be a sufficient cover, by their elevation and distance, against the fire of the place. In order to guard against the effect of grenades, on coming within their reach, or within 14 or 15 fathoms of the covert-way, care must be taken to cover this trench with blinds, or to cover the upper part of it. Fig. 1. and 2. of Plate DLX. shew this direct trench. The first exhibits the plan, and the second the profile, which passes over one of the traverses. This being done, and the third parallel finished in the manner supposed, they advance from this parallel on the glacis to each of the salient angles of the covert-way of the front attacked, and begin with making two or three short turnings, as marked on Plate DLX. fig. 6. along the ridge of the glacis, so as to occupy about one-third of it. These are to be made as deep as is necessary, to be a shelter against the fire of the covert-way; afterwards they may proceed directly along the ridge of the glacis by a deep ditch, to the salient angle of the covert-way. M. Vauban observes, that if we follow directly the ridge of the glacis, this trench is made without much danger; for the palisade which is placed at the salient angle of the covert-way, and the other two next it, do not present directly to the ridge, but only opposite to the faces, where at most there is only room for one or two fusileers to see the head of the trenches, and who are easily silenced by the fire of the third parallel, which ought to be well served, and likewise by that of the ricochet. On coming to the middle, or two-thirds of the glacis, two new saps are made, *b b*, *ibid.* which embrace both sides of the covert-way, to which they are almost parallel. Their length is 18 or 20 fathoms, and about five broad.

Plate DLX. fig. 1.

Fig. 6.

Military Tactics. broad. They are covered at the end with crochets and winding traverses, which prevent the fire of the covert-way from enfilading them easily.

Fig. 5. Plate DLXI. fig. 5. In this way is gradually effected a *lodgement* on the covert-way, as is represented in fig. 5. where AAAA, is the trench, with BBBB its traverses.

Plate DLXI. fig. 5. represents a profile of these works, with three banquettes next the trench, by which the parapet is raised, so that the soldiers may fire over into the covert-way. This work is called by Vauban, the *cavalier of the trench*.

51 Of batteries on the covert-way.

When the besieged are entirely driven out of the covert-way, the next thing to be done is the erecting of batteries, in order to ruin the defences of the place, and to make a breach. As it is necessary for the besiegers to make themselves masters of the half-moon C, (Plate DLX. fig. 6.) before they can come to the body of the place, which is defended by part of the faces of the bastions A and B opposite to its ditch, they must begin with erecting batteries on the covert-way opposite to these parts. They are marked on the plan *e e*. Batteries must also be erected to make a breach on the half-moon. But, before they are erected, it will be proper to consider what part of the face of the half-moon is to be attacked, or what part of the half-moon is to be entered. It must not be at its flanked angle, because an opening towards the point would not afford a sufficient space to make a lodgement able to withstand the enemy, and the troops would be seen in their passage by the two faces of the bastions by which its flanked angle is defended. The most favourable passage is towards the third part of its face, reckoning from its flanked angle, because by battering at the same time the two faces near this part, the whole point of the half-moon may be destroyed, and a large opening made there easier than anywhere else. Thus the batteries for making a breach in the half-moon C will be placed in *d* and *b*, and will occupy almost one-third of each of the faces of the half-moon from its flanked angle. These batteries are each to consist of four or five pieces of cannon. When the faces of the bastions A and B are well enfiladed by ricochet batteries, there will be no farther occasion for the batteries *e*, *e*, and when the half-moon is taken, the faces of the bastions A and B may be destroyed, by using the batteries *d*, *d*, placing them in the situation of *e*, *e*. Batteries must also be erected to destroy the flanks of the demibastions in the front of the attack; and it is evident that they can be placed nowhere but at *i*, *i*, on the covert-way. Besides these batteries, others are erected in the re-entering places of arms of the covert-way, as in *k*; and in *k* they serve to batter the tenaille when there is one, the curtain, and the faces of the bastions. Sometimes they are of mortars for throwing stones.

52 Descent and passage over the ditch of the half-moon.

While the workmen are employed in erecting batteries on the covert-way, preparations are made for passing the ditch of the half-moon. This is often a difficult and dangerous undertaking, as this ditch is commonly very deep, is well defended, and either filled with water, or in general capable of being so filled. The descent into the ditch is commonly effected by subterraneous passages or galleries, made like those of miners, and erected in such a manner, that its opening into the ditch may be opposite to the breach where it is intended to make the assault. These galleries are sloping, and in general there are several for the same passage. The passage is made on each side of the faces of the half moon. See *m m*, fig. 6. Plate DLXI.

As the business of forming these galleries is liable to be obstructed by mines from the besieged, the workmen are protected by a guard of grenadiers. At fig. 1. Plate DLXI. is seen a plan of the descent under ground, and of its opening into the dry ditch; and fig. 2. gives a profile of the same passage; fig. 3. gives a perspective view of the opening of this descent, seen from the bottom of the glacis, and fig. 4. a similar view of the opening of the same descent, seen from the top of the breach.

Plate DLXI. fig. 1—4.

At Plate DLXII. fig. 1. is seen the plan of the passage over a wet ditch in the open air; that is to say, the gallery of which is an open sap. A is the opening of it; at B, towards its opening, are seen the blinds laid on its upper part, to support the fascines with which it is covered. On these blinds, at first, is laid a bed of fascines, ranged according to the length of the gallery: over this first bed a second is laid, whereon the fascines are ranged according to the breadth of the gallery, as is seen at B and C. D is the epaulement of fascines, which covers the passage against the fire of the place by which it is flanked. E is part of the bridge of fascines; and F is an elevation also of fascines, intended to cover the head of the work, and to secure it from the immediate fire of the place. Fig. 2. represents the profile of this descent into the ditch. Fig. 3. gives its opening seen in perspective from the country; and fig. 4. its opening into the ditch, also in perspective, as it appears from the top of the breach.

Plate DLXII. fig. 1—5.

The following references will explain fig. 5. of Plate DLXII. *a*, cavaliers of the trenches. *b*, batteries of stone mortars. *c*, batteries to breach the half-moon before the hornwork. *d*, batteries against the defence of this half-moon. *e*, passages over the ditch before this half-moon. *f*, lodgement in it. *g*, batteries against the flanks of the hornwork. *h*, batteries to breach the half bastions of the hornwork. *i*, batteries against its curtain. *l*, lodgements in the half bastions, and in the hornwork. *m*, passages over the ditch before the retrenchments in the hornwork. *n*, lodgements in these retrenchments. *o*, batteries against the defences of the collateral half-moon. *p*, batteries to breach those half-moons. *q*, passages over the ditch before these works. *r*, lodgements in the same. *s*, batteries to breach the redoubts of the half-moon. *t*, passages over the ditch before the redoubts. *u*, lodgements in the redoubts. *x*, bridge of fascines. *y*, batteries against the defences of the bastion A. *z*, batteries to breach this bastion. B, passages over its ditch. C, lodgements in the bastion A. D, lodgements on the border of the ditch before the retrenchment of the bastion A. E, passages over the ditch before this retrenchment.

Fig. 5.

There are places which, without any fore-ditch, have lunettes opposite to the salient and re-entering angles of the glacis, which are also enveloped by a second covert-way: sometimes they are vaulted and bomb-proof, as at Luxemburg; and sometimes they have only a ditch, a parapet, and covert-way. Those which are vaulted and bomb-proof are not easily taken, because the ricochet firing and the bombs can do them no mischief. In that case they must either be turned, or be taken by mines. A work is said to be turned, when the besie-gers

Military Tactics.

gers get between that work and the place, and so cut off their communication. Sometimes the lunettes have communication under ground, and then there is scarcely any other way of driving out the enemy but by mines. This is tedious, but there is no other remedy. The lunettes of the ditch are always defended by branches of the covert-way, with which they have also a communication like those of the lunettes, A, A, Plate DLXIII. fig. 1. This plate, which represents part of Landau and its attacks in 1713, may serve to give an idea of the manner in which a work is turned. The advanced lunette B, as well as the work C, called a *tenaille*, is turned; that is, the trenches cut off the communication betwixt them and the place.

Plate DXLIII.

53 Principles to be observed in the attack of fortified places.

We shall conclude this subject of the attack of fortified places, with the following principles to be observed by the besieging army.

The approaches ought to be made, without being seen from the town, either directly, obliquely, or in flank.

No more works should be made than are necessary for approaching the place without being seen; that is, the besiegers ought to carry on their approaches the shortest way possible, consistently with being covered against the enemy's fire.

All the parts of the trenches should mutually support each other, and those which are furthest advanced ought not to be distant from those which are to defend them above 120 or 130 fathoms.

The parallels or places of arms the most distant from the town, ought to have a greater extent than those which are nearest, that the besiegers may be able to take the enemy in flank, should they resolve to attack the nearest parallels.

The trench should be opened or begun as near as possible to the place, without exposing the troops too much, in order to accelerate and diminish the operations of the siege.

There is no such thing as giving any exact rule in regard to the distance which ought to be observed on opening the trenches. On level ground, this distance may be 800 or 900 fathoms; but if there should be a hollow way in the vicinity of the place, the besiegers are to take advantage of it, and open the trenches nearer. In general, they are to regulate themselves according to the nature of the ground, more or less favourable to the opening of the trenches. We shall suppose in the present work, that the opening ought to be made within 800 fathoms of the covert-way; the first parallel within 300 fathoms, the second within 150, and the third at the foot of the glacis.

Care must be taken to join the attacks, that they may be able to support each other.

Never to advance a work unless it be well supported; and for this reason, in the interval between the second and third places of arms, the besiegers should make, on both sides of the trenches, smaller places of arms, extending 40 or 50 fathoms in length, parallel to the others, and constructed in the same manner, which will serve to lodge the soldiers who are to protect the works designed to reach the third place of arms.

The batteries of cannon must be placed in the continuations of the faces of the pieces attacked, to silence their fire, and that the approaches being protected, may advance with greater safety and expedition.

For this reason the besiegers should always embrace the whole front attacked, to have as much space as is requisite to plant the batteries on the produced faces of the works attacked.

The attack must not be commenced with works that lie close to each other, or with re-entrant angles, which would expose the attack to the cross fire of the enemy.

54 General remarks on the defence of fortified towns.

Many circumstances respecting the defence of fortified towns have already been anticipated, or may be collected from what has been said respecting the operations of the besieging army. It is evident that the success or duration of the defence will depend in a great measure on the nature and strength of the works which form the fortification. Much, however, will also depend on the number, resolution, and resources of the garrison, and on the movements of the friendly army by which the besiegers may be opposed. It is estimated by M. Vauban, that the operations for a regular siege of a well fortified town, will take up about 41 days, before the place can be carried by assault. Hence is deduced a computation of the quantity of provisions, ammunition, and stores which ought to be collected for maintaining the siege. The same celebrated engineer calculates that the garrison ought to consist of 600 times as many men as there are bastions in the fortification, allowing 600 men to each bastion. Besides the necessary defence of the works by the cannon on the ramparts, and the musketry of the soldiers, the garrison must make occasional sallies; if weak, to disturb the operations of the besiegers, and if very strong, to engage them in the field. As the siege advances, and the attacking army approaches the glacis, mines should be sprung, and subterraneous passages excavated, to destroy the enemy's works, or cut off a part of their men.

55 Reference to authors on military tactics.

Towards supplying the unavoidable deficiencies in the above sketch of military tactics, we may refer our readers to Clairac's *Field Engineer*, translated by Muller; Le Cointe, *Science des Postes Militaires*, or the English translation; Jeney's work entitled *Le Partisan*, also translated into English; O'Rourke's *Treatise on the Art of War; Essai General de Tactique;* Tielke *on the Art of War*, and his *Field Engineer;* Dundas's *Principles of Military Movements;* Landmann's *Elements of Tactics;* Maizeroy's *Systeme de Tactique;* Archives *Militaires;* Feuquiere's *Memoires;* Bland on *Military Discipline; Military Instructions for Officers detached in the Field;* and the articles BATTALION and BATTLE in Rees's *Cyclopædia.*

PART II. NAVAL TACTICS.

BY naval tactics is understood the art of arranging fleets or squadrons in such an order or disposition as may be most convenient for attacking the enemy, defending themselves, or of retreating with the greatest advantage. Naval tactics are founded on those principles which time and experience have enabled us to deduce from

Naval Tactics.

from the improved state of modern naval warfare, which has occasioned, not only a difference in the mode of constructing and working ships, but even in the total disposition and regulation of fleets and squadrons.

In the present part we propose to lay down the general principles of naval tactics, and to describe as briefly as is consistent with perspicuity, the most improved systems which are now adopted in the French and British navy. As we have elsewhere (see NAVIGATION and SEAMANSHIP) detailed the methods of working single ships, as they are unconnected with military operations, we shall presume that our readers are already acquainted with these ordinary movements.

56 Ordinary division of fleets.

Fleets are generally divided into three squadrons, the van, centre, and rear, each under the command of a flag officer. The admiral of the fleet, or chief in command, leads the centre division, while the van is usually commanded by a vice-admiral, and the rear by a rear-admiral. Each squadron is distinguished by the position of the colours in the ships of which it is composed. Thus, the ships of the centre squadron carry their pendants at the main-top-gallant mast-head; while those of the van division have their pendants at the fore-top gallant mast-head, and those of the rear at the mizen-top-mast head. Each squadron, as far as possible, consists of the same number of ships, and as nearly as may be of the same force. In large fleets, the squadrons are sometimes again divided in a similar manner; the van and rear of the squadron being headed by rear-admirals, or senior captains, called commodores. In the usual mode of forming the lines, each commanding admiral arranges his ship in the centre of his own squadron, and thus the admiral of the fleet is in the centre of the line. When no enemy is in sight, the sloops, store-ships, fire-ships, and other small vessels, are dispersed to windward of the fleet, that they may be more easily supported, and more readily answer signals. The frigates lie to windward of the van and rear of the convoy, thus keeping a good look-out, and keeping the small vessels in their proper station. When sailing in three columns, the centre still keeps in the middle, while the van and rear form the starboard or the larboard column, according to circumstances. These arrangements are called orders of sailing, and will be better understood from the following definitions.

57 Definitions.

The *starboard line of bearing*, is that line on which the arranged ships of a fleet bear from each other, on a close-hauled line, whatever course they may be steering, so that when the ships haul their wind, or tack together, they may be on a line close hauled upon the starboard tack. The *larboard line of bearing* is that line on which the ships when hauling their wind, or tacking together, may be formed on a line close hauled on the larboard tack. The ships of a fleet are said to be *on a line abreast*, when their keels are parallel to each other, and their mainmasts lie in the same straight line. Ships are said to lie in a line on the bow or quarter, when they are arranged in a straight line, cutting their keels obliquely in the same angle, so that reckoning from any intermediate ship, the ships towards one extremity of the line will be on the bow of that ship, while those towards the other extremity will be on her quarter. When several ships in the same line steer the same course, while that course is different from the line of sailing, they are said to sail chequerwise.

When the ships of a fleet arranged in any of the orders of sailing, and on the same line, perform successively the same manœuvre, as each gets into the wake of the ship that leads the van of the line or squadron, tacking or veering, bearing away or coming to the wind in the same point of the wake of the leading ship, they are said to *manœuvre in succession*.

58 Illustration of the five orders of sailing. Plate DLXIV.

There are usually reckoned five orders of sailing, exclusive of the line of battle, the order of retreat, &c. In the first order (see Plate DLXIV. fig. 1. and 2.) the fleet is arranged on the *starboard* or *larboard* line of bearing, all the ships steering the same course. In these cases the fleet, by hauling the wind when in the starboard line, as in fig. 1. will be ready to form the line on the starboard tack; and when ranged on the larboard line of bearing, as in fig. 2. it will, by tacking, be ready to form the line on the larboard tack. N. B. The arrows annexed to the diagrams on the plates, mark the direction of the wind, as in ordinary charts. Fig. 1. and 2.

This first order of sailing is now seldom employed, except in passing through a narrow strait. In the second order of sailing, the fleet steering any proper course, is ranged in a line perpendicular to the direction of the wind, as in fig. 3. This second order, besides being equally defective with the former, is subject to the additional disadvantage of rendering it extremely difficult for the ships to tack, without each ship falling on board that next a-stern. Fig. 3.

In the third order of sailing, the whole fleet is close hauled, and ranged on the two lines of bearing, so as to form an angle of 12 points, having the admiral's ship (A fig. 4.) in the angular point, and the whole fleet steering the same course. Thus, supposing, as in the plate, the wind at north, the starboard division of the fleet will bear W. N. W. of the admiral, and the larboard E. N. E. This order in small fleets or squadrons, is superior to either of the former; but when the fleet is numerous, the line will be too much extended. Fig. 4.

In the fourth order, the fleet is divided into six or more columns, and is thus more concentrated. The commanders, ranged on the two lines of bearing, have their squadrons astern of them on two lines parallel to the direction of the wind; the first ships of each column being, with respect to the commander of the squadron, the one on his starboard, and the other on his larboard quarter. The distance between the columns should be such that the fleet may readily be reduced to the third order of sailing, and from that to the order of battle. This order is adapted for fleets or convoys crossing the ocean, and is represented in fig. 5. But as it requires much time to reduce a fleet from this order to that of battle, it is defective when in presence of an enemy. Fig. 5.

In the fifth order, the fleet, close hauled, is arranged in three columns parallel to each other; the van commonly forming the weather, and the rear the lee column. See fig. 6. Fig. 7. represents the same order, except that each column is here subdivided into two, with the ship bearing the commander of each squadron in the centre of each subdivision. Fig. 6. and 7.

59 Order of battle.

In forming the order or line of battle, the ships of the fleet are drawn up in a line nearly close hauled, standing

Naval Tactics.

Plate DLXIV. fig. 8.

standing under easy sail, so that each ship may be at a certain distance from the ship immediately a-head, as a cable's length, or half that distance. The fireships and frigates a-head and astern, form a line parallel to the former, and to the windward of it, if the enemy be to the leeward; but to the leeward if the enemy be to windward. This order is denoted by fig. 8. where the fleet is sailing on the starboard tack, with the wind at north.

60 Order of retreat.

When a fleet is compelled to retreat before a superior force, it is usually arranged in an order, the reverse of the third order of sailing; the divisions of the fleet being ranged in the two lines of bearing, so as to form an angle of 135° or 12 points, the admiral's ship being in the angular point, and the frigates, transports, &c. included within the wings to leeward. See fig. 9. where the fleet is sailing right before the wind. Though any other direction may be taken, the two lines still form the same angle.

Fig. 9.

61 Order of convoy.

The order of convoy is that in which the ships are all in each others wake, steering in the same point of the compass, and forming a right line. If the fleet is numerous, it may be divided into three columns, which are to be ranged parallel to each other, that of the admiral occupying the centre, and all steering the same course.

Having thus described the ordinary positions of a fleet, we must explain the manœuvres by which they are produced, and we shall begin with the orders of sailing.

62 Method of forming the first order of sailing.

To form a fleet in the first order of sailing, supposing the ships to be in no particular order, that ship which is to lead on the proposed line of bearing for the order of sailing, runs to leeward of the greater part of the fleet, and then hauls her wind under an easy sail. Each of the other ships then proceeds to take the proper station, by chasing the ship, which is to be a-head of her, and when in the wake of the leading ship, adjusts her quantity of canvas so as to preserve the proper distance. The ships thus arranged astern of each other, are in the line of battle, and from this the first order of sailing is formed, by each ship bearing away at the same time, and all steering the proposed course.

63 Second order of sailing.

In forming the second order of sailing, the leading ship runs to leeward of so many of the fleet as that each ship may readily fetch her wake, and then steers a course eight points from the wind, under an easy sail. The line is formed by each ship in the same manner as in the first order, except that before bearing away, the line is perpendicular to the direction of the wind, or each ship has the wind on her beam.

64 Third order.

As, in the third order of sailing, the admiral's ship is in the centre; to produce this position, the fleet being formed in a line on one of the lines of bearing, and the ships steering in each others wake, ten points from the wind, the leading or leewardmost ship first hauls her wind. The second ship does the same as soon as she gets into the wake of the former, and this is done by each ship till the admiral's ships haul their wind, when they reach the wake of the leading ship. At the same time that the admiral's ship hauls her wind, the sternmost half of the fleet does the same. The ships are now in the third order of sailing, from which the fleet can be formed in the line of battle on either tack.

To form the fourth order of sailing (see N° 58.), the commanding admirals range themselves on the two lines of bearing, at a proper distance from each other, steering the proposed course, and the ships of the several columns take each their respective places, parallel to each other, and forming lines in the direction of the wind.

65 Fourth order.

66 Fifth order.

To form the fifth order, the three leading ships of the divisions take their posts abreast and to leeward of each other, keeping their wind under an easy sail; then the ships of each squadron make sail, and take their respective stations at the proper distance astern of their leaders, while the commanders of each division, and the corresponding ships of each, keep mutually abreast of each other.

67 To form the line of battle.

In forming from the first order of sailing, if the ships are running large on the tack that answers to the line of bearing on which they sail, and if the line is to be formed on the same tack, all the ships haul their wind at once, or as quickly as possible after the next to windward; but if they be on the other tack, with respect to the line of bearing, they all haul their wind and tack or veer together. If the line of battle is to be formed on the other line of bearing, the ship most to leewards veers or tacks, and hauls her wind, while the rest of the fleet veer or tack at the same time, and steer with the wind four points free, and each ship hauls her wind as soon as she gets within the wake of the leader. See fig. 10. Plate DLXIV. and fig. 1. Plate DLXV.

Fig. 10.

Plate DLXV. fig. 1.

Suppose the fleet running before the wind in the second order of sailing; to form the line from this position, all the ships haul up together on the proper tack, presenting their heads eight points from the wind at the line on which they are arranged; the leading ship then hauls her wind, immediately making sail, or shortening sail, so as to close or open the order, and the same is done successively by all the rest (see fig. 2.).

Fig. 2.

In a fleet running large in the third order, the line of battle is formed by the wing which is in the line of bearing corresponding to the tack on which the line is to be formed, and the ship at the angle, hauling their wind together, while the ships of the other wing haul up together eight points from the wind. Each ship moving in this direction, till she reach the wake of the other wing, when she hauls close up (see fig. 3.).

Fig. 3.

In forming the line of battle on the same tack from the fifth order of sailing (as the fourth is not calculated for forming a line of battle), the centre brings to, so as only to keep steerage way; the weather column bears away two points, and when it gets a-head of the centre, hauls its wind, while the ships of the lee column tack together, and crowd sail to gain the wake of the centre, when they retack together, and complete the line (see fig. 4.); or, the weather column brings to, while the centre and lee tack together, and bear away two points free. When the ships of the centre column have gained the wake of the van, they retack together, and bring to; and when those of the lee have gained the rear line, they retack together, and all stand on; or lastly, the lee column brings to, the centre runs under easy sail two points free, to get a-head of the rear squadron, while the rear bears away under a press of sail two points free, to get a-head of the centre division.

Fig. 4.

2. Suppose the weather and centre columns to interchange. To form the line under these circumstances; the centre stands on, while the weather column bears away 8

Naval Tactics.

points, and having reached the wake of the centre, which now forms the van, hauls up; the ships of the lee column tack together, and run under a press of sail, within two points free, so as just to gain the rear of the line when they retack together (see fig. 5.), or the lee column brings to, while the centre squadron bears away three points under easy sail; and having reached the wake of the van, hauls up, to form the centre division.

Plate DLXV. fig. 5.

3. Suppose the centre and lee columns to interchange. The lee column stands on close hauled under an easy sail, the weather column bears away to points under a press of sail, till it reach the head of the line, when it hauls up, and the centre bears away eight points, and when in the wake of the lee, now the centre, hauls its wind. (See fig. 6.).

Fig. 6.

4. If the weather and lee columns interchange; the lee column stands on under a press of sail close hauled, while the centre, under easy sail, bears away two points, and when it reaches the wake of the now van squadron, hauls its wind, and the weather column bears away eight points, hauling up when in the wake of the centre. (See fig. 7.).

Fig. 7.

5. Suppose the centre column to form the van, and the weather the rear division. Here the lee column brings to, while the centre bears away two points, forming the line a-head of the former, now the centre, and the weather column veers away seven points on the other tack, forming the rear squadron. (See fig. 1. Plate DLXVI.).

Plate DLXVI. fig. 1.

6. To form the line so that the lee column may form the van, and the centre the rear. The lee column is to stand on under a press of sail, while the weather bears away three points under easy sail, and the centre bears away eight points, the ships of each column hauling their wind, when in the wake of the now van division. (See fig. 2.).

Fig. 2.

7. If the line of battle is to be formed on the other tack, so that the weather shall form the van division, as in the first case, the ships of the weather column first tack successively, while those of the centre and lee stand on, the former under easy sail, and the latter shortening sail, the leading ships tacking when in the wake of the now van, taking great care that the ships of the centre and lee draw not too near to the sternmost ships of the van, or to each other. (See fig. 3.).

Fig. 3.

8. To form the line on the other tack, when the centre and weather columns interchange. The weather column brings to, while the centre column stands on, till the leading ship be fully able to clear the weather column, when the ships of the centre tack successively as they reach the wake of the van. The lee column stands on, tacking successively, as the ships get into the wake of the van, under moderate sail. (See fig. 4.).

Fig. 4.

9. In forming the line on the other tack, when the centre and lee interchange. The centre brings to, while the ships of the weather tack under shortened sail, and the lee under a press of sail stands on, the leading ship having gained the wake of the line, tacks, and is followed in succession by her division. The centre column fills and stands on, when the first ship of that column, and the last of the lee, bear from each other in a direction perpendicular to that of the wind. (See fig. 5.).

Fig. 5.

10. To form on this same tack, so that the weather and lee may interchange. The weather and centre bring to, while the lee crowds sail, till it can pass a-head of the weather column, when the ships tack in succession. As soon as the leading ship of the centre, and the last of the lee bear from each other in a line perpendicular to the wind, the centre fills, and tacks in succession when in the wake of the now van, and the ships of the weather column do the same when their leading ship and the last of the centre are under similar circumstances. (See fig. 6.).

Fig. 6.

11. Suppose the centre is to form the van, and the weather the rear, in forming the line on the other tack. The weather brings to, while the other columns make sail, till they can pass a-head of the former on the other tack, when they tack successively. The weather column, when the others have passed it, fills, and tacks to form the rear. (See fig. 7.).

Fig. 7.

12. Suppose now the lee column is to form the van. The weather and centre bring to, while the lee crowds sail, and tacks when it can pass a-head of the weather column. When the last ship of the now van has passed to windward of the former weather column, the van shortens sail, to give time for the other columns to form, and the weather and centre fill at the same time, to gain the wake of the van, when they tack in succession. (See fig. 8.).

Fig. 8.

68 To form the orders of sailing from the line of battle.

We must now show how a fleet may be disposed in the principal orders of sailing from the line of battle; and here, as before, we have several varieties.

1. To form the first order of sailing from the line of battle on the same tack. All the ships are to bear away together as many points as the admiral may direct, keeping in the line of bearing for the proper tack. The sternmost first bears away, and the others follow in quick succession to prevent running foul of each other.

2. If they are to form on the other tack; the leading ship bears away four points to leeward, and the rest follow in succession. The sternmost ship having bore away, the whole haul up, and will be in bearing for the line on the other tack. (See fig. 9.).

Fig. 9.

3. To form the second order of sailing from the line of battle, the whole fleet is to bear away together 10 points, so that when the headmost ship, which first presses sail, shall come abreast of the second ship, the second ship adapts her sail to keep in this bearing, and so in succession, each taking care to keep the preceding ship in a line with herself, perpendicular to the direction of the wind. The whole fleet will now be before the wind. (See fig. 10.).

Fig. 10.

4. To form the third order, the whole fleet is to bear away together ten points, the headmost half, including the centre ship, carrying a degree of sail to preserve their line of bearing, while each of the remaining ships is successively to shorten sail, so as to form the other line of bearing with respect to that on which they were before arranged. (See fig. 1. Plate DLXVII.).

Plate DLXVII. fig. 1.

5. To change from the line of battle to the fifth order on the same tack. Of this evolution there are several varieties, but we shall mention only two; first, when the van is to form the weather, and the rear the lee column, and the fleet to keep as much as possible to windward.—In this case the van and centre tack together, and run close hauled in bow and quarter line, while the rear proceeds in its former course under easy sail. When each ship of the centre is abreast of the corresponding ship of the rear, the centre retacks, while

Naval Tactics.

while the van stands on, till the centre and rear come up, when it also retacks, and all the columns regulate their distances. (See fig. 2.). Secondly, when the van is to form the lee, and the rear the weather column.—The van bears away under easy sail, and goes at right angles with the line a-head, while the centre runs two points free, each ship steering for that ship of the van which is to be a-breast of her when in column. The distance must be determined by the leader of the van, who is not to haul up with her division, till she and the sternmost ship of the centre column are in a line at right angles with the wind, when both stand on under easy sail, while the rear crowds sail to pass to windward of both. (See fig. 3.).

Plate DLXVII. fig. 2.

Fig. 3.

6. To form the fifth order of sailing from the line of battle on the other tack—of which there are also several varieties; but we shall confine ourselves to two: First, when the van is to form the weather, and the rear the lee column; the van tacks in succession, while the leading ship of the centre is to tack when the leader of the van passes him exactly to windward, in which she is followed by her division, and the rear manœuvres in the same manner with respect to the centre. (See fig. 4.). Secondly, when the rear is to form the weather and the van the lee column; the van tacks in succession, and when about, either shortens sail, or brings to, to allow the other columns time to form. The centre and rear then crowd sail, and tack in succession, the former tacking when its leader has the centre of the lee column in a line at right angles with the wind, or when its centre passes a-stern of the lee column. When the centre has tacked, it regulates its rate of sailing by the lee, and both wait for the rear to pass to windward. The rear tacks when the leader has the first ship of the lee in a line at right angles with the wind, or when its centre ship passes a-stern of the centre column. (See fig. 5.).

Fig. 4.

Fig. 5.

Fig. 6.

7. Fig. 6. represents the order of retreat formed from the line of battle, the whole fleet going four points free. This evolution is so seldom required in a British fleet, that we need not dwell on it.

69

To manœuvre in line of battle.

There are various evolutions or manœuvres performed by a fleet when in line of battle, some of which we must here describe.

Sometimes the fleet has to form the line on the other tack, by tacking in succession. To do this, the leading ship of the fleet tacks first, after making more sail, or after the second has shortened sail, to increase the interval between them. When the first ship is about, either the second makes more sail, or the third shortens sail, and as soon as the second gets into the wake of the leader, she tacks, putting down the helm just as she opens the weather quarter of the first ship, already on the other tack. In the same manner, each of the other ships tacks when in the wake of the leader; and the ships already about must preserve their proper distances, by shortening sail, if necessary, till the whole fleet be on the other tack. If a ship should miss stays, she must immediately fill again on the same tack, and make sail with all possible expedition, taking care not to fall to leeward. Thus she will get a-head, and to windward of the following ships, which will successively perform their evolutions in the wake of the ships that are already on the other tack, standing on rather further than if the ship a-head had not missed stays. (See fig. 7.).

Fig. 7.

But suppose the ships are not to tack in succession. To form the line on the other tack, the whole fleet veers together; the rear ship hauls her wind on the other tack, and stands on, while the rest go two points free on the other tack, and haul up as they successively gain the wake of the leading ship. (See fig. 8.).

Fig. 8.

If the line is to veer in succession, the van ship veers, and stands four points free on the other tack, hauling her wind when clear of the sternmost ship, and the rest follow and haul up in succession. (See fig. 9.).

Fig. 9.

Sometimes the fleet has to turn to windward while in line of battle. The best way to do this, when there is good sea-room, is for all the ships to tack together, when the fleet will be in a line of battle on the one board, and in bow and quarter line on the other. If, however, the fleet be turning to windward in a narrow channel, it is best for the ships to tack in succession, as, were they all to tack together, the van would be soon in with the land on one side, while the stern ship, soon after the fleet had retacked, would be too near the land on the other side.

If the van and centre are to interchange; the van is to bear away a little, and then bring to, while the centre passess on to windward, edging a little, to get a-head of the former van on the same line; the rear, coming on under an easy sail, edges away likewise, to gain the wake of the now centre squadron. (See fig. 10.).

Fig. 10.

If the van and rear are to interchange; the van and centre are to bear away a little, and then bring to, so that the van may bear away a little more to the leeward than the centre. The rear stands on to gain the head of the line; and when a-breast of the former van, the centre fills, and both standing on, form a-head of the now rear, by edging down till they are in a line with it. (See fig. 11.).

Fig. 11.

If the centre and rear are to interchange; the van stands on under an easy sail, while the centre bears away a little, and brings to, and the rear at the same time carries a press of sail to pass the centre to windward, and get into the wake of the van. The van and centre then edge away to gain the line, with the now rear squadron, which then fills. (See fig. 12.).

Fig. 12.

70

To manœuvre in the fifth order of sailing.

Several evolutions are required while a fleet is in the fifth order of sailing, and of these we shall notice some of the more important.

When the columns are to tack in succession, the ships of the lee must tack first, as they have most distance to run, and when the leader of the centre comes a-breast of the leader to leeward, or at right angles with the close-hauled line on the other tack on which the leader of the lee is now moving, she tacks and is followed successively by the ships of her division. The weather column manœuvres in the same manner, paying the same regard to the centre. Here the weather column is still to windward, and should the columns have closed too much, or be too far asunder, the order may be recovered, either by the lee or windward column bearing away, so as to make an angle equal to that proposed between any column, and a line joining the leader of that column, and the sternmost ship of the next. (See fig. 13.)

Fig. 13.

When all the columns are to tack together; the sternmost ships put in stays together; and when in stays, their seconds a-head put down their helms, and so on through the whole fleet. Each column will then be in bow and quarter line. (See fig. 14.).

Fig. 14.

When

Naval Tactics.

Plate DLXVII. fig. 15.

When the columns are to veer in succession; the leader of the lee column must steer four points free on the other tack, followed by the ships of that division, and when she is clear of the sternmost ships of that division, she hauls up. The same evolution is performed by the centre and weather ships successively, standing on till they bring the point at which the lee column began to veer to bear in a right line to leeward of them. They likewise successively spring their luffs when the point at which the lee column hauled its wind, bears right to leeward. (See fig. 15.).

Suppose the fleet, when in the fifth order of sailing is to turn to windward; let the ships be so arranged that the leaders and corresponding ships may be in the direction of the wind. The van ships must tack together, which are followed in succession, each by the remaining ships of the division, when they reach the wake of their leaders, or the same point when they tacked; so that there will always be three ships in stays at once, till the whole fleet is on the other tack. The fleet then stands on to any proposed distance, and retacks as before. (See fig. 1. Plate DLXVIII.).

Plate DLXVIII. fig. 1.

When the weather and centre columns interchange; the weather and lee lie to, or only keep steerage way. The centre column tacks together, and forming a bow and quarter line, goes close hauled to gain the wake of the weather column; it then tacks together, and stands on, while the weather column bears away to its new station in the centre, and the lee column fills. (See fig. 2.).

Fig. 2.

When the weather and lee columns are to interchange; the centre column must bring to; while the lee stands on under a press of sail; and when its sternmost ship can pass to windward of the van of the centre column, that is, when the centre ship of the lee is in a perpendicular line to the direction of the wind with the van of the centre column, the lee column then tacks together, and stands on close hauled till it comes in a line with the centre column, when it goes large two points to get into the situation which the weather column left; and then veers together, hauling the wind for the other tack. At the beginning of the evolution the weather column bears away together under little sail, and goes large six points on the other tack, to get into the wake of the centre column; it then hauls to the former tack, going two points large, till it comes abreast of the centre column, when it brings to, and waits for the now weather column. (See fig. 3.)

Fig. 3.

Suppose the weather column is to pass to leeward; the weather column is to stand on under easy sail, while the centre and lee tack together, carrying a press of sail till they reach the wake of the weather column, when they retack, and crowd sail till they come up with it. The weather column, when the others have gained its wake, bears away two points, to gain its station to leeward, when it brings to, till the other columns, now the weather and centre, come up. (See fig. 4.).

Fig. 4.

Suppose the lee column is to pass to windward. The weather and centre columns bring to, while the lee column carries sail and tacks in succession as soon as the leading ship can weather the headmost ship of the weather column; and when arrived on the line on which the weather column is formed, it retacks in succession, forms on the same line, and either brings to or stands on under easy sail. If it brings to, the other two columns bear away together two points, to put themselves a-breast of the column now to windward; but if the now weather column stood on under an easy sail, they may bear away only one point, to gain their proper stations: (See fig. 5.).

Naval Tactics

Fig. 5.

It is of the greatest importance that each ship of a fleet or squadron preserve her proper station and distance with respect to the rest. These may be regulated in two ways, either by observation with the quadrant, or by what is called the *naval square*. This square is usually constructed in the following manner.

71 Construction and use of the naval square, fig. 6.

On some convenient place in the middle of the quarter-deck is described the square ABCD, fig. 6. having the sides AD and BC parallel to the keel of the ship. Through the centre G, the line EF is drawn parallel to AD or BC, and the diagonals AC and BD are drawn. The angles EGD, EGC are bisected by the straight lines GH, GI, and thus the naval square is completed. Now the angles FGD, FGC are = 4 points each, being each half a right angle, therefore the angles EGD, EGC, the complements of these angles, are each = 12 points, and consequently the angles EGH, EGI are each = 6 points, being each half of the last angles. Now, if a ship be running close hauled on the starboard tack, in the direction FE, the direction of the wind will be IG, and her close-hauled course on the other tack will be GC; but if she be running close hauled on the larboard tack in the same direction, her direction when close hauled on the starboard tack will be GD.

Now, to apply the naval square to the keeping of ships in their respective stations, suppose the fleet formed on the fifth order of sailing, close hauled, the corresponding ships of the columns coinciding with the direction of the wind, in order to run to windward with greater facility. The corresponding ships in the column must be kept in the direction of GH, or GI, according to the direction of the wind and the tack they are on, while all the ships of the same column must be in the direction of EF. (See fig. 7.). Fig. 7.

Again, suppose the ships arranged in three columns on one of the lines of bearing, and close hauled on the other tack. The ships of each column will be in the direction of one of the diagonals, while the corresponding ships of the other columns will be in the direction of the other diagonal. (See fig. 8.). Fig. 8.

72 To restore the order of battle, on shifts of the wind.

Sometimes the line of battle is disordered on the wind's shifting, and requires to be restored. Of this there are several cases, a few of which we shall notice.

1. When the wind comes forward less than 6 points. In this case the whole fleet except the leader brings to. The leading ship, that the same distances between the ships may be preserved on restoring the line, steers a course as *a b* (fig. 9.), so as to be at right angles with the middle point between the former and present direction of the wind. His required course may be known by adding half the number of points the wind has shifted to eight points, and applying this sum to the former close-hauled course. When the leader has arrived at the new close-hauled line with respect to the second ship a-head, this ship immediately fills, and bears away as many points as the leader; and when both these have reached the close-hauled line with respect to the third ship, she also fills, and bears away; and thus with the rest in succession; and when they have got into the close-hauled Fig. 9.

Naval Tactics.

close-hauled line *b c* with the sternmost ship, they all haul their wind together, and the sternmost ship fills and stands on close hauled.

Plate DLXVIII. This may be expeditiously performed, if the whole fleet fall off as soon as the wind shifts, the same number of points, and the leader bear away eight points from the middle between the former and present directions of the wind, or when the wind shifts nearly six points, if the leader bear away eight points from the present direction of the wind, and hauls her wind as soon as the sternmost ship bears from her in the close-hauled line, while the second ship bears away when she reaches the wake of the leader, and hauls her wind when she has again gained his wake. The third, fourth, &c. ships bear away, and also haul their wind in succession, till the sternmost and the whole line be formed again. (See fig. 10.)

Fig. 10.

2. Suppose the wind comes forward less than six points, and the order of battle is to be re-formed on the other tack. In this case all the ships are to veer round till their heads come to the requisite point with respect to their former course, when the rear ship, now become the van, hauls close by the wind, followed successively by the other ships. Should the wind come a-head more than six points, but less than twelve, the fleet is to manœuvre as before, but if it shift exactly twelve points a-head, the tack must be changed.

3. Lastly, suppose the wind to shift oft—if less than two points, the leader hauls her wind, while the fleet stands on as before, each successively hauling her wind as she gains the wake of her leader. If the tack is to be changed, the whole fleet tack together, and the sternmost ship, now the leader, hauls up, while the rest bear down and haul up in succession.

Should the wind change 16 points, all the ships immediately brace about for the other tack, by which means the fleet will be going four points large; then the ships instantly tacking or veering together, the order of battle will be restored or formed again on the same tack as before the wind changed.

It is inconsistent with the nature of our plan to be more minute on the various evolutions of a fleet, when not in action with the enemy. Our nautical readers will find abundant information of this kind in the usual works on naval tactics, especially the *Elements and Practice of Rigging, Seamanship, Naval Tactics*, &c. of which the latest edition is in 4 vols 8vo.; and *The System of Naval Tactics, with coloured figures*, both published by Steel.

Having described and illustrated the principal evolutions which are performed by fleets or squadrons under ordinary circumstances, we are prepared to consider the nature and consequences of a naval engagement.

73 Circumstances to be considered in forming a fleet for action.

In forming a fleet for battle, it is proper to consider the size and number of the ships of which it is to consist, and the distance at which they are to be placed with respect to each other. In the present system of naval warfare, it is generally deemed of advantage to have the ships that are to form the principal line as large as possible; for though large ships are not so easily and expeditiously worked as those of a smaller size, they are most serviceable during the action, both as carrying a greater weight of metal, and as being less exposed to material injury, either from the enemy's shot, or from the weather. In boarding, too, a large ship must have greatly the superiority over a smaller, both from her greater height, and from the number of hands which she contains. With respect to the number of ships, it is of advantage that they be not too numerous, as if the line be too extensive, the signals from the centre are with difficulty observed.

In arranging a fleet in line of battle, it is proper to regulate the distance so that the ships shall be sufficiently near to support each other, but not so close as that a disabled ship may not readily be got out of the line without disturbing the rest of the fleet.

74 Advantages and disadvantages of the weather gage.

It has long been deemed a point of great consequence with the commander of a fleet to gain the weather gage, or to get to windward of the enemy, before coming to action. In deciding on the propriety of this, much will depend on the relative strength of each fleet, and on the state of the weather at the time. We shall state the advantages and disadvantages of the weather gage, as they are commonly laid down by writers on naval tactics, though we may observe by the way, that if a fleet be much superior to its opponent, it is seldom of consequence whether it engages to windward or to leeward.

A fleet to windward of the enemy is thought to possess the following advantages. It may approach the leeward fleet at pleasure, and can of course accelerate or delay the beginning of the engagement. If more numerous, it may send down a detachment on the rear of the enemy, and thus throw him into confusion. It may also readily send down fireships on the enemy's fleet, when thrown into confusion or disabled. It may board at any time, and is scarcely incommoded by the smoke of the enemy. The reverse of these circumstances, of course, act against a leeward fleet.

The disadvantages of being to windward of the enemy respect chiefly the circumstances attending a retreat, should this be necessary. The windward fleet can seldom retire without passing through the enemy's line; and if in attempting to retreat, the windward ships tack together, those of the leeward fleet may do the same, rake the weather ships in stays, and follow them on the other tack, having now the advantage of the wind. In stormy weather, the windward ships can seldom open their lower deck ports, and the lee guns are not easily managed after firing. Again, any disabled ships cannot easily quit the line without disordering the rest of the fleet, and exposing either that or themselves to be raked by the enemy to leeward. A leeward fleet has the advantages of serving their lower deck guns in all weathers; of being able to retreat at pleasure; of drawing off without difficulty their disabled ships; of forming with more readiness the order of retreat; or of continuing the action as long as convenient; of having it in their power, when superior in number, to double the enemy, and of cannonading with great effect the windward ships as they bear down for the attack.

As an engagement between two adverse ships is in some measure an epitome of an engagement between two fleets, we shall first briefly describe the former, as it takes place under ordinary circumstances, and shall then notice the usual manner of conducting a general engagement.

A naval engagement may be divided into three stages, the *preparation*, the *action*, and the *repair*.

When

Naval Tactics.

75 Description of an engagement between two ships.

76 Preparation.

When an enemy's ship heaves in sight, and it is thought advisable to bring her to an engagement, orders are first given to clear for action, which is begun by the boatswain and his mates piping up the hammocks, in order to clear the space between decks, for the more easy management of the guns, as well as to afford the men on the quarter-deck, &c. a better protection against the enemy's shot, the hammocks being stowed in the nettings above the gunwale and bulwarks. After this, the boatswain's mates go to work to secure the yards, which is done by fastening them with strong chains or ropes in addition to those by which they are suspended. They likewise get ready such materials as may be necessary for repairing the rigging, if it should be cut away, or otherwise damaged by the enemy's shot. In the mean time the carpenter and his mates prepare shot plugs and mauls, to stop any dangerous shot holes that may be made in the hull near the surface of the water, and provide the necessary iron work for refitting the chain-pumps, if their machinery should be injured during the engagement; while the gunner and his mates, and the quarter gunners, examine the guns, to see that their charges are dry, and provide every thing that may be required for supplying the great guns and small arms with ammunition. The master and master's mates see that the sails are properly trimmed, according to the situation of the ship, and increase or reduce them as may be found necessary; and the lieutenants visit the different decks, to see that all is clear, and to take care that the inferior officers do their duty.

When the hostile ships have approached within a proper distance of each other, the drums beat to arms; the boatswain and his mates pipe *all hands to quarters!* All the men who are to manage the great guns repair immediately to their respective stations. The crows, handspikes, rammers, sponges, powder-horns, matches, and train tackles, are placed in order by the side of the guns: the hatches are immediately closed, to prevent skulkers from getting below; the marines are drawn up on the quarter-deck, &c. the lashings of the guns are cast loose, and the tompions withdrawn. The whole artillery, above and below, is run out at the ports, and levelled to the point-blank range, ready for firing.

77 The action.

When these necessary preparations are completed, and the officers and crew ready at their respective stations, and when the two ships are sufficiently near each other, in a proper relative situation for the shot to take full effect, the action commences with a vigorous cannonade from the great guns, accompanied by the whole efforts of the swivels and small arms. The firing is seldom performed in vollies, as that would shake the ship too much, but the guns are loaded and fired one after another, with as much dispatch and as little confusion as possible, care being taken to fire only when each gun is properly directed to its object. During the firing, the lieutenants traverse the decks, to see that the battle is prosecuted with vivacity, and that the men do their duty, while the midshipmen second their injunctions, and give the necessary assistance where required, at the guns committed to their charge. The youngest of these inferior officers are generally employed to carry orders from the captain. The gunners are all this time employed in the magazines, filling cartridges, which are carried along the decks in boxes by the boys of the ship. When the action has continued so long, or has produced such an effect, that one of the ships must yield or retreat, if the vanquished ship cannot get off, she acknowledges her inferiority by striking, or hauling down her colours, when she is, as soon as possible, taken possession of by the victor, the commander of which sends a part of his own crew into the captured ship, and brings away most of her officers and men on board his own ship, as prisoners of war.

78 Repair.

The engagement being concluded, they begin to repair; the guns are secured by their breechings and tackles, with all convenient expedition. Whatever sails have been rendered unserviceable are unbent, and the wounded masts and yards struck upon deck, to be fished or replaced by others. The standing rigging is knotted, and the running rigging spliced where necessary. Proper sails are bent in the room of those which have been displaced as useless. The carpenter and his mates are employed in repairing the breaches made in the ship's hull, by shot plugs, pieces of plank, and sheet lead. The gunner and his assistants are busied in replenishing the allotted number of charged cartridges, to supply the place of those which have been expended, and in refitting whatever furniture of the guns may have been damaged by the action.

79 Engagement between two fleets.

A general engagement between two adverse fleets of course involves a greater variety of circumstances, and requires greater judgment, and more comprehensive skill in the commanding officer.

When the commander of a fleet has discovered an enemy's fleet, his principal object, if he be sufficiently strong, is to bring it to action as soon as possible. Every inferior consideration gives way to this important object, and all necessary preparations are immediately made to prepare for such an event. The state of the wind and situation of the enemy will in general regulate his conduct with regard to the disposition of his ships on that occasion. To facilitate the execution of the admiral's orders, the whole fleet is disposed in three squadrons, and each of these classed into three divisions, under the command of different officers. Before the action begins, the adverse fleets are drawn up in two lines, as formerly described. As soon as the admiral displays the signal for the line of battle, the several divisions separate from the columns in which they were disposed in the usual order in sailing, and every ship crowds sail to get into its station in the wake of the next ahead; and a proper distance from each other is regularly observed from the van to the rear. The admiral, however, occasionally contracts or extends his line, so as to regulate the length of his line by that of his adversary. This is more particularly necessary to prevent his being doubled, by which his van and rear would be thrown into disorder. When the hostile fleets approach each other, the courses are commonly hauled upon the brails, and the top-gallant sails and stay sails furled. The movement of each ship is regulated chiefly by the main and fore-top sails and the jib: the mizen-top sail being reserved to hasten or retard the course of the ship; and by filling or backing, hoisting or lowering it, to determine her velocity. The signal for a general engagement is usually displayed when the fleets are sufficiently near each other, to be within the range of point-blank shot, so that the guns may be levelled with some certainty of execution. After the battle has commenced, it is carried on much in the same manner as between two ships, except that each vessel

Naval Tactics.

vessel of the fleet, besides attending to her own movements, has to observe the signals made by the commanding officer, and repeated by the frigates on the van and rear. The chief object of the admiral is to keep his line as complete as possible, by ordering ships from those in reserve to supply the place of such as may have been disabled, and to annoy the enemy as much as possible, both by strengthening the feeble parts of his own line, and, if circumstances admit of it, by sending down fire-ships upon that of the enemy. When the engagement draws near a close, either by the defeat of the enemy, or by the disabled state of either fleet, signals are made from the admiral to take possession of such of the enemy's ships as have struck, to tow his own disabled ships into a place of security, and either to chase the remainder of the enemy's squadron, or, if that be impracticable, to draw off his own ships to be refitted. *

Such are the general incidents attending an engagement at sea, modified of course by numerous circumstances, of which a general description can convey no idea. There are, however, various movements and evolutions connected with a naval engagement, which it will be necessary for us to notice.

* For particular British naval actions, see *Campbell's Lives of the Admirals*, and *Beatson's Naval and Military Memoirs of Great Britain.*

80
To dispute the weather gage with an enemy.

Where the weather-gage is deemed of sufficient importance, it is often an object with two fleets to dispute it with each other. When the enemy is to windward, and it is wished to gain the weather-gage of him, the fleet to leeward should avoid extending itself the length of the enemy's line, in order to oblige them to edge down upon theirs, if they intend to attack them; which will be a mean, if they still persist in doing so, of losing the advantage of the wind. It is impossible for a fleet to leeward to gain to windward, so long as the enemy keep the wind, unless a change happens in their favour; therefore all that a fleet to leeward can do must be to wait with patience for such a change, of which they will undoubtedly avail themselves, as well as of any inadvertency the enemy may commit in the mean time. And as long as the fleet to leeward does not extend its line the length of the enemy's, it will be impossible for the latter to bring them to action without running the hazard, by bearing down, of losing the advantage of the wind, which both fleets will be so desirous of preserving. That an admiral may take advantage of such shifts of wind as occasionally happen, he must endavour to get his ships into such situations where these shifts most frequently take place. It is well known to experienced naval officers, that particular winds reign most on certain coasts, or off certain headlands. Here, therefore, the admiral should await the approach of the enemy; and though by this plan he may sometimes be unsuccessful, he will more frequently gain a material advantage. The disposition of projecting headlands, and the setting of tides and currents, often contribute materially towards gaining the wind of the enemy. The fleet to windward should keep that to leeward as much as possible abreast of it; and thus unless the wind changes considerably, they will preserve the advantage they have gained. They should also force them to keep their wind, unless they think it prudent not to engage, in which case it would be better to keep altogether out of sight.

81
To force the enemy to action.

When the enemy appears desirous of avoiding an action, there are various methods of attempting to force him to engage; as first, when he has the weather gage. In this case the lee fleet, which is desirous of bringing on an engagement, must keep always on the same tack with the enemy to windward, taking care to keep their own ships so exactly abreast of the enemy, as to prevent losing sight of them; and hence be ready to take advantage of the first favourable shift of wind to make the attack. An alteration of the course may be best attempted in the night. The lee fleet must have frigates on the look-out, and these must continually give notice by signal of the manœuvres and course of the retreating fleet to windward. Thus the weather fleet is always exposed to pursuit, without being able to get off unseen; hence must sooner or later be compelled to an engagement, unless they can get into some friendly port, or should be favoured by a gale of wind sufficient to disperse both fleets, and thus prevent the possibility of a general engagement.

Secondly, when the enemy is to leeward.—If the lee fleet keep close to the wind in the order of battle, the fleet to windward is to stand on in the same manner till it be abreast of the enemy, ship to ship, and at the same time to bear away, and steer so as to bring their respective opponents on the same point of the compass with themselves. Thus the adverse fleets will be sufficiently near each other to begin the action, by each ship's presenting her bow to the ship abreast of her in the order of sailing, which may be easily changed for the order of battle, by all the ships hauling together close to the wind, in the moment which precedes the action. If the fleet to leeward appear inclined to engage, it may bring to, to prevent losing time, and after this they will fill as soon as the action commences, because it is of advantage to a lee line to be advancing a-head. As the lee fleet fills and stands in close by the wind, the weather line should keep a-breast, before it bears away, to come within the requisite distance, that the van ship of the weather fleet may always keep to windward of the leading ship of the lee line, and be guarded against any shift of wind a-head.

If the lee fleet bear away four points to move their order of battle on the other tack, and avoid the action, filing off in succession in the wake of the van ship, the weather line, by bearing away all together eight points, cannot fail, as both fleets are supposed to sail equally, to pass through the middle of their line, and force them to fight with disadvantage, if their extent be double the distance between the two fleets. If the extent of the fleet be less than the above limitation, then the weather fleet will divide the lee fleet more unequally; and if the distance between the fleets be considerable, the weather fleet will be able to break through the line. If the lee fleet bear away four points all together, being of equal extent with the fleet to windward, and their distance from each other equal to that of the length of one of the lines; should the weather fleet bear away at the same time eight points, they will approach very near the sternmost of the retreating fleet; but they will not have it in their power to cut off any part of that fleet, even with an equality of sailing; so that the only advantage gained by this manœuvre will be an ability of attacking the rear, and bringing it to action.

If the van ship and the rest of the weather fleet had a sufficient velocity to keep the centre ship of the lee line on the same point of bearing; in that case, the leading ship may break through the enemy's line about the middle

Naval Tactics.

middle ship of the centre division; for, supposing the fleets in the order of battle, on the starboard tack, steering east, with the wind at south-south-east, being at two leagues distance from each other, both the lines being four leagues in extent; then the lee line bearing away all together four points, will run north-east; while the fleet to windward, bearing away all together eight points, will steer north; the van ship of which will keep the centre division of the lee line in the point of bearing north-west. As she is supposed to be able to continue in this position, it follows, that the van of the weather line must close the centre of the flying line to leeward, after having run four leagues. The time and distance necessary to cut off a retreating fleet may always be known according to the last supposition. If the lee fleet should get on the other tack, and run large, still in the order of battle, they will be sooner forced to action by the weather fleet, who have only to bear away eight or nine points on the same tack, or run right before the wind.

81 To avoid coming to action.

As in forcing a fleet to action, there are two principal cases in which a fleet may avoid an action, where circumstances are not sufficiently favourable; first, when the enemy is to windward, and secondly, when he is to leeward. In the former case the lee fleet should form the order of retreat, if the enemy are in view, and run on the same tack as their leading ship; but if he is still out of sight, and they have received intelligence of his approach, by their frigates on the look-out, they may bear away large, without confining themselves to keep the wind directly off, unless when in the order of retreat. In the second case, it seldom happens that the weather fleet can be forced to an engagement, because it can always stand on that tack which increases its distance from the enemy; that is, by standing on one tack while the enemy is on the other. The windward fleet must of course not keep too near the enemy, and take all possible means of avoiding being abreast of him.

82 To double an enemy.

It is often of advantage to double the enemy; that is, to bring a part of the fleet round upon his van or rear so as to place him between two fires. This manœuvre also resolves itself into two principal cases; first, when the enemy is to windward; secondly, when he is to leeward. In the first case, the lee fleet that attempts to double the enemy, should extend itself abreast of him, so that its van or rear may extend beyond his line, in order to overreach him, by tacking in succession, so that the extended part of the line may get up to windward. If this manœuvre be properly executed, it will be impossible for the ships of the weather line long to maintain their stations, for no vessel closely attacked by two others of equal force can long resist.

It is of some consequence to determine whether the attempt to double should be made on the van or the rear of the enemy, as on the propriety of adopting the one or the other of these measures, may in a great measure depend the issue of the battle. In the present case, it is most easy to double the van of the enemy, because if they are engaged by the ships abreast of them, those which are advanced ahead will be able, by making all sail, to get in the perpendicular to the direction of the wind with the van of the enemy, and tack in succession to gain the wind of them on the other board, thus keeping them to leeward; and when they are come sufficiently to windward, they are again to go about, in order to keep the two headmost ships of the enemy's line continually under their fire. If there be two or three ships to tack in succession and gain the wind of the enemy, they may edge down on the van of the water line at pleasure, keeping themselves a little to the windward of it; and as that van is already engaged by the other ships abreast on the other side, she must necessarily be soon disabled. If they bear away, they must drop upon the line with which they are engaged to leeward, while the ships to windward still continue to cannonade them. If they attempt going about, in order to attack more closely the ships to windward, they will be raked, while in stays, by their opponents to leeward and to windward, who enfilading them with whole broadsides which they cannot return, must complete their disorder. If they make sail, in order to frustrate the design of the ships inclined to double, those with which they are engaged abreast to leeward have only to perform the same manœuvre, and keep them under their fire; while the others, after having harassed them as much as possible, will do their best to perform the same manœuvre on the succeeding ships.

If any of the ships in the van of the weather line are disabled in the masts or yards, they will drop astern, and run foul of the next succeeding ship, and these again on the next astern. Thus, the enemy's order of battle will be broken, while on the other hand the lee line is preserved; and those ships which have gained the wind of the enemy will, without engaging more ships than they can manage, contribute to increase the confusion.

When the enemy is to leeward, and the weather fleet attempts to double, the ships of the weather line must extend their van beyond that of the enemy, and then veer in order to bring the headmost ships of the lee line between two fires. It must not, however, be concealed, that it is much more dangerous to the ships engaged in this service to attempt doubling a fleet to leeward, than one to windward, as if disabled, or separated too far from their own fleet, they cannot so easily extricate themselves, and rejoin the fleet.

83 To avoid being doubled.

When one fleet attempts to double another, this latter will of course do all in their power to avoid the impending danger; and this they will the more readily do, according to their number, or their situation. If the fleet thus threatened be to windward, one of the methods proposed to avoid being doubled, is to extend the line towards the point threatened, so as to leave a greater space between the ships; but in doing this, there is a risk of having the line broken by the superior enemy. Another method suggested is, for the flag ships of the windward fleet to oppose themselves to those of the lee line, which is supposed to render several of the enemy's ships in the intervals of little use; but one great inconvenience of this manœuvre is, that it leaves the van and rear most exposed to the enemy's fire, and that the rear division in particular is in great danger of being doubled. To remedy these defects, the largest ships should be placed in the van and rear of each division, and the fleet must regulate its sailing in such a manner that its rear shall never be astern of the rear of the enemy.

When the enemy is to leeward, the weather fleet is to keep astern of the enemy, so that the van of the weather fleet, may be opposed to, and attack the enemy's centre. Hence the enemy's van will become useless for some

some time; and should it attempt to tack and double on the weather fleet, much time will be lost in performing that evolution; and it also runs the risk of being separated by the calm which often happens in the course of an engagement, occasioned by the discharge of the guns. A considerable interval might also be left between the centre and van, if necessary precautions be taken to prevent the van from being cut off.

84 Of chasing.

There are several circumstances of importance to be considered in the subject of chasing, i. e. when one ship or fleet pursues another, called the *chase*, either to bring her or them to action, or to oblige them to surrender.

85 In the case of single ships.

When a single ship chases another, it is to be presumed in general, that one of them is the better sailor, though this is not always the case, and still by proper manœuvring the chasing ship, or *chaser*, may gain on the chase. In the following observations, however, we shall suppose the chaser to sail faster than the chase. The manœuvres of the chaser will depend on her being to windward or leeward of the chase.

When the chase is to windward, it is evident that as soon as she perceives a strange ship which she takes for an enemy, she will haul her wind, in order to prolong the chase, as otherwise her retreat would soon be cut off. The chaser then stands on also nearly close hauled, till she has the chase on her beam; she then tacks, and stands on close hauled till the chase is again on her beam, and then retacks. In this manner she continues tacking every time she brings the chase perpendicular to her course on either board; and by thus manœuvring, it is certain that the chaser will, by the superiority only of her sailing, join the other in the shortest time. For since the chaser tacks always as soon as the chase is perpendicular to her course, she is then at the shortest distance possible on that board; and since the chaser is supposed to be the fastest sailer, these shortest distances will decrease every time the chaser tacks. It is therefore of advantage to the chase to keep constantly on the same course, without losing her time in going about, as tacking cannot be so favourable to her as to her adversary, whose sailing is superior. If the captain of the chaser should so little understand his profession as to stand on a long way, and tack in the wake of the chase, the best thing she can do is to heave in stays, and pass to windward of him on the other tack, except she should find herself likely gaining advantage by going large; for if the chaser persists in tacking in the wake of the other ship, the pursuit will be very much prolonged.

When the chase is to leeward, the chaser is to steer that course by which she thinks she will gain most on the chase. If, after having run a short time, the chase is found to draw more aft, the chaser should then bear away a little more; but if the chase draw a head, the chaser should haul up a little, and thus the course may be so regulated, that the chase may always bear on the same point, and then the chaser will get up with the chase in the shortest time possible; for if any other course were steered, the chaser would be either too far ahead or too far astern, and hence the pursuit would be prolonged. The chase should run on that course which will carry her directly from the chaser, and should consider which is her best trim with respect to the wind, that she may move with the greatest possible rapidity from the chaser; for some ships have more advantage in going large, others with the wind right aft, and others when close hauled.

Another method has been proposed for chasing a ship to leeward, that is, by constantly steering directly for the chase: in this case, the tract described by the chaser is called the line or *curve of pursuit*. To illustrate this, let A (fig. 11. Plate DLXVIII.) represent the chaser, and B the chase directly to leeward of her, and running with less velocity than the pursuer, in the direction BC, perpendicular to that of the wind. Now, to construct this curve, let B *b* be the distance run by the chase in any short interval of time; join A *b* and make A 1 equal the distance run by the chaser in the same time. Again, make *b c*, *c d*, *d e*, *e f*, &c. each equal to B *b*; join 1 *c*, and make 1, 2=A 1; join 2 *d*, and make 2, 3 equal to A 1; proceed in like manner till the two distances carried forward meet as at C, and a curve described through the points A, 1, 2, 3, &c. will represent nearly the curve of pursuit; and the less the interval A 1 is taken, the more accurately will the curve be formed. In this particular case, the length of the distance BC may be found as follows, provided the distance AB and the proportional velocities of the two ships be known. 86 Curve of pursuit. Plate DLXVIII. fig. 11.

Let the velocity of the chase be denoted by a fraction, that of the chaser being unity. Multiply the given distance AB by this fraction, and divide the product by the complement of the square of the same fraction, and the quotient will be the distance run by the chase B. Suppose AB, the distance of the chase directly to leeward of the chaser, be taken at 12 miles, and suppose the velocity of the chase three-fourths of that of the chaser; what will be the distance run by the chase before she is overtaken? Now $\frac{12\times\frac{3}{4}}{1-\frac{3}{4}|^2}=\frac{9}{\frac{7}{16}}=9\times\frac{16}{7}=20\frac{4}{7}$ miles; and since the velocity of the chaser to that of the chase is as 4 to 3, hence the distance run by the chaser will be $=20\frac{2}{7}\times\frac{3}{4}=27\frac{3}{7}$ miles. As the chaser alters her course at every point, and probably sails better with the wind in one direction with respect to her course than when the wind is in another direction, her velocity will be different at different points of the course. Thus, suppose her to sail faster when the wind is on the quarter, her velocity will constantly increase to a certain point, and will then diminish. Hence in real practice the curve of pursuit will not be exactly what is laid down in the above problem, and of course the measure of BC will differ a little from what we have there laid down. See *Resistance of Fluids* and Seamanship.

If the whole fleet is to give chase, the admiral will make the proper signal, and then each ship will instantly make all the sail possible. If the retreating fleet is not much inferior to the other, a few of the fastest sailing vessels only are to be detached from the superior fleet, in order to pick up any stragglers, or those ships which may have fallen astern; and the remaining part of the fleet will keep in the same line or order of sailing as the retreating fleet, so that they may, if possible, force them to action. But if the retreating fleet is much inferior, the admiral of the superior fleet will make the 87 In the case of fleets.

 signal

signal for a general chase, and then each ship will immediately crowd all the sail possible after the retreating fleet; or, if the chase be still less numerous, the admiral will detach one of the squadrons of his fleet, by hoisting the proper signal for that purpose, and he will follow with the remainder of the fleet. The squadron that chases, should be very careful not to engage too far in the chase, for fear of being overpowered; but at the same time to endeavour to satisfy themselves with regard to the object of their chase. They must pay great attention to the admiral's signals at all times; and in order to prevent separation, they should collect themselves before night, especially if there be any appearance of foggy weather coming on, and endeavour to join the fleet again. The ships are diligently to observe when the admiral makes the signal to give over chase; that each regarding the admiral's ship as a fixed point, is to work back into her station, to form the order of line again as quickly as the nature of the chase and the distance will permit.

When a fleet is obliged to run from an enemy who is in sight, it is usual to draw up the ships in that form or order, called the *order of retreat;* and the admiral, when hard pursued, without any probability of escaping, ought, if practicable, to run his ships ashore, rather than suffer them to be taken afloat, and thereby give additional strength to the enemy. In short, nothing should be neglected that may contribute to the preservation of his fleet, or prevent any part of it from falling into the hands of the conqueror.

We have now gone through the principal evolutions of fleets and squadrons, nearly as they are described in the *Elements of rigging, seamanship, and naval tactics,* and other approved publications on similar subjects. We have indeed omitted the method of forcing an enemy's line, and of avoiding being forced, because the former will be readily understood from what we have to add on the improved method of tactics of M. Grenier, and Mr Clerk of Eldin.

88
Defects of the usual line of battle.

Various defects have been observed in the tactics usually employed at sea, especially in a line of battle, and in the mode of bringing an enemy to action. The usual order of battle first introduced by the duke of York, afterwards James II. of England, is defective from its length. Its great extent makes it difficult for the admiral to judge what orders are proper to be issued, to the ships stationed at the extremities, while his signals, however distinctly made, are liable to be mistaken by the commanders of these ships. Besides, the extremities of a long line, especially if it be to leeward, are necessarily defenceless, as the enemy may throw himself with a superior force on the van or rear, and cut either of these off before it can be properly supported by the other squadrons. Viscount de Grenier, who was, we believe, one of the first to notice these defects, proposed to remedy them by introducing a new order of battle.

89
Principles of de Grenier's method of tactics.
Plate DLXVIII. fig. 12.

The leading principles of De Grenier's tactics are founded on the following considerations. It is evident that each ship of a fleet must at all times occupy the centre of a certain horizon. This horizon De Grenier divides into two unequal parts, calling the greater the *direct and graduated space,* and the less the *indirect, crossed, and ungraduated space.* The reason of these appellations is, that on the greater segment of the horizontal circle there are 20 different points, which may be marked by degrees from one of the close-hauled lines to the other, and to which a ship may sail from the centre by so many direct courses without tacking; whereas from the other 12 points, including that from which the wind blows, she cannot arrive but by steering cross courses, which must necessarily delay her progress. Suppose now a fleet to leeward, so disposed that only a part of it can fight with another equally numerous, and ranged to windward in a single line, and let the lee fleet be ranged on three sides of a lozenge *a b, c d, e f,* (fig. 12.). The squadron *a b,* which is most to windward, being drawn up in line of battle, cannot be fought but by an equal number AB, CD, EF. All the rest of that fleet therefore must remain inactive, unless the ships which are not engaged should try to pass to leeward of the fleet *a b, c d, e f.* But should the ships of the weather fleet, which are placed between B and F, bear away as they appear in the figure between C *i* and F *i,* the ships between A and B, which are fighting to windward, cannot bear away with them. Suppose now that the ships between C *i* and F *i* have passed to leeward, the squadrons *c d, e f,* which are ranged according to De Grenier's system, and have not yet been engaged, should come to windward and join with their friends *a b* against that squadron of the enemy AB which is still to windward and engaged; it is almost impossible but that the squadron AB must be destroyed by so great a superiority, before it could receive assistance from the ships to leeward between C *i* and F *i.*

90
His orders of sailing.

De Grenier proposes only three orders of sailing, one when a fleet is to pass a strait; a second when it steers in open sea, on the look-out for an enemy, or with a view to avoid him; and a third when on an extensive cruise disposed so that it cannot be easily suprised or broken. Of these three orders, only the second and third differ from the usual orders of sailing. The former of these is represented by fig. 1. Plate DLXIX. where the columns *a b, c d, e f,* are disposed on three sides of a regular lozenge, on the two close-hauled lines. The ships of the two divisions *c d, e f,* sometimes to windward (as in fig. 2.) and sometimes to leeward (as in fig. 1.) of the third division *a b,* are to be formed on two parallels of one of the close-hauled lines in the wakes of their respective headmost ships; while the third division *a b* is to be ranged ahead or astern of the others on the other close-hauled line, steering chequerwise the same course as the other divisions.

Plate DLXIX. fig. 1. and 2.

When *a b* is to windward of *c d* and *e f* (fig. 1.), De Grenier calls that the *windward primitive order of sailing,* and when to leeward (fig. 2.), the fleet is said to be in the *leeward primitive order of sailing.* These are the two principal positions in almost every case, and with very little variety, may become the order of battle, of chasing, &c.

His third order is illustrated by fig. 3. where the divisions *a b* and *e f,* are supposed at the distance of about six leagues from each other; *c d* and *e f* resting on the extremities of the base of a triangle STV, while the centre ship of the division *a b* rests on its summit T; none of the divisions could be cut off by an enemy, however formidable, seen from its centre ship at the distance of six leagues. For if, on the proper signal, the division *a b* should steer from T toward X, on the course opposite

Fig. 3.

Naval Tactics.

opposite to the close-hauled line it steered before, and the two divisions *c d* and *e f* steer from V and S towards X likewise, it is plain that each of these divisions would have only three leagues to run to join the other two, while the enemy which was first perceived at the distance of six leagues, must run nine before he can come up with the nearest of these squadrons.

91 His order of battle. Plate DLXIX. figs. 4. and 5.

To form De Grenier's order of battle represented in fig. 4. and 5. it will be sufficient for the ships of the three divisions ranged in the windward primitive order of sailing (see N° 90.) to heave in stays all together, and get on the other tack on the opposite line of bearing (fig. 4.); or for the ships in the leeward primitive order at once to haul the wind on the same tack as they steer; and they will find themselves in order of battle, fig. 5. When the two columns *c d* and *e f*, are to leeward of the third division *a b*, ranged in order of battle, this is called the *natural order of battle*, and when *c d* and *e f* are to windward of *a b*, this is the *inverted order of battle*. The former of these is calculated for a fleet combating to leeward, and the latter for a fleet which must fight to windward.

Fig. 6.

To explain the advantages of these dispositions, let us suppose the line AB, CD, EF, fig. 6. to represent an enemy's fleet to windward in the usual order of battle, on the close-hauled line, and on the starboard tack, and let *a b* be one of the divisions of a fleet disposed according to the now natural order, on the starboard tack, while the line *c d*, *e f*, represent the other two divisions standing on chequerwise on the same tack, but formed on the opposite close-hauled line. When the enemy comes to attack this latter fleet on a supposition that it is inferior to their own, their divisions AB and EF, in order to attack the ships *a* or *b*, must bear away. Now, to prevent the attack, each of the divisions *c d*, *e f*, must make the following evolutions according to their respective situations, and the manœuvres of the enemy. 1. The ships of the division *a b* are to slacken as much as possible their headway, and form a very close line, till the enemy makes a movement to attack the headmost or sternmost ship of that division. 2. The ships of the division *c d* are to make sail till they come under the second or third ship of the rear of the line of battle *a b*, when they will take the same sail as the ships of that division, to preserve that position until the hostile ships make their evolution to attack the rear ships of that division. In this situation the ships of the division *c d* will be able to observe the manœuvres of the enemy, in order to change tack, and form themselves in order of battle on the opposite board as soon as the hostile ships shall have run over a certain space; because the ships of the division *c d*, steering afterwards close hauled in the wake of the sternmost ship of the division *a b*, will be able to cover the rear ships of that division, and get the weather-gage of the hostile divisions which are bearing away; rake their ships; run along side of them; double their rear-guard, and put it between two fires, if those hostile ships are following in the wake of each other; divide it, if they bear away chequerwise; or gain to windward, and put between two fires the enemy's division CD, while engaged with the division *a b*. 3. The division *e f* may abandon their post, and run chequerwise under a press of sail as soon as the enemy falls a-head of *a b*; that if the enemy's division AB attempts to fall on *e f*, or on the van of *a b*, they may, by going about, steer in order of battle close hauled on the opposite line, and cover the ship *a*, double the hostile division CD a-head, or divide AB which is running chequerwise on the opposite tack.

Fig. 7.

Fig. 7. marks another method of manœuvring by the divisions *c d*, *e f*, when the enemy's ships are arranged in a single line not well formed.

92 De Grenier's method of arranging the admiral's ship, frigates and transports. Figs. 8. and 9.

Figs. 8. and 9. illustrate De Grenier's method of placing the admiral's ship, and the frigates and transports attached to a fleet. A, fig. 8. is the admiral placed a-head of the fleet, at a short distance from the headmost of the second division, and in the same direction of the wind as the headmost ship of the first division; *f f* are two frigates observing the same rule and position with respect to the van ship of the third, and rear of the first division. When the fleet is in order of battle, as in fig. 9. the admiral's ship A is in the centre of the lozenge, and two of the frigates, *f f*, on the fourth side of the lozenge. The transports and store-ships, when the fleet is in order of sailing or convoy, occupy the space circumscribed by the lozenge, but in order of battle they are disposed in a line opposite to that of the enemy.

We cannot enter on a more minute or satisfactory account of this system; for a full exposition of which we must refer to the original work entitled *L'Art de Guerre en Mer, ou Tactique Navale*, &c. par M. le Viscompte de Grenier, or the extracts from it contained in the *Elements and Practice of Rigging and Seamanship.*

93 Mr Clerk's tactics.

We must now turn our attention to the improvements in tactics suggested by our countryman Mr Clerk;—improvements which have received the approbation of several distinguished officers of the British navy, and to hints derived from which we are in a great measure indebted for some of the most signal victories which have heaped additional honour on the naval power of Britain.

94 Mr Clerk's objections to the usual method of attack.

Before entering on an explanation of Mr Clerk's tactics, we must briefly state his objections to the usual method of bringing ships to action, by the weather ship or fleet steering directly down upon the enemy. By doing this, the enemy to leeward often has an opportunity of completely disabling the ships making the attack, as the former can use all their guns on one side, while the latter can only use their bow chases. Suppose B, fig. 10. Plate DLXIX. to represent a ship of 80 guns to windward, in sight of an enemy's ship of equal force F, to leeward. Now, if B bears down directly upon F, the latter, by lying to, as in fig. 11. will present a broadside of 40 guns, all bearing for a considerable time on B, while the latter coming down headwise, can only bring the two light guns of her forecastle to bear on F, not to mention that F, by lying broadside to, will have her masts and rigging little exposed to the enemy's shot, while B standing head on, is exposed to be raked by every shot from F, and in particular her rigging is in the utmost danger.

Plate DLXIX. figs. 10. and 11.

95 His new method. Figs. 12. and 13.

Instead of this objectionable mode of attack, Mr Clerk proposes that B having the wind, should run down astern as in the dotted line at fig. 12. till she gets into the course of F, near her wake, or in such a position as will bring her parallel to F's course, and within a proper distance, when she can run up close along side of F, and engage on equal terms; or, that she should shoot a-head, then veer, and run down on the weather bow of F, as in fig. 13. till she can force the chase to bear

Naval Tactics.

bear away to leeward, keeping close by her, on equal terms, taking care in both cases not to put it in the power of F to bring her broadside to bear on her without retaliation.

96 Effects of firing at the hull or rigging. Plate DLXIX. fig. 14.

Fig. 14. is employed by Mr Clerk to illustrate the different procedure of a French and British man of war in firing, the former at the rigging, and the latter at the hull of the enemy, with their effects. Let F represent a large ship desirous of avoiding a close engagement, but lying to, to receive with advantage an enemy's ship B, of equal force. Suppose that F, by firing at the rigging of B, may have carried away some of the principal stays, several of the windward shrouds, a fore-topmast, or other rigging of less consequence, without having wounded a single man; and suppose a second ship consort to F, receiving an enemy's ship like B, but firing only at her hull, so as to kill 30 or 40 men, without damaging her rigging. Now, when F and her consort wish to avoid a close engagement, it is evident that that ship B, which has lost part of her rigging, is much more disabled from coming to close action than her consort whose rigging is entire, though she may have lost a great number of her men.

97 One ship of a line of battle cannot be exposed to the fire of many hostile ships at once. Fig. 15.

By the scheme at fig. 15. it is intended to illustrate the impossibility of one ship being exposed to the fire of many ships at one time. Let I, H, F, H, I, represent five ships in line of battle a-head, about a cable's length, or 240 yards asunder, and suppose the length of each ship to be 40 yards, so that the whole space between the head of one ship and the head of that next adjacent equals 280 yards. Let the perpendicular line FK, extending from the beam of F six cables lengths or 1440 yards, be divided into six equal parts. It is evident that any ship stationed at E in the line FK, 720 yards distant, cannot long be exposed to the fire of more than the centre ship F of this squadron. For if we suppose that H and K a-head and a-stern of F, can bring their broadsides to bear on E; by putting themselves in positions for that purpose, they will not only disorder their own line, but one will leave her head and the other her stern exposed to a raking fire from the opposite ships BB in the enemy's line. If B can suffer little from the two ships H, H, at the distance of 720 yards, it is evident that she will suffer still less from these ships as she approaches nearer the enemy's line. Again, if instead of a cable's length asunder, we suppose the ships I, F, I, two cables length asunder, to bear on the ship B. It is evident from the figure that in this case B will not be more exposed to the fire of I and I at the distance of 1440 yards than she was to that of H and H at half that distance; and so in similar cases.

98 Principles on which the bringing of ships to action is founded. Fig. 17.

In explaining the principles on which we are to judge of the advantages or defects of different modes of bringing ships to action, Mr Clerk supposes a fleet of 10, 20, or more ships of 80 guns each, drawn up in line of battle to leeward, as at F, fig. 16. and lying to with an intention to avoid an action; while another fleet, as B, of equal number and force, also drawn up in line of battle, three or four miles to windward, wishes to make an attack, and come to close quarters on equal terms. The fleets being thus disposed, should the fleet at B attempt running down to attack the fleet at F, each ship standing head on to the opposite ship in the leeward line, it is to be expected, from what we have already stated, that the attacking ships will be disabled, at least in their rigging, before they can come to close action; but suppose that the commander of the weather fleet, though his ships have been disabled in their rigging during their course *aaa* to leeward, fig. 17. has made them bring to at a great distance, but sufficiently near to injure F. This latter fleet, which has been endeavouring to avoid an action, will now bear away with little injury to a new station, as G, and there remain out of the reach of B's shot, and this fleet must repair its rigging before it can make another attack.

Fig. 17.

Again, suppose that the fleet B, instead of standing head on, were to run down in an angular course, as at fig. 18. It is plain that if any ship in this angular line should be crippled, her defect in sailing will occasion a confusion of several of the other ships in that line. It may be said that the stoppage of one ship a-head will not necessarily produce a stoppage of every ship a-stern of her, because they may run to leeward of the disabled ship; but we must observe that by this time the ships a-head in the van A may be engaged, and consequently not having much head way, are nearly stationary, so that each ship a-stern, in attempting to bear down as at D, D, must be confined to a certain course, and must run the risk of being raked in coming down before the wind, and consequently of being disabled before coming up with the enemy. Fig. 18.

Thirdly, the van of the fleet B having attained their station at A, a-breast of the van of F, fig. 19. and having begun the action, the van ships of F, with a view to retreat, may throw in a broadside on the van of B, and then bear away in succession, as at H, followed by the rest of the fleet F, which, after exchanging broadsides with the van of B, may draw up in a new line two or three miles to leeward at I I, fig. 20. Fig. 19.

Suppose again, for further illustration, that B, fig. 1. Plate DLXX. represents a fleet putting before the wind, each ship intending, when brought to at a determined distance at A, to take up her particular antagonists in the line of the enemy F to leeward; and let F be supposed at rest, without any motion a-head. It is easy to conceive that while the alternate ships of F's line, under cover of the smoke, withdraw from battle to GGG, the intermediate ships left behind them in the line will be sufficient to amuse even the whole of B's fleet, till the ships G shall form a new line HH as a support from the leeward. In such case B, after being disabled, and not having foreseen the manœuvre, will neither be able to prevent the intermediate ships with which he is engaged from bearing away to join their friends, nor, were he able, would it be advisable to follow them, for the same manœuvre with equal success can again and again be repeated. Plate DLXX. fig. 1.

To explain the relative motion of these two fleets, let F, fig. 2. represent a fleet of 12 ships in line of battle, a cable's length asunder, and suppose the length of each ship from the end of the jib-boom to the stern to be 36⅔ fathoms. The whole fleet will occupy a space of two English miles; and if it be supposed to sail in the direction FG, at the rate of four knots an hour, it will in an hour have moved to G, four miles from its former position. Fig. 2.

Now, let there be an opposite fleet B, also 12 ships, situated four miles to windward, and let the point A be a quarter of a mile right to windward of the point G. Then, if B by bearing away in the direction BA, gain the

Naval Tactics.

the point A at the same time that the leeward fleet F has arrived at G, B will have moved nearly at the rate of $5\frac{1}{7}$ miles an hour, and the angle contained between the direction of its line of bearing and its present course will be nearly four points.

Secondly, in fig. 3. if F, by carrying more sail, move at the rate of six miles an hour, from F to G, then B, with a more slanting course, will have more difficulty in keeping the line a-breast while coming down to the attack, owing to the additional obstruction which will attend each succeeding ship in such a slanting course. Again, if the leeward fleet shall lie up one point higher, as FG, fig. 4. the rears of the two fleets will be removed to a much greater distance, and the van A must be sooner up with the enemy's van, and of course so much farther from support, while F bringing up his ships in succession, may disable the van of A, and afterwards bear away at pleasure with little injury, as at H. Now B being supposed disabled, and having his rear D distracted, will be unable to prevent F from escaping.

From these considerations it appears that a fleet to windward, by extending its line of battle with a view to stop and attack the whole line of an enemy's fleet to leeward, must labour under considerable disadvantages, and will scarcely succeed in the attempt.

99 New mode of attack from the windward.

On these principles Mr Clerk explains the reason why, before the commencement of the present contest between Britain and France, the French fleets so repeatedly escaped from the British without any serious defeat or loss, viz. by avoiding a general engagement, and disabling the British van as it bore down to attack them. He therefore recommends a different mode of attack from the windward, which we shall proceed to illustrate by proper diagrams.

Fig. 5. Let F (fig. 5.) represent a fleet in line of battle, under easy sail, willing to avoid an action, but ready to receive an attack in the usual way, from another fleet B, three or four miles to windward, arranged in three columns. How shall B make the attack on F, so as, without aiming at the improbable advantage of taking or destroying the greater part of this fleet, they may secure three or four of the sternmost ships? Mr Clerk advises, that a sufficient strength be detached to secure these ships, while the admiral keeps aloof with the rest of his fleet, disposed as in the figure, ready to make the necessary observations and give the requisite support to the detached ships. If F continues to avoid an action by standing on in line, the detachment, coming into the position BA, will secure the three ships at I; and if the headmost ships of F were to tack, and be followed by the rest in succession as at fig. 6. not only the three ships at I will be left at the mercy of the ships detached from B, but two more, as G, will be exposed to an attack from another squadron of B at C. If all the ships of F tack together, as in fig. 7. the delay, and probably the confusion, consequent on this manœuvre, will still more endanger the sternmost ships, or will bring on a general and close action. Again, if F attempts to haul off, beginning with his sternmost ship G, and then runs to leeward, as at fig. 8. he will expose his ships to a raking fire from B, and still endanger his sternmost ships by getting too far to leeward for their support; or if the headmost ships at H, fig. 9. veer first, to be followed by the rest astern, the danger would be still greater. Thus it appears that in every assignable case, a fleet to leeward, avoiding an attack from an equal or superior windward, as here advised, by preserving the line, will risk the loss of three or more of their sternmost ships.

Fig. 6. Fig. 7. Fig. 8. and 9.

Fig. 10. 11. 12. Now, let us suppose that F, while standing on a line on the larboard tack, when threatened with an attack on his rear from B, veers and passes on opposite tacks to leeward (see fig. 10.). The consequence of this will be, that his headmost ships will be forced to leeward by B, and compelled to engage under disadvantageous circumstances, and the disadvantage to F will be much the same, whether he again veers and resumes his former position, as at G, fig. 11. or stands on before the wind, as at P, fig. 12.

Fig. 13. We have hitherto supposed that the wind has been fixed in one point; but let us suppose it to shift, and let us inquire what will be the effect of such a circumstance on the two lines F and B. While the fleets are in the former position, F in line, and B in four divisions, B, B, B, A, steering E, with the wind at N, fig. 13. let the wind shift to the west. The only consequence of this will be, that F will be thrown still farther to leeward, to its greater disadvantage. But let the wind shift to E, so as to be a-head, as in figs. 14. and 15. Still if the admiral of B manages properly, and carefully watches the motions of F, this change will produce no advantage to the latter. For B has nothing to do but veer as the wind comes round, so as to bring his ships to windward of the three sternmost ships of F, and to leeward of the rest of his line, so as to cut off the three sternmost ships. Figs. 14. and 15.

If the wind should be supposed to veer from point to point all round the compass, so that the fleet F, maintaining the weather-gage of B, shall make a circuit round B to leeward; still if B act cautiously, F will lose the three threatened ships.

Fig. 16. Lastly, suppose the wind should instantly shift to a point opposite to what it was at the commencement of the attack, as from N. to S. Before it can be ascertained whether such a change will be to the advantage or disadvantage of F, the relative situations of the two fleets must be considered. Suppose that the van and centre be separated at some distance from his rear, and that in consequence this fleet shall have taken such a position as is shown at fig. 16. Though in this case he will have got to windward, his three ships can never be regained or preserved from the attack of B. The most favourable situation for F would be when the fleets were in the position denoted by fig. 13. as then he could not only support his three ships with advantage, but even threaten, and cut off a part of B's detachment. In attempting this, however, he incurs the risk of coming to a close engagement, which we have supposed him to be sedulously avoiding. Fig. 16.

100 From the leeward.

Besides this method of attack from the windward by detachments from the main fleet, Mr Clerk shows how a successful attack may be made by a fleet *to leeward*, by its breaking the enemy's line, and this either near the rear, near the centre, or not far from the van, of which cases the two former will be most likely to prove successful. The enemy's line can only be cut when the two hostile fleets veer on opposite tacks. The most simple method of effecting this is for the van ship of the attacking squadron, instead of ranging parallel to that of the enemy, and to leeward of him, to pass through the

Naval Tactics.

the first interval that offers, followed by the rest of the line, which is thus led across that of the enemy. In consequence of this manœuvre, the van of the leeward fleet will be to windward of the enemy's rear, and thus the attacking squadron will have its line entire, while that of its adversary is divided. Again, the ships of the rear division, having their progress obstructed, will probably crowd on each other, get into confusion, and be driven to leeward. We cannot detail the different cases mentioned by Mr Clerk; but for these and many other valuable suggestions on the subject of naval tactics, we must refer to his useful and ingenious Essay *.

* See *Clerk's Essay on Naval Tactics*, second Edition.

The above is a very faint and meagre outline of Mr Clerk's tactics, but it is all which our limits enable us to give. It will afford general readers some idea of the nature of the proposed improvements, and professional men will naturally consult the original *essay*.

On these or similar principles is founded the method of *breaking through the enemy's line*, and thus cutting off a part of his fleet, so successfully adopted by the British admirals in the great naval actions that have distinguished the late and present wars with France. We cannot better illustrate the principles above laid down, than by giving a short detail of the last of these memorable engagements, the BATTLE OF TRAFALGAR. With this we shall conclude our sketch of *naval tactics*, and our practical observations on the art of WAR.

101 Battle of Trafalgar, October 21st, 1805.

After having been long blocked up in the harbour of Cadiz, the combined French and Spanish fleet effected their escape, while the British fleet, under the command of Lord Nelson, was at a considerable distance. On the 19th of October 1805, the ships which had been left to watch the motions of the enemy, communicated to the commander in chief the agreeable intelligence, that the combined fleet had put to sea, and was sailing with light winds in a westerly direction. Lord Nelson concluding that their destination must be the Mediterranean, immediately made all sail with his ships for the entrance of the straits. Here he was informed by Captain Blackwood, that the enemy had not yet passed the straits.

On the 21st of October, at daylight, Cape Trafalgar bearing east by south about seven leagues distant, the combined fleet was discovered about six or seven miles to the eastward. The wind was about west, and very light. As Lord Nelson had long expected to fall in with the enemy's fleet, he had concerted with his officers the best and most expeditious measures for bringing them to a speedy and decisive action. As soon, therefore, as they hove in sight, he immediately made the signal for the British fleet to bear up in two columns, as they formed in order of sailing. The combined fleet was drawn up in line of battle, with their heads to the northward, and had formed the line with great closeness and correctness. It consisted of 33 ships of the line, 18 French, and 15 Spanish, under Admiral Villeneuve, as commander in chief, who occupied the centre in the Bucentaure, while the Spanish admiral, Gravina, led the rear in the Prince of Asturias. The British fleet consisted of 27 ships, including three sixty-fours. Lord Nelson headed the van in the Victory, having under him the Temeraire, Neptune, Conqueror, Leviathan, Ajax, Orion, Agamemnon, Minotaur, Spartiate, Britannia, Africa, with the Euryalus, Sirius, Phœbe, and Naiad frigates, Pickle schooner, and Entreprenante cutter; while the rear, consisting of the Royal Sovereign, Mars, Belleisle, Tonnant, Bellerophon, Colossus, Achille, Polyphemus, Revenge, Swiftsure, Defence, Thunderer, Defiance, Prince, and Dreadnought, was led by Vice-admiral Collingwood in the Royal Sovereign.

As the mode of attack adopted by the British was unusual, the combined fleet was obliged to draw up their line in a new manner. It formed a crescent, with its convexity to leeward, so that in leading down to their centre, the rear division of the British had both their van and rear abaft the beam. Before the action commenced, every alternate ship was about a cable's length to windward of her second ahead and astern, thus forming a kind of double line, and appearing, when on their beam, to leave a small interval between them without crowding their ships. The French and Spaniards were not formed in separate divisions, but intermixed without any apparent regard to order of national squadrons. As the British commander had previously communicated to his flag-officers and captains his preconcerted mode of attack, few signals were necessary, and none were made on approaching the enemy, except to direct close order as the lines bore down.

The action commenced at noon, by the leading ships of both columns breaking through the enemy's line; the Victory about the tenth ship from the van, and the Royal Sovereign about the twelfth from the rear; the succeeding ships breaking through in every part astern of their leaders, and engaging the enemy at the very muzzles of their guns. By this manœuvre the van of the enemy was unengaged, and thus the inferiority of the British, in point of number, was of less consequence, while the superior skill and bravery of British seamen soon acquired a decided advantage. The conflict was severe, as the enemy's ships were fought with a gallantry highly honourable to their commanders. The British attack, however, was irresistible. About three P. M. many of the enemy's ships had struck their colours, and their line had given way. Ten ships of the line, and the frigates, under Admiral Gravina, made their escape, and stood to leeward towards Cadiz. The five headmost ships of their van tacked, and standing to the southward, to windward of the British line, were brought to action, and the sternmost of them taken. Nineteen ships of the line, with three flag-officers, including the commander in chief, remained in the hands of the British. Never was there a victory more glorious or more decisive; never was the pre-eminence of the British flag more triumphantly conspicuous.

The events subsequent to this memorable battle, and the losses sustained on either side, having little connection with the subject of the present article, need not be here detailed. They are fresh in the memory of our readers, and Britain still laments the loss of her immortal Nelson *.

Man-of-WAR Bird. See PELICANUS, ORNITHOLOGY *Index*.

WAR-Cry was formerly customary in the armies of most nations, when just upon the point of engaging. Sometimes they were only tumultuous shouts, or horrid yells, uttered with an intent to strike terror into their adversaries; such as is now used by the Indians in America, called the *war whoop*.

WARBLES, a disease of horses. See FARRIERY *Index*.

WARBURTON, WILLIAM, a learned English bishop, was descended from an ancient family in Cheshire, and was the second son of George Warburton, an attorney at Newark in the county of Nottingham, was born at Newark, December 24. 1698. He was first put to school there under a Mr Twells, but had the chief part of his education at Okeham in Rutlandshire, where he continued till the beginning of the year 1714, and soon after he was put out clerk to an eminent attorney of Greak Markham in Nottinghamshire, where he continued till the year 1719, when he returned to his family at Newark; but whether he practised there or elsewhere as an attorney, is not known.

He had always expressed a strong inclination to take orders; and the love of letters, which tended to retard, rather than forward, his progress in the profession chosen for him by his friends, growing every day stronger in him, it was deemed expedient to give way to that inclination. He therefore devoted himself to the studies necessary to fit him for the church, and at length in 1723 he was ordained deacon, and priest in 1727.

In 1728 he was presented by Sir Robert Sutton to the rectory of Brand-Broughton, in the diocese of Lincoln, where he spent the greater part of his life, and composed all the great works which will carry his fame down to posterity. In the same year he was put upon the king's list of Masters of Arts, erected on his majesty's visit to the university of Cambridge. He had already published some juvenile performances, which displayed genius and reading, and attracted considerable notice; but it was not till the year 1736 that he may be said to have emerged from the obscurity of a private life into the notice of the world.—The first publication which rendered him afterwards famous now appeared, under the title of "The Alliance between Church and State; or, the Necessity and Equity of an Established Religion and a Test Law; demonstrated from the Essence and End of Civil Society, upon the fundamental Principles of the Law of Nature and Nations." In this treatise, says Bishop Horsley *, the author "hath shown the general good policy of an establishment, and the necessity of a TEST for its security, upon principles which republicans themselves cannot easily deny. His work is one of the finest specimens that are to be found perhaps in any language, of scientific reasoning applied to a political subject."

* *Review of the Case of the Protestant Dissenters*, Lond. 1787, PREFACE.

At the close of the Alliance was announced the scheme of the Divine Legation of Moses, in which he had then made considerable progress. The first volume of this work was published in January 1737 8, under the title of "The Divine Legation of Moses demonstrated on the Principles of a religious Deist, from the Omision of the Doctrine of a future State of Rewards and Punishments in the Jewish Dispensation, in six books, by William Warburton, M. A. author of the Alliance between Church and State;" and met with a reception which neither the subject, nor the manner in which it was treated, seemed to authorise. It was, as the author afterwards observed, fallen upon in so outrageous and brutal a manner as had been scarce pardonable, had it been "The Divine Legation of Mahomet."—It produced several answers, and so much abuse from the authors of "The Weekly Miscellany," that in less than two months he was constrained to defend himself, in "A Vindication of the Author of the Divine Legation of Moses, from the Aspersions of the Country Clergyman's Letter in the Weekly Miscellany of February 24. 1737-8, 8vo."

Mr Warburton's extraordinary merit had now attracted the notice of the heir apparent to the crown, in whose immediate service we find him in June 1738, when he published "Faith working by Charity to Christian Edification, a Sermon, preached at the last episcopal Visitation for Confirmation in the Diocese of Lincoln; with a Preface, showing the Reason of its Publication; and a Postscript, occasioned by some Letters lately published in the Weekly Miscellany; by William Warburton, M. A. Chaplain to his Royal Highness the Prince of Wales."

The "Essay on Man" had now been published some years; and it is universally supposed, that the author had, in the composition of it, adopted the philosophy of Lord Bolingbroke, whom, on this occasion, he had followed as his guide, without understanding the tendency of his principles. In 1738, M. de Crousaz wrote some remarks on it, accusing the author of Spinozism and Naturalism; which falling into Mr Warburton's hands, he published a defence of the first epistle, and soon after of the remaining three, in seven letters; of which six were printed in 1739, and the seventh in June 1740, under the title of "A Vindication of Mr Pope's Essay on Man, by the author of the Divine Legation." The opinion which Mr Pope conceived of these defences, as well as of their author, will be best seen in his letters. In consequence, a firm friendship was established between them, which continued with undiminished fervour until the death of Mr Pope; who, during the remainder of his life, paid a deference and respect to his friend's judgment and abilities, which will be considered by many as almost bordering on servility.

Towards the end of the year 1739, Mr Warburton published a new and improved edition of the first volume of the Divine Legation; and in 1741, appeared the second part, which completed the argument, though not the entire plan of that work. "A work, says Bishop Hurd *, in all views of the most transcendant merit, whether we consider the invention or the execution. A plain simple argument, yet perfectly new, proving the divinity of the Mosaic law, and laying a sure foundation for the support of Christianity, is there drawn out to a great length by a chain of reasoning so elegantly connected, that the reader is carried along it with ease and pleasure; while the matter presented to him is so striking for its own importance, so embellished by a lively fancy, and illustrated from all quarters by exquisite learning and the most ingenious disquisition, that in the whole compass of modern or ancient theology, there is nothing equal or similar to this extraordinary performance."

* *Life of Warburton prefixed to his Works.*

This is the panegyric of a man reflecting with tenderness

derness on the memory of his friend and benefactor; but it approaches much nearer to the truth than the censures of those cabalistic critics, who, fastening upon some weak part of the Divine Legation, or perhaps never having looked into it, have ridiculously contended that the author was far from being eminent as a scholar, and that his work is inimical to the cause of Christianity! Putting partiality aside, there is in the Divine Legation of Moses abundant evidence of the malignant folly of this charge, as no man can read and understand that work without being convinced that its author was a Christian, not only sincere but zealous; that he was, what Johnson calls him*, "a man of vigorous faculties, of a mind fervent and vehement, supplied, by unlimited and incessant inquiry, with a wonderful extent and variety of knowledge, which had neither depressed his imagination nor clouded his perspicuity; and that to every work, and this work in particular, he brought a memory full fraught, with a fancy fertile of original combinations, exerting at once the powers of the scholar, the reasoner, and the wit." But we think it must be acknowledged, that his learning was too multifarious to be always exact, and his inquiries too eagerly pushed to be always cautious. We have no hesitation, however, to say, that to the divine this great work, with all its imperfections, is, in our opinion, one of the most valuable that is to be found in any language.

* *Life of Pope.*

In the summer 1741, Mr Pope and Mr Warburton, in a country ramble, took Oxford in their way. The university was naturally pleased at the arrival of two such strangers, and seemed desirous of enrolling their names among their graduates. The degree of D. D. was intended for the divine, and that of LL. D. for the poet: but intrigue and envy defeated this scheme; and the university lost the honour of decorating at the same time the two greatest geniuses of the age, by the fault of one or two of its members. Pope retired with some indignation to Twickenham, where he consoled himself and his friend with this sarcastic reflection—"We shall take our degree together in fame, whatever we do at the university."

The friendship of this eminent poet was of service to Mr Warburton in more respects than that of increasing his fame. He introduced and warmly recommended him to most of his friends, and among others to Mr Murray, afterwards earl of Mansfield, and Ralph Allen, Esq. of Prior-park. In consequence of this introduction, we find Mr Warburton at Bath 1742; where he printed a sermon which had been preached at the Abbey-church on the 24th of October, for the benefit of Mr Allen's favourite Charity, the General Hospital or Infirmary. In this year also he printed a Dissertation on the origin of books of chivalry, at the end of Jarvis's Preface to a translation of Don Quixote, which Mr Pope tells him, he had not got over two paragraphs of, before he cried out, *Aut Erasmus, aut Diabolus.*

In 1742, Mr Warburton published "A Critical and Philosophical Commentary on Mr Pope's Essay on Man, in which is contained a Vindication of the said Essay from the Misrepresentation of M. de Resnal, the French Translator, and of M. de Crousaz, Professor of Philosophy and Mathematics in the Academy of Lausanne, the Commentator." It was at this period, when Mr Warburton had the entire confidence of Mr Pope, that he advised him to complete the Dunciad, by changing the hero, and adding to it a fourth book. This was accordingly executed in 1742, and published early in 1743, with notes by our author; who, in consequence of it, received his share of the abuse which Mr Cibber liberally bestowed on both Mr Pope and his annotator. In the latter end of the same year he published complete editions of "The Essay on Man," and "The Essay on Criticism;" and from the specimen which he there exhibited of his abilities, it may be presumed Mr Pope determined to commit the publication of those works which he should leave to Mr Warburton's care. At Mr Pope's desire, he, about this time, revised and corrected the "Essay on Homer," as it now stands in the last edition of that translation.

The publication of "The Dunciad" was the last service which our author rendered Mr Pope in his life time. After a lingering and tedious illness, the event of which had been long foreseen, this great poet died on the 30th of May 1744; and by his will, dated the 12th of the preceding December, bequeathed to Mr Warburton one half of his library, and the propery of all such of his works already printed as he had not otherwise disposed of or alienated, and all the profits which should arise from any edition to be printed after his death: but at the same time directed that they should be published without any future alterations.

"In 1744, Mr Warburton turned his attention to the several attacks which had been made on the "Divine Legation," and defended himself in a manner which, if it did not prove him to be possessed of much humility or diffidence, at least demonstrated, that he knew how to wield the weapons of controversy with the hand of a master. His first defence now appeared, under the title of "Remarks on several occasional Reflections, in Answer to the Reverend Dr Middleton, Dr Pococke, the Master of the Charter-house, Dr Richard Grey, and others; serving to explain and justify divers Passages in the Divine Legation, objected to by those learned Writers. To which is added, A general Review of the Argument of the Divine Legation, as far as it is yet advanced; wherein is considered the Relation the several Parts bear to each other and the whole. Together with an Appendix, in Answer to a late Pamphlet intitled, An Examination of Mr W——'s second Proposition." This was followed next year by "Remarks on several occasional Reflections, in Answer to the Reverend Doctors Stebbing and Sykes; serving to explain and justify the Two Dissertations in the Divine Legation, concerning the command to Abraham to offer up his Son, and the Nature of the Jewish Theocracy, objected to by these learned Writers. Part II. and last." Both these answers are couched in those high terms of confident superiority, which marked almost every performance that fell from his pen during the remainder of his life.

On the 5th of September 1745, the friendship between him and Mr Allen was more closely cemented by his marriage with Miss Tucker, who survived, and is now, if alive, Mrs Stafford Smith of Prior-park. At that important crisis our author preached and published three seasonable sermons: 1. "A faithful Portrait of Popery, by which it is seen to be the Reverse of Christianity, as it is the Destruction of Morality, Piety, and Civil Liberty. Preached at St James's, Westminster, October

Warburton. October 1745." 2. A Sermon occasioned by the present unnatural Rebellion, &c, Preached in Mr Allen's Chapel at Prior park, near Bath, November 1745." 3. "The Nature of National Offences truly stated.—Preached on the General Fast-day, Dec. 18. 1745-6." On account of the last of these sermons, he was again involved in a controversy with his former antagonist Dr Stebbing, which occasioned "An Apologetical Dedication to the Reverend Dr Henry Stebbing, in Answer to his Censure and Misrepresentations of the Sermon preached on the General Fast, &c.

Notwithstanding his great connections, his acknowledged abilities, and his established reputation, a reputation founded on the durable basis of learning, and upheld by the decent and attentive performance of every duty incident to his station; yet we do not find that he received any addition to the preferments given him in 1728 by Sir Robert Sutton (except the chaplainship to the prince of Wales), until April 1746, when he was unanimously called by the Society of Lincoln's Inn to be their preacher. In November he published "A Sermon preached on the Thanksgiving appointed to be observed the 9th of October, for the Suppression of the late unnatural Rebellion." In 1747 appeared his edition of Shakespeare and his Preface to Clarissa; and in the same year he published, 1. "A Letter from an Author to a Member of Parliament concerning Literary Property." 2. "Preface to Mrs Cockburn's Remarks upon the Principles and Reasonings of Dr Rutherford's Essay on the Nature and Obligations of Virtue, &c." 3. "Preface to a Critical Inquiry into the Opinions and Practice of the ancient Philosophers, concerning the Nature of a Future State, and their Method of teaching by double Doctrine," (by Mr Towne) 1747, second edition. In 1748, a third edition of "The Alliance between Church and State, corrected and enlarged."

"In 1749, a very extraordinary attack was made on the moral character of Mr Pope, from a quarter where it could be least expected. An insignificant pamphlet, under the name of *A Patriot King*, was that year published by Lord Bolingbroke, or by his direction, with a preface to it, reflecting highly on Mr Pope's honour. The provocation was simply this: The manuscript of that trivial declamation had been intrusted to the care of Mr Pope, with the charge (as it was pretended) that only a *certain* number of copies should be printed. Mr Pope, in his excessive admiration of his *guide*, *philosopher*, and friend, took that opportunity, for fear so invaluable a treasure of patriot eloquence should be lost to the public, to exceed his commission, and to run off more copies, which were found, after his death, in the printer's warehouse. This charge, however frivolous, was aggravated beyond measure; and, notwithstanding the proofs which Lord Bolingbroke, had received of Pope's devotion to him, envenomed with the utmost malignity. Mr Warburton thought it became him to vindicate his deceased friend; and he did it so effectually, as not only to silence his accuser, but to cover him with confusion *."

* *Hurd's Life of Warburton.*

About this time the publication of Dr Middleton's Inquiry concerning the miraculous Powers of the Christian church, gave rise to a controversy, which was managed with great warmth and asperity on both sides, and not much to the credit of either party. On this occasion Mr Warburton published an excellent performance, written with a degree of candour and temper, which, it is to be lamented, he did not always exercise. The title of it was "Julian; or a Discourse concerning the Earthquake and fiery Eruption which defeated that Emperor's attempt to rebuild the Temple at Jerusalem, 1750." A second edition of this discourse, "with Additions," appeared in 1751, in which year he gave the public his edition of Mr Pope's Works, with Notes, in nine volumes 8vo.; and in the same year printed "An Answer to a Letter to Dr Middleton, inserted in a Pamphlet intitled, The Argument of the Divine Legation fairly stated," &c.; and "An Account of the Prophecies of Arise Evans, the Welsh Prophet in the last Century," annexed to the first volume of Dr Jortin's Remarks on Ecclesiastical History, which afterwards subjected him to much trouble.

In 1752, Mr Warburton published the first volume of a course of sermons, preached at Lincoln's Inn, intitled, "The Principles of Natural and Revealed Religion, occasionally opened and explained;" and this was two years afterwards followed by a second. After the public had been some time promised, it may, from the alarm which was taken, be almost said threatened with, the appearance of Lord Bolingbroke's Works, they were about this time printed. The known abilities and infidelity of this nobleman had created apprehensions in the minds of many people, of the pernicious effects of his doctrines; and nothing but the appearance of his whole force could have convinced his friends, how little there was to be dreaded from arguments against religion so weakly supported. Many answers were soon published, but none with more acuteness, solidity, and sprightliness, than "A view of Lord Bolingbroke's Philosophy, in two Letters to a Friend, 1754;" the third and fourth letters were published in 1755, with another edition of the two former; and in the same year a smaller edition of the whole; which, though it came into the world without a name, was universally ascribed to Mr Warburton, and afterwards publicly owned by him. To some copies of this is prefixed an excellent complimentary epistle from the president Montesquieu, dated May 26. 1754.

At this advanced period of his life, that preferment which his abilities might have claimed, and which had hitherto been withheld, seemed to be approaching towards him. In September 1754, he was appointed one of his majesty's chaplains in ordinary; and in the next year was presented to a prebend in the cathedral of Durham. About this time the degree of Doctor of Divinity was conferred on him by Dr Herring, then archbishop of Canterbury. A new impression of the Divine Legation being now called for, he printed a fourth edition of the first part of it, corrected and enlarged, divided into two volumes, with a dedication to the earl of Hardwicke. The same year appeared "A Sermon preached before his Grace Charles Duke of Marlborough, President, and the Governors of the Hospital for the Smallpox and for Inoculation, at the Parish-church of St Andrew, Holborn, April the 24th, 1755." And in 1756, Natural and Civil Events the Instruments of God's Moral Government; a Sermon, preached on the last public Fast-day, at Lincoln's Inn Chapel."

In 1757, Dr Warburton meeting with Mr Hume's

 tract,

Warburton. tract, entitled, The Natural History of Religion, filled the margin of the book, as well as some interleaved slips of paper, with many severe and shrewd remarks on the infidelity and naturalism of the author. These he put into the hands of his friend Dr Hurd, who, making a few alterations of the style, added a short introduction and conclusion, and published them in a pamphlet, entitled, "Remarks on Mr David Hume's Natural History of Religion, by a Gentleman of Cambridge, in a Letter to the Reverend Dr Warburton." This lively attack upon Mr Hume gave him so much offence, that he thought proper to vent his spleen on the supposed author, in the posthumous discourse which he called his *Life*; and thus to do greater honour to Dr Hurd than to any other of his numerous antagonists.

Towards the end of the year 1757, Dr Warburton was promoted to the deanery of Bristol; and in the beginning of the year 1760, he was, through Mr Allen's interest with Mr Pitt, afterwards earl of Chatham, advanced to the bishopric of Gloucester. That great minister is known to have declared, "that nothing of a private nature, since he had been in office, had given him so much pleasure as bringing our author on the bench." There was, however, another minister, who dreaded his promotion, and thought he saw a second Atterbury in the new bishop of Gloucester; but Warburton, says Bishop Hurd, had neither talents nor inclination for parliamentary intrigue or parliamentary eloquence: he had other instruments of fame in his hands, and was infinitely above the vanity of being caught

"With the fine notion of a busy man*."

* *Dryden.*

He was consecrated on the 20th of January 1760, and on the 30th of the same month preached before the house of lords. In the next year he printed "A Rational Account of the Nature and End of the Sacrament of the Lord's Supper." In 1762, he published "The Doctrine of Grace; or the Office and Operations of the Holy Spirit vindicated from the Insults of Infidelity and the Abuses of Fanaticism," 2 vols 12mo; and in the succeeding year drew upon himself much illiberal abuse from some writers of the popular party, on occasion of his complaint in the house of lords, on the 15th of November 1763, against Mr Wilkes, for putting his name to certain notes on the infamous "Essay on Woman."

In 1765 he published a new edition of the second part of the Divine Legation, in three volumes; and as it had now received his last hand, he presented it to his great friend Lord Mansfield, in a dedication which deserves to be read by every person who esteems the well-being of society as a concern of any importance. It was the appendix to this edition which produced the well-known controversy between him and Dr Lowth, which we have noticed elsewhere (see LOWTH), as doing no great honour, by the mode in which it was conducted, to either party. In the next year he gave a new and much improved edition of the Alliance between the Church and State. This was followed, in 1767, by a third volume of sermons, to which is added, his first Triennial Charge to the Clergy of the Diocese of Gloucester; which may be safely pronounced one of the most valuable discourses of the kind that is to be found in our own or any other language. With this publication he closed his literary course; except that he made an effort towards publishing, and actually printed, the ninth and last book of the Divine Legation. This book, with one or two occasional sermons, and some valuable directions for the study of *theology*, have been given to the world in the splendid edition of his works in seven volumes 4to, by his friend and biographer the present bishop of Worcester. That prelate confesses, that the ninth book of the Divine Legation displays little of that vigour of mind and fertility of invention which appear so conspicuous in the former volumes; but he adds, perhaps truly, that under all the disadvantages with which it appears, it is the noblest effort which has hitherto been made to give a *rationale* of Christianity.

While the bishop of Gloucester was thus exerting his last strength in the cause of religion, he projected a method by which he hoped to render it effectual service after his death. He transferred 500l. to Lord Mansfield, Sir Eardley Wilmot, and Mr Charles Yorke, upon trust, to found a lecture, in the form of a course of sermons, to prove the truth of revealed religion in general, and of the Christian in particular, from the completion of the prophecies in the Old and New Testament, which relate to the Christian church, especially to the apostasy of Papal Rome. To this foundation we owe the admirable Introductory Lectures of Hurd, and the well-adapted Continuation of Halifax and Bagot.

It is a melancholy reflection, that a life spent in the constant pursuit of knowledge, frequently terminates in the loss of those powers, the cultivation and improvement of which are attended to with too strict and unabated a degree of ardour. This was the case with Dr Warburton; and it seems probable that this decline of intellectual vigour was aggravated by the loss of his only son, a promising young man, who died of a consumption but a short time before the bishop, who himself resigned to fate in the year 1779, and in the 81st of his age. A neat marble monument was erected to his memory in the cathedral of Gloucester.

Ward. WARD, Dr SETH, an English prelate, chiefly distinguished for his knowledge in mathematics and astronomy, was born at Buntingford in Hertfordshire, about the year 1617. He was admitted of Sidney college, Cambridge, where he applied with great vigour to his studies, particularly to the mathematics, and was chosen fellow of his college. He was much involved in the consequences of the civil war, but soon after the Restoration obtained the bishopric of Exeter; in 1667, he was translated to Salisbury; and in 1671 was made chancellor of the order of the Garter; he was the first Protestant bishop that enjoyed that honour, and he procured it to be annexed to the see of Salisbury. Bishop Ward was one of those unhappy persons who have the misfortune to survive their senses, which happened in consequence of a fever ill cured; he lived to the Revolution, without knowing any thing of the matter, and died in 1690. He was the author of several Latin works in mathematics and astronomy, which were thought excellent in their day; but their use has been superseded by later discoveries and the Newtonian philosophy.

WARD, is variously used in our old books: a ward in London is a district or division of the city, committed to the special charge of one of the aldermen; and in London there are 26 wards, according to the number of the mayor and aldermen, of which every one has his

Ward | Wardrobe.

his ward for his proper guard and jurisdiction. A forest is divided into wards; and a prison is called a *ward*. Lastly, the heir of the king's tenant, that held *in capite*, was termed a *ward* during his nonage; but this wardship is taken away by the statute 12 Car. II. c. 24.

WARD-Holding, in *Scots Law*. See LAW, N° clxv. 1. and clxvi. 3.

WARD-Hook, or *Wadd-hook*, in *Gunnery*, a rod or staff, with an iron end turned serpentwise, or like a screw, to draw the wadding out of a gun when it is to be unloaded.

WARDEN, or GUARDIAN, one who has the charge or keeping of any person, or thing, by office. Such is the warden of the Fleet, the keeper of the Fleet prison; who has the charge of the prisoners there, especially such as are committed from the court of chancery for contempt.

WARDHUYS, a port of Norwegian Lapland, 120 miles south-east of the North Cape. E. Long. 31. 12. N. Lat. 70. 23.

WARDMOTE, in London, is a court so called, which is kept in every ward of the city; answering to the *curiata comitia* of Rome.

WARDROBE, a closet or little room adjoining to a bedchamber, serving to dispose and keep a person's apparel in; or for a servant to lodge in, to be at hand to wait, &c.

WARDROBE, in a prince's court, is an apartment wherein his robes, wearing apparel, and other necessaries, are preserved under the care and direction of proper officers.

In Britain, the *Master or Keeper of the Great Wardrobe* was an officer of great antiquity and dignity. High privileges and immunities were conferred on him by King Henry VI. which were confirmed by his successors; and King James I. not only enlarged them, but ordained that this office should be a corporation or body politic for ever.

It was the duty of this office to provide robes for the coronations, marriages, and funerals of the royal family; to furnish the court with hangings, cloths of state, carpets, beds, and other necessaries; to furnish houses for ambassadors at their first arrival; cloths of state, and other furniture, for the lord lieutenant of Ireland, and all his majesty's ambassadors abroad; to provide all robes for foreign knights of the garter, robes for the knights of the garter at home; robes and all other furniture for the officers of the garter; coats for kings, heralds, and pursuivants at arms; robes for the lords of the treasury, and chancellor of the exchequer, &c.; livery for the lord chamberlain, grooms of his majesty's privy chamber, officer of his majesty's robes; for the two chief justices, for all the barons of the exchequer, and several officers of these courts; all liveries for his majesty's servants, as yeomen of the guard, and wardens of the Tower, trumpeters, kettle-drummers, and fifes; the messengers, and all belonging to the stables, as coachmen, footmen, littermen, postilions, and grooms, &c. all the king's coaches, chariots, harnesses, saddles, bits, bridles, &c. the king's watermen, game-keepers, &c. also furniture for the royal yachts, and all rich embroidered tilts, and other furniture for the barges.

Beatson's Political Index, vol. ii.

Besides the master or keeper of the wardrobe, who had a salary of 2000l. there was his deputy, who had 150l. and a comptroller and a patent clerk, each of whom had a salary of 300l. Besides many other inferior officers and servants, who were all sworn servants to the king.

Wardrobe, | Wardship.

There was likewise a removing wardrobe, who had its own set of officers, and standing wardrobe-keepers at St James's, Windsor Castle, Hampton Court, Kensington, and Somerset House; but the whole of the wardrobe establishment was abolished by act of parliament in 1782, and the duty of it in future to be done by the lord chamberlain.

WARDSHIP, in chivalry, one of the incidents of tenure by knight-service. See *FEODAL System*, *KNIGHT Service*, and TENURE.

Upon the death of a tenant, if the heir was under the age of 21, being a male, or 14, being a female, the lord was intitled to the wardship of the heir, and was called the *guardian in chivalry*. This wardship consisted in having the custody of the body and lands of such heir, without any account of the profits, till the age of 21 in males, and 16 in females. For the law supposed the heir-male unable to perform knight-service till 21; but as for the female, she was supposed capable at 14 to marry, and then her husband might perform the service. The lord therefore had no wardship, if at the death of the ancestor the heir-male was of the full age of 21, or the heir-female of 14: yet if she was then under 14, and the lord once had her in ward, he might keep her so till 16, by virtue of the statute of Westminster, 1. 3 Edw. I. c. 22. the two additional years being given by the legislature for no other reason but merely to benefit the lord.

This wardship, so far as it related to land, though it was not nor could be part of the law of feuds, so long as they were arbitrary, temporary, or for life only; yet when they became hereditary, and did consequently often descend upon infants, who by reason of their age could neither perform nor stipulate for the services of the feud, does not seem upon feudal principles to have been unreasonable. For the wardship of the land, or custody of the feud, was retained by the lord, that he might out of the profits thereof provide a fit person to supply the infant's services till he should be of age to perform them himself. And if we consider a feud in its original import, as a stipend, fee, or reward for actual service, it could not be thought hard that the lord should withhold the stipend so long as the service was suspended. Though undoubtedly to our English ancestors, where such stipendary donation was a mere supposition or figment, it carried abundance of hardship; and accordingly it was relieved by the charter of Henry I. which took this custody from the lord, and ordained that the custody, both of the land and the children, should belong to the widow or next of kin. But this noble immunity did not continue many years.

The wardship of the body was a consequence of the wardship of the land; for he who enjoyed the infant's estate was the properest person to educate and maintain him in his infancy: and also in a political view, the lord was most concerned to give his tenant a suitable education, in order to qualify him the better to perform those services which in his maturity he was bound to render.

When the male heir arrived at the age of 21, or the heir female at that of 16, they might sue out their livery or *ousterlemain*; that is the delivery of their lands

out-

Wardship ‖ Warn. out of their guardian's hands. For this they were obliged to pay a fine, namely, half-a-year's profits of the land; though this seems expressly contrary to *magna charta*. However, in consideration of their lands having been so long in ward, they were excused all reliefs, and the king's tenants also all primer seisins. In order to ascertain the profits that arose to the crown by these fruits of tenure, and to grant the heir his livery, the itinerant justices, or justices in eyre, had it formerly in charge to make inquisition concerning them by a jury of the county, commonly called an *inquisitio post mortem;* which was instituted to inquire (at the death of any man of fortune) the value of his estate, the tenure by which it was holden, and who, and of what age, his heir was; thereby to ascertain the relief and value of the primer seisin, or the wardship and livery accruing to the king thereupon. A manner of proceeding that came in process of time to be greatly abused, and at length an intolerable grievance; it being one of the principal accusations against Empson and Dudley, the wicked engines of Henry VII. that by colour of false inquisitions they compelled many persons to sue out livery from the crown, who by no means were tenants thereunto. And afterwards a court of wards and liveries was erected, for conducting the same inquiries in a more solemn and legal manner.

When the heir thus came of full age, provided he held a knight's fee, he was to receive the order of knighthood, and was compelled to take it upon him, or else pay a fine to the king. For in those heroical times no person was qualified for deeds of arms and chivalry who had not received this order, which was conferred with much preparation and solemnity. We may plainly discover the footsteps of a similar custom in what Tacitus relates of the Germans, who, in order to qualify their young men to bear arms, presented them in a full assembly with a shield and lance; which ceremony is supposed to have been the original of the feodal knighthood. This prerogative, of compelling the vassals to be knighted, or to pay a fine, was expressly recognised in parliament by the statute *de militibus*, 1 Edw. II.; was exerted as an expedient for raising money by many of our best princes, particularly by Edw. VI. and Queen Elizabeth; but this was the occasion of heavy murmurs when exerted by Charles I.; among whose many misfortunes it was, that neither himself nor his people seemed able to distinguish between the arbitrary stretch and the legal exertion of prerogative. However, among the other concessions made by that unhappy prince before the fatal recourse to arms, he agreed to divest himself of this undoubted flower of the crown; and it was accordingly abolished by statute 16 Car. I. c. 20.

WARE, a town of Hertfordshire, with a market on Tuesdays, and a fair on the last Tuesday in April, and Tuesday before St Matthew's day (Sept. 21.) for horses and other cattle. It is a large, well frequented town, seated on the river Lea, 21 miles north of London, and contained 3369 inhabitants in 1811. It carries on a great trade in malt and corn, which they are continually sending in large quantities to London. E. Long. 0. 3. N. Lat. 51. 50.

WARN, in *Law*, is to summon a person to appear in a court of justice.

WARNING *of* TENANTS, in *Scots Law*. See LAW, N° clxvii. 16. Warning ‖ Warrant.

WARP, in the manufactures, a name for the threads, whether of silk, wool, linen, hemp, &c. that are extended lengthwise on the weaver's loom; and across which the workman, by means of his shuttle, passes the threads of the woof, to form a cloth, ribband, fustian, or the like.

WARP, a small rope employed occasionally to remove a ship from one place to another, in a port, road, or river. And hence,

To WARP, is to change the situation of a ship, by pulling her from one part of a harbour, &c. to some other, by means of warps, which are attached to buoys; to anchors sunk in the bottom; or to certain stations upon the shore, as posts, rings, trees, &c. The ship is accordingly drawn forwards to those stations, either by pulling on the warps by hand, or by the application of some purchase, as a tackle, windlass, or capstern, upon her deck.

When this operation is performed by the ship's lesser anchors, these machines, together with their warps, are carried out in the boats alternately towards the place where the ship is endeavouring to arrive: so that when she is drawn up close to one anchor, the other is carried out to a competent distance before her, and being sunk, serves to fix the other warp, by which she is farther advanced.

Warping is generally used when the sails are unbent, or when they cannot be successfully employed, which may either arise from the unfavourable state of the wind, the opposition of the tide, or the narrow limits of the channel.

WARRANDICE, in *Scots Law*. See LAW, N° cxliv. 11.

WARRANT, is a power and charge to a constable or other officer to apprehend a person accused of any crime. It may be issued in extraordinary cases by the privy council, or secretaries of state; but most commonly it is issued by justices of the peace. This they may do in any cases where they have a jurisdiction over the offence, in order to compel the person accused to appear before them; for it would be absurd to give them power to examine an offender, unless they had also power to compel him to attend and submit to such examination. And this extends to all treasons, felonies, and breaches of the peace; and also to all such offences as they have power to punish by statute. Before the granting of the warrant, it is fitting to examine upon oath the party requiring it, as well as to ascertain that there is a felony or other crime actually committed, without which no warrant should be granted; as also to prove the cause and probability of suspecting the party against whom the warrant is prayed. Blackst. Comment. vol. iv. p. 290.

This warrant ought to be under the hand and seal of the justice; should set forth the time and place of making, and the cause for which it is made; and should be directed to the constable or other peace officer, or it may be to any private person by name. A general warrant to apprehend all persons suspected, without naming or particularly describing any person in special, is illegal and void for its uncertainty; for it is the duty of the magistrate, and ought not to be left to the officer, to judge of the ground of suspicion. Also a warrant to apprehend

prehend all persons guilty of such a crime, is no legal warrant; for the point upon which its authority rests, is a fact to be decided on a subsequent trial; namely, whether the person apprehended thereupon be guilty or not guilty. When a warrant is received by the officer, he is bound to execute it, so far as the jurisdiction of the magistrate and himself extends. A warrant from any of the justices of the court of king's bench extends over all the kingdom, and is tested or dated *England:* but a warrant of a justice of the peace in one county, must be backed, that is, signed, by a justice of another county, before it can be executed there. And a warrant for apprehending an English or a Scotch offender, may be indorsed in the opposite kingdom, and the offender carried back to that part of the united kingdom in which the offence was committed.

WARRANTY, Warrantia, in *Law*, a promise, or covenant by deed, made by the bargainer for himself and his heirs, to warrant and secure the bargainee and his heirs, against all men, for enjoying the thing agreed on or granted between them.

WARREN, Sir Peter, an admiral, distinguished by his virtue, learning, and undaunted courage, was descended from an ancient family in Ireland, and received a suitable education to qualify him for a command in the royal navy, in which he served for several years with great reputation; but the transaction which placed his great abilities in their full light, was the taking of Louisbourg in the year 1745, when he was appointed commodore of the British squadron sent on that service. He joined the fleet of transports from Boston in Canso bay on the 25th of April, having under his command the Superb of 60, and the Launceston and Eltham of 40 guns; he was afterwards joined by several other men of war sent from England, and took possession of Louisbourg on the 17th of June. The French, exasperated at this loss, were constantly on the watch to retake it; and in 1747 fitted out a large fleet for that purpose, and at the same time another squadron to prosecute their success in the East Indies. These squadrons sailed at the same time; but the views of the French were rendered abortive by the gallant Admiral Anson and Sir Peter Warren, who had been created rear-admiral, who with a large fleet of ships fell in with the French, defeated the whole fleet, and took the greatest part of the men of war. This was the last service Sir Peter rendered to his country as a commander in the British fleet; for a peace being concluded in the succeeding year, the fleet was laid up in the several harbours.

He was now chosen one of the representatives in parliament for Westminster; and in the midst of his popularity he paid a visit to Ireland, his native country, where he died of an inflammatory fever in 1752, sincerely lamented by all ranks of people; and an elegant monument of white marble was erected to his memory in Westminster abbey.

Warren, is a franchise or place privileged by prescription or grant from the king, for the keeping of beasts and fowls of the warren; which are hares and coneys, partridges, pheasants, and some add quails, woodcocks, and water-fowl, &c. These being *feræ naturæ*, every one had a natural right to kill as he could: but upon the introduction of the forest laws at the Norman conquest, these animals being looked upon as royal game, and the sole property of our savage monarchs, this franchise of free-warren was invented to protect them, by giving the grantee a sole and exclusive power of killing such game, so far as his warren extended, on condition of his preventing other persons. A man therefore that has the franchise of warren, is in reality no more than a royal game-keeper: but no man, not even a lord of a manor, could by common law justify sporting on another's soil, or even on his own, unless he had the liberty of free-warren. This franchise is almost fallen into disregard since the new statutes for preserving the game; the name being now chiefly preserved in grounds that are set apart for breeding hares and rabbits. There are many instances of keen sportsmen in ancient times, who have sold their estates, and reserved the free-warren, or right of killing game, to themselves: by which means it comes to pass that a man and his heirs have sometimes free-warren over another's ground.

A warren may lie open; and there is no necessity of inclosing it as there is of a park. If any person offend in a free warren, he is punishable by the common law, and by statute 21 Edw. III. And if any one enter wrongfully into any warren, and chase, take, or kill, any coneys without the consent of the owner, he shall forfeit treble damage, and suffer three months imprisonment, &c. by 22 and 23 Car. II. c. 25. When coneys are on the soil of the party, he hath a property in them by reason of the possession, and action lies for killing them; but if they run out of the warren and eat up a neighbour's corn, the owner of the land may kill them, and no action will lie.

WARSAW, a large city, capital of the province of Masovia, and of the ancient, as well as the revived kingdom of Poland. It is built partly in a plain, and partly on a gentle ascent rising from the banks of the Vistula, which is about as broad as the Thames at Westminster, but very shallow in summer. This city and its suburbs occupy a vast extent of ground, and contained in 1797, 70,000 inhabitants, among whom is a great number of foreigners. The whole has a melancholy appearance, exhibiting the strong contrast of wealth and poverty, luxury and distress. The streets are spacious, but ill paved; the churches and public buildings, and the palaces of the nobility are numerous and splendid; but the greatest part of the houses are mean and ill constructed wooden hovels.—At the final division of Poland in 1795, Warsaw fell to the share of Prussia, but was ceded by her to Bonaparte at the peace of Tilsit 1807; and on the overthrow of the French power, was assigned to Russia, with the territory named the duchy of Warsaw, which has since taken the name of the kingdom of Poland. E. Long. 21. 6. N. Lat. 52. 14.

WARWICK, the capital of Warwickshire in England, and from which this county derives its name. It is very ancient, and supposed by Camden to be the place called by the Romans *Præsidium*, where the Dalmatian horse were posted. It stands on a rock of freestone, of which all the public edifices in the town are built. At the Norman invasion it was a considerable place; and had many burgesses, of whom 12 were obliged by their tenure to accompany the king in his wars. It is supplied with water brought in pipes from springs half a mile from the town, besides what it derives from the wells within it made in the rock: and it is easily kept clean, by being situated upon a declivity. Four streets, from the four cardinal points of the compass, meet in the centre of the town. The principal public buildings are

St

Warwick, Warwickshire.

St Mary's, a very stately edifice, an hospital, a town-house of freestone, three charity schools, and a noble bridge over the Avon. It has had several charters; but is governed at present by a mayor, 12 brethren, 24 burgesses, &c. It contained 6497 inhabitants in 1811; and gives title of earl to the family of the Grevilles. W. Long. 1. 36. N. Lat. 52. 20.

WARWICKSHIRE, a county of England, 47 miles in length, by 30 in breadth. It is bounded at its northern extremity by a point of Derbyshire; on the north-west by Staffordshire; on the north-east by Leicestershire; on the east by Northamptonshire; on the south-west by Gloucestershire, and on the south-east by Oxfordshire. It is situated partly in the diocese of Litchfield and Coventry, and partly in that of Worcester; it contains four hundreds, and one liberty, one city, 12 market towns, 158 parishes; sends six members to parliament, and the population in 1811 amounted to 228,735. The air is mild, pleasant, and healthy. The river Avon divides the north part of it, or the Woodlands, from the south, called the Feldon; and the soil of both is rich and fertile. Its productions are corn, malt, wood, wool, cheese, coal, iron, and limestone. The chief rivers of this county are the Avon, Tame, and Arrow. Warwick is the capital; but Birmingham is far superior to it in respect of trade and manufactures, and even to any other town in England.

Birmingham, in this county, of which the account given in the order of the alphabet is very deficient, is one of the most remarkable towns in England, or perhaps in Europe, for the extent, variety, elegance, and utility of its manufactures. This town was little distinguished previous to the reign of Charles II. but since that period it continued to increase in extent and importance. In the year 1700, the number of streets in Birmingham was only 30; they are now nearly 250. In the year 1779 there were only three houses on a particular spot, which in 1791 contained 833.

Birmingham owes its prosperity and population to its manufactures, which are in a great measure the consequence of its vicinity to coal, aided by the spirited and industrious exertions of a few individuals. It has been stated, and no doubt with great truth, that its prosperity is in no small degree indebted to its exemption from the restrictions of borough and corporate laws. To give some notion of the progress and extent of the manufactures of this place, it may be mentioned that the late Mr Taylor, who introducted gilt buttons, japanned, gilt, and painted snuff-boxes, with various articles of manufacture in enamel, died in 1775, at the age of 64, having amassed a fortune of 200,000l. In painting snuff-boxes at so low a rate as one farthing each, one man could gain 3l. 10s. per week. The weekly produce of Mr Taylor's manufacture of buttons amounted to 800l. beside many other valuable and curious productions.

The manufactory of Messrs Boulton and Watt, which for its extent, variety, and importance, stands unrivalled in Europe, has been already noticed under the word SOHO. The new coinage of copper, which is so often deservedly admired, and the re-stamped dollars, are the productions of the Soho manufactory. The first coining mill was erected at Soho in 1783. It is now so much improved, that eight machines driven by the steam engine, are going on at the same time. Each of those machines strikes from 70 to 84 pieces of the size of a guinea per minute, and hence the whole eight machines work off in one hour between 30,000 and 40,000 coins. The different processes of the machinery are, 1. Rolling the masses of copper into sheets. 2. Rolling them through cylindrical steel rollers. 3. Clipping the pieces of copper for the dye. 4. Shaking the coin in bags. 5. Striking both sides of the coin, and then milling it; after which it is displaced, and another is introduced, to be subjected to the same operation. But the most extraordinary contrivance of this ingenious machinery is, that a precise account of every coin which passes through it is regularly kept, so that it is impossible to practise fraud.

5

Warwickshire, Washing.

Beside the branches of industry already mentioned, there are manufactories of guns, bayonets, and swords, of sporting guns, of whips, of japan ware, of numerous works in brass and steel, both for ornament and use, and at one time of leather to a considerable extent.

Birmingham contains a museum of natural and artificial curiosities, a handsome theatre, rebuilt since 1791, several churches belonging to the establishment, various dissenting meeting houses, and a number of charitable establishments. By means of canals Birmingham has the advantage of easy communication with almost every part of the kingdom. See WARWICKSHIRE, SUPPLEMENT.

WASH, among distillers, the fermentable liquor used by malt distillers. See BREWERY.

WASHING, in *Painting*, is when a design, drawn with a pen or crayon, has some one colour laid over it with a pencil, as Indian ink, bistre, or the like, to make it appear the more natural, by adding the shadow of prominences, apertures, &c. and by imitating the particular matters whereof the thing is supposed to consist.

Thus a pale red is employed to imitate brick and tile; a pale Indian blue, to imitate water and slate; green, for trees and meadows; saffron or French berries, for gold or brass; and several colours for marbles.

WASHING of Ores, the separation of the ores of metals, by means of water, from earths and stones, which would otherwise render it difficult of fusion. See ORES, *Reduction of*.

WASHINGTON, a city of North America, and now the metropolis of the United States. It is seated at the junction of the rivers Potomac and the Eastern Branch, extending about four miles up each, including a tract of territory scarcely to be exceeded, in point of convenience, salubrity, and beauty, by any in the world. This territory, which is called *Columbia*, lies partly in Virginia, and partly in Maryland, and was ceded by those two states to the Republic; it was placed under the immediate government of Congress, and established as the seat of government in the year 1800. It is divided into squares or grand divisions, by streets running due north and south, and east and west, which form the ground-work of the plan. However, from the Capitol, the president's house, and some of the important areas in the city, run diagonal streets, from one material object to another, which not only produce a variety of charming prospects, but remove the insipid sameness which renders some other great cities unpleasing. The great leading streets are all 160 feet wide, including a pavement of 10 feet, and a gravel walk of 30 feet planted with trees on each side, which will leave 80 feet of paved street for carriages. The rest of the streets are in general

Washington.

general 110 feet wide, with a few only 90 feet, except North, South, and East Capitol Streets, which are 160 feet. The diagonal streets are named after the respective states composing the Union, while those running north and south are, from the Capitol eastward, named *East First Street, East Second Street*, &c. The squares or divisions of the city amount to 1150. The rectangular squares generally contain from three to six acres, and are divided into lots of from 40 to 80 feet in front, and their depth from about 110 to 300 feet, according to the size of the square. All the houses must be of brick or stone. The Capitol (or house for the legislative bodies) is situated upon the most beautiful eminence in the city, about a mile from the Eastern Branch, and not much more from the Potomac, commanding a full view of every part of the city, as well as a considerable extent of the country around. It is not yet finished (1818), but is allowed to be a magnificent structure. Its front extends 650 feet in length, with a colonnade of 260 feet. The height of the dome is 150 feet. The president's house stands upon a rising ground, not far from the banks of the Potomac, possessing also a delightful prospect. By the Potomac, vessels of considerable burden come out to Washington; and, by means of short canals at the falls, this river with its branches is open for some hundred miles above the town to boat navigation. Washington, however, has not advanced so rapidly as was expected. In 1818, according to Mr Fearon, it contained only about 9000 inhabitants, or 15,000, including Georgetown. The lines which have received the name of streets, are in general only marked by a slight trace, or by rows of poplars; and altogether it presents the appearance of straggling houses irregularly scattered over an open field.

In 1814 Washington was taken by a British force of 6500 men; who abandoned the town the following day, after having set fire to the capitol, president's house, navy-yard, and wooden-bridge over the river. The loss sustained by the Americans in the buccaneering expedition was estimated at 1,031,000 dollars.

WASHINGTON, *George*, the celebrated commander of the American army, and the first president of the United States, after their separation from the mother-country, was born in the year 1732, in the parish of Washington in Virginia. He was descended from an ancient family in Cheshire, of which a branch was established in Virginia about the middle of the 17th century. Little is known concerning his education, or the early years of his life. Before he was 20 years of age, he was appointed a major in the colonial militia, and had then an opportunity of displaying those military and political talents which have since rendered his name so famous throughout the world. In the disputes which arose between the French and English officers, about settling the limits of Canada and Louisiana, Major Washington was employed by the governor of Virginia as a negociator, and he succeeded in preventing a threatened invasion of the English frontiers by the French and their Indian allies; but, in the following year, when hostilities seemed inevitable, he was appointed lieutenant-colonel, and soon after to the command of a regiment raised by the colony for its own defence. In 1755, Colonel Washington served as a volunteer in the unfortunate expedition of General Braddock, and in that expedition, which was attended with great difficulty, he exhibited so much calmness and intrepidity, that the utmost confidence was reposed in his talents, and perfect obedience paid to his commands by the whole army. After having been employed in a different and more successful expedition, to the river Ohio, the state of his health required him, about the year 1758, to resign his military situation; and in the sixteen following years, during which period he married Mrs Custis, a Virginian lady, of amiable character and respectable connections, it would appear that he resided chiefly at his beautiful seat of Mount Vernon, and was occupied in the cultivation of his estate.

When the disaffection of the Americans to the British government had become pretty general, and had at last spread to the colony of Virginia, Colonel Washington was appointed a delegate from that state to the congress which met at Philadelphia on the 26th October 1774, and soon after he was appointed to the command of the American army, which had assembled in the provinces of New England. The conduct of Washington during the whole of the war, as well as during the period that he presided in the government of the United States, has been so fully detailed in another part of this work, that it would be unnecessary repetition, even to give a general outline of it in this place. See AMERICA.

Washington resigned the presidency in 1796, after having published a farewell address to his countrymen. This address was remarkably distinguished for the simplicity and ingenuousness, moderation and sobriety, the good sense, prudence and honesty, as well as sincere affection for his country and for mankind, which the author of it had always exhibited; it seemed to be a perfect picture of his whole life. From the time of his resignation till the month of July 1798, he lived in retirement at his seat of Mount Vernon. At this period, when the unprincipled actors in the French revolution were carrying on their wicked machinations in every part of the world to which their influence extended, the United States resolved to arm by land and sea in their own defence. General Washington was called from his retirement, and the command of the army was bestowed upon him. This he accepted, because he considered, as he himself expressed it, "every thing we hold dear and sacred was seriously threatened, although he had flattered himself that he had quitted for ever the boundless field of public action, incessant trouble, and high responsibility, in which he had long acted so conspicuous a part." In this situation he continued during the remaining short period of his life. On Thursday the 12th of December 1799, he was seized with an inflammation in the throat, and was carried off on Saturday the 14th of the same month, in the 68th year of his age. In his dying moments he displayed the same calmness, simplicity, and regularity, which had uniformly marked his conduct through life. He saw the approaches of death without fear; and he met them without parade. Even the perfectly well ordered state of the minutest particulars of his private business bears the stamp of that constant authority of prudence and practical reason over his actions which was always the most prominent feature of his character.

WASHINGTON is the name of many counties, towns, and villages in the American states; a circumstance which affords a striking proof in what degree of esteem

Washington || Watch.

and veneration the name from which they are derived was held by the inhabitants of the new world.

WASP. See VESPA, ENTOMOLOGY *Index*.

WATCH, in the art of war, a number of men posted at any passage, or a company of the guards who go on the patrole.

WATCH, in the navy, the space of time wherein one division of a ship's crew remains upon deck, to perform the necessary services, whilst the rest are relieved from duty, either when the vessel is under sail or at anchor.

The length of the sea-watch is not equal in the shipping of different nations. It is always kept four hours by our British seamen, if we except the dog-watch, between four and eight in the evening, that contains two reliefs, each of which are only two hours on deck. The intent of this is to change the period of the night-watch every 24 hours; so that the party watching from eight till 12 in one night, shall watch from midnight till four in the morning on the succeeding one. In France the duration of the watch is extremely different, being in some places six hours, and in others seven or eight; and in Turkey and Barbary it is usually five or six hours.

A ship's company is usually classed into two parties; one of which is called the *starboard* and the other the *larboard* watch. It is, however, occasionally separated into three divisions, as in a road or in particular voyages.

In a ship of war the watch is generally commanded by a lieutenant, and in merchant ships by one of the mates; so that if there are four mates in the latter, there are two in each watch; the first and third being in the larboard, and the second and fourth in the starboard watch: but in the navy, the officers who command the watch usually divide themselves into three parties, in order to lighten their duty.

WATCH, is also used for a small portable movement, or machine, for the measuring of time; having its motion regulated by a spiral spring.

Watches, strictly taken, are all such movements as show the parts of time; as clocks are such as publish it, by striking on a bell, &c. But commonly the name *watch* is appropriated to such as are carried in the pocket; and *clock* to the large movements, whether they strike the hour or not. See CLOCK.

The invention of spring or pocket watches belongs to the present age. It is true, we find mention made of a watch presented to Charles V. in the history of that prince: but this, in all probability, was no more than a kind of clock to be set on a table, some resemblance whereof we have still remaining in the ancient pieces made before the year 1670. There was also a story of a watch having been discovered in Scotland belonging to King Robert Bruce; but this we believe has turned out altogether apocryphal. The glory of this very useful invention lies between Dr Hooke and M. Huygens; but to which of them it properly belongs, has been greatly disputed; the English ascribing it to the former, and the French, Dutch, &c. to the latter. Mr Derham in his Artificial Clockmaker, says roundly, that Dr Hooke was the inventor; and adds, that he contrived various ways of regulation. One way was with a loadstone: Another with a tender straight spring, one end whereof played backwards and forwards with the balance; so that the balance was to the spring as the bob to a pendulum, and the spring as the rod thereof: A third method was with two balances, of which there were divers sorts; some having a spiral spring to the balance for a regulator, and others without. But the way that prevailed, and which continues in mode, was with one balance, and one spring running round the upper part of the verge thereof: Though this has a disadvantage, which those with two springs, &c. were free from; in that a sudden jerk, or confused shake, will alter its vibrations, and put it in an unusual hurry.

The time of these inventions was about the year 1658; as appears among other evidences, from an inscription on one of the double balance watches presented to King Charles II. viz. Rob. Hooke *inven.* 1658. T. Tompion *fecit*, 1675. The invention presently got into reputation, both at home and abroad; and two of them were sent for by the dauphin of France. Soon after this M. Huygens's watch with a spiral spring got abroad, and made a great noise in England, as if the longitude could be found by it. It is certain, however, that his invention was later than the year 1673, when his book *de Horol. Oscillat.* was published; wherein he has not one word of this, though he has of several other contrivances in the same way.

One of these the lord Brouncker sent for out of France, where M. Huygens had got a patent for them. This watch agreed with Dr Hooke's in the application of the spring to the balance; only M. Huygens's had a longer spiral spring, and the pulses and beats were much slower. The balance, instead of turning quite round, as Dr Hooke's, turns several rounds every vibration.

Mr Derham suggests, that he has reason to doubt M. Huygens's fancy first was set to work by some intelligence he might have of Dr Hooke's invention from Mr Oldenburgh, or some other of his correspondents in England; and this, notwithstanding Mr Oldenburgh's attempt to vindicate himself in the Philosophical Transactions, appears to be the truth. Huygens invented divers other kinds of watches, some of them without any string or chain at all; which he called, particularly, *pendulum watches.*

Striking WATCHES are such as, besides the proper watch-part for measuring of time, have a clock part for striking the hours, &c.

Repeating WATCHES, are such as by pulling a string, &c. repeat the hour, quarter, or minute, at any time of the day or night.—This repetition was the invention of Mr Barlow, and first put in practice by him in larger movements or clocks about the year 1676. The contrivance immediately set the other artists to work, who soon contrived divers ways of effecting the same. But its application to pocket-watches was not known before King James II.'s reign; when the ingenious inventor above mentioned, having directed Mr Thompson to make a repeating watch, was soliciting a patent for the same. The talk of a patent engaged Mr Quare to resume the thoughts of a like contrivance, which he had had in view some years before: he now effected it; and being pressed to endeavour to prevent Mr Barlow's patent, a watch of each kind was produced before the King and council; upon trial of which, the preference was given to Mr Quare's. The difference between them was, that Barlow's was made to repeat by pushing in two pieces on each side the watch-box; one of which repeated the hour, and the other the quarter: whereas Quare's was made to repeat by a pin that struck out near the pendant, which being thrust in (as now

Watch.

now it is done by thrusting in the pendant itself), repeated both the hour and quarter with the same thrust.

Of the Mechanism of a WATCH, properly so called. Watches, as well as clocks, are composed of wheels and pinions, and a regulator to direct the quickness or slowness of the wheels, and of a spring which communicates motion to the whole machine. But the regulator and spring of a watch are vastly inferior to the weight and pendulum of a clock, neither of which can be employed in watches. In place of a pendulum, therefore, we are obliged to use a balance (fig. 1.) to regulate the motion of a watch; and a spring (fig. 2.) which serves in place of a weight, to give motion to the wheels and balance.

Plate DLXXI. Fig. 1. Fig. 2.

The wheels of a watch, like those of a clock, are placed in a frame formed of two plates and four pillars. Fig. 3. represents the inside of a watch, after the plate (fig. 4.) is taken off. A is the barrel which contains the spring (fig. 2.); the chain is rolled about the barrel, with one end of it fixed to the barrel A (fig. 5.), and the other to the fusee B.

Fig. 3. Fig. 4. Fig. 5.

When a watch is wound up, the chain which was upon the barrel winds about the fusee, and by this means the spring is stretched; for the interior end of the spring is fixed by a hook to the immoveable axis, about which the barrel revolves; the exterior end of the spring is fixed to the inside of the barrel, which turns upon an axis. It is therefore easy to perceive how the spring extends itself, and how its elasticity forces the barrel to turn round, and consequently obliges the chain which is upon the fusee to unfold and turn the fusee; the motion of the fusee is communicated to the wheel C (fig. 5.); then, by means of the teeth, to the pinion *c*, which carries the wheel D; then to the piston *d*, which carries the wheel E: then to the pinion *e*, which carries the wheel F; then to the point *f*, upon which is the balance-wheel G, whose pivot runs in the pieces A called the *potance*, and B called a *follower*, which are fixed on the plate fig. 4. This plate, of which only a part is represented, is applied to that of fig. 3. in such a manner that the pivots of the wheels enter into holes made in the plate fig. 3. Thus the impressed force of the spring is communicated to the wheels: and the pinion *f* being then connected to the wheel F, obliges it to turn (fig. 5.). This wheel acts upon the palettes of the verge, 1, 2, (fig. 1.), the axis of which carries the balance HH, (fig. 1.). The pivot I, in the end of the verge, enters into the hole *c* in the potance A (fig. 4.). In this figure the palettes are represented; but the balance is on the other side of the plates, as may be seen in fig. 6. The pivot 3 of the balance enters into a hole of the cock BC (fig. 7.), a perspective view of which is represented in fig. 8. Thus the balance turns between the cock and the potance *c* (fig. 4.), as in a kind of cage. The action of the balance wheel upon the palettes 1, 2, (fig. 1.), is the same with what we have described with regard to the same wheel in the clock; *i. e.* in a watch, the balance-wheel obliges the balance to vibrate backwards and forwards like a pendulum. At each vibration of the balance a palette allows a tooth of the balance-wheel to escape; so that the quickness of the motion of the wheels is entirely determined by the quickness of the vibrations of the balance; and these vibrations of the balance and motion of the wheels are produced by the action of the spring.

Fig. 6. Fig. 7. Fig. 8.

But the quickness or slowness of the vibrations of the balance depend not solely upon the action of the great spring, but chiefly upon the action of the spring *a*, *b*, *c*, called *the spiral spring* (fig. 9.), situated under the balance H, and represented in perspective (fig. 6.). The exterior end of the spiral is fixed to the pin *a*, (fig. 9.). This pin is applied near the plate in *a*, (fig. 6.); the interior end of the spiral is fixed by a peg to the centre of the balance. Hence if the balance is turned upon itself, the plates remaining immoveable, the spring will extend itself, and make the balance perform one revolution. Now, after the spiral is thus extended, if the balance be left to itself, the elasticity of the spiral will bring back the balance, and in this manner the alternate vibrations of the balance are produced.

Fig. 9.

In fig. 5. all the wheels above described are represented in such a manner, that you may easily perceive at first sight how the motion is communicated from the barrel to the balance.

In fig. 10. are represented the wheels under the dial-plate by which the hands are moved. The pinion *a* is adjusted to the force of the prolonged pivot of the wheel D (fig. 5.), and is called a *cannon pinion*. This wheel revolves in an hour. The end of the axis of the pinion *a*, upon which the minute-hand is fixed, is square; the pinion (fig. 10.) is indented into the wheel *b*, which is carried by the pinion *a*. Fig. 11. is a wheel fixed upon a barrel, into the cavity of which the pinion *a* enters, and upon which it turns freely. This wheel revolves in 12 hours, and carries along with it the hour-hand. For a full account of the principles upon which watches and all time-keepers are constructed, we must refer our readers to a short treatise, entitled *Thoughts on the Means of improving Watches*, by Thomas Mudge.

Fig. 10. Fig. 11.

WATCH-Glasses, in a ship, are glasses employed to measure the period of the watch, or to divide it into any number of equal parts, as hours, half-hours, &c. so that the several stations therein may be regularly kept and relieved, as at the helm, pump, look-out, &c.

WATCH-Work. There is one part of the movements of clocks and watches of which we have yet given no particular account. This is the method of applying the maintaining power of the wheels to the regulator of the motions, so as not to injure its power of regulation. This part of the construction is called SCAPEMENT, and falls to be described under the present article, to which we have referred from SCAPEMENT.

1 Objects of scapements.

The motions of a clock or watch are regulated by a pendulum or balance, without which check the wheels impelled by the weight in the clock, or spring in the watch, would run round with a rapidly accelerating motion, till this should be rendered uniform by friction, and the resistance of the air. If, however, a pendulum or balance be put in the way of this motion, in such a manner that only one tooth of a wheel can pass, the revolution of the wheels will depend on the vibration of the pendulum or balance.

We cannot here enter on an historical account of the improvements that have been made on the regulating powers of clocks and watches, nor can we detail the principles on which their action depends. It will be sufficient here to notice the most simple construction of scapements, and then to describe two or three of the most improved constructions that have been applied to time-keepers.

We know that the motion of a pendulum or balance

Watch.

is alternate, while the pressure of the wheels is constantly exerted in the same direction. Hence it is evident that some means must be employed to accommodate these different motions to each other. Now, when a tooth of the wheel has given the pendulum or balance a motion in one direction, it must quit it, that the pendulum or balance may receive an impulsion in the opposite direction. This *escape* of the tooth has given rise to the term *scapement*.

2
Best ordinary scapement for clocks.
Fig. 12.

The ordinary scapement is extremely simple, and may be thus illustrated. Let $x\,y$, fig. 12. Plate DLXXI. represent a horizontal axis, to which the pendulum p is attached by a slender rod. This axis has two leaves c and d, one near each end, and not in the same plane, but so that when the pendulum hangs perpendicularly at rest, c spreads a few degrees to the right, and d as much to the left. These are called the pallets. Let $a\,f\,b$ represent a wheel, turning on a perpendicular axis $e\,o$ in the order $a\,f\,e\,b$. The teeth of this wheel are in the form of those of a saw, leaning forward in the direction of the rim's motion. This wheel is usually called the crown-wheel, or in watches the balance-wheel. See CLOCK and WATCH. It generally contains an odd number of teeth. In the figure the pendulum is represented at the extremity of its excursion towards the right, the tooth a having just escaped from the pallet c, and b having just dropt on d. Now it is evident that while the pendulum is moving to the left, in the arch $p\,g$, the tooth b still presses on the pallet d, and thus accelerates the pendulum, both in its descent along $p\,h$, and its ascent up $h\,g$, and that when d, by turning round the axis $x\,y$, raises its point above the plane of the wheel, the tooth b escapes from it, and i drops on c, now nearly perpendicular. Thus c is pressed to the right, and the motion of the pendulum along $g\,p$ is accelerated. Again, while the pendulum hangs perpendicularly in the line $x\,h$, the tooth b, by pressing on d, will force the pendulum to the left, in proportion to its lightness, and if it be not too heavy, will force it so far from the perpendicular, that b will escape, and i will catch on c, and force the pendulum back to p, when the same motion will be repeated. This effect will be more remarkable, if the rod of the pendulum be continued through $x\,y$, and have a ball q on the other end, to balance p. When b escapes from d, the balls are moving with a certain velocity and momentum, and in this condition the balance is checked when i catches on c. It is not, however, instantly stopped, but continues to move a little to the left, and i is forced a little backward by the pallet c. It cannot make its escape over the top of the tooth i, as all the momentum of the balance was generated by the force of b, and i is of equal power. Besides, when i catches on c, and the motion of c to the left continues, the lower point of c is applied to the face of i, which now acts on the balance by a long lever, soon stops its motion in that direction, and continuing to press on c, urges the balance in the opposite direction. It is easy to see that the motion of the wheel here must be hobbling and unequal, which has given to this scapement the name of the *recoiling* scapement.

3
Vibrations of pendulums are isochronous.

In considering the utility of the following improved scapement for clocks, we must keep in mind the following proposition, which, after the above illustration, scarcely requires any direct proof. It is, that the natural vibrations of a pendulum are *isochronous*, or are performed in equal times. The great object of the scapement is to preserve this isochronous motion of the pendulum.

4
Cumming's scapement for clocks.

As the defect of the recoiling scapement was long apparent, several ingenious artists attempted to substitute in its place a scapement that should produce a more regular and uniform motion. Of these, the scapement contrived by Mr Cumming appears to be one of the most ingenious in its construction, and most perfect in its operation. The following construction is similar to that of Mr Cumming, but rendered rather less complex for the purpose of shortening the description.

Fig. 13.

Let ABC, fig. 13. represent a portion of the swing wheel, of which O is the centre, and A one of the teeth; Z is the centre of the crutch, pallets, and pendulum. The crutch is represented of the form of the letter A, having in the circular cross piece a slit $i\,k$, also circular, Z being the centre. The arm ZF forms the first detent, and the tooth A is represented as locked on it at F. D is the first pallet on the end of the arm Zd moveable round the same centre with the detents, but independent of them. The arm $d\,e$ to which the pallet D is attached, lies wholly behind the arm ZF of the detent, being fixed to a round piece of brass $e\,f\,g$, having pivots turning concentric with the axis of the pendulum. To the same piece of brass is fixed the horizontal arm e H, carrying to its extremity the ball H, of such size, that the action of the tooth A on the pallet D is just able to raise it up to the position here drawn. ZPp represents the fork, or pendulum rod, behind both detent and pallet. A pin p projects forward, coming through the slit $i\,k$, without touching either margin of it. Attached to the fork is the arm $m\,n$, of such length that, when the pendulum rod is perpendicular, the angular distance of $n\,q$ from the rod $e\,q$ H is just equal to the angular distance of the left side of the pin p from the left end i of the slit $i\,k$.

Now, the natural position of the pallet D is at δ, represented by the dotted lines, resting on the back of the detent F. It is naturally brought into this position by its own weight, and still more by the weight of the ball H. The pallet D, being set on the foreside of the arm at Z, comes into the same plane with the detent F and the swing-wheel, though here represented in a different position. The tooth C of the wheel is supposed to have escaped from the second pallet, on which the tooth A immediately seizes the pallet D, situated at δ, forces it out, and then rests on the detent F, the pallet D leaning on the tip of the tooth. After the escape of C, the pendulum, moving down the arch of semivibration, is represented as having attained the vertical position. Proceeding still to the left, the pin p reaches the extremity i of the slit $i\,k$; and, at the same instant, the arm n touches the rod e H in q. The pendulum proceeding a hairsbreadth further, withdraws the detent F from the tooth, which now even pushes off the detent, by acting on the inclining face of it. The wheel being now unlocked, the tooth following C on the other side acts on its pallet, pushes it off, and rests on its detent, which has been rapidly brought into a proper position by the action of A on the inclining face of F. By a similar action of C on its detent at the moment of escape, F was brought into a position proper for the wheels being locked by the tooth A. As the pendulum still goes on, the ball H, and pallet connected with it, are carried by the arm $m\,n$, and before the pin p again reaches the end

Watch.

end of the slit, which had been suddenly withdrawn by the action of A on F, the pendulum comes to rest. It now returns towards the right, loaded with the ball H on the left, and thus the motion lost during the last vibration is restored. When the pin *p*, by its motion to the right, reaches the end *k* of *i k*, the wheel on the right side is unlocked, and at the same instant the weight H being raised from the pendulum by the action of a tooth like B on the pallet D, ceases to act.

In this scapement, both pallets and detents are detached from the pendulum, except in the moment of unlocking the wheel, so that, except during this short interval, the pendulum may be said to be free during its whole vibration, and of course its motion must be more equable and undisturbed.

5 Scapements for watches.

The constructing of a proper scapement for watches requires peculiar delicacy, owing to the small size of the machine, from which the error of $\frac{1}{100}$ of an inch has as much effect as the error of a whole inch in a common clock. From the necessary lightness of the balance, too, it is extremely difficult to accumulate a sufficient quantity of regulating power. This can be done only by giving the balance a great velocity, which is effected by concentrating as much as possible of its weight in the rim, and making its vibrations very wide. The balance rim of a tolerable watch should pass through at least ten inches in every second.

6 Vibrations of a balance are isochronous.

In considering the most proper scapements for watches, we may assume the following principle, viz. that the oscillations of a balance urged by its spring, and undisturbed by extraneous forces, are isochroneus.

7 Best ordinary scapement for watches. Fig. 14.

In ordinary pocket watches, the common recoiling scapement of clocks is still employed, and answers the common purposes of a watch tolerably well, so that, if properly executed, a good ordinary watch will keep time within a minute in the day. These watches, however, are subject to great variation in their rate of going, from any change in the power of the wheels.

The following is considered as the best construction of the common watch scapement, and is represented by fig. 14. as it appears when looking straight down on the end of the balance arbor. C marks the centre of the balance and verge; CA represents the upper pallet, or that next the balance, and CB the lower pallet; F and D are two teeth of the crown wheel, moving from left to right; E, G, are two teeth in the lower part, moving from right to left. The tooth D appears as having just escaped from the point of CA, and the tooth E as having just come in contact with CB. In practice, the scapement should not be quite so close, as by a small inequality of the teeth, D might be kept from escaping at all. The following are thought the best proportions: The distance between the front of the teeth (that is, of G, F, E, D), and the axis C of the balance, is $\frac{1}{4}$ of FA, the distance between the points of the teeth. The length CA, CB of the pallets is $\frac{1}{3}$ of the same degrees, and the front DH or FK of the teeth makes an angle of 25° with the axis of the crown wheel. The sloping side of the tooth must be of an epicycloidal form, suited to the relative motion of the tooth and pallet.

It appears from these proportions, that by the action of the tooth D, the pallet A can *throw out* till it reach *a*, 120° from CL, the line of the crown-wheel axis. To this if we add BCA=95°, we shall have LC *a*=120°. Again, B will throw out as far on the other side. Now, if from 240°, the sum of the extent of vibration of both pallets, we take 95° the angle of the pallets, the remainder 145° will express the greatest vibration which the balance can make, without striking the front of the teeth. From several causes, however, this measure is too great, and 120° is reckoned a sufficient vibration in the best ordinary scapement.

8 Graham's horizontal scapement. Fig. 15. and 16.

Of the improvements on the scapements of watches, one of the most important is that by Mr George Graham, which we shall proceed to describe. DE, fig. 15. represents part of the rim of the balance wheel; A and C, two of its teeth with their faces *b e* formed into planes, inclined to the circumference of the wheel in an angle of about 15°, so that the length *b e* of the face may be nearly quadruple of its height *e m*. Let a circular arch ABC be described round the centre of the wheel, and through the middle of the faces of the teeth. The axis of the balance will pass through some point B of this arch, and the mean circumference of the teeth may be said to pass through the centre of the verge. On this axis is fixed a portion of a thin hollow cylinder *bcd*, made of hard tempered steel, or of some hard and tough stone, such as ruby or sapphire. By this construction the portion of the cylinder occupies 210° of the circumference. The edge *b*, to which the tooth approaches from without, is rounded off on both angles. The other edge *d* is formed into a plane, inclined to the radius about 30°. Now, suppose the wheel pressed forward in the direction AC, the point *b* of the tooth, touching the rounded edge, will push it outwards, turning round the balance in the direction *b c d*. The heel *e* of the tooth will escape from this edge when it is in the position *h*, and *e* is in the position *f*. The point *b* of the tooth will now be at *d*, but the edge of the cylinder will be at *i*. The tooth therefore rests in the inside of the cylinder, while the balance continues its vibration a little way, in consequence of the impulse it has received from the action of the inclined plane. When this vibration is ended, by the opposition of the balance spring, the balance will return, and the tooth now in the position B, rubbing on the inside of the cylinder, the balance comes back into its natural position *b c d*, with an accelerated motion by the action of its spring, and would of itself vibrate as far as the other side. It is, however, assisted again by the tooth, which presses on the edge *d*, pushes it aside till it attain the position *k*, when the tooth entirely escapes from the cylinder. At this instant the other edge of the cylinder, having attained the position *l*, is in the way of the next tooth, which is now in the position A, while the balance continues its vibration, the tooth resting and rubbing on the outside of the cylinder. When this vibration is finished, the balance, by the action of the spring, resumes its first motion, and as soon as the balance gets into its natural position, the tooth begins to act on the edge *b*, pushes it aside, escapes from it, and drops as before in the inside of the cylinder. In this construction the arch of action or scapement is 30°= twice the angle which the face of a tooth makes with the circumference.

It is necessary to explain how the cylinder is connected with the verge, so as to make such a great revolution round the tooth of the wheel. The triangular tooth *e b m* is placed on the top of a little pillar fixed into the end of the piece of brass *m* D formed in the rim of the wheel. Thus the plane of the wedge tooth is parallel

Watch. rallel to the plane of the wheel, but at a small distance above it. The verge is represented at fig. 16. and consists of a long hollow cylinder of cast steel, having a great portion of the metal cut out. If spread out flat, this cylinder would assume the form of fig. 17.; and if we conceive this flat piece rolled up till the edges GH and G′ H′ unite, we shall have the exact form. The part acted on by the point of the tooth is denoted by the dotted line *b d*, and the part D, I, F, E serves to connect the two ends.

This scapement of Mr Graham is called a *horizontal* scapement, because the balance is parallel to the other wheels.

9 Lepaute's improvement. Fig. 18. and 19.

Another scapement of a superior construction was contrived by M. Lepaute of Paris, and is of such a singular form as to render it extremely difficult to illustrate it by a figure. The representations at fig. 18. and 19. will, however, give general readers some idea of its mode of action, and a skilful artist will easily see how the several parts may be adapted to each other. ABC fig. 18. represents part of the rim of the balance wheel, having the pins 1, 2, 3, 4, 5, &c. projecting from its faces; the pins 1, 3, 5, being on the side next the eye, and the pins 2 and 4 on the opposite side. D is the centre of the balance and verge, and the small circle round D represents its thickness. But the verge in this place is crooked, that the rim of the wheel may not be intercepted by it. To it is attached a piece of hard tempered steel *a b c d*, of which the part *a b c* is a concave arch of a circle, having D for its centre. It wants about 30° of a semicircle. The rest *c d* is also an arch of a circle having the rame radius with the balance-wheel. In the natural position of the balance, a line drawn from D, through the middle of the face *c d* is a tangent to the circumference of the wheel. But if the balance be turned round till the point *d* of the horn come to *d′*, and the point *c* come to 2 in the circumference in which the pins are placed, the pin pressing on the beginning of the horn or pallet, pushes it aside, slides along it, and escapes at *d*, having generated a certain velocity in the balance. Let another pallet similar to that now described be placed on the other side of the wheel, but in a contrary position, with the acting face of the pallet turned away from the centre of the wheel. Let it be so placed at E, that the moment the pin 1 on the upper side of the wheel escapes from the pallet *c d*, the pin 4 on the lower side of the wheel falls on the end of the circular arch *e f g* of the other pallet. Now, if the pallets be connected by equal pulleys G and F on the axis of each, and a thread round both so that they shall turn one way; the balance on the axis D having received an impulse from the pin 1, will continue its motion from A towards *i*, and will carry the other pallet with a similar motion round the centre E from *h* to *k*. The pin 4 will therefore rest in the concave arch *g f e* as the pallet turns round. When the force of the balance is spent, the pallet *c d* returns towards its first position. The pallet *g h* turns with it, and when the point of the first has arrived at *d*, the beginning *g* of the other arrives at the pin 4; and, proceeding farther, this pin escapes from the concave arch *e f g*, and slides along the pallet *g h*, pushing it aside, and of course urging the pallet round the centre E, and the balance on the axis D round at the same time, and in the same direction. The pin 4 escapes from the pallet *g h*, when *h* arrives at 3; but while the pin 4 is sliding along the yielding pallet *g h*, the pin 3 is moving in the circumference BDA; and the instant that the pin 4 escapes from *h* at 3, the pin 3 arrives at 2, where the beginning *c* of the concave arch *c b* is ready to receive it. It therefore rests on this arch, while the balance continues its motion, and this may continue till the point *b* of the arch comes to 2. The balance now stops, its force being spent, and then returns; and the pin 3 escapes from the circle at *c*, slides along the yielding pallet *c d*, and when it escapes at 1, another pin on the lower side of the wheel arrives at 4, and finds the arch *g f e* ready to receive it. And thus the vibration of the balance will be continued.

From the above description we may deduce the proper dimensions of the parts of the pallet. Thus, the length of the pallet *c d* or *g h*, must be equal to the interval between two succeeding pins, and the distance of the centres DE, must be double of that interval. The radius D *e* or F *g*, may be as small as we choose. The concave arches *c b a* and *g f e*, must be continued so far as to allow a pin to rest on them during the whole excursion of the balance. The angle of scapement, in which the balance remains under the influence of the wheels, is obtained by drawing the lines D *c* and D *d*, and we shall find that this angle *c* D *d* is here about 30°, though it may be made either greater or less than this.

Fig. 19. Fig. 19. explains how the two pallets may be combined on one verge. KL is the verge with a pivot at each end. It is bent like a crank MNO, to admit the balance wheel between its branches. BC represents this wheel, seen edgewise, with its pin alternately on different sides. The pallets are also represented by *b c d* and *h g f*, sized to the inside of the branches of the crank, fronting each other. The position of their acting faces may be seen in the preceding figure, on the verge D, where the pallet *g h* is represented by the dotted line 2 *i′*, as situated behind the pallet *c d*. The remote pallet 2 *i* is so placed, that when the point *d* of the near pallet is quitted by a pin 1 on the upper side of the wheel, the angle formed by the face and the arch of rest of the other pallet is just ready to receive the next pin 2, which lies on the lower side of the rim. It is plain that the action here will be the same as if the pallets were on separate axes. The pin 1 escapes from *d*, and the pin 2 is received on the arch of rest, and locks the wheel, while the balance continues in motion. When the balance returns, 2 gets off the arch of rest, pushes aside the pallet 2 *i*, escapes from it when *i* gets to 1, and then the point *c* is ready to receive the pin 3, &c. The vibrations may be increased by giving a sufficient impulse through the angle of scapement, but they cannot exceed a certain quantity, otherwise N, the top of the crank, would strike the rim of the wheel. The vibrations may be easily increased to 180°, by placing the pins at the very edge of the wheel; and by placing them at the points of long teeth, so that the crank may get in between them, the vibrations may be carried to a much greater extent.

The construction just described is exceedingly ingenious; and if the machinery be well executed, this scapement will excel the horizontal scapement of Graham, both as it has but two acting faces to form, and as it admits of making the circle of rest extremely small, without lessening the acting face of the pallet. The construction is, however, very delicate and difficult, and must require a very nice workman.

10 Duplaie's scapement. Fig. 20.

An excellent scapement of much more easy construction, is that commonly called *Duplaie's scapement*, and with this we shall conclude our account of watch-work. Fig. 20. represents the essential parts somewhat magnified. AD a portion of the balance-wheel, having teeth *f*, *h*, *g*, at the circumference. These teeth are for producing the *rest* of the wheel, while the balance is making excursions beyond the scapement. This is effected by an agate cylinder *s p g*, on the verge. This cylinder has a notch *o*. When the cylinder turns round in the direction *o p g*, the notch easily passes the tooth B which is resting on the cylinder surface; but when it returns in the direction *b p o*, the tooth B gets into the notch and follows it, pressing on one side of it till the notch comes into the position *o*. The tooth being then in the position *h*, escapes from the notch, and another tooth drops on the convex surface of the cylinder at B. The balance-wheel is also furnished with a set of flat-sided pins, standing upright on its rim represented by *a* D. There is likewise fixed on the verge a larger cylinder GFC above the smaller one *o p q*, with its lower surface clear of the wheel, and having a pallet C, of sapphire, firmly indented into it, and projecting so far as to keep clear of the pins on the wheel. The position of this cylinder, with respect to the smaller one below it, is such that the tooth *b* being escaped from the notch, the pallet C has just past the pin *a*, which was at A while B rested on the small cylinder; but it moved from A to *a*, while B moved to *b*. The wheel being now at liberty, the pin *a* exerts its pressure on the pallet C in the most direct manner, and gives it a strong impulsion, following and accelerating it till another tooth stops on the little cylinder. The angle of scapement depends partly on the projection of the pallet, and partly on the diameter of the small cylinder, and the advance of the tooth B into the notch. Independent of the action on the small cylinder, the angle of scapement would be the whole arch of the large cylinder between C and *x*. But *a* stops before it be clear of the pallet, and the arch of impulsion is shortened by all the space described by the pin while a tooth moves from B to *b*. It stops at *d*.

For an account of other scapements we must refer our readers to the *Memoirs of the Academy of Sciences at Paris* for 1748, Cummin's *Elements of Clock and Watch-work*, a French work entitled *Machines approuvées par l'Academie des Sciences*, and Young's *Lectures on Natural Philosophy*, vol. i. p. 193, and Plate 16, vol. ii. p. 193.

WATCHING, in *Medicine*, is when the patient cannot sleep. In fevers it is a dangerous symptom, and if long continued ends in a delirium.

WATER, a well known fluid, diffused through the atmosphere, and over the surface of the globe, and abounding in a certain proportion in animals, vegetables, and minerals.

The uses of water are so universally known, that it would be superfluous to enumerate them in this article. It is essential to animal and vegetable life; it makes easy the intercourse between the most distant regions of the world; and it is one of the most useful powers in the mechanic arts. It is often found combined with various substances, and is then frequently beneficial in curing or alleviating diseases.

Those properties of water which fit it for answering mechanical purposes are explained in other articles of this work (see HYDRODYNAMICS, PNEUMATICS, N° 3, RESISTANCE, and RIVERS); and for the discovery of the composition of water, see CHEMISTRY *Index*.

Water.

Mineral WATERS. For the method of analysing them, see also CHEMISTRY *Index*.

Under the title of *MINERAL Waters*, we have given an analysis of the most remarkable waters in Europe.

Holy WATER, which is made use of in the church of Rome, as also by the Greeks, and by the other Christians of the East of all denominations, is water with a mixture of salt, blessed by a priest according to a set form of benediction. It is used in the blessing of persons, things, and places; and is likewise considered as a ceremony to excite pious thoughts in the minds of the faithful.

The priests, in blessing it, first, in the name of God, commands the devils not to hurt the persons who shall be sprinkled with it, nor to abuse the things, nor disquiet the places, which shall likewise be so sprinkled: He then prays that health, safety, and the favour of heaven, may be enjoyed by such persons, and by those who shall use such things, or dwell in such places. Vestments, vessels, and other such things that are set apart for divine service, are sprinkled with it. It is sometimes sprinkled on cattle, with an intention to free or preserve them from diabolical enchantments; and in some spiritual books there are prayers to be said on such occasions, by which the safety of such animals, as being a temporal blessing to the possessors, is begged of God, whose providential care is extended to all his creatures. The hope which Catholics entertain of obtaining such good effects from the devout use of holy water, is grounded on the promise made to believers by Christ (St Mark xvi. 17.), and on the general efficacy of the prayers of the church; the petition of which prayers God is often pleased to grant; though sometimes, in his Providence, he sees it not expedient to do so. That such effects have been produced by holy water in a remarkable manner, has been asserted by many authors of no small weight; as, namely, by St Epiphanius, Haer. 30th; St Hierom, in the Life of St Hilarion; Theodoret *Hist. Eccl.* lib. v. cap. 21.; Palladius, *Hist. Laus.*; Bede, lib. v. cap. 4.

As a ceremony (says the Catholic), water brings to our remembrance our baptism; in which, by water, we were cleansed from original sin. It also puts us in mind of that purity of conscience which we ought to endeavour always to have, but especially when we are going to worship our God. The salt, which is put into the water to preserve it from corrupting, is also a figure of divine grace, which preserves our souls from the corruption of sin; and is likewise an emblem of that wisdom and discretion which ought to season every action that a Christian does, and every word that he says. It is wont to be blessed and sprinkled in churches on Sundays, in the beginning of the solemn office. It is kept in vessels at the doors of the same churches, that it may be taken by the faithful as they enter in. It is also often kept in private houses and chambers.

Putrid WATER, is that which has acquired an offensive smell and taste by the putrescence of animal or vegetable substances contained in it. It is in the highest degree pernicious to the human frame, and capable of bringing on mortal diseases even by its smell. It is not always from the apparent muddiness of waters that we

can

Water.

can judge of their disposition to putrefy; some which are seemingly very pure, being more apt to become putrid than others which appear much more mixed with heterogeneous matters. Under the article ANIMALCULE, N° 33, is mentioned a species of insects which have the property of making water stink to an incredible degree, though their bulk in proportion to the fluid which surrounds them is less than that of one to a million. Other substances no doubt there are which have the same property; and hence almost all water which is confined from the air is apt to become offensive, even though kept in glass or stoneware vessels. Indeed it is a common observation, that water keeps much longer sweet in glass vessels, or in those of earthen or stoneware than in those of wood, where it is exceedingly apt to putrefy. Hence, as ships can only be supplied with water kept in wooden casks, sailors are extremely liable to those diseases which arise from putrid water; and the discovery of a method by which water could easily be prevented from becoming putrid at sea would be exceedingly valuable. This may indeed be done by quicklime; for when water is impregnated with it, all putrescent matters are either totally destroyed, or altered in such a manner as never to be capable of undergoing the putrefactive fermentation again. But a continued use of lime-water could not fail of being pernicious, and it is therefore necessary to throw down the lime; after which the water will have all the purity necessary for preserving it free from putrefaction. This can only be done by means of fixed air; and mere exposure in broad shallow vessels to the atmosphere would do it without any thing else, only taking care to break the crust which formed upon it. Two methods, however, have been thought of for doing this with more expedition. The one, invented by Dr Alston, is, by throwing into the water impregnated with lime a quantity of magnesia. The lime attracts fixed air more powerfully than magnesia; in consequence of which the latter parts with it to the lime: and thus becoming insoluble, falls along with the caustic magnesia to the bottom, and thus leaves the water perfectly pure. Another method is that of Mr Henry, who proposes to throw down the lime by means of an effervescing mixture of oil of vitriol and chalk put down to the bottom of the water cask. His apparatus for this purpose is as simple as it can well be made, though is is hardly probable that sailors will give themselves the trouble of using it; and Dr Alston's scheme would seem better calculated for them, were it not for the expence of the magnesia; which indeed is the only objection made to it by Mr Henry. Putrid water may be restored and made potable by a process of the same kind.

Of late it has been discovered that charcoal possesses many unexpected properties, and, among others, that of preserving water from corruption, and of purifying it after it has been corrupted. Mr Lowitz, whose experiments on charcoal have been published in Crell's Chemical Journal, has turned his attention to this subject in a memoir read to the Economical Society at Petersburgh. He found that the effect of charcoal was rendered much more speedy by using along with it some sulphuric acid. One ounce and a half of charcoal in powder, and 24 drops of concentrated sulphuric acid (oil of vitriol), are sufficient to purify three pints and a half of corrupted water, and do not communicate to it any sensible acidity. This small quantity of acid renders it unnecessary to use more than a third part of the charcoal powder which would otherwise be wanted; and the less of that powder is employed, the less is the quantity of water lost by the operation, which, in sea-voyages, is an object worthy of consideration. In proportion to the quantity of acid made use of, the quantity of charcoal may be diminished or augmented. All acids produce nearly the same effects: neutral salts also, particularly nitre and sea-salt, may be used, but sulphuric acid is preferable to any of these; water which is purified by means of this acid and charcoal will keep a longer time than that which is purified by charcoal alone. When we mean to purify any given quantity of corrupted water, we should begin by adding to it as much powder of charcoal as is necessary to deprive it entirely of its bad smell. To ascertain whether that quantity of powdered charcoal was sufficient to effect the clarification of the said water, a small quantity of it may be passed through a linen bag, two or three inches long; if the water, thus filtrated, still has a turbid appearance, a fresh quantity of powdered charcoal must be added, till it is become perfectly clear: the whole of the water may then be passed through a filtering bag, the size of which should be proportioned to the quantity of water. If sulphuric acid, or any other, can be procured, a small quantity of it should be added to the water, before the charcoal powder.

The cleaning of the casks in which water is to be kept in sea-voyages should never be neglected: they should be well washed with hot water and sand, or with any other substance capable of removing the mucilaginous particles, and afterwards a quantity of charcoal dust should be employed, which will entirely deprive them of the musty or putrid smell they may have contracted.—The charcoal used for purifying water should be well burnt, and afterwards beat into a fine powder.

Sea-WATER. See *SEA-Water*.

WATER-Carts, carriages constructed for the purpose of watering the roads for several miles round London; a precaution absolutely necessary near the metropolis, where, from such a vast daily influx of carriages and horses, the dust would otherwise become quite insufferable in hot dry weather. Pumps are placed at proper distances to supply these carts.

WATER-Ordeal. See ORDEAL.

WATER, among jewellers, is properly the colour or lustre of diamonds and pearls. The term, though less properly, is sometimes used for the hue or colour of other stones.

WATER-Bellows. See *Machines for blowing Air into FURNACES*.

WATER-Colours, in *Painting*, are such colours as are only diluted and mixed up with gum-water, in contradistinction to oil-colours. See *COLOUR-Making*.

WATER-Gang, a channel cut to drain a place by carrying off a stream of water.

WATER-Hen. See PARRA, ORNITHOLOGY *Index*.

WATER-Lines of a Ship, certain horizontal lines supposed to be drawn about the outside of a ship's bottom, close to the surface of the water in which she floats. They are accordingly higher or lower upon the bottom, in proportion to the depth of the column of water required to float her.

WATER-Logged, the state of a ship when, by receiving a great quantity of water into the hold, by leaking, &c. she

Water logged ‖ Water Spout.

she has become heavy and inactive upon the sea, so as to yield without resistance to the efforts of every wave rushing over her decks. As, in this dangerous situation, the centre of gravity is no longer fixed, but fluctuating from place to place, the stability of the ship is utterly lost: she is therefore almost totally deprived of the use of her sails, which would operate to overset her, or press the head under water. Hence there is no resource for the crew, except to free her by the pumps, or to abandon her by the boats as soon as possible.

WATER-Sail, a small sail spread occasionally under the lower studding-sail, or driver boom, in a fair wind and smooth sea.

WATER-Ouzel. See TURDUS, ORNITHOLOGY *Index*.

WATER-Spout, an extraordinary meteor, consisting of a large mass of water collected into a sort of column, and moved with rapidity along the surface of the sea.

The best account of the water-spout which we have met with is in the Phil. Trans. Abridged, vol. iii. as observed by Mr Joseph Harris, May 21. 1732, about sunset, lat. 32° 30′ N.; long. 9° E. from Cape Florida.

"When first we saw the spout (says he), it was whole and entire, and much of the shape and proportion of a speaking trumpet; the small end being downwards, and reaching to the sea, and the big end terminated in a black thick cloud. The spout itself was very black, and the more so the higher up. It seemed to be exactly perpendicular to the horizon, and its sides perfectly smooth, without the least ruggedness. Where it fell the spray of the sea rose to a considerable height, which made somewhat the appearance of a great smoke. From the first time we saw it, it continued whole about a minute, and till it was quite dissipated about three minutes. It began to waste from below, and so gradually up, while the upper part remained entire, without any visible alteration, till at last it ended in the black cloud above; upon which there seemed to fall a very heavy rain in that neighbourhood.—There was but little wind, and the sky elsewhere was pretty serene."

Water-spouts have by some been supposed to be merely electrical in their origin; particularly by Signior Beccaria, who supported his opinion by some experiments. But if we attend to the successive phenomena necessary to constitute a complete water-spout through their various stages, we shall be convinced, that recourse must be had to some other principle in order to obtain a complete solution.

Dr Franklin, in his Physical and Meteorological Observations, supposes a water-spout and a whirlwind to proceed from the same cause; their only difference being, that the latter passes over the land, and the former over the water. This opinion is corroborated by M. de la Pryme, in the Philosophical Transactions, where he describes two spouts observed at different times in Yorkshire, whose appearances in the air were exactly like those of the spouts at sea, and their effects the same as those of real whirlwinds.

A fluid moving from all points horizontally towards a centre, must at that centre either mount or descend. If a hole be opened in the middle of the bottom of a tub filled with water, the water will flow from all sides to the centre, and there descend in a whirl: but air flowing on or near the surface of land or water, from all sides towards a centre, must at that centre ascend; because the land or water will hinder its descent.

Water Spout.

The doctor, in proceeding to explain his conceptions, begs to be allowed two or three positions, as a foundation for his hypothesis. 1. That the lower region of air is often more heated, and so more rarefied, than the upper, and by consequence specifically lighter. The coldness of the upper region is manifested by the hail, which falls from it in warm weather. 2. That heated air may be very moist, and yet the moisture so equally diffused and rarefied as not to be visible till colder air mixes with it; at which time it condenses and becomes visible. Thus our breath, although invisible in summer, becomes visible in winter.

These circumstances being granted, he presupposes a tract of land or sea, of about 60 miles in extent, unsheltered by clouds and unrefreshed by the wind, during a summer's day, or perhaps for several days without intermission, till it becomes violently heated, together with the lower region of the air in contact with it; so that the latter becomes specifically lighter than the superincumbent higher region of the atmosphere, wherein the clouds are usually floated: he supposes also that the air surrounding this tract has not been so much heated during those days, and therefore remains heavier. The consequence of this, he conceives, should be, that the heated lighted air should ascend, and the heavier descend; and as this rising cannot operate throughout the whole tract at once, because that would leave too extensive a vacuum, the rising will begin precisely in that column which happens to be lightest or most rarefied; and the warm air will flow horizontally from all parts of this column, where the several currents meeting, and joining to rise, a whirl is naturally formed, in the same manner as a whirl is formed in a tub of water, by the descending fluid receding from all sides of the tub towards the hole in the centre.

And as the several currents arrive at this central rising column with a considerable degree of horizontal motion, they cannot suddenly change it to a vertical motion: therefore as they gradually, in approaching the whirl, decline from right to curve or circular lines, so, having joined the whirl, they ascend by a spiral motion; in the same manner as the water descends spirally through the hole in the tub before mentioned.

Lastly, as the lower air nearest the surface is more rarefied by the heat of the sun, it is more impressed by the current of the surrounding cold and heavy air which is to assume its place, and consequently its motion towards the whirl is swiftest, and so the force of the lower part of the whirl strongest, and the centrifugal force of its particles greatest. Hence the vacuum which incloses the axis of the whirl should be greatest near the earth or sea, and diminish gradually as it approaches the region of the clouds, till it ends in a point.

This circle is of various diameters, sometimes very large.

If the vacuum passes over water, the water may rise in a body or column therein to the height of about 32 feet. The whirl of air may be as invisible as the air itself, though reaching in reality from the water to the region of cool air, in which our low summer thunder-clouds commonly float; but it will soon become visible at its extremities. The agitation of the water under the whirling of the circle, and the swelling and rising of the water in the commencement of the vacuum, render it visible below. It is perceived above by the warm

warm air being brought up to the cooler region, where its moisture begins to be condensed by the cold into thick vapour, and is then first discovered at the highest part, which being now cooled condenses what rises behind it, and this latter acts in the same manner on the succeeding body; where, by the contact of the vapours, the cold operates faster in a right line downwards, than the vapours themselves can climb in a spiral line upwards: they climb however; and as by continual addition they grow denser, and by consequence increase their centrifugal force, and being risen above the concentrating currents that compose the whirl, they fly off, and form a cloud.

It seems easy to conceive, how by this successive condensation from above, the spout appears to drop or descend from the cloud, although the materials of which it is composed are all the while ascending. The condensation of the moisture contained in so great a quantity of warm air as may be supposed to rise in a short time in this prodigiously rapid whirl, is perhaps sufficient to form a great extent of cloud; and the friction of the whirling air on the sides of the column may detach great quantities of its water, disperse them into drops, and carry them up in the spiral whirl mixed with the air. The heavier drops may indeed fly off, and fall into a shower about the spout; but much of it will be broken into vapour, and yet remain visible.

As the whirl weakens, the tube may apparently separate in the middle; the column of water subsiding, the superior condensed part drawing up to the cloud. The tube or whirl of air may nevertheless remain entire, the middle only becoming invisible, as not containing any visible matter.

Dr Lindsay, however, in several letters published in the Gentleman's Magazine, has controverted this theory of Dr Franklin, and endeavoured to prove that water-spouts and whirlwinds are distinct phenomena; and that the water which forms the water-spout, does not ascend from the sea, as Dr Franklin supposes, but descends from the atmosphere. Our limits do not permit us to insert his arguments here, but they may be seen in the Gentleman's Magazine, volume li. p. 559, 615; vol. liii. p. 1025; and vol. lv. p. 594. We cannot avoid observing, however, that he treats Dr Franklin with a degree of asperity to which he is by no means entitled, and that his arguments, even if conclusive, prove nothing more than that some water-spouts certainly descend; which Dr Franklin hardly ever ventured to deny. There are some very valuable dissertations on this subject by Professor Wilcke of Upsal.

WATER-WORKS.

UNDER this name may be comprehended almost every hydraulic structure or contrivance; such as canals, conduits, locks, mills, water engines, &c. But they may be conveniently arranged under two general heads, 1st, Works which have for their object the conducting, raising, or otherwise managing, of water; and, 2dly, Works which derive their efficacy from the impulse or other action of water. The *first* class comprehends the methods of simply conducting water in aqueducts or in pipes for the supply of domestic consumption or the working of machinery: It comprehends also the methods of procuring the supplies necessary for these purposes, by means of pumps, water, or fire engines. It also comprehends the subsequent management of the water thus conducted, whether in order to make the proper distribution of it according to the demand, or to employ it for the purpose of navigation, by lockage, or other contrivances. —And in the prosecution of these things many subordinate problems will occur, in which practice will derive great advantages from a scientific acquaintance with the subject. The *second* class of water-works is of much greater variety, comprehending almost every kind of hydraulic machine; and would of itself fill volumes. Many of these have already occurred in various articles of this Dictionary. In describing or treating them, we have tacitly referred the discussion of their general principles, in which they all resemble each other, to some article where they could be taken in a connected body, susceptible of general scientific discussion, independent of the circumstances which of necessity introduced the particular modifications required by the uses to which the structures were to be applied. That part of the present article, therefore, which embraces these common principles, will chiefly relate to the theory of water mills, or rather of water wheels; because, when the necessary motion is given to the axis of the water wheel, this may be set to the performance of any task whatever.

CLASS I.

1. *Of the Conducting of Water.*

THIS is undoubtedly a business of great importance, and makes a principal part of the practice of the civil engineer: It is also a business so imperfectly understood, that we believe that very few engineers can venture to say, with tolerable precision, what will be the quantity of water which his work will convey, or what plan and dimensions of conduit will convey the quantity which may be proposed. For proof of this we shall only refer our readers to the facts mentioned in the article RIVERS, N° 27, &c.

In that article we have given a sort of history of the progress of our knowledge in hydraulics, a branch of mechanical philosophy which seems to have been entirely unknown to the ancients. Even Archimedes, the author of almost all that we know in hydrostatics, seems to have been entirely ignorant of any principles by which he could determine the motion of water. The mechanical science of the ancients seems to have reached no farther than the doctrine of equilibrium among bodies at rest. Guglielmini first ventured to consider the motion of water in open canals and in rivers. Its motion in pipes had been partially considered in detached

Water-works.

tached scraps by others, but not so as to make a body of doctrine. Sir Isaac Newton first endeavoured to render hydraulics susceptible of mathematical demonstration: But his fundamental proposition has not yet been freed from very serious objections; nor have the attempts of his successors, such as the Bernoullis, Euler, D'Alembert, and others, been much more successful: so that hydraulics may still be considered as very imperfect, and the general conclusions which we are accustomed to receive as fundamental propositions are not much better than matters of observation, little supported by principle, and therefore requiring the most scrupulous caution in the application of them to any hitherto untried case. When experiments are multiplied so as to include as great a variety of cases as possible; and when these are cleared of extraneous circumstances, and properly arranged, we must receive the conclusions drawn from them as the general laws of hydraulics. The experiments of the abbé Bossut, narrated in his *Hydrodynamique*, are of the greatest value, having been made in the cases of most general frequency, and being made with great care. The greatest service, however, has been done by the chevalier Buat, who saw the folly of attempting to deduce an accurate theory from any principles that we have as yet learned, and the necessity of adhering to such a theory as could be deduced from experiment alone, independent of any more general principles. Such a theory must be a just one, if the experiments are really general, unaffected by the particular circumstances of the case, and if the classes of experiment are sufficiently comprehensive to include all the cases which occur in the most important practical questions. Some principle was necessary, however, for connecting these experiments. The sufficiency of this principle was not easily ascertained. Mr Buat's way of establishing this was judicious. If the principle is ill-founded, the results of its combination in cases of actual experiments must be irregular; but if experiments, seemingly very unlike, and in a vast variety of dissimilar cases, give a train of results which is extremely regular and consistent, we may presume that the principle, which in this manner harmonizes and reconciles things so unlike, is founded in the nature of things; and if this principle be such as is agreeable to our clearest notions of the internal mechanism of the motions of fluids, our presumption approaches to conviction.

Proceeding in this way, the chevalier Buat has collected a prodigious number of facts, comprehending almost every case of the motion of fluids. He first classed them according to their resemblance in some one particular, and observed the differences which accompanied their differences in other circumstances; and by considering what could produce these differences, he obtained general rules, deduced from fact, by which these differences could be made to fall into a regular series. He then arranged all the experiments under some other circumstances of resemblance, and pursued the same method; and by following this out, he has produced a general proposition, which applies to the whole of this numerous list of experiments with a precision far exceeding our utmost hopes. This proposition is contained in N° 59. of the article RIVERS, and is there offered as one of the most valuable results of modern science.

We must, however, observe, that of this list of experiments there is a very large class, which is not direct, but requires a good deal of reflection to enable us to draw a confident conclusion; and this is in cases which are very frequent and important, viz. where the declivity is exceedingly small, as in open canals and rivers. The experiments were of the following forms: Two large cisterns were made to communicate with each other by means of a pipe. The surface of the water in these cisterns were made to differ only by a small fraction of an inch: and it is supposed that the motion in the communicating pipe will be the same as in a very long pipe, or an open canal, having this very minute declivity. We have no difficulty in admitting the conclusion; but we have seen it contested, and it is by no means intuitive. We had entertained hopes that this important case would have been determined by direct experiments, which the writer of this article was commissioned to make by the Board for Encouraging Improvements and Manufactures in Scotland: But the infirm state of his health was always an effectual bar to the accomplishment of this desirable object. This, however, need not occasion any hesitation in the adoption of M. Buat's general proposition, because the experiments which we are now criticising fall in precisely with the general train of the rest, and show no *general* deviation which would indicate a fallacy in principle.

We apprehend it to be quite unnecessary to add much to what has been already delivered on the motion of waters in an open canal. Their *general progressive* motion, and consequently the quantity delivered by an aqueduct of any slope and dimension, are sufficiently determined; and all that is wanted is the tables which we promised in N° 65. of the article RIVERS, by which any person who understands common arithmetic may, in five minutes time or less, compute the quantity of water which will be delivered by the aqueduct, canal, conduit, or pipe; for the theorem in N° 59. of this article applies to them all without distinction. We therefore take this opportunity of inserting these tables, which have been computed on purpose for this work with great labour.

TABLE I. *Logarithms of the Values of the Numerator of the Fraction* $\frac{307\,(\sqrt{d}-0,1)}{\sqrt{s}-\mathrm{L}\sqrt{s+1,6}}$ *for every Value of the Hydraulic mean Depth* d: *Also the Value of* $0,3\,(\sqrt{d}-0,1)$.

d.	Log. of 307 ($\sqrt{d}$—0,1)	0,3 × ($\sqrt{d}$—0,1)	d.	Log. of 307 ($\sqrt{d}$—0,1)	0,3 × ($\sqrt{d}$—0,1)	d.	Log. of 307 ($\sqrt{d}$—0,1)	0,3 × ($\sqrt{d}$—0,1)	d.	Log. of 307 ($\sqrt{d}$—0,1)	0,3 × ($\sqrt{d}$—0,1)

TABLE

Water-works.

TABLE I. consists of three columns.—*Column* 1. entitled d, contains the hydraulic mean depths of any conduit in inches. This is set down for every 10th of an inch in the first 10 inches, that the answers may be more accurately obtained for pipes, the mean depth of which seldom exceeds three or four inches. The column is continued to 100 inches, which is fully equal to the hydraulic mean depth of any canal.

Column 2. contains the logarithms of the values of $\sqrt{d}-0.1$, multiplied by 307; that is, the logarithm of the numerator of the fraction $\frac{307(\sqrt{d}-0.1)}{\sqrt{s}-\text{L}\sqrt{s+1.6}}$ in N° 65. of the article RIVERS.

Column 3. contains the product of the values of $\sqrt{d}-0.1$ multiplied by 0.3.

TABLE II. consists of two columns.—*Column* 1. entitled s, contains the denominator of the fraction expressing the slope or declivity of any pipe or canal; that is, the quotient of its length divided by the elevation of one extremity above the other. Thus, if a canal of one mile in length be three feet higher at one end than the other, then s is $\frac{5280}{3}$, $=1760$.

Column 2. contains the logarithms of the denominators of the above-mentioned fraction, or of the different values of the quantity $\sqrt{s}-\text{L}\sqrt{s+1.6}$.

These quantities were computed true to the third decimal place. Notwithstanding this, the last figure in about a dozen of the first logarithms of each table is not absolutely certain to the nearest unit. But this cannot produce an error of 1 in 100,000.

Examples of the Use of these Tables.

Example 1. Water is brought into the city of Edinburgh in several mains. One of these is a pipe of five inches diameter. The length of the pipe is 14.637 feet; and the reservoir at Comiston is 44 feet higher than the reservoir into which it delivers the water on the Castle Hill. *Query*, The number of Scotch pints which this pipe should deliver in a minute?

1. We have $d=\frac{5}{4}$, $=1.25$ inches. The logarithm corresponding to this d, being nearly the mean between the logarithms corresponding to 1.2 and 1.3 is 2.49472.

2. We have $s=\frac{14637}{44}$, or 332.7. The logarithm corresponding to this in Table II. is had by taking proportional parts for the difference between the logarithms for $s=330$ and $s=340$, and is 1.18533.

3. From 2.49472
Take 1.18533

Remains 1.30939, the logarithm of 20.385 inches.

4. In column 3. of Table I. opposite to $d=1.2$ and $d=1.3$ are 0.3 and 0.31, of which the mean is 0.305 inches, the correction for viscidity.

5. Therefore the velocity in inches per second is $20.385-0.305$, or 20.08.

6. To obtain the Scotch pints per minute (each containing 103.4 cubic inches), multiply the velocity by 60, and this product by 5^2, and this by 0.7854 (the area of a circle whose diameter is 1), and divide by 103.4. Or, by logarithms,

Add the log. of 20.08	- -	1.30276
log. of 60″	- -	1.77815
log. of 5^2 or 25	- -	1.39794
log. of 0.7854	- -	9.89509
		4.37394
Subtract the log. of 103.4	- -	2.01451
Remains the log. of 228.8 pints	-	2.35943

Example 2. The canal mentioned in the article RIVERS, N° 63. was 18 feet broad at the surface, and 7 feet at the bottom. It was 4 feet deep, and had a declivity of 4 inches in a mile. *Query*, The mean velocity?

1. The slant side of the canal, corresponding to 4 feet deep and $5\frac{1}{2}$ projection, is 6.8 feet; therefore the border touched by the water is $6.8+7+6.8$, $=20.6$. The area is $4\times\frac{18+7}{2}$, $=50$ square feet. Therefore $d=\frac{50}{20.6}$, $=2.427$ feet, or 29.124 inches. The logarithm corresponding to this in Table I. is 3.21113, and the correction for viscidity from the third column of the same Table is 1.58.

2. The slope is one-third of a foot in a mile, or one foot in three miles. Therefore s is 15.840. The logarithm corresponding to this is 2.08280.

3. From 3.21113
Subtract 2.08280

Remains $1.12833=$log. of 13.438 inches.
Subtract for viscidity 1.58

Velocity per second - 11.858

This velocity is considerably smaller than what was observed by Mr Watt. And indeed we observe, that in the very small declivities of rivers and canals, the formula is a little different. We have made several comparisons with a formula which is essentially the same with Buat's, and comes nearer in these cases. Instead of taking the hyperbolic logarithm of $\sqrt{s+1.6}$, multiply its common logarithm by $2\frac{1}{4}$, or multiply it by 9, and divide the product by 4; and this process is vastly easier than taking the hyperbolic logarithm.

We have not, however, presumed to calculate tables on the authority of our own observations, thinking too respectfully of this gentleman's labours and observations. But this subject will, ere long, be fully established on a series of observations on canals of various dimensions and declivities, made by several eminent engineers during the execution of them. Fortunately Mr Buat's formula is chiefly founded on observations on small canals; and is therefore most accurate in such works where it is most necessary, viz. in mill courses, and other derivations for working machinery.

We now proceed to take notice of a few circumstances which deserve attention, in the construction of canals, in addition to those delivered in the article RIVERS.

When a canal or aqueduct is brought off from a bason or or larger stream, it ought always to be widened at the entry, if it is intended for drawing off a continued stream of water: For such a canal has a slope, without which it can have no current. Suppose it filled to a dead level to the farther end: Take away the bar, and the water immediately begins to flow off at that end. But it is some time before any motion is perceived at the head of the canal, during all which time the motion of the water is augmenting in every part of the canal; consequently the slope is increasing in every part, this being the sole cause of its stream. When the water at the entry *begins* to move, the slope is scarcely sensible there; but it sensibly steepens every moment with the increase of velocity, which at last attains its maximum relative to the slope and dimensions of the whole canal; and this regulates the depth of water in every point down the stream. When all has attained a state of permanency, the slope at the entry *remains* much greater than in any other part of the canal; for this slope must be such as will produce a velocity sufficient for supplying its TRAIN.

And it must be remembered, that the velocity which must be produced greatly exceeds the mean velocity corresponding to the train of the canal. Suppose that this is 25 inches. There must be a velocity of 30 inches at the surface, as appears by the Table in the article RIVERS, N° 80. This must be produced by a real fall at the entry.

In every other part the slope is sufficient, if it merely serves to give the water (already in motion) force enough for overcoming the friction and other resistances. But at the entry the water is stagnant, if in a bason, or it is moving past laterally, if the aqueduct is derived from a river; and, having no velocity whatever in the direction of the canal, it must derive it from its slope. The water therefore which has acquired a permanent form in such an aqueduct, must necessarily take that form which exactly performs the offices requisite in its different portions. The surface remains horizontal in the bason, as to KC (fig. 1.), till it comes near the entry of the canal AB, and there it acquires the form of an undulated curve CDE; and then the surface acquires an uniform slope EF, in the lower part of the canal, where the water is in train.

Plate DLXXIII. fig. 1.

If this is a drain, the discharge is much less than might be produced by the same bed if this sudden slope could be avoided. If it is to be navigated, having only a very gentle slope in its whole length, this sudden slope is a very great imperfection, both by diminishing the depth of water, which might otherwise be obtained along the canal, and by rendering the passage of boats into the bason very difficult, and the coming out very hazardous.

All this may be avoided, and the velocity at the entry may be kept equal to that which forms the train of the canal, by the simple process of enlarging the entry. Suppose that the water could accelerate along the slopes of the canal, as a heavy body would do on a finely polished plane. If we now make the width of the entry in its different parts inversely proportional to the fictitious velocities in those parts, it is plain that the slope of the surface will be made parallel to that of the canal which is in train. This will require a form somewhat like a bell or speaking trumpet, as may easily be shown by a mathematical discussion. It would, however, be so much evasated at the bason as to occupy much room, and it would be very expensive to make such an excavation. But we may, at a very moderate expence of money and room, make the increase of velocity at the entry almost insensible. This should always be done, and it is not all expence: for if it be not done, the water will undermine the banks on each side, because it is moving very swiftly, and will make an excavation for itself, leaving all the mud in the canal below. We may observe this enlargement at the entry of all natural derivations from a bason or lake. It is a very instructive experiment, to fill up this enlargement, continuing the parallel sides of the drain quite to the side of the lake. We shall immediately observe the water grow shallower in the drain, and its performance will diminish. Supposing the ditch carried on with parallel sides quite to the side of the bason, if we build two walls or dykes from the extremities of those sides, bending outwards with a proper curvature (and this will often be less costly than widening the drain), the discharge will be greatly increased. We have seen instances where it was nearly doubled.

The enlargement at the mouths of rivers is generally owing to the same cause. The tide of flood up the river produces a superficial slope opposite to that of the river, and this widens the mouth. This is most remarkable when the tides are high, and the river has little slope.

After this great fall at the entry of the canal, in which all the filaments are much accelerated, and the inferior ones most of all, things take a contrary turn. The water, by rubbing on the bottom and the sides, is retarded; and therefore the section must, from being shallow, become a little deeper, and the surface will be convex for some distance till all comes into train. When this is established, the filaments nearest the bottom and side are moving slowest, and the surface (in the middle especially) retains the greatest velocity, gliding over the rest. The velocity in the canal, and the depth of the section, adjust themselves in such a manner that the difference between the surface of the bason and the surface of the uniform section of the canal corresponds exactly to the velocity. Thus, if this be observed to be two feet in a second, the difference of height will be $\frac{1}{16}$th of an inch.

All the practical questions that are of considerable importance respecting the motion of water in aqueducts, may be easily, though not elegantly, solved by means of the tables.

But it is to be remembered, that these tables relate only to uniform motion, that is, to water that is in train, and where the velocity suffers no change by lengthening the conduit, provided the slope remain the same. It is much more difficult to determine what will be the velocity, &c. in a canal of which nothing is given but the form, and slope, and depth of the entry, without saying how deep the water runs in it. And it is here that the common doctrines of hydraulics are most in fault, and unable to teach us how deep the water will run in a canal, though the depth of the bason at the entry be perfectly known. Between the part of the canal which is in train and the bason, there is an interval where the water is in a state of acceleration, and is afterwards retarded.

The determination of the motions in this interval is exceedingly

Water-works.

exceedingly difficult, even in a rectangular canal. It was one great aim of M. Buat's experiments to ascertain this by measuring accurately the depth of the water. But he found that when the slope was but a very few inches in the whole length of his canal, it was not in train for want of greater length; and when the slope was still less, the small fractions of an inch, by which he was to judge of the variations of depth, could not be measured with sufficient accuracy. It would be a most desirable point to determine the length of a canal, whose slope and other dimensions are given, which will bring it into train; and what is the ratio which will then obtain between the depth at the entry and the depth which will be maintained. Till this be done, the engineer cannot ascertain by a direct process what quantity of water will be drawn off from a reservoir by a given canal. But as yet this is out of our reach. Experiments, however, are in view which will promote the investigation.

But this and similar questions are of such importance, that we cannot be said to have improved hydraulics, unless we can give a tolerably precise answer. This we can do by a sort of retrograde process, proceeding on the principles of uniform motion established by the Chevalier Buat. We may suppose a train maintained in the canal, and then examine whether this train *can* be produced by any fall that is possible at the entry. If it can, we may be certain that it is so produced, and our problem is solved.

We shall now point out the methods of answering some chief questions of this kind.

Quest. 1. Given the slope s and the breadth w of a canal, and the height H of the surface of the water in the bason above the bottom of the entry; to find the depth h and velocity V of the stream, and the quantity of water Q which is discharged?

The chief difficulty is to find the depth of the stream where it is in train. For this end, we may simplify the hydraulic theorem of uniform motion in N° 59. of the article RIVER; making $V=\frac{\sqrt{Ngd}}{\sqrt{S}}$, where g is the velocity (in inches) acquired in a second by falling, d is the hydraulic mean depth, and $\sqrt{S}$ stands for $\sqrt{S}-L\sqrt{S+1.6}$. N is a number to be fixed by experiment (see RIVER, N° 53.) depending on the contraction or obstruction sustained at the entry of the canal, and it may in most common cases be taken $=244$; so that $\sqrt{Ng}$ may be somewhat less that 307. To find it, we may begin by taking for our depth of stream a quantity h, somewhat smaller than H the height of the surface of the bason above the bottom of the canal. With this depth, and the known width w of the canal, we can find the hydraulic depth d (See RIVERS, N° 48). Then with $\sqrt{d}$ and the slope find V by the Table: make this $V=\frac{\sqrt{Ngd}}{\sqrt{S}}$. This gives $\sqrt{Ng}=\frac{V\sqrt{S}}{\sqrt{d}}$. This value of N$g$ is sufficiently exact; for a small error of depth hardly affects the hydraulic mean depth.

After this preparation, the expression of the mean velocity in the canal will be $\frac{\sqrt{Ng}\sqrt{\frac{wh}{w+2h}}}{\sqrt{S}}$. The height which will produce this velocity is $\frac{Ng}{2GS}\left(\frac{wh}{w+2h}\right)$. Now this is the slope at the entry of the canal which produces the velocity that is afterwards maintained against the obstructions by the slope of the canal. It is therefore $=H-h$. Hence we deduce

$$h=\frac{-\left(w\left(\frac{Ng}{2GS}+1\right)-2H\right)}{4}+\frac{\sqrt{8Hw+\left(w\left(\frac{Ng}{2GS}+1\right)-2H\right)^2}}{4}.$$

If there be no contraction at the entry, $g=G$ and $\frac{9}{2G}=\frac{1}{2}$.

Having thus obtained the depth h of the stream, we obtain the quantity of water by combining this with the width w and the velocity V.

But as this was but an approximation, it is necessary to examine whether the velocity V be possible. This is very easy. It must be produced by the fall $H-h$. We shall have no occasion for any correction of our first assumption, if h has not been extravagantly erroneous, because a small mistake in h produces almost the same variation in d. The test of accuracy, however, is, that h, together with the height which will produce the velocity V, must make up the whole height H. Assuming h too small, leaves $H-h$ too great, and will give a small velocity V, which requires a small value of $H-h$. The error of $H-h$ therefore is always greater than the error we have committed in our first assumption. Therefore when this error of $H-h$ is but a trifle, such as one-fourth of an inch, we may rest satisfied with our answer.

Perhaps the easiest process may be the following: Suppose the whole stream in train to have the depth H. The velocity V obtained for this depth and slope by the Table requires a certain productive height u. Make $\sqrt{H+u}:H=H:h$, and h will be exceedingly near the truth. The reason is obvious.

Quest. 2. Given the discharge (or quantity to be furnished in a second) Q, the height H of the bason above the bottom of the canal, and the slope; to find the dimensions of the canal?

Let x and y be the depth and mean width. It is plain that the equation $\frac{Q}{xy}=\sqrt{2G}\sqrt{H-x}$ will give a value of y in terms of x. Compare this with the value of y obtained from the equation $\frac{Q}{xy}=\frac{\sqrt{Ng}}{\sqrt{S}}\sqrt{\frac{xy}{y+2x}}$. This will give an equation containing only x and known quantities. But it will be very complicated, and we must have recourse to an approximation. This will be best understood in the form of an example.

Suppose the depth at the entry to be 18 inches, and the slope $\frac{1}{1000}$. Let 1200 cubic feet of water per minute be the quantity of water to be drawn off, for working machinery or any other purpose; and let the canal be be supposed of the best form, recommended in N° 69. of the article RIVER, where the base of the sloping side is four-thirds of the height.

The slightest consideration will show us that if $\frac{V^2}{744}$ be taken for the height producing the velocity, it cannot exceed 3 inches, nor be less than 1. Suppose it $=2$, and therefore the depth of the stream in the canal to be 16 inches; find the mean width of the canal by the equation $w=\frac{Q}{h\left(\sqrt{d}-0.1\left(\frac{307}{\sqrt{S}}-0.3\right)\right)}$, in which Q is 20 cubic feet (the 60th part of 1200), $\sqrt{S}$ is $=28.153, =\sqrt{1000}-L\sqrt{1000+1.6}$, and $h=16$. This gives $w=5.52$ feet. The section $n=7.36$ feet, and $V=32.6$ inches. This requires a fall of 1.52 inches instead of 2 inches. Take this from 18, and there remains 16.48, which we shall find not to differ one-tenth of an inch from the exact depth which the water will acquire and maintain. We may therefore be satisfied with assuming 5.36 feet as the mean width, and 3.53 feet for the width at the bottom.

This approximation proceeds on this consideration, that when the width diminishes by a small quantity, and in the same proportion that the depth increases, the hydraulic mean depth remains the same, and therefore the velocity also remains, and the quantity discharged changes in the exact proportion of the section. Any minute error which may result from this supposition, may be corrected by increasing the fall producing the velocity, in the proportion of the first hydraulic mean depth to the mean depth corresponding to the new dimensions found for the canal. It will now become 1.53, and V will be 32.72, and the depth will be 16.47. The quantity discharged being divided by V, will give the section $=7.335$ feet, from which, and the new depth, we obtain 5.344 for the width.

This and the foregoing are the most common questions proposed to an engineer. We asserted with some confidence that few of the profession are able to answer them with tolerable precision. We cannot offend the professional gentlemen by this, when we inform them that the Academy of Sciences at Paris were occupied during several months with an examination of a plan proposed by M. Parcieux, for bringing the waters of the Yvette into Paris; and after the most mature consideration, gave in a report of the quantity of water which M. De Parcieux's aqueduct would yield, and that their report has been found erroneous in the proportion of at least 2 to 5: For the waters have been brought in, and exceed the report in this proportion. Indeed long after the giving in the report, M. Perronet, the most celebrated engineer in France, affirmed that the dimensions proposed were much greater than were necessary, and said that an aqueduct of $5\frac{1}{2}$ feet wide, and $3\frac{1}{2}$ deep with a slope of 15 inches in a thousand fathoms, would have a velocity of 12 or 13 inches per second, which would bring in all the water furnished by the proposed sources. The great diminution of expence occasioned by the alteration encouraged the community to undertake the work. It was accordingly begun, and a part executed. The water was found to run with a velocity of near 19 inches when it was $3\frac{2}{3}$ feet deep. M. Perronet founded his computation on his own experience alone, acknowledging that he had no theory to instruct him. The work was carried no farther, it being found that the city could be supplied at a much smaller expence by steam engines erected by Boulton and Watt. But the facts which occurred in the partial execution of the aqueduct are very valuable. If M. Perronet's aqueduct be examined by our general formula, s will be found $=\frac{1}{4800}$, and $d=18.72$, from which we deduce the velocity $=18\frac{2}{7}$, agreeing with the observation with astonishing precision.

The experiments at Turin by Michaelotti on canals were very numerous, but complicated with many circumstances which would render the discussion too long for this place. When cleared of these circumstances, which we have done with scrupulous care, they are also abundantly conformable to our theory of the uniform motion of running waters. But to return to our subject:

Should it be required to bring off at once from the bason a mill-course, having a determined velocity for driving an undershot wheel, the problem becomes easier, because the velocity and slope combined determine the hydraulic mean depth at once; and the depth of the stream will be had by means of the height which must be taken for the whole depth at the entry, in order to produce the required velocity.

In like manner, having given the quantity to be discharged, and the velocity and the depth at the entry, we can find the other dimensions of the channel; and the mean depth being found, we can determine the slope.

When the slope of a canal is very small, so that the depth of the uniform stream differs but a little from that at the entry, the quantity discharged is but small. But a great velocity, requiring a great fall at the entry, produces a great diminution of depth, and therefore it may not compensate for this diminution, and the quantity discharged may be smaller. Improbable as this may appear, it is not demonstrably false; and hence we may see the propriety of the following

Question 3. Given the depth H at the entry of a rectangular canal, and also its width w; required the slope, depth, and velocity which will produce the greatest possible discharge?

Let x be the unknown depth of the stream. $H-x$ is the productive fall, and the velocity is $\sqrt{2G}\sqrt{H-x}$. This multiplied by wx will give the quantity discharged. Therefore $wx\sqrt{2G}\sqrt{H-x}$ must be made a maximum. The common process for this will give the equation, $2H=3x$, or $x=\frac{2}{3}H$. The mean velocity will be $\sqrt{2G}, \sqrt{\frac{1}{3}H}$; the section will be $\frac{2}{3}wH$, and the discharge $=\frac{2}{3}\sqrt{2G}\,wH\sqrt{\frac{1}{3}H}$, and $d=\frac{\frac{2}{3}wH}{w+\frac{4}{3}H}$. With these data the slope is easily had by the formula for uniform motion.

If the canal is of the trapezoidal form, the investigation is more troublesome, and requires the resolution of a cubic equation.

It may appear strange that increasing the slope of a canal beyond the quantity determined by this problem can diminish the quantity of water conveyed. But one of these two things must happen; either the motion will not acquire uniformity in such a canal for want of length,

Water-works.

length, or the discharge must diminish. Supposing, however, that it could augment, we can judge how far this can go. Let us take the extreme case by making the canal vertical. In this case it becomes a simple weir or wasteboard. Now the discharge of a wasteboard is $\frac{2}{3}\sqrt{2\,G}\,w\,(h^{\frac{3}{2}}-(\frac{1}{3}h)^{\frac{3}{2}}$. The maximum determined by the preceding problem is to that of the wasteboard of the same dimensions as $H\sqrt{\frac{1}{3}H} : H^{\frac{3}{2}} - (\frac{1}{3}H)^{\frac{3}{2}}$, or as $H\sqrt{\frac{1}{3}H} : H\sqrt{H} - \frac{1}{3}H\sqrt{\frac{1}{3}H}, = 5773 : 6465$, nearly $= 9 : 10$.

Having given the dimensions and slope of a canal, we can discover the relation between its expenditure and the time: or we can tell how much it will sink the surface of a pond in 24 hours, and the gradual progress of this effect; and this might be made the subject of a particular problem. But it is complicated and difficult. In cases where this is an interesting object, we may solve the question with sufficient accuracy, by calculating the expenditure at the beginning, supposing the bason kept full. Then from the known area of the pond, we can tell in what time this expenditure will sink an inch; do the same on the supposition that the water is one-third lower, and that it is two-thirds lower (noticing the contraction of the surface of the pond occasioned by this abstraction of its waters). Thus we shall obtain three rates of diminution, from which we can easily deduce the desired relation between the expenditure and the time.

Aqueducts derived from a bason or river are commonly furnished with a sluice at the entry. This changes exceedingly the state of things. The slope of the canal may be precisely such as will maintain the mean velocity of the water which passes under the sluice; in which case the depth of the stream is equal to that of the sluice, and the velocity is produced at once by the head of water above it. But if the slope is less than this, the velocity of the issuing water is diminished, and the water must rise in the canal. This must check the efflux at the sluice, and the water will be as it were stagnant above what comes through below it. It is extremely difficult to determine at what precise slope the water will begin to check the efflux. The contraction at the lower edge of the board hinders the water from attaining at once the whole depth which it acquires afterwards, when its velocity diminishes by the obstructions. While the regorging which these obstructions occasion does not reach back to the sluice, the efflux is not affected by it.—Even when it does reach to the sluice, there will be a less depth immediately behind it than farther down the canal, where it is in train; because the swift moving water which is next the bottom drags with it the regorged water which lies on it: but the canal must be rapid to make this difference of depth sensible. In ordinary canals, with moderate slopes and velocities, the velocity at the sluice may be safely taken as if it were that which corresponds to the difference of depths above and below the sluice, where both were in train.

Let therefore H be the depth above the sluice, and h the depth in the canal. Let e be the elevation of the sluice above the sole, and let b be its breadth. The discharge will be $e\,b\sqrt{H-h}\sqrt{2\,G}$ for the sluice, and $w\,h\frac{\sqrt{N\,g}}{\sqrt{s}}\sqrt{\frac{w\,h}{w+2\,h}}$ for the canal. These must be the same. This gives the equation $e\,b\sqrt{H-h}\sqrt{2\,G} = w\,h\frac{\sqrt{N\,g}}{\sqrt{s}}\sqrt{\frac{w\,h}{w+2\,h}}$ containing the solution of all the questions which can be proposed. The only uncertainty is in the quantity G, which expresses the velocity competent to the passage of the water through the orifice, circumstanced as it is, namely, subjected to contraction. This may be regulated by a proper form given to the entry into this orifice. The contraction may be almost annihilated by making the masonry of a cycloidal form on both sides, and also at the lower edge of the sluice-board, so as to give the orifice a form resembling fig. 5. D, in the article RIVERS. If the sluice is thin in the face of a bason, the contraction will reduce 2 G to 296. If the sluice be as wide as the canal, 2 G will be nearly 500.

Question 4. Given the head of water in the bason H, the breadth b, and the elevation e of the sluice, and the breadth w and slope s of the canal, to find the depth h of the stream, the velocity, and the discharge?

We must (as in *Question* 2.) make a first supposition for h, in order to find the proper value of d. Then the equation $e\,b\sqrt{H-h}\sqrt{2\,G} = w\,h\frac{\sqrt{N\,g}}{\sqrt{s}}$ gives $h = \frac{G\,e^2\,b^2\,s}{w^2\,N\,g\,d} + \sqrt{\frac{G\,e^2\,b^2\,s\,H}{w^2\,N\,g\,d} + \left(\frac{G\,e^2\,b^2\,s}{w^2\,N\,g\,d}\right)^2}$. If this value shall differ considerably from the one which we assumed in order to begin the computation, make use of it for obtaining a new value of d, and repeat the operation. We shall rarely be obliged to perform a third operation.

The following is of frequent use:

Question 5. Given the dimensions and the slope, with the velocity and discharge of a river in its ordinary state, required the area or section of the sluice which will raise the waters to a certain height, still allowing the same quantity of water to pass through? Such an operation may render the rivers navigable for small craft or rafts above the sluice.

The problem is reduced to the determination of the size of orifice which will discharge this water with a velocity competent to the height to which the river is to be raised; only we must take into consideration the velocity of the water above the sluice, considering it as produced by a fall which makes a part of the height productive of the whole velocity at the sluice. Therefore H, in our investigation, must consist of the height to which we mean to raise the waters, and the height which will produce the velocity with which the waters approach the sluice: h, or the depth of the stream, is the ordinary depth of the river. Then (using the former symbols) we have $e\,b\,\frac{w\,h\sqrt{N\,g\,d}}{\sqrt{2\,G\,s\,(H-h)}}, = \frac{Q}{\sqrt{2\,G\,(H-h)}}$.

If the area of the sluice is known, and we would learn the height to which it will raise the river, we have $H-h = \frac{Q^2}{2\,G\,e^2\,b^2}$ for the expression of the rise of the

water

Water-works.

water above its ordinary level. But from this we must take the height which would produce the velocity of the river; so that if the sluice were as wide as the river, and were raised to the ordinary surface of the water, $\frac{Q^2}{2 G e^2 b^2}$, which expresses the height that produces the velocity under the sluice, must be equal to the depth of the river, and H—h will be =0.

The performance of aqueduct drains is a very important thing, and merits our attention in this place. While the art of managing waters, and of conducting them so as to answer our demands, renders us very important service by embellishing our habitations, or promoting our commercial intercourse, the art of draining creates as it were new riches, fertilizing tracts of bog or marsh, which was not only useless, but hurtful by its unwholesome exhalations, and converting them into rich pastures and gay meadows. A wild country, occupied by marshes which are inaccessible to herds or flocks, and serve only for the haunts of water-fowls, or the retreat of a few poor fishermen, when once it is freed from the waters in which it is drowned, opens its lap to receive the most precious seeds, is soon clothed in the richest garb, gives life and abundance to numerous herds, and never fails to become the delight of the industrious cultivator who has enfranchised it, and is attached to it by the labour which it cost him. In return, it procures him abundance, and supplies him with the means of daily augmenting its fertility. No species of agriculture exhibits such long-continued and progressive improvement. New families flock to the spot, and there multiply; and there nature seems the more eager to repay their labours, in proportion as she has been obliged, against her will, to keep her treasures locked up for a longer time, chilled by the waters. The countries newly inhabited by the human race, as is a great part of America, especially to the southward, are still covered to a great extent with marshes and lakes; and they would long remain in this condition, if population, daily making new advances, did not increase industry, by multiplying the cultivating hands, at the same time that it increases their wants. The Author of this beautiful world has at the beginning formed the great masses of mountain, has scooped out the dales and sloping hills, has traced out the courses, and even formed the beds of the rivers: but he has left to man the care of making his place of abode, and the field which must feed him, dry and comfortable. For this task is not beyond his powers, as the others are. Nay, by having this given to him in charge, he is richly repaid for his labour by the very state in which he finds those countries into which he penetrates for the first time. Being covered with lakes and forests, the juices of the soil are kept for him as it were in reserve. The air, the burning heat of the sun, and the continual washing of rains, would have combined to expend and dissipate their vegetative powers, had the fields been exposed in the same degree to their action as the inhabited and cultivated countries, the most fertile moulds of which are long since lodged in the bottom of the ocean. All this would have been completely lost through the whole extent of South America, had it not been protected by the forests which man must cut down, by the rank herbage which he must burn, and by the marsh and bog which he must destroy by draining. Let not ungrateful man complain of this. It is his duty to take on himself the task of opening up treasures, preserved on purpose for him with so much judgment and care. If he has discernment and sensibility, he will even thank the Author of all good, who has thus husbanded them for his use. He will co-operate with his beneficent views, and will be careful not to proceed by wantonly snatching at present any partial good, and by picking out what is most easily got at, regardless of him who is to come afterwards to uncover and extract the remaining riches of the ground. A wise administration of such a country will think it their duty to leave a just share of this inheritance to their descendants, who are entitled to expect it as the last legatees. National plans of cultivation should be formed on this principle, that the steps taken by the present cultivators for realizing part of the riches of the infant country shall not obstruct the works which will afterwards be necessary for also obtaining the remainder. This is carefully attended to in Holland and in China. No man is allowed to conduct the drains, by which he recovers a piece of marsh, in such a way as to render it much more difficult for a neighbour, or even for his own successor, to drain another piece, although it may at present be quite inaccessible. There remain in the middle of the most cultivated countries many marshes, which industry has not yet attempted to drain, and where the legislature has not been at pains to prevent many little abuses which have produced elevations in the beds of rivers, and rendered the complete draining of some spots impossible. Administration should attend to such things, because their consequences are great. The sciences and arts, by which alone these difficult and costly jobs can be performed, should be protected, encouraged, and cherished. It is only from science that we can obtain principles to direct these arts. The problem of draining canals is one of the most important, and yet has hardly ever occupied the attention of the hydraulic speculatist. We apprehend that M. Buat's theory will throw great light on it; and regret that the very limited condition of our present work will hardly afford room for a slight sketch of what may be done on the subject. We shall, however, attempt it by a general problem, which will involve most of the chief circumstances which occur in works of that kind.

Quest. 6. Let the hollow ground A (fig. 2.) be inundated by rains or springs, and have no outlet but the canal AB, by which it discharges its water into the neighbouring river BCDE, and that its surface is nearly on a level with that of the river at D. It can only drain when the river sinks in the droughts of summer; and even if it could then drain completely, the putrid marsh would only be an infecting neighbour. It may be proposed to drain it by one or more canals; and it is required to determine their lengths and other dimensions, so as to produce the best effects?

It is evident that there are many circumstances to determine the choice, and many conditions to be attended to.

If the canals AC, AD, AG, are respectively equal to the proportions BC, BD, BF, of the river, and have the same slopes, they will have the same discharge; but they are not for this reason equivalent. The long canal AE may drain the marsh completely, while the short

Water-works.

one AC will only do it in part; because the difference of level between A and C is but inconsiderable. Also the freshes of the river may totally obstruct the operation of AC, while the canal AE cannot be hurt by them, E being so much lower than C. Therefore the canal must be carried so far down the river, that no freshes there shall ever raise the waters in the canal so high as to reduce the slope in the upper part of it to such a level that the current shall not be sufficient to carry off the ordinary produce of water in the marsh.

Still the problem is indeterminate, admitting many solutions. This requisite discharge may be accomplished by a short but wide canal, or by a longer and narrower. Let us first see what solution can be made, so as to accomplish our purpose in the most economical manner, that is, by means of the smallest equation.—We shall give the solution in the form of an example.

Suppose that the daily produce of rains and springs raises the water $1\frac{1}{2}$ inch on an area of a square league, which gives about 120,000 cubic fathoms of water. Let the bottom of the bason be three feet below the surface of the freshes in the river at B in winter. Also, that the slope of the river is 2 inches in 100 fathoms, or $\frac{1}{3600}$dth, and that the canal is to be 6 feet deep.

The canal being supposed nearly parallel to the river, it must be at least 1800 fathoms long before it can be admitted into the river, otherwise the bottom of the bog will be lower than the mouth of the canal; and even then a hundred or two more fathoms added to this will give it so little slope, that an immense breadth will be necessary to make the discharge with so small a velocity. On the other hand, if the slope of the canal be made equal to that of the river, an extravagant length will be necessary before its admission into the river, and many obstacles may then intervene. And even then it must have a breadth of 13 feet, as may easily be calculated by the general hydraulic theorem. By receding from each of these extremes, we shall diminish the expence of excavation. Therefore,

Let x and y be the breadth and length, and h the depth (6 feet), of the canal. Let q be the depth of the bog below the surface of the river, opposite to the bason, D the discharge in a second, and $\frac{1}{a}$ the slope of the river. We must make $h\,x\,y$ a minimum, or $x\dot{y}+y\dot{x}=0$.

The general formula gives the velocity

$$V=\frac{\sqrt{n\,g}\,(\sqrt{d}-0{,}1)}{\sqrt{s}-L\sqrt{s+1{,}6}}-0{,}3(\sqrt{d}-0{,}1).$$ This would give x and y; but the logarithmic term renders it very complicated. We may make use of the simple form $V=\frac{\sqrt{N\,g\,d}}{\sqrt{S}}$, making $\sqrt{n\,g}$ nearly $2\,y\,b$. This will be sufficiently exact for all cases which do not deviate far from this, because the velocities are very nearly in the subduplicate ratio of the slopes.

To introduce these data into the equation, recollect that $V=\frac{D}{h\,x}$; $d=\frac{h\,x}{x+2\,h}$. As to S, recollect that the canal being supposed of nearly equal length with the river, $\frac{y}{a}$ will express the whole difference of height, and $\frac{y}{a}-q$ is the difference of height for the canal. This quantity being divided by y, gives the value of $\frac{1}{S}=\frac{\frac{y}{a}-q}{y}$. Therefore the equation for the canal becomes $\sqrt{N\,g}\sqrt{\frac{h\,x}{x+2\,h}}\sqrt{\frac{\frac{y}{a}-q}{y}}$. Hence we deduce

$$y=\frac{N\,g\,q\,h^3x^3}{\frac{N\,g\,h^3x^3}{a}-D^2(x+2h)}\text{ and }\dot{y}=\frac{3\,N\,g\,q\,h^3x^2\dot{x}}{\frac{N\,g\,h^3x^3}{a}-D^2(x+2h)}$$

$$-\frac{N\,g\,q\,h^3x^3\dot{x}\left(\frac{3\,N\,g\,h^3\,x^2}{a}-D^2\right)}{\left(\frac{N\,g\,h^3\,x^3}{a}-D^2\,(x+2\,h)\right)^2}.$$ If we substitute these values in the equation $y\,\dot{x}+x\,\dot{y}=0$, and reduce it, we obtain finally,

$$\frac{N\,g\,h^3\,x^3}{a\,D^2}-3\,x=8\,h.$$

If we resolve this equation by making $N\,g=(296)^2$, or 87616 inches; $h=72$, $\frac{1}{a}=\frac{1}{3600}$, and $D=518400$, we obtain $x=392$ inches, or 32 feet 8 inches, and $\frac{D}{hx}$, or $V=18{,}36$ inches. Now putting these values in the exact formula for the velocity, we obtain the slope of the canal, which is $\frac{1}{11664}$, nearly 0,62, inches in 100 fathoms.

Let l be the length of the canal in fathoms. As the river has 2 inches fall in 100 fathoms, the whole fall is $\frac{2\,l}{100}$, and that of the canal is $\frac{0{,}62\,l}{100}$. The difference of these two must be 3 feet, which is the difference between the river and the entry of the canal. We have therefore $\left(\frac{2-0.62}{100}\right)\,l=36$ inches. Hence $l=2604$ fathoms; and this multiplied by the section of the canal gives 14177 cubic fathoms of earth to be removed.

This may surely be done, in most cases, for eight shillings each cubic fathom, which does not amount to 6000l. a very moderate sum for completely draining of nine square miles of country.

In order to judge of the importance of this problem, we have added two other canals, one longer and the other shorter, having their widths and slopes so adjusted as to ensure the same performance.

Width. Feet.	Velocity. Inches.	Slope.	Length.	Excavation.
42	14.28	$\frac{1}{18788}$	2221	15547
$32\frac{2}{3}$	18.36	$\frac{1}{11664}$	2604	14177
21	28.57	$\frac{1}{4761}$	7381	15833

We have considered this important problem in its most simple state. If the bason is far from the river, so that the drains are not nearly parallel to it, and therefore have less slope attainable in their course, it is more difficult. Perhaps the best method is to try two very extreme cases and a middle one, and then a fourth, nearer to that extreme which differs least from the middle one in the

the quantity of excavation. This will point out on which side the minimum of excavation lies, and also the law by which it diminishes and afterwards increases. Then draw a line, on which set off from one end the lengths of the canals. At each length erect an ordinate representing the excavation; and draw a regular curve through the extremities of the ordinates. From that point of the curve which is nearest to the base line, draw another ordinate to the base. This will point out the best length of the canal with sufficient accuracy. The length will determine the slope, and this will give the width, by means of the general theorem. *N. B.* These draining canals must always come off from the bason with evasated entries. This will prevent the loss of much fall at the entry.

Two canals may sometimes be necessary. In this case expence may frequently be saved, by making one canal flow into the other. This, however, must be at such a distance from the bason, that the swell produced in the other by this addition may not reach back to the immediate neighbourhood of the bason, otherwise it would impede the performance of both. For this purpose, recourse must be had to Problem III. in N° 104. of the article RIVER. We must here observe, that in this respect canals differ exceedingly from rivers; rivers enlarge their beds, so as always to convey every increase of waters; but a canal may be gorged through its whole length, and will then greatly diminish its discharge. In order that the lower extremity of a canal may convey the waters of an equal canal admitted into it, their junction must be so far from the bason that the swell occasioned by raising its waters nearly $\frac{2}{7}$ more (viz. in the subduplicate ratio of 1 to 2) may not reach back to the bason.

This observation points out another method of economy. Instead of one wide canal, we may make a narrower one of the whole length, and another narrow one reaching part of the way, and communicating with the long canal at a proper distance from the bason. But the lower extremity will now be too shallow to convey the waters of both. Therefore raise its banks by using the earth taken from its bed, which must at any rate be disposed of. Thus the waters will be conveyed, and the expence, even of the lower part of the long canal, will scarcely be increased.

These observations must suffice for an account of the management of open canals; and we proceed to the consideration of the conduct of water in pipes.

This is much more simple and regular, and the general theorem requires very trifling modifications for adapting it to the cases or questions that occur in the practice of the civil engineer. Pipes are always made round, and therefore d is always $\frac{1}{4}$th of the diameter. The velocity of water in a pipe which is in train, is

$$= V, = \frac{307\ (\sqrt{d}-0{,}1)}{\sqrt{s}-L\sqrt{s+1{,}6}} - 0{,}3(\sqrt{d}-0{,}) \text{ or } = (\sqrt{d} - 0{,}1)\left(\frac{307}{\sqrt{s}-L\sqrt{s+1{,}6}} - 0{,}3\right).$$

The chief questions are the following:

Quest. 1. Given the height H of the reservoir above the place of delivery, and the diameter and length of the pipe, to find the quantity of water discharged in a second.

Let L be the length, and h the fall which would produce the velocity with which the water enters the pipe, and actually flows in it, after overcoming all obstructions. This may be expressed in terms of the velocity by $\frac{V^2}{2G}$, G denoting the acceleration of gravity, corresponding to the manner of entry. When no methods are adopted for facilitating the entry of the water, by a bell-shaped funnel or otherwise, 2 G may be assumed as = 500 inches, or 42 feet, according as we measure the velocity in inches or feet. The slope is $\frac{1}{s}$, $= \frac{H - \frac{V^2}{2G}}{L}$, which must be put into the general formula. This would make it very complicated. We may simplify it by the consideration that the velocity is very small in comparison of that arising from the height H: consequently h is very small. Also, in the same pipe, the resistances are nearly in the duplicate ratio of the velocities when these are small, and when they differ little among themselves. Therefore make $b = \frac{L}{h}$, taking h by guess, a very little less than H. Then compute the mean velocity v corresponding to these data, or take it from the table. If $h + \frac{v^2}{2G}$ be = H, we have found the mean velocity $V = v$. If not, make the following proportion:

$$h : \frac{v^2}{2G} = H - \frac{V^2}{2G} : \frac{V^2}{2G},$$ which is the same with this, $h + \frac{v^2}{2G} : v^2 = H : V^2$, and V^2 is $= \frac{v^2 H}{h + \frac{v^2}{2G}}$,

$$= \frac{v^2 H}{\frac{2G\,h + v^2}{2G}} = \frac{v^2 \cdot 2GH}{v^2 + 2Gh}.$$

If the pipe has any bendings, they must be calculated for in the manner mentioned in the article RIVER, N° 101; and the head of water necessary for overcoming this additional resistance being called $\frac{V^2}{m}$, the last proportion must be changed for

$$h + v^2\left(\frac{1}{2G} + \frac{1}{m}\right) : v^2 = H : V^2.$$

Quest. 2. Given the height of the reservoir, the length of the pipe, and the quantity of water which is to be drawn off in a second; to find the diameter of the pipe which will draw it off?

Let d be considered as $= \frac{1}{4}$th of the diameter, and let $1 : c$ represent the ratio of the diameter of a circle to its circumference. The section of the pipe is $4\,c\,d^2$. Let the quantity of water per second be Q; then $\frac{Q}{4\,c\,d^2}$ is the mean velocity. Divide the length of the pipe by the height of the reservoir above the place of delivery, diminished by a very small quantity, and call the quotient S. Consider this as the slope of the conduit; the general formula now becomes

$$\frac{Q}{4d^2} = \frac{307(\sqrt{d}-0{,}1)}{\sqrt{s}-L\sqrt{s+1{,}06}} - 0{,}3\ (\sqrt{d}-0{,}1), \text{ or}$$

$$\frac{Q}{4cd^2}$$

Water-works.

$$\frac{Q}{4cd^2}=\frac{307(\sqrt{d}-0,1)}{\sqrt{S}}-0,3\ (\sqrt{d}-0,1).$$ We may neglect the last term in every case of civil practice, and also the small quantity 0,1. This gives the very simple formula,

$$\frac{Q}{4cd^2}=\frac{307\sqrt{d}}{\sqrt{S}}$$

from which we readily deduce

$$d=\left|\frac{Q\sqrt{S}}{4c\times 307}\right|^{\frac{2}{5}}=\left|\frac{Q\sqrt{S}}{3858}\right|^{\frac{2}{5}}$$

This process gives the diameter somewhat too small. But we easily rectify this error by computing the quantity delivered by the pipe, which will differ a little from the quantity proposed. Then observing, by this equation, that two pipes having the same length and the same slope give quantities of water, of which the squares are nearly as the fifth powers of the diameter, we form a new diameter in this proportion, which will be almost perfectly exact.

It may be observed that the height assumed for determining the slope in these two questions will seldom differ more than an inch or two from the whole height of the reservoir above the place of delivery; for in conduits of a few hundred feet long, the velocity seldom exceeds four feet per second, which requires only a head of three inches.

As no inconvenience worth minding results from making the pipes a tenth of an inch or so wider than is barely sufficient, and as this generally is more than the error arising from even a very erroneous assumption of *h*, the answer first obtained may be augmented by one or two-tenths of an inch, and then we may be confident that our conduit will draw off the intended quantity of water.

We presume that every person who assumes the name of engineer knows how to reduce the quantity of water measured in gallons, pints, or other denominations, to cubic inches, and can calculate the gallons, &c. furnished by a pipe of known diameter, moving with a velocity that is measured in inches per second. We farther suppose that all care is taken in the construction of the conduit, to avoid obstructions occasioned by lumps of solder hanging in the inside of the pipes; and, particularly, that all the cocks and plugs by the way have waterways equal to the section of the pipe. Undertakers are most tempted to fail here, by making the cocks too small, because large cocks are very costly. But the employer should be scrupulously attentive to this; because a simple contraction of this kind may be the throwing away of many hundred pounds in a wide pipe, which yields no more water than can pass through the small cock.

The chief obstructions arise from the deposition of sand or mud in the lower parts of pipes, or the collection of air in the upper parts of their bendings. The velocity being always very moderate, such depositions of heavy matters are unavoidable. The utmost care should therefore be taken to have the water freed from all such things at its entry by proper filtration; and there ought to be cleansing plugs at the lower parts of the bendings, or rather a very little way beyond them. When these are opened, the water issues with greater velocity, and carries the depositions with it.

It is much more difficult to get rid of the air which chokes the pipes by lodging in their upper parts. This is sometimes taken in along with the water at the reservoir, when the entry of the pipe is too near the surface. This should be carefully avoided, and it costs no trouble to do so. If the entry of the pipe is two feet under the surface, no air can ever get in. Floats should be placed above the entries, having lids hanging from them, which will shut the pipe before the water runs too low.

But air is also disengaged from spring-water by merely passing along the pipe. When pipes are supplied by an engine, air is very often drawn in by the pumps in a disengaged state. It is also disengaged from its state of chemical union, when the pumps have a suction-pipe of 10 or 12 feet, which is very common. In whatever way it is introduced, it collects in all the upper part of bendings, and chokes the passage, so that sometimes not a drop of water is delivered. Our cocks should be placed there, which should be opened frequently by persons who have this in charge. Desaguliers describes a contrivance to be placed on all such eminences, which does this of itself. It is a pipe with a cock, terminating in a small cistern. The key of the cock has a hollow ball of copper at the end of a lever. When there is no air in the main pipe, water comes out by this discharger, fills the cistern, raises the ball, and thus shuts the cock. But when the bend of the main contains air, it rises into the cistern, and occupies the upper part of it. Thus the floating ball falls down, the cock opens and lets out the air, and the cistern again filling with water, the ball rises, and the cock is again shut.

A very neat contrivance for this purpose was invented by the late Professor Russel of Edinburgh. The cylindrical pipe BCDE (fig. 3.), at the upper end of a bending of the main, is screwed on, the upper end of which is a flat plate perforated with a small hole F. This pipe contains a hollow copper cylinder G, to the upper part of which is fastened a piece of soft leather H. When there is air in the pipe, it comes out by the hole A, and occupies the discharger, and then escapes through the hole F. The water follows, and, rising in the discharger, lifts up the hollow cylinder G, causing the leather H to apply itself to the plate CD, and shut the hole. Thus the air is discharged without the smallest loss of water. Fig. 3.

It is of the most material consequence that there be no contraction in any part of a conduit. This is evident; but it is also prudent to avoid all unnecessary enlargements. For when the conduit is full of water moving along it, the velocity in every section is inversely proportional to the area of the section: it is therefore diminished wherever the pipe is enlarged; but it must again be increased where the pipe contracts. This cannot be without expending force in the acceleration. This consumes part of the impelling power, whether this be a head of water, or the force of an engine. See what is said on this subject in the article PUMPS, N° 83, &c. Nothing is gained by any enlargement; and every contraction, by requiring an augmentation of velocity, employs a part of the impelling force precisely equal to the weight of a column of water whose base is the contracted passage, and whose height is the fall which would produce a velocity equal to this augmentation. This point seems to have been quite overlooked by engineers of the first eminence, and has in many instances ...tly greatly diminished the performance of their best works. It is no less detrimental in open canals; because at every contraction a small fall is required for restoring the velocity lost in the enlargement of the canal, by which the general slope and velocity are diminished. Another point which must be attended to in the conducting of water is, that the motion should not be subsultory, but continuous. When the water is to be driven along a main by the strokes of a reciprocating engine, it should be forced into an air-box, the spring of which may preserve it in motion along the whole subsequent main. If the water is brought to rest at every successive stroke of the piston, the whole mass must again be put in motion through the whole length of the main. This requires the same useless expenditure of power as to communicate this motion to as much dead matter; and this is over and above the force which may be necessary for raising the water to a certain height; which is the only circumstance that enters into the calculation of the power of the pump-engine.

An air-box removes this imperfection, because it keeps up the motion during the returning stroke of the piston. The compression of the air by the active stroke of the piston must be such as to continue the impulse in opposition to the contrary pressure of the water (if it is to be raised to some height), and in opposition to the friction or other resistances which arise from the motion that the water really acquires. Indeed a very considerable force is employed here also in changing the motion of the water, which is forced out of the capacious air-box into the narrow pipe; and when this change of motion is not judiciously managed, the expenditure of power may be as great as if all were brought to rest and again put in motion. It may even be greater, by causing the water to move in the opposite direction to its former motion. Of such consequence is it to have all these circumstances scientifically considered. It is in such particulars, unheeded by the ordinary herd of engineers or pump-makers, that the superiority of an intelligent practitioner is to be seen.

Another material point in the conduct of water in pipes is the distribution of it to the different persons who have occasion for it. This is rarely done from the rising main. It is usual to send the whole into a cistern, from which it is afterwards conducted to different places in separate pipes. Till the discovery of the general theorem by the chevalier Buat, this has been done with great inaccuracy. Engineers think that the different purchasers from water-works receive in proportion to their respective bargains when they give them pipes whose areas are proportional to these payments. But we now see, that when these pipes are of any considerable length, the waters of a larger pipe run with a greater velocity than those of a smaller pipe having the same slope. A pipe of two inches diameter will give much more water than four pipes of one inch diameter; it will give as much as five and a half such pipes, or more; because the squares of the discharges are very nearly as the fifth powers of the diameters. This point ought therefore to be carefully considered in the bargains made with the proprietors of water-works, and the payments made in this proportion. Perhaps the most unexceptionable method would be to make a double distribution. Let the water be first let off in its proper proportions into a second series of small cisterns, and let each have a pipe which will convey the whole water that is discharged into it. The first distribution may be made entirely by pipes of one inch in diameter; this would leave nothing to the calculation of the distributor, for every man would pay in proportion to the number of such pipes which run into his own cistern.

In many cases, however, water is distributed by pipes derived from a main. And here another circumstance comes into action. When water is passing along a pipe, its pressure on the sides of the pipe is diminished by its velocity; and if a pipe is now derived from it, the quantity drawn off is also diminished in the subduplicate ratio of the pressures. If the pressure is reduced to one-fourth, one-ninth, one-sixteenth, &c. the discharge from the lateral pipe is reduced to one-half, one-third, one-fourth, &c.

It is therefore of great importance to determine, what this diminution of pressure is which arises from the motion along the main.

It is plain, that if the water suffered no resistance in the main, its velocity would be that with which it entered, and it would pass along without exerting any pressure. If the pipe were shut at the end, the pressure on the sides would be the full pressure of the head of water. If the head of water remain the same, and the end of the tube be contracted, but not stopped entirely, the velocity in the pipe is diminished. If we would have the velocity in the pipe with this contracted mouth augmented to what it was before the contraction was made, we must employ the pressure of a piston, or of a head of water. This is propagated through the fluid, and thus a pressure is immediately excited on the sides of the pipe. New obstructions of any kind, arising from friction or any other cause, produce a diminution of velocity in the pipe. But when the natural velocity is checked, the particles react on what obstructs their motion; and this action is uniformly propagated through a perfect fluid in every direction. The resistance therefore which we thus ascribe to friction, produces the same lateral pressure, which a contraction of the orifice, which equally diminishes the velocity in the pipe, would do. Indeed this is demonstrable from any distinct notions that we can form of these obstructions. They proceed from the want of perfect smoothness, which obliges the particles next the sides to move in undulated lines. This excites transverse forces in the same manner as any constrained curvilineal motion. A particle in its undulated path tends to escape from it, and acts on the lateral particles in the same manner that it would do if moving singly in a capillary tube having the same undulations; it would press on the concave side of every such undulation. Thus a pressure is exerted among the particles, which is propagated to the sides of the pipe; or the diminution of velocity may arise from a viscidity or want of perfect fluidity. This obliges the particle immediately pressed to drag along with it another particle which is withheld by adhesion to the sides. This requires additional pressure from a piston, or an additional head of water; and this pressure also is propagated to the sides of the pipe.

Hence it should follow, that the pressure which water in motion exerts on the sides of its conduit is equal to that which is competent to the head of water which impels

Water-works.

impels it into the pipe, diminished by the head of water competent to the actual velocity with which it moves along the pipe. Let H represent the head of water which impels it into the entry of the pipe, and h the head which would produce the actual velocity; then $H-h$ is the column which would produce the pressure exerted on its sides.

This is abundantly verified by very simple experiments. Let an upright pipe be inserted into the side of the main-pipe. When the water runs out by the mouth of the main, it will rise in this branch till the weight of the column balances the pressure that supports it; and if we then ascertain the velocity of the issuing water by means of the quantity discharged, and compute the head or height necessary for producing this velocity, and subtract this from the height of water above the entry of the main, we shall find the height in the branch precisely equal to their difference. Our readers may see this by examining the experiments related by Gravesande, and still better by consulting the experiments narrated by Bossut, § 558. which are detailed with great minuteness; the results corresponded accurately with this proposition. The experiments indeed were not heights of water supported by this pressure, but water expelled by it through the same orifice. Indeed the truth of the proposition appears in every way we can consider the motion of water. And as it is of the first importance in the practice of conducting water (for reasons which will presently appear), it merits a particular attention. When an inclined tube is in train, the accelerating power of the water (or its weight diminished in the proportion of the length of the oblique column to its vertical height, or its weight multiplied by the fraction $\frac{1}{s}$, which expresses the slope), is in equilibrio with the obstructions; and therefore it exerts no pressure on the pipe but what arises from its weight alone. Any part of it would continue to slide down the inclined plane with a constant velocity, though detached from what follows it. It therefore derives no pressure from the head of water which impelled it into the pipe. The same must be said of a horizontal pipe infinitely smooth, or opposing no resistance. The water would move in this pipe with the full velocity due to the head of water which impels it into the entry. But when the pipe opposes an obstruction, the head of water is greater than that which would impel it into the pipe with the velocity that it actually has in it; and this additional pressure is propagated along the pipe, where it is balanced by the actual resistance, and therefore excites a *quaqua versum* pressure on the pipe. In short, whatever part of the head of water in the reservoir, or of the pressure which impels it along the tube, is not employed in producing velocity, is employed in acting against some obstruction, and excites (by the reaction of this obstruction) an equal pressure on the tube. The rule therefore is general, but is subject to some modifications which deserve our attention.

Fig. 4. In the simply inclined pipe BC (fig. 4.) the pressure on any point S is equal to that of the head AB of water which impels the water into the pipe, wanting or *minus* that of the head of water which would communicate to it the velocity with which it actually moves. This we shall call x, and consider it as the weight of a column of water whose length also is x. In like manner H may be the column AB, which impels the water into the pipe, and would communicate a certain velocity; and h may represent the column which would communicate the actual velocity. We have therefore $x = H-h$.

In the pipe HIKL, the pressure at the point I is $AH-h-IO, =H-h-IO$; and the pressure at K is $H-h+PK$.

And in the pipe DEFG, the pressure on E is $=AR-h-EM, =H-h-EM$; and the pressure at F is $H-h+FN$.

We must carefully distinguish this pressure on any square inch of the pipe from the obstruction or resistance which that inch actually exerts, and which is part of the cause of this pressure. The pressure is (by the laws of hydrostatics) the same with that exerted on the water by a square inch of the piston or forcing head of water. This must balance the united obstructions of the whole pipe, in as far as they are not balanced by the relative weight of the water in an enclosed pipe. Whatever be the inclination of a pipe, and the velocity of the water in it, there is a certain part of this resistance which may not be balanced by the tendency which the water has to slide along it, provided the pipe be long enough; or if the pipe is too short, the tendency down the pipe may more than balance all the resistances that obtain below. In the first case, this overplus must be balanced by an additional head of water; and in the latter case the pipe is not in train, and the water will accelerate. There is something in the mechanism of these motions which makes a certain length of pipe necessary for bringing it into train; a certain portion of the surface which acts in concert in obstructing the motion. We do not completely understand this circumstance, but we can form a pretty distinct notion of its mode of acting. The film of water contiguous to the pipe is withheld by the obstruction, but glides along; the film immediately within this is withheld by the outer film, but glides through it: and thus all the concentric films glide within those around them, somewhat like the sliding tubes of a spyglass, when we draw it out by taking hold of the end of the innermost. Thus the second film passes beyond the first or outermost, and becomes the outermost, and rubs along the tube. The third does the same in its turn; and thus the central filaments come at last to the outside, and all sustain their greatest possible obstruction. When this is accomplished, the pipe is in train. This requires a certain length, which we cannot determine by theory. We see, however, that pipes of greater diameter must require a greater length, and this in a proportion which is probably that of the number of filaments, or the square of the diameter. Buat found this supposition agree well enough with his experiments. A pipe of one inch in diameter sustained no change of velocity by gradually shortening it till he reduced it to six feet, and then it discharged a little more water. A pipe of two inches diameter gave a sensible augmentation of velocity when shortened to 25 feet. He therefore says, that the square of the diameter in inches, multiplied by 72, will express (in inches) the length necessary for putting any pipe in train.

The resistance exerted by a square inch of the pipe makes but a small part of the pressure which the whole resistances

Water-works.

resistances occasion to be exerted there before they can be overcome. The resistance may be represented by $\frac{d}{s}$, when d is the hydraulic depth (one-fourth of the diameter), and s the length of a column whose vertical height is one inch, and it is the relative weight of a column of water whose base is a square inch, and height is d. For the resistance of any length s of pipe which is in train, is equal to the tendency of the water to slide down (being balanced by it); that is, is equal to the weight of this column multiplied by $\frac{1}{s}$. The magnitude of this column is had by multiplying its length by its section. The section is the product of the border b or circumference, multiplied by the mean depth d, or it is $b\,d$. This multiplied by the length, is $b\,d\,s$; and this multiplied by the slope $\frac{1}{s}$ is $b\,d$, the relative weight of the column whose length is s. The relative weight of one inch is therefore $\frac{b\,d}{s}$; and this is in equilibrio with the resistance of a ring of the pipe one inch broad. This, when unfolded, is a parallelogram b inches in length. One inch of this therefore is $\frac{d}{s}$, the relative weight of a column of water having d for its height and a square inch for its base. Suppose the pipe four inches in diameter, and the slope $= 253$, the resistance is one grain; for an inch of water weighs 253 grains.

This knowledge of the pressure of water in motion is of great importance. In the management of rivers and canals it instructs us concerning the damages which they produce in their beds by tearing up the soil; it informs us of the strength which we must give to the banks: but it is of more consequence in the management of close conduits. By this we must regulate the strength of our pipes; by this also we must ascertain the quantities of water which may be drawn off by lateral branches from any main conduit.

With respect to the first of these objects, where security is our sole concern, it is proper to consider the pressure in the most unfavourable circumstances, viz. when the end of the main is shut. This case is not unfrequent. Nay, when the water is in motion, its velocity in a conduit seldom exceeds a very few feet in a second. Eight feet per second requires only one foot of water to produce it. We should therefore estimate the strain on all conduits by the whole height of the reservoir.

In order to adjust the strength of a pipe to the strain, we may conceive it as consisting of two half cylinders of insuperable strength, joined along the two seams, where the strength is the same with the ordinary strength of the materials of which it is made. The inside pressure tends to burst the pipe by tearing open these seams; and each of these two seams is equal to the weight of a column of water whose height is the depth of the seam below the surface of the reservoir, and whose base is an inch broad and a diameter of the pipe in length. This follows from the common principles of hydrostatics.

Suppose the pipe to be of lead, one foot in diameter and 100 feet under the surface of the reservoir. Water weighs $62\frac{1}{2}$ pounds per foot. The base of our column is therefore $\frac{1}{12}$th of a foot, and the tendency to burst the pipe is $100 \times 62\frac{1}{2} \times \frac{1}{12}th=\frac{6250}{12}$, $= 521$ pounds nearly. Therefore an inch of one seam is strained by $260\frac{1}{2}$ pounds. A rod of lead one inch square is pulled asunder by 860 pounds, (see *Strength of Materials*, N° 40.). Therefore if the thickness of the seam is $=\frac{260}{860}$ inches, or one-third of an inch, it will just withstand this strain. But we must make it much stronger than this, especially if the pipe leads from an engine which sends the water along it by starts. Belidor and Desaguliers have given tables of the thickness and weights of pipes which experience has found sufficient for the different materials and depths. Desaguliers says, that a leaden pipe of three-fourths of an inch in thickness is strong enough for a height of 140 feet and diameter of seven inches. From this we may calculate all others. Belidor says, that a leaden pipe 12 inches diameter and 60 feet deep should be half an inch thick: but these things will be more properly computed by means of the list given in N° 40 of the article *Strength of Materials*.

The application which we are most anxious to make of the knowledge of the pressure of moving waters is the derivation from a main conduit by lateral branches. This occurs very frequently in the distribution of waters among the inhabitants of towns; and it is so imperfectly understood by the greatest part of those who take the name of engineers, that individuals have no security that they shall get even one half of the water they bargain and pay for; yet this may be as accurately ascertained as any other problem in hydraulics by means of our general theorem. The case therefore merits our particular attention.

It appears to be determined already, when we have ascertained the pressures by which the water is impelled into these lateral pipes, especially after we have said that the experiments of Bossut on the actual discharges from a lateral pipe fully confirm the theoretical doctrine. But much remains to be considered. We have seen that there is a vast difference between the discharge made through a hole, or even through a short pipe, and the discharge from the far end of a pipe derived from a main conduit. And even when this has been ascertained by our new theory, the discharge thus modified will be found considerably different from the real state of things: For when water is flowing along a main with a known velocity, and therefore exerting a known pressure on the circle which we propose for the entry of a branch, if we insert a branch there water will go along it: but this will generally make a considerable change in the motion along the main, and therefore in the pressure which is to expel the water. It also makes a considerable change in the whole quantity which passes along the anterior part of the main, and a still greater change on what moves along that part of it which lies beyond the branch: it therefore affects the quantity necessary for the whole supply, the force that is required for propelling it, and the quantity delivered by other branches. This part therefore of the management of water in conduits is of considerable importance and intricacy. We can propose in this place nothing more than a solution of such leading questions as involve the chief circumstances, recommending to our readers the perusal of original works on this subject. M. Bossut's experiments

experiments are fully competent to the establishment of the fundamental principle. The hole through which the lateral discharges were made was but a few feet from the reservoir. The pipe was successively lengthened, by which the resistances were increased, and the velocity diminished. But this did not affect the lateral discharges, except by affecting the pressures; and the discharges from the end of the main were supposed to be the same as when the lateral pipe was not inserted. Although this was not strictly true, the difference was insensible, because the lateral pipe had but about the 18th part of the area of the main.

Suppose that the discharge from the reservoir remains the same after the derivation of this branch, then the motion of the water all the way to the insertion of the branch is the same as before; but, beyond this, the discharge is diminished by all that is discharged by the branch, with the head x equivalent to the pressure on the side. The discharge by the lower end of the main being diminished, the velocity and resistance in it are also diminished. Therefore the difference between x and the head employed to overcome the friction in this second case, would be a needless or inefficient part of the whole load at the entry, which is impossible; for every force produces an effect, or it is destroyed by some reaction. The effect of the forcing head of water is to produce the greatest discharge corresponding to the obstructions; and thus the discharge from the reservoir, or the supply to the main, must be augmented by the insertion of the branch, if the forcing head of water remains the same. A greater portion therefore of the forcing head was employed in producing a greater discharge at the entry of the main, and the remainder, less then x, produced the pressure on the sides. This head was the one competent to the obstructions resulting from the velocity beyond the insertion of the branch; and this velocity, diminished by the discharge already made, was less than that at the entry, and even than that of the main without a branch. This will appear more distinctly by putting the case into the form of an equation. Therefore let $H-x$ be the height due to the velocity at the entry, of which the effect obtains only horizontally. The head x is the only one which acts on the sides of the tube, tending to produce the discharge by the branch, at the same time that it must overcome the obstructions beyond the branch. If the orifice did not exist, and if the force producing the velocity on a short tube be represented by $2\,G$, and the section of the main be A, the supply at the entry of the main would be $A\sqrt{2\,G}\sqrt{H-x}$; and if the orifice had no influence on the value of x, the discharge by the orifice would be $D\sqrt{\frac{x}{H}}$, D being its discharge by means of the head H, when the end of the main is shut; for the discharges are in the subduplicate ratio of the heads of water by which they are expelled; and therefore $\sqrt{H} : \sqrt{x} = D : D\sqrt{\frac{x}{H}} (=\delta)$. But we have seen that x must diminish; and we know that the obstructions are nearly as the square roots of the velocities, when these do not differ much among themselves. Therefore calling y the pressure or head which balances the resistances of the main without a branch, while x is the head necessary for the main with a branch, we may institute this proportion, $y : H-y = x \frac{x(H-y)}{y}$; and this 4th term will express the head producing the velocity in the main beyond the branch (as $H-y$ would have done in a main without a branch). This velocity beyond the branch will be $\sqrt{2\,G}\sqrt{\frac{x(H-y)}{y}}$, and the discharge at the end will be $A\sqrt{2\,G}\sqrt{\frac{x(H-y)}{y}}$. If to this we add the discharge of the branch, the sum will be the whole discharge, and therefore the whole supply. Therefore we have the following equation, $A\sqrt{2\,G}\sqrt{H-y} = A\sqrt{2G}\sqrt{\frac{x(H-y)}{y}} + D\sqrt{\frac{x}{H}}$. From this we deduce the value of x

$$= \frac{2GHA^2}{\left(A\sqrt{2\,G}\sqrt{\frac{H-y}{y}} + \frac{D}{\sqrt{H}}\right)^2 + 2GA^2}.$$

This value of x being substituted in the equation of the discharge δ of the branch, which was $= D\sqrt{\frac{x}{H}}$, will give the discharges required, and they will differ so much the more from the discharges calculated according to the simple theory, as the velocity in the main is greater. By the simple theory, we mean the supposition that the lateral discharges are such as would be produced by the head $H-h$, where H is the height of the reservoir, and h the head due to the actual velocity in the main.

And thus it appears that the proportion of the discharge by a lateral pipe from a main that is shut at the far end, and the discharge from a main that is open, depends not only on the pressures, but also on the size of the lateral pipe, and its distance from the reservoir. When it is large, it greatly alters the train of the main, under the same head, by altering the discharge at its extremity, and the velocity in it beyond the branch; and if it be near the reservoir, it greatly alters the train, because the diminished velocity takes place through a greater extent, and there is a greater diminution of the resistances.

When the branch is taken off at a considerable distance from the reservoir, the problem becomes more complicated, and the head x is resolved into two parts; one of which balances the resistance in the first part of the main, and the other balances the resistances beyond the lateral pipe, with a velocity diminished by the discharge from the branch.—A branch at the end of the main produces very little change in the train of the pipe.

When the lateral discharge is great, the train may be so altered, that the remaining part of the main will not run full, and then the branch will not yield the same quantity. The velocity in a very long horizontal tube may be so small (by a small head of water and great obstructions in a very long tube) that it will just run full. An orifice made in its upper side will yield nothing; and yet a small tube inserted into it will carry a column almost as high as the reservoir. So that we cannot judge in all cases of the pressures by the discharges, and *vice versa*.

If

If there be an inclined tube, having a head greater than what is competent to the velocity, we may bring it into train by an opening on its upper side near the reservoir. This will yield some water, and the velocity will diminish in the tube till it is in train. If we should now enlarge the hole, it will yield no more water than before.

And thus we have pointed out the chief circumstances which affect these lateral discharges. The discharges are afterwards modified by the conduits in which they are conveyed to their places of destination. These being generally of small dimensions, for the sake of economy, the velocity is much diminished. But, at the same time, it approaches nearer to that which the same conduit would bring directly from the reservoir, because its small velocity will produce a less change in the train of the main conduit.

We should now treat of jets of water, which still make an ornament in the magnificent pleasure grounds of the wealthy. Some of these are indeed grand objects, such as the two at Peterhoff in Russia, which spout about 60 feet high a column of nine inches diameter, which falls again, and shakes the ground with its blow. Even a spout of an inch or two inches diameter, lancing to the height of 150 feet, is a gay object, and greatly enlivens a pleasure ground; especially when the changes of a gentle breeze bend the jet to one side. But we have no room left for treating this subject, which is of some nicety; and must conclude this article with a very short account of the management of water as an active power for impelling machinery.

II. *Of Machinery driven by Water.*

This is a very comprehensive article, including almost every possible species of mill. It is no less important, and it is therefore matter of regret, that we cannot enter into the detail which it deserves. The mere description of the immense variety of mills which are in general use, would fill volumes, and a scientific description of their principles and maxims of construction would almost form a complete body of mechanical science. But this is far beyond the limits of a work like ours. Many of these machines have been already described under their proper names, or under the articles which give an account of their manufactures; and for others we must refer our readers to the original works, where they are described in minute detail. The great academical collection *Des Arts et Metiers*, published in Paris in many folio volumes, contains a description of the peculiar machinery of many mills; and the volumes of the *Encyclopédie Methodique*, which particularly relate to the mechanic arts, already contain many more. All that we can do in this place is, to consider the chief circumstances that are common to all water-mills, and from which all must derive their efficacy. These circumstances are to be found in the manner of employing water as an acting power, and most of them are comprehended in the construction of water-wheels. When we have explained the principles and the maxims of construction of a water-wheel, every reader conversant in mechanics knows, that the axis of this wheel may be employed to transmit the force impressed on it to any species of machinery. Therefore nothing subsequent to this can with propriety be considered as *water-works*.

Water-wheels are of two kinds, distinguished by the manner in which water is made an impelling power, viz. by its weight, or by its impulse. This requires a very different form and manner of adaptation; and this forms an ostensible distinction, sufficiently obvious to give a name to each class. When water is made to act by its weight, it is delivered from the spout as high on the wheel as possible, that it may continue long to press it down: but when it is made to strike the wheel, it is delivered as low as possible, that it may have previously acquired a great velocity. And thus the wheels are said to be OVERSHOT or UNDERSHOT.

Of Overshot Wheels.

This is nothing but a frame of open buckets, so disposed round the rim of a wheel as to receive the water delivered from a spout; so that one side of the wheel is loaded with water, while the other is empty. The consequence must be, that the loaded side must descend. By this motion the water runs out of the lower buckets, while the empty buckets of the rising side of the wheel come under the spout in their turn, and are filled with water.

If it were possible to construct the buckets in such a manner as to remain completely filled with water till they come to the very bottom of the wheel, the pressure with which the water urges the wheel round its axis would be the same as if the extremity of the horizontal radius were continually loaded with a quantity of water sufficient to fill a square pipe, whose section is equal to that of the bucket, and whose length is the diameter of the wheel. For let the buckets BD and EF (fig. 5.) Fig. 5.
be compared together, the arches DB and EF are equal. The mechanical energy of the water contained in the bucket EF, or the pressure with which its weight urges the wheel, is the same as if all this water were hung on that point T of the horizontal arm CF, where it is cut by the vertical or plumb-line BT. This is plain from the most elementary principles of mechanics. Therefore the effect of the bucket BD is to that of the bucket EF as CT to CF or CB. Draw the horizontal lines PB $b\,b$, QD $d\,d$. It is plain, that if BD is taken very small, so that it may be considered as a straight line, $BD : BO = CB : BP$, and $EF : b\,d = CF : CT$, and $EF \times CT = b\,d \times CF$. Therefore if the prism of water, whose vertical section is $b\,b\,d\,d$, were hung on at F, its force to urge the wheel round would be the same as that of the water lying in the bucket BD. The same may be said of every bucket; and the effective pressure of the whole ring of water AfHKFI, in its natural situation, is the same with the pillar of water $a\,h\,h\,a$ hung on at F. And the effect of any portion BF of this ring is the same with that of the corresponding portion b F$f$$b$ of the vertical pillar. We do not take into account the small difference which arises from the depth B or Ff, because we may suppose the circle described through the centres of gravity of the buckets. And in the farther prosecution of this subject, we shall take similar liberties, with the view of simplifying the subject, and saving time to the reader.

But such a state of the wheel is impossible. The bucket at the very top of the wheel may be completely filled with water; but when it comes into the oblique position BD, a part of the water must run over the outer edge δ, and the bucket will only retain the quantity

Water-works.

tity ZBD 3; and if the buckets are formed by partitions directed to the axis of the wheel, the whole water must be run out by the time that they descend to the level of the axis. To prevent this many contrivances have been adopted. The wheel has been surrounded with a hoop or sweep, consisting of a circular board, which comes almost into contact with the rim of the wheel, and terminates at H, where the water is allowed to run off. But unless the work is executed with uncommon accuracy, the wheel made exactly round, and the sweep exactly fitting it, a great quantity of water escapes between them; and there is a very sensible obstruction to the motion of such a wheel, from something like friction between the water and the sweep. Frost also effectually stops the motion of such a wheel. Sweeps have therefore been generally laid aside, although there are situations where they might be used with good effect.

Mill-wrights have turned their whole attention to the giving a form to the buckets which shall enable them to retain the water along a great portion of the circumference of the wheel. It would be endless to describe all these contrivances; and we shall therefore content ourselves with one or two of the most approved. The intelligent reader will readily see that many of the circumstances which concur in producing the ultimate effect (such as the facility with which the water is received into the buckets, the place which it is to occupy during the progress of the bucket from the top to the bottom of the wheel, the readiness with which they are evacuated, or the chance that the water has of being dragged beyond the bottom of the wheel by its adhesion, &c. &c.) are such as do not admit of precise calculation on reasoning about their merits; and that this or that form can seldom be evidently demonstrated to be the very best possible. But, at the same time, he will see the general reasons of preference, and his attention will be directed to circumstances which must be attended to, in order to have a good bucketed wheel.

Fig. 6.

Fig. 6. is the outline of a wheel having 40 buckets. The ring of board contained between the concentric circles QDS and PAR, making the ends of the buckets, is called the SHROUDING, in the language of the art, and QP is called the *depth of shrouding*. The inner circle PAR is called the SOLE of the wheel, and usually consists of boards nailed to strong wooden rings of compass timber of considerable scantling, firmly united with the ARMS or radii. The partitions, which determine the form of the buckets, consist of three different planes or boards AB, BC, CD, which are variously named by different artists. We have heard them named the START or SHOULDER, the ARM, and the WREST (probably for wrist, on account of a resemblance of the whole line to the human arm); B is also called the ELBOW. Fig. 7. represents a small portion of the same bucketing on a larger scale, that the proportions of the parts may be more distinctly seen. AG, the sole of one bucket, is made about $\frac{1}{4}$th more than the depth GH of the shrouding. The start AB is $\frac{1}{3}$ of AI. The plane BC is so inclined to AB that it would pass through H; but it is made to terminate in C, in such a manner that FC is $\frac{5}{12}$ths of GH or AI. Then CD is so placed that HD is about $\frac{1}{3}$th of IH.

Fig. 7.

By this construction, it follows that the area FABC is very nearly equal to DABC; so that the water which will fill the space FABC will all be contained in the bucket when it shall come into such a position that AD is a horizontal line; and the line AB will then make an angle of nearly 35° with the vertical, or the bucket will be 35° from the perpendicular. If the bucket descend so much lower that one half of the water runs out, the line AB will make an angle of 25°, or 24° nearly, with the vertical. Therefore the wheel, filled to the degree now mentioned will *begin* to lose water at about $\frac{1}{8}$th of the diameter from the bottom, and *half of the water will be discharged* from the lowest bucket, about $\frac{1}{22}$th of the diameter farther down. These situations of the discharging bucket are marked at T and V in fig. 6. Had a greater proportion of the buckets been filled with water when they were under the spout, the discharge would have begun at a greater height from the bottom, and we should lose a greater portion of the whole fall of water. The loss by the present construction is less than $\frac{1}{10}$th (supposing the water to be delivered into the wheel at the very top), and may be estimated at about $\frac{1}{12}$th; for the loss is the versed sine of the angle which the radius of the bucket makes with the vertical. The versed sine of 35° is nearly $\frac{1}{5}$th of the radius (being 0.18085), or $\frac{1}{10}$th of the diameter. It is evident, that if only $\frac{1}{2}$ of this water were supplied to each bucket as it passes the spout, it would have been retained for 10° more of a revolution, and the loss of fall would have been only about $\frac{1}{14}$th.

These observations serve to show, in general, that an advantage is gained by having the buckets so capacious that the quantity of water which each can receive as it passes the spout may not nearly fill it. This may be accomplished by making them of a sufficient length, that is, by making the wheel sufficiently broad between the two shroudings. Economy is the only objection to this practice, and it is generally very ill placed. When the work to be performed by the wheel is great, the addition of power gained by a greater breadth will soon compensate for the additional expence.

The third plane CD is not very frequent; and mill-wrights generally content themselves with continuing the board all the way from the elbow B to the outer edge of the wheel at H; and AB is generally no more than one-third of the depth AI. But CD is a very evident improvement, causing the wheel to retain a very sensible addition to the water. Some indeed make this addition more considerable, by bringing BC more outward, so as to meet the rim of the wheel at H, for instance, and making HD coincide with the rim. But this makes the entry of the water somewhat more difficult during the very short time that the opening of the bucket passes the spout. To facilitate this as much as possible, the water should get a direction from the spout, such as will send it into the buckets in the most perfect manner. This may be obtained by delivering water through an aperture that is divided by thin plates of board or metal, placed in the proper position, as we have represented in fig. 6. The form of bucket last mentioned, having the wrest concentric with the rim, is unfavourable to the ready admission of the water; whereas an oblique wrest conducts the water which has missed one bucket into the next below.

The mechanical consideration of this subject also shows us, that a deep shrouding, in order to make a capacious bucket,

bucket, is not a good method: it does not make the buckets retain their water any longer; and it diminishes the effective fall of water: for the water received at the top of the wheel immediately falls to the bottom of the bucket, and thus shortens the fictitious pillar of water, which we showed to be the measure of the effective or useful pressure on the wheel: and this concurs with our former reasons for recommending as great a breadth of the wheel, and length of buckets, as economical considerations will permit.

A bucket wheel was some time ago executed by Mr Robert Burns, at the cotton mills of Houston, Burns, and Co. at Cartside in Renfrewshire, of a construction entirely new, but founded on a good principle, which is susceptible of great extension. It is represented in fig. 8. The bucket consists of a start AB, an arm BC, and a wrest CD, concentric with the rim. But the bucket is also divided by a partition LM, concentric with the sole and rim, and so placed as to make the inner and outer portions of nearly equal capacity. It is evident, without any farther reasoning about it, that this partition will enable the bucket to retain its water much longer. When they are filled one-third, they retain the whole water at 18° from the bottom; and they retain one half at 11°. They do not admit the water quite so freely as buckets of the common construction; but by means of the contrivance mentioned a little ago for the spout (also the invention of Mr Burns, and furnished with a rack-work, which raised or depressed it as the supply of water varied, so as at all times to employ the whole fall of the water), it is found, that a slow-moving wheel allows one-half of the water to get into the inner buckets, especially if the partition do not altogether reach the radius drawn through the lip D of the outer bucket.

This is a very great improvement of the bucket wheel; and when the wheel is made of a liberal breadth, so that the water may be very shallow in the buckets, it seems to carry the performance as far as it can go. Mr Burns made the first trial on a wheel of 24 feet diameter; and its performance is manifestly superior to that of the wheel which it replaced, and which was a very good one. It has also another valuable property: When the supply of water is very scanty, a proper adjustment of the apparatus in the spout will direct almost the whole of the water into the outer buckets; which, by placing it at a greater distance from the axis, makes a very sensible addition to its mechanical energy.

We said that this principle is susceptible of considerable extension; and it is evident that two partitions will increase the effect, and that it will increase with the number of partitions: so that when the practice now begun, of making water-wheels of iron, shall become general, and therefore very thin partitions are used, their number may be greatly increased without any inconvenience: and it is obvious, that this series of partitions must greatly contribute to the stiffness and general firmness of the whole wheel.

There frequently occurs a difficulty in the making of bucket wheels, when the half-taught mill-wright attempts to retain the water a long time in the buckets. The water gets into them with a difficulty which he cannot account for, and spills all about, even when the buckets are not moving away from the spout. This arises from the air, which must find its way out to admit the water, but is obstructed by the entering water, and occasions a great spluttering at the entry. This may be entirely prevented by making the spout considerably narrower than the wheel. This will leave room at the two ends of the buckets for the escape of the air. This obstruction is vastly greater than one would imagine; for the water drags along with it a great quantity of air, as is evident in the *Water-blast* described by many authors.

There is another and very serious obstruction to the motion of an overshot or bucketed wheel. When it moves in back water, it is not only resisted by the water, when it moves more slowly than the wheel, which is very frequently the case, but it lifts a great deal in the rising buckets. In some particular states of back water, the descending bucket fills itself completely with water; and, in other cases, it contains a very considerable quantity, and air of common density; while in some rarer cases it contains less water, with air in a condensed state. In the first case, the rising bucket must come up filled with water, which it cannot drop till its mouth get out of the water. In the second case, part of the water goes out before this; but the air rarefies, and therefore there is still some water dragged or lifted up by the wheel, by suction as it is usually called. In the last case there is no such back load on the rising side of the wheel, but (which is as detrimental to its performance) the descending side is employed in condensing air; and although this air aids the ascent of the rising side, it does not aid it so much as it impedes the descending side, being (by the form of the bucket) nearer to the vertical line drawn through the axis.

All this may be completely prevented by a few holes made in the start of each bucket. Air being at least 800 times rarer than water, will escape through a hole almost 30 times faster with the same pressure. Very moderate holes will therefore suffice for this purpose: and the small quantity of water which these holes discharge during the descent of the buckets, produces a loss which is altogether insignificant. The water which runs out of one runs into another, so that there is only the loss of one bucket. We have seen a wheel of only 14 feet diameter working in nearly three feet of back water. It laboured prodigiously, and brought up a great load of water, which fell from it in abrupt dashes, which rendered the motion very hobbling. When three holes of an inch diameter were made in each bucket (12 feet long), the wheel laboured no more, there was no more plunging of water from its rising side, and its power on the machinery was increased more that one-fourth.

These practical observations may contain information that is new even to several experienced mill-wrights. To persons less informed they cannot fail of being useful. We now proceed to consider the action of water thus lying in the buckets of a wheel; and to ascertain its energy as it may be modified by different circumstances of fall, velocity, &c.

With respect to variations in the fall, there can be little room for discussion. Since the active pressure is measured by the pillar of water reaching from the horizontal plane where it is delivered on the wheel, to the horizontal plane where it is spilled by the wheel, it is evident that it must be proportional to this pillar, and therefore we must deliver it as high and retain it as long as possible.

This maxim obliges us, in the first place, to use a wheel

Water-works. wheel whose diameter is equal to the whole fall. We shall not gain any thing by employing a larger wheel; for although we should gain by using only that part of the circumference where the weight will act more perpendicularly to the radius, we shall lose more by the necessity of discharging the water at a greater height from the bottom: For we must suppose the buckets of both the wheels equally well constructed; in which case, the heights above the bottom, where they will discharge the water, will increase in the proportion of the diameter of the wheel. Now, that we shall lose more by this than we gain by the more direct application of the weight, is plain, without any further reasoning, by taking the extreme case, and supposing our wheel enlarged to such a size, that the useless part below is equal to our whole fall. In this case the water will be spilled from the buckets as soon as it is delivered into them. All intermediate cases, therefore, partake of the imperfection of this.

When our fall is exceedingly great, a wheel of an equal diameter becomes enormously big and expensive, and is of itself an unmanageable load. We have seen wheels of 58 feet diameter, however, which worked extremely well; but they are of very difficult construction, and extremely apt to warp and go out of shape by their weight. In cases like this, where we are unwilling to lose any part of the force of a small stream, the best form of a bucket wheel is an inverted chain pump. Instead of employing a chain pump of the best construction, ABCDEA (fig. 9.) to raise water through the upright pipe CB, by means of a force applied to the upper wheel A, let the water be delivered from a spout F, into the upper part of a pipe BC, and it will press down the plugs in the lower and narrower bored part of it with the full weight of the column, and escape at the dead level of C. This weight will urge round the wheel A without any defalcation; and this is the most powerful manner that any fall of water whatever can be applied, and exceeds the most perfect overshot wheel. But though it excels all chains of buckets in economy and in effect, it has all the other imperfections of this kind of machinery. Though the chain of plugs be of great strength, it has so much motion in its joints that it needs frequent repairs; and when it breaks, it is generally in the neighbourhood of A, on the loaded side, and all comes down with a great crash. There is also a loss of power by the immersion of so many plugs and chains in the water; for there can be no doubt but that if the plugs were big enough and light enough, they would buoy and even draw up the plugs in the narrow part at C. They must therefore diminish, in all other cases, the force with which this plug is pressed down.

Fig. 9.

The velocity of an overshot wheel is a matter of very great nicety; and authors, both speculative and practical, have entertained different, nay opposite, opinions on the subject. Mr Belidor, whom the engineers of Europe have long been accustomed to regard as sacred authority, maintains, that there is a certain velocity related to that obtainable by the whole fall, which will procure to an overshot wheel the greatest performance. Desaguliers, Smeaton, Lambert, De Parcieux, and others, maintain, that there is no such relation, and that the performance of an overshot wheel will be the greater, as it moves more slowly by an increase of its load of work. Belidor maintains, that the active power of water lying in a bucket wheel of any diameter is equal to that of the impulse of the same water on the floats of an undershot wheel, when the water issues from a sluice in the bottom of the dam. The other writers whom we have named assert, that the energy of an undershot wheel is but one half of that of an overshot, actuated by the same quantity of water falling from the same height.

To a manufacturing country like ours, which derives astonishing superiority, by which it more than compensates for the impediments of heavy taxes and luxurious living, chiefly from its machinery, in which it leaves all Europe far behind, the decision of this question, in such a manner as shall leave no doubt or misconception in the mind even of an unlettered artist, must be considered as a material service: and we think that this is easily attainable.

When any machine moves uniformly, the accelerating force or pressure actually exerted on the impelled point of the machine is in equilibrio with all the resistances which are exerted at the working point, with those arising from friction, and those that are excited in different parts of the machine by their mutual actions. This is an incontestable truth; and though little attended to by the mechanicians, is the foundation of all practical knowledge of machines. Therefore, when an overshot wheel moves uniformly, with *any velocity whatever*, the water is acting with its whole weight: for gravity would accelerate its descent, if not completely balanced by some reaction; and in this balance gravity and the reacting part of the machine exert equal and opposite pressures, and thus produce the uniform motion of the machine. We are thus particular on this point, because we observe mechanicians of the first name employing a mode of reasoning on the question now before us which is specious, and appears to prove the conclusion which they draw; but is nevertheless contrary to true mechanical principles. They assert, that the slower a heavy body is descending (suppose in a scale suspended from an axis *in peritrocheo*), the more does it press on the scale, and the more does it urge the machine round: and therefore the slower an overshot wheel turns, the greater is the force with which the water urges it round, and the more work will be done. It is very true that the machine is more forcibly impelled, and that more work is done; but this is not because a pound of water presses more strongly, but because there is more water pressing on the wheel; for the spout supplies at the same rate, and each bucket receives more water as it passes by it.

Let us therefore examine this point by the unquestionable principles of mechanics.

Let the overshot wheel A*f*H (fig. 5.) receive the water from a spout at the very top of the wheel; and in order that the wheel may not be retarded by dragging into motion the water simply laid into the uppermost bucket at A, let it be received at B, with the velocity (directed in a tangent to the wheel) acquired by the head of water AP. This velocity, therefore, must be equal to that of the rim of the wheel. Let this be *v*, or let the wheel and the water move over *v* inches in a second. Let the buckets be of such dimensions, that all the water which each receives as it passes the spout is retained till it comes to the position R, where it is discharged at once. It is plain that, in place of the separate quantities of water lying in each bucket, we may substitute a continued ring of water, equal to their sum,

Fig. 5.

sum, and uniformly distributed in the space BER $\varrho f \beta$. This constitutes a ring of uniform thickness. Let the area of its cross section β B and F f be called a. We have already demonstrated, that the mechanical energy with which this water on the circumference of the wheel urges it round, is the same with what would be exerted by the pillar $b\,r\,r\,b$ pressing on Ff, or acting by the lever CF. The weight of this pillar may be expressed by $a \times b\,r$, or $a \times$ PS; and if we call the radius CF of the wheel R, the momentum or mechanical energy of this weight will be represented by $a \times \text{PS} \times \text{R}$.

Now, let us suppose that this wheel is employed to raise a weight W, which is suspended by a rope wound round the axis of the wheel. Let r be the radius of this axle. Then $\text{W} \times r$ is the momentum of the work. Let the weight rise with the velocity u when the rim of the wheel turns with the velocity v, that is, let it rise u inches in a second.

Since a perfect equilibrium obtains between the power and the work when the motion is uniform, we must have $\text{W} \times r = a \times \text{PS} \times \text{R}$. But it is evident that $\text{R} : r = v : u$. Therefore $\text{W} \times u = a \times v \times \text{PS}$.

Now the performance of the machine is undoubtedly measured by the weight and the height to which it is raised in a second, or by $\text{W} \times u$. Therefore the machine is in its best possible state when $a \times v \times \text{PS}$ is a maximum. But it is plain that $a \times v$ is an invariable quantity; for it is the cubic inches of water which the spout supplies in a second. If the wheel moves fast, little water lies in each bucket, and a is small. When v is small, a is great, for the opposite reason; but $a \times v$ remains the same. Therefore we must make PS a maximum, that is, we must deliver the water as high up as possible. But this diminishes AP, and this diminishes the velocity of the wheel: and as this has no limit, the proposition is demonstrated; and an overshot wheel does the more work as it moves slowest.

Convincing as this discussion must be to any mechanician, we are anxious to impress the same maxim on the minds of practical men, unaccustomed to mathematical reasoning of any kind. We therefore beg indulgence for adding a popular view of the question, which requires no such investigation.

We may reason in this way: Suppose a wheel having 30 buckets, and that six cubic feet of water are delivered in a second on the top of a wheel, and discharged without any loss by the way at a certain height from the bottom of the wheel. Let this be the case, whatever is the rate of the wheel's motion; the buckets being of a sufficient capacity to hold all the water which falls into them. Let this wheel be employed to raise a weight of any kind, suppose water in a chain of 30 buckets, to the same height, and with the same velocity. Suppose, farther, that when the load on the rising side of the machine is one half of that on the wheel, the wheel makes four turns in a minute, or one turn in 15 seconds. During this time 90 cubic feet of water have flowed into the 30 buckets, and each has received three cubic feet. Then each of the rising buckets contains $1\frac{1}{2}$ feet; and 45 cubic feet are delivered into the upper cistern during one turn of the wheel, and 180 cubic feet in one minute.

Now, suppose the machine so loaded, by making the rising buckets more capacious, that it makes only two turns in a minute, or one turn in 30 seconds. Then each descending bucket must contain six cubic feet of water. If each bucket of the rising side contained three cubic feet, the motion of the machine would be the same as before. This is a point which no mechanician will controvert. When two pounds are suspended to one end of a string which passes over the pulley, and one pound to the other end, the descent of the two pounds will be the same with that of a four pound weight, which is employed in the same manner to draw up two pounds. Our machine would therefore continue to make four turns in the minute, and would deliver 90 cubic feet during each turn, and 360 in a minute. But, by supposition, it is making but two turns in a minute: this must proceed from a greater load than three cubic feet of water in each rising bucket. The machine must therefore be raising *more* than 90 feet of water during one turn of the wheel, and *more* than 180 in the minute.

Thus it appears, that if the machine be turning twice as slow as before, there is *more than twice the former quantity* in the rising buckets, and more will be raised in a minute by the same expenditure of power. In like manner, if the machine go three times as slow, there must be *more than three times* the former quantity of water in the rising buckets, and more work will be done.

But we may go farther, and assert, that the *more* we retard the machine, by loading it with more work of a similar kind, the greater will be its performance. This does not immediately appear from the present discussion: But let us call the first quantity of water in the rising bucket A; the water raised by four turns in a minute will be $4 \times 30 \times \text{A}, = 120$ A. The quantity in this bucket, when the machine goes twice as slow, has been shown to be greater than 2 A (call it $2\,\text{A} + x$); the water raised by two turns in a minute will be $2 \times 30 \times \overline{2\text{A} + x} = 120\ \text{A} + 60x$. Now, let the machine go four times as slow, making but one turn in a minute, the rising bucket must now contain more than twice $2\,\text{A} + x$, or more than $4\,\text{A} + 2x$; call it $4\,\text{A} + 2x + y$. The work done by one turn in a minute will now be $30 + \overline{4\,\text{A} + 2x + y} = 120\ \text{A} + 60x + 30y$.

By such an induction of the work, done with any rates of motion we choose, it is evident that the performance of the machine increases with every diminution of its velocity that is produced by the mere addition of a similar load of work or that it does the more work the slower it goes.

We have supposed the machine to be in its state of permanent uniform motion. If we consider it only in the beginning of its motion, the result is still more in favour of slow motion: For, at the first action of the moving power, the inertia of the machine itself consumes part of it, and it acquires its permanent speed by degrees; during which, the resistances arising from the work, friction, &c. increase, till they exactly balance the pressure of the water; and after this the machine accelerates no more. Now the greater the power and the resistance arising from the work are, in proportion to the inertia of the machine, the sooner will all arrive at its state of permanent velocity.

There is another circumstance which impairs the performance of an overshot wheel moving with a great velocity, viz. the effects of the centrifugal force on the water

Water-works.

water in the buckets. Our mill-wrights know well enough, that too great velocity will throw the water out of the buckets; but few, if any, know exactly the diminution of power produced by this cause. The following very simple construction will determine this:

Fig. 10.

Let AOB (fig. 10.) be an overshot wheel, of which AB is the upright diameter, and C is the centre. Make CF the length of a pendulum, which will make two vibrations during one turn of the wheel. Draw FE to the elbow of any of the buckets. The water in this bucket, instead of having its surface horizontal, as NO, will have it in the direction n O perpendicular to FE very nearly.

For the time of falling along half of FC is to that of two vibrations of this pendulum, or to the time of a revolution of the wheel, as the radius of a circle is to its circumference: and it is well known that the time of moving along half of AC, by the uniform action of the centrifugal force, is to that of a revolution as the radius of a circle to its circumference. Therefore the time of describing one half of AC by the centrifugal force, is equal to the time of describing one half of FC by gravity. These spaces, being similarly described in equal times, are proportional to the accelerating forces. Therefore $\frac{1}{2}$ FC : $\frac{1}{2}$ AC, or FC : AC = gravity : centrifugal force. Complete the parallelogram FCEK. A particle at E is urged by its weight in the direction KE, with a force which may be expressed by FC or KE; and it is urged by the centrifugal force in the direction CE, with a force = AC or CE. By their combined action it is urged in the direction FE. Therefore, as the surface of standing water is always at right angles to the action of gravity, that is, to the plumb-line, so the surface of the water in the revolving bucket is perpendicular to the action of the combined force FE.

Let NEO be the position of the bucket, which just holds all the water which it received as it passed the spout when not affected by the centrifugal force; and let NDO be its position when it would be empty. Let the vertical lines through D and E cut the circle described round C with the radius CF in the points H and I. Draw HC, IC, cutting the circle AOB in L and M. Make the arch $\alpha\delta$ equal to AL, and the arch $\alpha\varepsilon$ equal to AM: Then $C\delta$ and $C\varepsilon$ will be the positions of the bucket on the revolving wheel, corresponding to CDO and CEO on the wheel at rest. Water will begin to run out at ε, and it will be all gone at δ.—The demonstration is evident.

The force which now urges the wheel is still the weight *really* in the buckets: For though the water be urged in the direction with the force FE, one of its constitnents, CE, has no tendency to impel the wheel; and KE is the only impelling force.

It is but of late years that mills have been constructed or attended to with that accuracy and scientific skill which are necessary for deducing confidential conclusions from any experiments that can be made with them; and it is therefore no matter of wonder that the opinions of mill-wrights have been so different on this subject. There is a natural wish to see a machine moving briskly; it has the appearance of activity: but a very slow motion always looks as if the machine were overloaded. For this reason mill-wrights have always yielded slowly, and with some reluctance, to the repeated advices of the mathematicians: but they have yieldeé; and we see them adopting maxims of construction more agreeable to sound theory; making their wheels of great breadth, and loading them with a great deal of work. Mr Euler says, that the performance of the best mill cannot exceed that of the worst above $\frac{1}{3}$th: but we have seen a stream of water completely expended in driving a small flax mill, which now drives a cotton mill of 4000 spindles, with all its carding, roving, and drawing machinery, besides the lathes and other engines of the smith and carpenters workshops, exerting a force not less than ten times what sufficed for the flax mill.

The above discussion only demonstrates in general the advantage of slow motion; but does not point out in any degree the relation between the rate of motion and the work performed, nor even the principles on which it depends. Yet this is a subject fit for a mathematical investigation; and we would prosecute it in this place, if it were necessary for the improvement of practical mechanics. But we have seen that there is not, in the nature of things, a maximum of performance attached to any particular rate of motion which should therefore be preferred. For this reason we omit this discussion of mere speculative curiosity. It is very intricate: For we must not now express the pressure on the wheel by a *constant* pillar of water incumbent on the extremity of the horizontal arm, as we did before when we supposed the buckets completely filled; nor by a smaller *constant* pillar, corresponding to a smaller but equal quantity lying in every bucket. Each different velocity puts a different quantity of water into the bucket as it passes the spout; and this occasions a difference in the place where the discharge is begun and completed. This circumstance is some obstacle to the advantages of very slow motions, because it brings on the discharge sooner. All this may indeed be expressed by a simple equation of easy management; but the whole process of the mechanical discussion is both intricate and tedious, and the results are so much diversified by the forms of the buckets, that they do not afford any rule of sufficient generality to reward our trouble. The curious reader may see a very full investigation of this subject in two dissertations by Elvius in the Swedish Transactions, and in the *Hydrodynamique* of Professor Karstner of Gottingen; who has abridged these Dissertations of Elvius, and considerably improved the whole investigation, and has added some comparisons of his deductions with the actual performance of some great works. These comparisons, however, are not very satisfactory. There is also a valuable paper on this subject by Mr Lambert, in the Memoirs of the Academy of Berlin for the year 1775. From these dissertations, and from the *Hydrodynamique* of the abbe Bossut, the reader will get all that theory can teach of the relation between the pressures of the power and work on the machine and the rates of its motion. The practical reader may rest with confidence on the simple demonstration we have given, that the performance is improved by diminishing the velocity.

All we have to do, therefore, is to load the machine, and thus to diminish its speed, unless other physical circumstances throw obstacles in the way: but there are such obstacles. In all machines there are little inequalities of action that are unavoidable. In the action of a wheel and pinion, though made with the utmost judgement and care, there are such inequaities. These increase

Water-works

crease by the changes of form occasioned by the wearing of the machine—much greater irregularities arise from the subsultory motions of cranks, stampers, and other parts which move unequally or reciprocally. A machine may be so loaded as just to be in equilibrio with its work, in the favourable position of its parts. When this changes into one less favourable, the machine may stop; if not, it at least staggers, hobbles, or works unequally. The rubbing parts bear long on each other, with enormous pressures, and cut deep, and increase friction. Such slow motions must therefore be avoided. A little more velocity enables the machine to get over those increased resistances by its inertia, or the great quantity of motion inherent in it. Great machines possess this advantage in a superior degree, and will therefore work steadily with a smaller velocity. These circumstances are hardly susceptible of mathematical discussion, and our best reliance is on well-directed experience.

For this purpose, the reader will do well to peruse with care the excellent paper by Mr Smeaton in the Philosophical Transactions for 1759. This dissertation contains a numerous list of experiments, most judiciously contrived by him, and executed with the accuracy and attention to the most important circumstances, which is to be observed in all that gentleman's performances.

It is true, these experiments were made with small models; and we must not, without great caution, transfer the results of such experiments to large works. But we may safely transfer the laws of variation which result from a variation of circumstances, although we must not adopt the absolute quantities of the variations themselves. Mr Smeaton was fully aware of the limitations to which conclusions drawn from experiments on models are subject, and has made the applications with his usual sagacity.

His general inference is, that, in smaller works, the rim of the overshot-wheel should not have a greater velocity than three feet in a second; but that larger mills may be allowed a greater velocity than this. When every thing is executed in the best manner, he says that the work performed will amount to fully two-thirds of the power expended; that is, that three cubic feet of water descending from any height will raise two to the same height.

It is not very easy to compare these deductions with observations on large works; because there are few cases where we have good measures of the resistances opposed by the work performed by the machine. Mills employed for pumping water afford the best opportunities. But the inertia of their working gear diminishes their useful performance very sensibly; because their great beams, pump-rods, &c. have a reciprocating motion, which must be destroyed, and produced anew in every stroke. We have examined some machines of this kind which are esteemed good ones; and we find few of them whose performance exceeds one half of the power expended.

By comparing other mills with these, we get the best information of their resistances. The comparison with mills worked by Watt and Boulton's steam-engines is perhaps a better measure of the resistances opposed by different kinds of work, because their power is very distinctly known. We have been informed by one of the most eminent engineers, that a ton and a half of water per minute falling one foot will grind and dress one bushel of wheat per hour. This is equivalent to 9 tons falling 10 feet.

If an overshot-wheel opposed no resistance, and only one bucket were filled, the wheel would acquire the velocity due to a fall through the whole height. But when it is in this state of accelerated motion, if another bucket of water is delivered into it, its motion must be checked at the first, by the necessity of dragging forward this water. If the buckets fill in succession as they pass the spout, the velocity acquired by an unresisting wheel is but half of that which one bucket would give. In all cases, therefore, the velocity is diminished by the inertia of the entering water when it is simply laid into the upper buckets. The performance will therefore be improved by delivering the water on the wheel with that velocity with which the wheel is really moving. And as we cannot give the direction of a tangent to the wheel, the velocity with which it is delivered on the wheel must be so much greater than the intended velocity of the rim, that it shall be precisely equal to it when it is estimated in the direction of the tangent. Three or four inches of fall are sufficient for this purpose; and it should never be neglected, for it has a very sensible influence on the performance. But it is highly improper to give it more than this, with the view of impelling the wheel by its stroke. For even although it were proper to employ part of the fall in this way (which we shall presently see to be very improper), we cannot procure this impulse; because the water falls among other water, or it strikes the boards of the wheel with such obliquity that it cannot produce any such effect.

It is a much debated question among mill-wrights, Whether the diameter of the wheel should be such as that the water will be delivered at the top of the wheel? or larger, so that the water is received at some distance from the top, where it will act more perpendicularly to the arm? We apprehend that the observations formerly made will decide in favour of the first practice. The space below, where the water is discharged from the wheel, being proportional to the diameter of the wheel, there is an undoubted loss of fall attending a large wheel; and this is not compensated by delivering the water at a greater distance from the perpendicular. We should therefore recommend the use of the whole descending side, and make the diameter of the wheel no greater than the fall, till it is so much reduced that the centrifugal force begins to produce a sensible effect. Since the rim can hardly have a smaller velocity than three feet per second, it is evident that a small wheel must revolve more rapidly. This made it proper to insert the determination that we have given, of the loss of power produced by the centrifugal force. But even with this in view, we should employ much smaller wheels than are generally done on small falls. Indeed the loss of water at the bottom may be diminished, by nicely fitting the arch which surrounds the wheel, so as not to allow the water to escape by the sides or bottom. While this improvement remains in good order, and the wheel entire, it produces a very sensible effect; but the passage widens continually by the wearing of the wheel. A bit of a stick or stone falling in about the wheel tears off part of the shrouding or bucket, and frosty weather frequently binds all fast. It therefore seldom answers expectations. We have nothing to add on this case to

Water-works.

to what we have already extracted from Mr Smeaton's Dissertation on the Subject of Breast or half Overshot Wheels.

There is another form of wheel by which water is made to act on a machine by its weight, which merits consideration. This is known in this country by the name of *Barker's mill*, and has been described by Desaguliers, vol. ii. p. 460. It consists of an upright pipe or trunk AB (fig. 11.), communicating with two horizontal branches BC, B c, which have a hole C c near their ends, opening in opposite directions, at right angles to their lengths. Suppose water to be poured in at the top from the spout F, it will run out by the holes C and c with the velocity corresponding to the depth of these holes under the surface. The consequence of this must be, that the arms will be pressed backwards; for there is no solid surface at the hole C, on which the lateral pressure of the water can be exerted, while it acts with its full force on the opposite side of the arm. This unbalanced pressure is equal to the weight of a column having the orifice for its base, and twice the depth under the surface of the water in the trunk for its height. This measure of the height may seem odd, because if the orifice were shut, the pressure on it is the weight of a column reaching from the surface. But when it is open, the water issues with nearly the velocity acquired by falling from the surface, and the quantity of motion produced is that of a column of twice this length, moving with this velocity. This is actually produced by the pressure of the fluid, and must therefore be accompanied by an equal reaction.

Fig. 11.

Now suppose this apparatus set on the pivot E, and to have a spindle AD above the trunk, furnished with a cylindrical bobbin D, having a rope wound round it, and passing over a pulley G. A weight W may be suspended there, which may balance this backward pressure. If the weight be too small for this purpose, the retrograde motion of the arms will wind up the cord, and raise the weight; and thus we obtain an acting machine, employing the pressure of the water, and applicable to any purpose. A runner millstone may be put on the top of the spindle; and we should then produce a flour mill of the utmost simplicity, having neither wheel nor pinion, and subject to hardly any wear. It is somewhat surprising, that although this was invented at the beginning of this century, and appears to have such advantage in point of simplicity, it has not come into use. So little has Dr Desaguliers's account been attended to (although it is mentioned by him as an excellent machine, and as highly instructive to the hydraulist), that the same invention was again brought forward by a German professor (Segner) as his own, and has been honoured by a series of elaborate disquisitions concerning its theory and performance by Euler and by John Bernoulli. Euler's Dissertations are to be found in the Memoirs of the Academy of Berlin, 1751, &c. and in the *Nov. Comment. Petropol.* tom. vi. Bernoulli's are at the end of his Hydraulics. Both these authors agree in saying, that this machine excels all other methods of employing the force of water. Simple as it appears, its true theory, and the best form of construction, are most abstruse and delicate subjects; and it is not easy to give such an account of its principles as will be understood by an ordinary reader.

We see, in general, that the machine must press backwards; and little investigation suffices for understanding the intensity of this pressure, when the machine is at rest. But when it is allowed to run backwards, withdrawing itself from the pressure, the intensity of it is diminished; and if no other circumstances intervened, it might not be difficult to say what particular pressure corresponded to any rate of motion. Accordingly, Desaguliers, presuming on the simplicity of the machine, affirms the pressure to be the weight of a column, which would produce a velocity of efflux equal to the difference of the velocity of the fluid and of the machine; and hence he deduces, that its performance will be the greatest possible, when its retrograde velocity is one-third of the velocity acquired by falling from the surface, in which case, it will raise $\frac{8}{27}$ths of the water expended to the same height, which is double of the performance of a mill acted on by the impulse of water.

But this is a very imperfect account of the operation. When the machine (constructed exactly as we have described) moves round, the water which issues descends in the vertical trunk, and then, moving along the horizontal arms, partakes of this circular motion. This excites a centrifugal force, which is exerted against the ends of the arms by the intervention of the fluid. The whole fluid is subjected to this pressure (increasing for every section across the arm in the proportion of its distance from the axis), and every particle is pressed with the accumulated centrifugal forces of all the sections that are nearer to the axis. Every section therefore sustains an actual pressure proportional to the square of its distance from the axis. This increases the velocity of efflux, and this increases the velocity of revolution; and this mutual co-operation would seem to terminate in an infinite velocity of both motions. But, on the other hand, this circular motion must be given anew to every particle of water as it enters the horizontal arm. This can be done only by the motion already in the arm, and at its expence. Thus there must be a velocity which cannot be overpassed even by an unloaded machine. But it is also plain, that by making the horizontal arm very capacious, the motion of the water from the axis to the jet may be made very slow, and much of this diminution of circular motion prevented. Accordingly, Euler has recommended a form by which this is done in the most eminent degree. His machine consists of a hollow conoidal ring, of which fig. 12. is a section. Fig. 12. The part AH h a is a sort of funnel bason, which receives the water from the spout F; not in the direction pointing towards the axis, but in the direction, and with the precise velocity, of its motion. This prevents any retardation by dragging forward the water. The water then passes down between the outer conoid AC c a and the inner conoid HG g h along spiral channels formed by partitions soldered to both conoids. The curves of these channels are determined by a theory which aims at the annihilation of all unnecessary and improper motions of the water, but which is too abstruse to find a place here. The water thus conducted arrives at the bottom CG, c g. On the outer circumference of this bottom are arranged a number of spouts (one for each channel), which are all directed one way in tangents to the circumference.

Adopting the common theory of the reaction of fluids, this should be a very powerful machine, and should raise $\frac{8}{27}$ths of the water expended. But if we admit the reaction

Water-works.

action to be equal to the force of the issuing fluid (and we do not see how this can be refused), the machine must be nearly twice as powerful. We therefore repeat our wonder, that it has not been brought into use. But it appears that no trial has been made even of a model; so that we have no experiments to encourage an engineer to repeat the trial. Even the late author, Professor Segner, has not related any thing of this kind in his *Exercitationes Hydraulicæ*, where he particularly describes the machine. This remissness probably has proceeded from fixing the attention on Euler's improved construction. It is plain that this must be a most cumbrous mass, even in a small size requiring a prodigious vessel, and carrying an unwieldy load. If we examine the theory which recommends this construction, we find that the advantages, though real and sensible, bear but a small proportion to the whole performance of the simple machine as invented by Dr Barker. It is therefore to be regretted, that engineers have not attempted to realize the first project. We beg leave to recommend it, with an additional argument taken from an addition made to it by Mr Mathon de la Cour, in Rozier's *Journal de Physique*, January and August 1775. This gentleman brings down a large pipe FEH (fig. 13.) from a reservoir, bends it upward at H, and introduces it into two horizontal arms, DA, DB, which have an upright spindle DK, carrying a millstone in the style of Dr Barker's mill. The ingenious mechanician will have no difficulty of contriving a method of joining these pipes, so as to permit a free circular motion without losing much water. The operation of the machine in this form is evident. The water, pressed by the column FG, flows out at the holes A and B, and the unbalanced pressure on the opposite sides of the arms forces them round. The compendiousness and other advantages of this construction are more striking, allowing us to make use of the greatest fall without any increase of the size of the machine, It undoubtedly enables us to employ a stream of water too scanty to be employed in any other form. The author gives the dimensions of an engine which he had seen at Bourg Argental. AB is 92 inches, and its diameter 3 inches; the diameter of each orifice is $1\frac{1}{6}$; FG is 21 feet; the pipe D was fitted into C by grinding; and the internal diameter of D is 2 inches.

Fig. 13.

When the machine was performing no work, or was unloaded, and emitted water by one hole only, it made 115 turns in a minute. This gives a velocity of 46 feet per second for the hole. This is a curious fact: For the water would issue from this hole at rest with the velocity of $37\frac{1}{6}$. This great velocity (which was much less than the velocity with which the water actually quitted the pipe) was undoubtedly produced by the prodigious centrifugal force, which was nearly 17 times the weight of the water in the orifice.

The empty machine weighed 80 pounds, and its weight was half-supported by the upper pressure of the water, so that the friction of the pivots was much diminished. It is a pity that the author has given no account of any work done by the machine. Indeed it was only working ventilators for a large hall. His theory by no means embraces all its principles, nor is it well-founded.

We think that the free motion round the neck of the feeding-pipe without any loss of water or any considerable friction, may be obtained in the following manner: AB (fig. 14.) represents a portion of the revolving horizontal pipe, and CE*ec* part of the feeding pipe. The neck of the first is turned truly cylindrical, so as to turn easily, but without shake, in the collar C*c* of the feeding-pipe, and each has a shoulder which may support the other. That the friction of this joint may not be great, and the pipes destroy each other by wearing, the horizontal pipe has an iron spindle EF, fixed exactly in the axis of the joint, and resting with its pivot F in a step of hard steel, fixed to the iron bar GH, which goes across the feeding-pipe, and is firmly supported in it. This pipe is made bell-shaped, widening below. A collar or hose of thin leather is fitted to the inside of this pipe, and is represented (in section) by LKM*mkl*. This is kept in its place by means of a metal or wooden ring N*n*, thin at the upper edge, and taper-shaped. This is drawn in above the leather, and stretches it, and causes it to apply to the side of the pipe all around. There can be no leakage at this joint, because the water will press the leather to the smooth metal pipe; nor can there be any sensible friction, because the water gets at the edge of the leather, and the whole unbalanced pressure is at the small crevice, between the two metal shoulders. These shoulders need not touch, so that the friction must be insensible. We imagine that this method of tightening a turning joint may be used with great advantage in many cases.

We have only further to observe on this engine, that any imperfection by which the passage of the water is diminished or obstructed produces a saving of water, which is in exact proportion to the diminution of effect. The only inaccuracy that is not thus compensated is when the jets are not at right angles to the arms.

We repeat our wishes, that engineers would endeavour to bring this machine into use, seeing many situations where it may be employed to great advantage. Suppose, for instance, a small supply of water from a great height applied in this manner to a centrifugal pump, or to a hair belt passing over a pulley, and dipping in the water of a deep well. This would be a hydraulic machine exceeding all others in simplicity and durability, though inferior in effect to some other constructions.

2. *Of Undershot Wheels.*

All wheels go by this name where the motion of the water is quicker than that of the partitions or boards of the wheel, and it therefore impels them. These are called the *float boards*, or *floats*, of an undershot wheel. The water, running in a mill-row, with a velocity derived from a head of water, or from a declivity of channel, strikes on these floats, and occasions, by its deflections sidewise and upwards, a pressure on the floats sufficient for impelling the wheel.

There are few points of practical mechanics that have been more considered than the action of water on the floats of a wheel; hardly a book of mechanics being silent on the subject. But the generality of them, at least such as are intelligible to persons who are not very much conversant in dynamical and mathematical discussion, have hardly done any thing more than copied the earliest deductions from the simple theory of the resistance of fluids. The consequence has been, that our practical knowledge is very imperfect; and it is still chiefly from experience that we must learn the performance of undershot wheels. Unfortunately this stops their improvement; because those who have the only opportunities of making the experiments are not sufficiently acquainted with the principles of hydraulics, and are apt to ascribe differences in their performance to trifling nostrums in their construction, or in the manner of applying the impulse of the water.

We have said so much on the imperfection of our theories of the impulse of fluids in the article *Resistance of Fluids*, that we need not repeat here the defects of the common explanations of the motions of undershot wheels. The part of this theory of the impulse of fluids which agrees best with observation is, *that the impulse is in the duplicate proportion of the velocity with which the water strikes the float.* That is, if v be the velocity of the stream, and u the velocity of the float, we shall have F, the impulse on the float when held fast to its impulse f on the float moving with the velocity u, as v^2 to $\overline{v-u}^2$, and $f = F \times \frac{\overline{v-u}^2}{v^2}$.

This is the pressure acting on the float, and urging the wheel round its axis. The wheel must yield to this motion, if the resistance of the work does not exert a superior pressure on the float in the opposite direction. By yielding, the float withdraws from the impulse, and this is therefore diminished. The wheel accelerates, the resistances increase, and the impulses diminish, till they become an exact balance for the resistances. The motion now remains uniform, and the momentum of impulse is equal to that of resistance. The performance of the mill therefore is determined by this; and, whatever be the construction of the mill, its performance is best when the momentum of impulse is greatest. This is had by multiplying the pressure on the float by its velocity. Therefore the momentum will be expressed by $F \times \frac{\overline{v-u}^2}{v^2} \times u$. But since F and v^2 are constant quantities, the momentum will be proportional to $u \times \overline{v-u}^2$. Let x represent the relative velocity. Then $v-x$ will be $=u$, and the momentum will be proportional to $\overline{v-x} \times x^2$, and will be a maximum when $\overline{v-x} \times x^2$ is a maximum, or when $v x^2 - x^3$ is a maximum. This will be discovered by making its fluxion $=o$. That is,

$$2 v x \dot{x} - 3 x^2 \dot{x} = o,$$

and $2 v x - 3 x^2 = o$

or $2 v - 3 x = o$

and $2 v = 3 x$, and $x = \frac{2}{3} v$; and therefore $v-x$, or u, $= \frac{1}{3} v$. That is, the velocity of the float must be one-third of the velocity of the stream. It only remains to say what is the absolute pressure on the float thus circumstanced. Let the velocity v be supposed to arise from the pressure of a head of water h. The common theory teaches that the impulse on a given surface S at rest is equal to the weight of a column h S; put this in place of F, and $\frac{4}{9} v^2$ in place of $\overline{v-u}^2$ and $\frac{1}{3} v$ for u. This gives us $S h \times \frac{4}{27} v$ for the momentum. Now the power expended is $S h v$, or the column $S h$ moving with the velocity v. Therefore the greatest performance of an undershot wheel is equivalent to raising $\frac{4}{27}$ of the water that drives it to the same height.

But this is too small an estimation; for the pressure exerted on a plane surface, situated as the float of a mill-wheel, is considerably greater than the weight of the column S h. This is nearly the pressure on a surface wholly immersed in the fluid. But when a small vein strikes a larger plane, so as to be deflected on all sides in a thin sheet, the impulse is almost double of this. This is in some measure the case in a mill wheel. When the stream strikes it, it is heaped up along its face, and falls back again—and during this motion it is acting with a hydrostatic pressure on it. When the wheel dips into an open river, this accumulation is less remarkable, because much escapes laterally. But in a mill course it may be considerable.

We have considered only the action on one float, but several generally act at once. The impulse on most of them must be oblique, and is therefore less than when the same stream impinges perpendicularly; and this diminution of impulse is, by the common theory, in the proportion of the sine of the obliquity. For this reason it is maintained, that the impulse of the whole stream on the lowest floatboard, which is perpendicular to the stream, is equal to the sum of the impulses made on all the floats which then dip into the water; or that the impulse on any oblique float is precisely equal to the impulse which that part of the stream would have made on the lowest floatboard had it not been interrupted. Therefore it has been recommended to make such a number of floatboards, that when one of them is at the bottom of the wheel, and perpendicular to the stream, the next in succession should be just entering into the water. But since the impulse on a float by no means annihilates all the motion of the water, and it bends round it and hits the one behind with its remaining force, there must be some advantage gained by employing a greater number of floats than this rule will permit. This is abundantly confirmed by the experiments of Smeaton and Bossut. Mr Bossut formed three or four suppositions of the number of floats, and calculated the impulse on each; according to the observations made in a course of experiments made by the Academy of Sciences, and inserted by us in the article *Resistance of Fluids*; and when he summed them up, and compared the results with his experiments, he found the agreement very satisfactory. He deduces a general rule, that if the velocity of the wheel is one-third of that of the stream, and if 72 degrees of the circumference are immersed in the stream, the wheel should have 36 floats. Each will dip one-fifth of the radius. The velocity being still supposed the same, there should be more or fewer floats according as the arch is less or greater than 72 degrees.

Such is the theory, and such are the circumstances which it leaves undetermined. The accumulation of the water on a floatboard, and the force with which it may still strike another, are too intricate to be assigned with any tolerable precision: For such reasons we must acknowledge that the theory of undershot wheels is still very imperfect, and that recourse must be had to experience for their improvement. We therefore strongly recommend the perusal of Mr Smeaton's experiments on undershot wheels, contained in the same dissertation with those we have quoted on overshot wheels. We have only to observe, that to an ordinary reader the experiments will appear too much in favour of undershot wheels. His aim is partly to establish a theory, which will state the relation between their performance and the velocity of of the stream, and partly to state the relation between the power expended and the work done. The velocity in his experiments is always considerably below that which a body would acquire by falling from the surface of the head of water; or it is the velocity acquired by a shorter fall. Therefore if we estimate the power expended by the quantity of water multiplied by this diminished fall, we shall make it too small; and the difference in some cases is very great: yet, even with these concessions, it appears that the utmost performance of an undershot wheel does not surpass the raising one-third of the expended water to the place from which it came. It is therefore far inferior to an overshot wheel expending the same power; and Mr Belidor has led engineers into very mistaken maxims of construction, by saying that overshot wheels should be given up, even in the case of great falls, and that we should always bring on the water from a sluice in the very bottom of the dam, and bring it to the wheel with as great a velocity as possible. Mr Smeaton also says, that the maximum takes place when the velocity of the wheel is two-fifths of that of the stream, instead of two-sixths according to the theory; and this agrees with the experiments of Bossut. But he measured the velocity by means of the quantity of water which run past. This must give a velocity somewhat too small; as will appear by attending to Buat's observations on the superficial, the mean, and the bottom velocities.

The rest of his observations are most judicious, and well adapted to the instruction of practitioners. We have only to add to them the observations of Des Parcieux and Bossut, who have evinced, by very good experiments, that there is a very sensible advantage gained by inclining the floatboards to the radius of the wheel about 20 degrees, so that the lowest floatboard shall not be perpendicular, but have its point turned up the stream about 20 degrees. This inclination causes the water to heap up along the floatboard, and act by its weight. The floats should therefore be made much broader than the vein of water interrupted by them is deep.

Some engineers, observing the great superiority of overshot wheels above undershot wheels driven by the same expence of power, have proposed to bring the water home to the bottom of the wheel on an even bottom, and to make the floatboard no deeper than the aperture of the sluice, which would permit the water to run out. The wheel is to be fitted with a close sole and sides, exactly fitted to the end of this trough, so that if the wheel is at rest, the water may be dammed up by the sole and floatboard. It will therefore press forward the floatboard with the whole force of the head of water. But this cannot answer; for if we suppose no floatboards, the water will flow out at the bottom, propelled in the manner those persons suppose; and it will be supplied from behind, the water coming *slowly* from all parts of the trough to the hole below the wheel. But now add the floats, and suppose the wheel in motion with the velocity that is expected. The other floats must drag into motion all the water which lies between them, giving to the greatest part of it a motion vastly greater than it would have taken in consequence of the pressure of the water behind it; and the water out of the reach of the floats will remain still, which it would not have done independent of the floatboards above it, because it would have contributed to the expence of the hole. The motion therefore which the wheel will acquire by this construction must be so different from what is expected, that we can hardly say what it will be.

We are therefore persuaded that the best way of delivering the water on an undershot wheel in a close mill-course is, to let it slide down a very smooth channel, without touching the wheel till near the bottom, where the wheel should be exactly fitted to the course; or, to make the floats exceedingly broader than the depth of the vein of water which glides down the course, and allow it to be partly intercepted by the first floats, and heap up along them, acting by its weight, after its impulse has been expended. If the bottom of the course be an arch of a circle described with a radius much greater than that of the wheel, the water which slides down will be thus gradually intercepted by the floats.

Attempts have been made to construct water-wheels which receive the impulse obliquely, like the sails of a common wind-mill. This would, in many situations, be a very great acquisition. A very slow but deep river could in this manner be made to drive our mills; and although much power is lost by the obliquity of the impulse, the remainder may be very great. It is to be regretted, that these attempts have not been more zealously prosecuted; for we have no doubt of their success in a very serviceable degree. Engineers have been deterred, because when such wheels are plunged in an open stream, their lateral motion is too much impeded by the motion of the stream. We have seen one, however, which was very powerful: It was a long cylindrical frame, having a plate standing out from it about a foot broad, and surrounding it with a very oblique spiral like a cork-screw. This was plunged about one-fourth of its diameter (which was about 12 feet), having its axis in the direction of the stream. By the work which it was performing, it seemed more powerful than a common wheel which occupied the same *breadth* of the river. Its length was not less than 20 feet: it might have been twice as much, which would have doubled its power, without occupying more of the water-way. Perhaps such a spiral, continued to the very axis, and moving in a hollow canal wholly filled by the stream, might be a very advantageous way of employing a deep and slow stream.

But mills with oblique floats are most useful for employing small streams, which can be delivered from a spout with a great velocity. Mr Bossut has considered these with due attention, and ascertained the best modes of construction. There are two which have nearly equal performances: 1. The vanes being placed like those of a wind-mill, round the rim of a horizontal or vertical wheel, and being made much broader than the vein of water which is to strike them, let the spout be so directed that the vein may strike them perpendicularly. By this measure it will be spread about on the vane in a thin sheet, and exert a pressure nearly equal to twice the weight of a column whose base is the orifice of the spout, and whose height is the fall producing the velocity.

Mills of this kind are much in use in the south of Europe. The wheel is horizontal, and the vertical axis carries the millstone; so that the mill is of the utmost simplicity: and this is its chief recommendation; for its power is greatly inferior to that of a wheel constructed in the usual manner.

2. The vanes may be arranged round the rim of the wheel.

Water-works.

wheel, not like the sails of a wind-mill, but in planes inclined to the radii, but parallel to the axis, or to the planes passing through the axis. They may either stand on a sole, like the oblique floats recommended by De Parcieux, as above mentioned: or they may stand on the side of the rim, not pointing to the axis, but aside from it.

This disposition will admit the spout to be more conveniently disposed either for a horizontal or a vertical wheel.

We shall conclude this article by describing a contrivance of Mr Burns, the inventor of the double bucketed wheel, for fixing the arms of a water-wheel. It is well known to mill-wrights that the method of fixing them by making them to pass through the axle, weakens it exceedingly, and by lodging water in the joint, soon causes it to rot and fail. They have, therefore, of late years put cast-iron flanches on the axis, to which each arm is bolted: or the flanches are so fashioned as to form boxes, serving as mortises to receive the ends of the arms. These answer the purpose completely, but are very expensive; and it is found that arms of fir bolted into flanches of iron, are apt to work loose. Mr Burns has made wooden flanches of a very curious construction, which are equally firm, and cost much less than the iron ones.

Fig. 15. This flanch consists of eight pieces, four of which compose the ring represented in fig. 15. meeting in the joints *a b*, *a b*, *a b*, *a b*, directed to the centre O. The other four are covered by these, and their joints are represented by the dotted lines $\alpha\,\beta$, $\alpha\,\beta$, $\alpha\,\beta$, $\alpha\,\beta$. These two rings break joint in such a manner that an arm MN is contained between the two nearest joints $a'\,b'$ of the one, and $\alpha'\,\beta'$ of the other. The tenon formed on the one end of the arm A, &c. is of a particular shape: one side, GF, is directed to the centre O; the other side, BCDE, has a small shoulder BC; then a long side CD directed to the centre O; and then a third part DE parallel to GF, or rather diverging a little from it, so as to make up at E the thickness of the shoulder BC; that is, a line from B to E would be parallel to CD. This side of the tenon fits exactly to the corresponding side of the mortise; but the mortise is wider on the other side, leaving a space GFK *h* a little narrower at FK than at G *h*. These tenons and mortises are made extremely true to the square; the pieces are put round the axle, with a few blocks or wedges of soft wood put between them and the axle, leaving the space empty opposite to the place of each arm, and firmly bolted together by bolts between the arm-mortises. The arms are then put in, and each is pressed home to the side CDE, and a wedge HF of hard wood is then put into the empty part of the mortise and driven home. When it comes through the flanch and touches the axle, the part which has come through is cut off with a thin chisel, and the wedge is driven better home. The spaces under the ends of the arms are now filled with wedges, which are driven home from opposite sides, till the circle of the arms stands quite perpendicular on the axle, and all is fast. It needs no hoops to keep it together, for the wedging it up round the axle makes the two half rings draw close on the arms, and it cannot start at its own joints till it crushes the arms. Hoops, however, can do no harm, when all is once wedged up, but it would be improper to put them on before this be done.

A very curious hydraulic machine was erected at Zurich by H. Andreas Wirtz, a tinplate worker of that place. The invention shows him to be a person of very uncommon mechanical knowledge and sagacity. As it is a machine which operates on a principle widely different from all other hydraulic machines, and is really excellent in its kind, we presume that our readers will not be displeased with some account of it.

Fig. 16. is a sketch of the section of the machine, as it was first erected by Wirtz at a dyehouse in Limmat, in the suburbs or vicinity of Zurich. It consists of a hollow cylinder, like a very large grindstone, turning on a horizontal axis, and partly plunged in a cistern of water. The axis is hollow at one end, and communicates with a perpendicular pipe CBZ′, part of which is hid by the cylinder. This cylinder or drum is formed into a spiral canal by a plate coiled up within it like the main-spring of a watch in its box; only the spires are at a distance from each other, so as to form a conduit for the water of uniform width. This spiral partition is well joined to the two ends of a cylinder, and no water escapes between them. The outermost turn of the spiral begins to widen about three-fourths of a circumference from the end, and this gradual enlargement continues from Q to S nearly a semicircle: this part may be called the Horn. It then widens suddenly, forming a Scoop or shovel SS′. The cylinder is supported so as to dip several inches into the water, whose surface is represented by VV′.

When this cylinder is turned round its axis in the direction ABEO, as expressed by the two darts, the scoop SS′ dips at V′, and takes up a certain quantity of water before it emerges again at V. This quantity is sufficient to fill the taper part SQ, which we have called the Horn; and this is nearly equal in capacity to the outermost uniform spiral round.

After the scoop has emerged, the water passes along the spiral by the motion of it round the axis, and drives the air before it into the rising-pipe, where it escapes.—In the mean time, air comes in at the mouth of the scoop; and when the scoop again dips into the water, it again takes in some. Thus there is now a part filled with water and a part filled with air. Continuing this motion, we shall receive a second round of water and another of air. The water in any turn of the spiral will have its two ends on a level; and the air between the successive columns of water will be in its natural state; for since the passage into the rising-pipe or Main is open, there is nothing to force the water and air into any other position. But since the spires gradually diminish in their length, it is plain that the column of water will gradually occupy more and more of the circumference of each. At last it will occupy a complete turn of some spiral that is near the centre; and when sent farther in, by the continuance of the motion, some of it will run back over the top of the succeeding spiral. Thus it will run over at K 4 into the right-hand side of the third spiral. Therefore it will push the water of this spire backwards, and raise its other end, so that it also will run over backwards *before* the next turn be completed. And this change of disposition will at last reach the first or outermost spiral, and some water will run over into the horn and scoop, and finally into the cistern.

But as soon as water gets into the rising-pipe, and rises

rises a little in it, it stops the escape of the air when the next scoop of water is taken in. Here are now two columns of water acting against each other by hydrostatic pressure and the intervening column of air. They must compress the air between them, and the water and air columns will now be unequal. This will have a general tendency to keep the whole water back, and cause it to be higher on the left or rising side of each spire than on the right descending side. The excess of height will be just such as produces the compression of the air between that and the preceding column of water. This will go on increasing as the water mounts in the rising-pipe; for the air next to the rising-pipe is compressed at its inner end with the weight of the whole column in the main. It must be as much compressed at its outer end. This must be done by the water column without it; and this column exerts this pressure partly by reason that *its* outer end is higher than its inner end, and partly by the transmission of the pressure on its outer end by air, which is similarly compressed from without. And thus it will happen that each column of water, being higher at its outer than at its inner end, compresses the air on the water column beyond or within it, which transmits this pressure to the air beyond it, adding to it the pressure arising from its own want of level at the ends. Therefore the greatest compression, viz. that of the air next the main, is produced by *the sum of all the transmitted pressures;* and these are the sum of all the differences between the elevation of the inner ends of the water columns above their outer ends: and the height to which the water will rise in the main will be just equal to this sum.

Draw the horizontal lines K'K 1, K'K 2, K'K 3, &c. and *m n*, *m n*, *m n*, &c. Suppose the left-hand spaces to be filled with water, and the right-hand spaces to be filled with air. There is a certain gradation of compression which will keep things in this position. The spaces evidently decrease in arithmetical progression; so do the hydrostatic heights and pressures of the water columns. If therefore the air be dense in the same progression, all will be in hydrostatical equilibrium. Now this is evidently producible by the mere motion of the machine; for since the density and compression in each air column is supposed inversely as the bulk of the column, the absolute quantity of air is the same in all; therefore the column first taken in will pass gradually inwards, and the increasing compression will cause it to occupy precisely the whole right-hand side of every spire. The gradual diminution of the water columns will be produced during the motion by the water running over backwards at the top, from spire to spire, and at last coming out by the scoop.

It is evident that this disposition of the air and water will raise the water to the greatest height, because the hydrostatic height of each water column is the greatest possible, viz. the diameter of the spire. This disposition may be obtained in the following manner: Take CL to CB as the density of the external air to its density in the last column next the rising-pipe or main; that is, make CL to CB as 33 feet (the height of the column of water which balances the atmosphere), to the sum of 33 feet and the height of the rising-pipe. Then divide BL into such a number of turns, that the sum of their diameters shall be equal to the height of the main; then bring a pipe straight from E to the centre C. The reason of all this is very evident.

But when the main is very high, this construction will require a very great diameter of the drum, or many turns of a very narrow pipe. In such cases it will be much better to make the spiral in the form of a corkscrew, as in fig. 17. instead of this flat form like a watch-spring. The pipe which forms the spiral may be lapped round the frustum of a cone, whose greatest diameter is to the least (which is next to the rising-pipe) in the same proportion that we assigned to CB and CL. By this construction the water will stand in every round so as to have its upper and lower surfaces tangents to the top and bottom of the spiral, and the water columns will occupy the whole ascending side of the machine, while the air occupies the descending side. Fig. 17.

This form is vastly preferable to the flat: it will allow us to employ many turns of a large pipe, and therefore produce a great elevation of a large quantity of water.

The same thing will be still better done by lapping the pipe on a cylinder, and making it taper to the end, in such a proportion that the contents of each round may be the same as when it is lapped round the cone. It will raise the water to a greater height (but with an increase of the impelling power) by the same number of turns, because the vertical or pressing height of each column is greater.

Nay, the same thing may be done in a more simple manner, by lapping a pipe of uniform bore round a cylinder. But this will require more turns, because the water columns will have less differences between the heights of their two ends. It requires a very minute investigation to show the progress of the columns of air and water in this construction, and the various changes of their arrangement, before one is attained which will continue during the working of the machine.

We have chosen for the description of the machine that construction which made its principle and manner of working most evident, namely, which contained the same material quantity of air in each turn of the spiral, more and more compressed as it approaches to the rising-pipe. We should otherwise have been obliged to investigate in great detail the gradual progress of the water, and the frequent changes of its arrangement, before we could see that one arrangement would be produced which would remain constant during the working of the machine. But this is not the best construction. We see that, in order to raise water to the height of a column of 34 feet, which balances the atmosphere, the air in the last spire is compressed into half its bulk; and the quantity of water delivered into the main at each turn is but half of what was received into the first spire, the rest flowing back from spire to spire, and being discharged at the spout.

But it may be constructed so as that the quantity of water in each spire may be the same that was received into the first; by which means a greater quantity (double in the instance now given) will be delivered into the main, and raised to the same height by very nearly the same force.—This may be done by another proportion of the capacity of the spires, whether by a change of their caliber or of their diameters. Suppose the bore to be the same, the diameter must be made such that the constant column of water, and the column of air, compressed

Water-works. pressed to the proper degree, may occupy the whole circumference. Let A be the column of water which balances the atmosphere, and h the height to which the water is to be raised. Let A be to $A+h$ as 1 to m.

It is plain that m will represent the density of the air in the last spire, if its natural density be 1, because it is pressed by the column $A+h$, while the common air is pressed by A. Let 1 represent the constant water column, and therefore nearly equal to the air column in the first spire. The whole circumference of the last spire must be $1+\frac{1}{m}$, in order to hold the water 1, and the air compressed into the space $\frac{1}{m}$ or $\frac{A}{A+h}$.

The circumference of the first spire is $1+1$ or 2. Let D and d be the diameters of the first and last spires; we have $2:1+\frac{1}{m}=D:d$, or $2m:m+1=D:d$. Therefore if a pipe of uniform bore be lapped round a cone, of which D and d are the end diameters, the spirals will be very nearly such as will answer the purpose. It will not be quite exact, for the intermediate spirals will be somewhat too large. The conoidal frustum should be formed by the revolution of a curve of the logarithmic kind. But the error is very trifling.

With such a spiral, the full quantity of water which was confined in the first spiral will find room in the last, and will be sent into the main at every turn. This is a very great advantage, especially when the water is to be much raised. The saving of power by this change of construction is always in proportion of the greatest compression of the air.

The great difficulty in the construction of any of these forms is in determining the form and position of the horn and the scoop; and on this greatly depends the performance of the machine. The following instructions will make it pretty easy.

Fig. 18. Let ABEO (fig. 18.) represent the first or outermost round of the spiral, of which the axis is C. Suppose it immerged up to the axis in the water VV′, we have seen that the machine is most effective when the surfaces KB and O n of the water columns are distant the whole diameter BO of the spiral. Therefore let the pipe be first supposed of equal caliber to the very mouth E e, which we suppose to be just about to dip into the water. The surface O n is kept there, in opposition to the pressure of the water column BAO, by the compressed air contained in the quadrant OE, and in the quadrant which lies behind EB. And this compression is supported by the columns behind, between this spire and the rising pipe. But the air in the outermost quadrant EB is in its natural state, communicating as yet with the external air. When, however, the mouth E e has come round to A, it will not have the water standing in it in the same manner, leaving the half space BEO filled with compressed air; for it took in and confined only what filled the quadrant BE. It is plain, therefore, that the quadrant BE must be so shaped as to take in and confine a much greater quantity of air; so that when it has come to A, the space BEO may contain air sufficiently dense to support the column AO. But this is not enough: For when the wide mouth, now at A a, rises up to the top, the surface of the water in it rises also, because the part AO o a is more capacious than the cylindric part OE e o which succeeds it, and which cannot contain all the water that it does. Since, then, the water in the spire rises above A, it will press the water back from O n to some other position m' n', and the pressing height of the water column will be diminished by this rising on the other side of O. In short, the horn must begin to widen, not from B, but from A, and must occupy the whole semicircle ABE; and its capacity must be to the capacity of the opposite cylindrical side as the sum of BO, and the height of a column of water which balances the atmosphere to the height of that column. For then the air which filled it, when of the common density, will fill the uniform side BEO, when compressed so as to balance the vertical column BO. But even this is not enough; for it has not taken in enough of water. When it dipped into the cistern at E, it carried air down with it, and the pressure of the water in the cistern caused the water to rise into it a little way; and some water must have come over at B from the other side, which was drawing narrower. Therefore when the horn is in the position EOA, it is not full of water. Therefore when it comes into the situation OAB, it cannot be full nor balance the air on the opposite side. Some will therefore come out at O, and rise up through the water. The horn must therefore, 1st, Extend at least from O to B, or occupy half the circumference; and, 2dly, It must contain at least twice as much water as would fill the side BEO. It will do little harm though it be much larger; because the surplus of air which it takes in at E will be discharged, as the end E e of the horn rises from O to B, and it will leave the precise quantity that is wanted. The overplus water will be discharged as the horn comes round to dip again into the cistern. It is possible, but requires a discussion too intricate for this place, to make it of such a size and shape, that while the mouth moves from E to B, passing through O and A, the surface of the water in it shall advance from E e to O n, and be exactly at O when the beginning or narrow end of the horn arrives there.

We must also secure the proper quantity of water. When the machine is so much immersed as to be up to the axis in water, the capacity which thus secures the proper quantity of air will also take in the proper quantity of water. But it may be erected so as that the spirals shall not even reach the water. In this case it will answer our purpose if we join to the end of the horn a scoop or shovel QRSB (fig. 19.), which is so formed as to take in at least as much water as will fill the horn. Fig. 19. This is all that is wanted in the beginning of the motion along the spiral, and more than is necessary when the water has advanced to the succeeding spire; but the overplus is discharged in the way we have mentioned. At the same time, it is needless to load the machine with more water than is necessary, merely to throw it out again. We think that if the horn occupies fully more than one half of the circumference, and contains as much as will fill the whole round, and if the scoop lifts as much as will certainly fill the horn, it will do very well.

N. B. The scoop must be very open on the side next the axis, that it may not confine the air as soon as it enters the water. This would hinder it from receiving water enough.

Water-works.

The following dimensions of a machine erected at Florence, and whose performance corresponded extremely well with the theory, may serve as an example.

The spiral is formed on a cylinder of 10 feet diameter, and the diameter of the pipe is 6 inches. The smaller end of the horn is of the same diameter; and it occupies three-fourths of the circumference, and it is $7\frac{8}{10}$ths inches wide at the outer end. Here it joins the scoop, which lifts as much water as fills the horn, which contains 4340 Swedish cubic inches, each $=1.577$ English. The machine makes six turns in a minute, and raises 1354 pounds of water, or 22 cubic feet, 10 feet high in a minute.

The above account will, we hope, sufficiently explain the manner in which this singular hydraulic machine produces its effect. When every thing is executed by the maxims which we have deduced from its principles, we are confident that its performance will correspond to the theory; and we have the Florentine machine as a proof of this. It raises more than $\frac{10}{11}$ths of what the theory promises, and it is not perfect. The spiral is of equal caliber, and is formed on a cylinder. The friction is so inconsiderable in this machine, that it need not be mended: but the great excellency is that whatever imperfection there may be in the arrangement of the air and water columns, this only affects the elegance of the execution, causing the water to make a few more turns in the spiral before it can mount to the height required; but wastes no power, because the power employed is always in proportion to the sum of the vertical columns of water in the rising side of the machine; and the height to which the water is raised by it is in the very same proportion. It should be made to move very slow, that the water be not always dragged up by the pipes, which would cause more to run over from each column, and diminish the pressure of the remainder.

If the rising-pipe be made wide, and thus room be made for the air to escape freely up through the water, it will rise to the height assigned; but if it be narrow, so that the air cannot get up, it rises almost as slow as the water, and by this circumstance the water is raised to a much greater height mixed with air, and this with hardly any more power. It is in this way that we can account for the great performance of the Florentine machine, which is almost triple of what a man can do with the finest pump that ever was made: indeed the performance is so great, that one is apt to suspect some inaccuracy in the accounts. The entry into the rising-pipe should be no wider than the last part of the spiral; and it would be advisable to divide it into four channels by a thin partition, and then to make the rising-pipe very wide, and to put into it a number of slender rods, which would divide it into slender channels that would completely entangle the air among the water. This will greatly increase the height of the heterogeneous column. It is surprising that a machine that is so very promising should have attracted so little notice. We do not know of any being erected out of Switzerland except at Florence in 1778. The account of its performance was in consequence of a very public trial in 1779, and honourable declaration of its merit, by Sig. Lorenzo Ginori, who erected another, which fully equalled it. It is shortly mentioned by Professor Sulzer of Berlin, in the *Sammlungen Vermischten Schriften* for 1754. A description of it is published by the Philosophical Society of Zurich in 1766, and in the descriptions published by the Society in London for the encouragement of arts in 1766. The celebrated Daniel Bernoulli has published a very accurate theory of it in the Petersburgh Commentaries for 1772, and the machines at Florence were erected according to his instructions. Baron Alstromer in Sweden caused a glass model of it to be made, to exhibit the internal motions for the instruction of artists, and also ordered an operative engine to be erected; but we have not seen any account of its performance. It is a very intricate machine in its principles; and an ignorant engineer, nay the most intelligent, may erect one which shall hardly do any thing; and yet, by a very trifling change, may become very powerful. We presume that failures of this kind have turned the attention of engineers from it; but we are persuaded that it may be made very effective, and we are certain that it must be very durable. Fig. 20. is a section of the manner in which the author has formed the communication between the spiral and the rising pipe. P is the end of the hollow axis which is united with the solid iron axis. Adjoining to P, on the under side, is the entry from the last turn of the spiral. At Q is the collar which rests on the supports, and turns round in a hole of bell-metal. *ff* is a broad flanch cast in one piece with the hollow part. Beyond this the pipe is turned somewhat smaller, very round and smooth, so as to fit into the mouth of the rising pipe, like the key of a cock. This mouth has a plate *ee* attached to it. There is another plate *dd*, which is broader than *ee*, and is not fixed to the cylindrical part, but moves easily round it. In this plate are four screws, such as *g*, *g*, which go into holes in the plate *ff*, and thus draw the two plates *ff* and *dd* together, with the plate *ee* between them. Pieces of thin leather are put on each side of *ee*; and thus all escape of water is effectually prevented, with a very moderate compression and friction. Fig. 20.

Waterford.

WATERFORD, a city and sea-port of Ireland, in a county of the same name, with a bishop's see. It is the second place in the kingdom, and is a wealthy, populous city, enjoying many ample privileges. The streets are narrow, and the air is not very healthy; but it has an excellent harbour, seated as well for trade as any in the world, and ships of the greatest burden may ride at the quay. It stands on the river Sure, 8 miles north of St George's Channel, 26 south of Kilkenny, and 75 south-by-west of Dublin. W. Long. 7. 8. N. Lat. 52. 14.

WATERFORD, a county of Ireland, 46 miles in length, and 25 in breadth; bounded on the south by St George's Channel; on the west by Cork; on the north by the river Sure, which separates it from Tipperary and Kilkenny; and on the east by Waterford haven, which parts it from Wexford. It contains 71 parishes, and sends two members to parliament. It is a fine country, very pleasant and rich, and the principal place is of the same name. See WATERFORD, SUPPLEMENT.

Waterford, Watering.

WATERING, in the manufactures, is to give a lustre

lustre to stuffs, &c. by wetting them lightly with gum-water, and then passing them through the press or calender whether hot or cold.

WATERLAND, Dr Daniel, a learned English divine who distinguished himself greatly in theological controversies, was born in 1683 at Wasely in Lincolnshire, of which place his father was rector. He had his academical learning at Magdalen college, Cambridge, where he drew up a useful tract, which went through several editions, intitled, *Advice to a Young Student, with a Method of Study for the first four years*. In 1713 he became master of the college, was soon after appointed chaplain to George I.; and at the time of his death in 1740, was canon of Windsor, archdeacon of Middlesex, and vicar of Twickenham, Besides his controversial writings, he published two volumes of sermons.

WATSON, Dr Robert, an elegant historian, was born at St Andrew's in Scotland, about the year 1730. He was the son of an apothecary of that place, who was also a brewer. Having gone through the usual course of languages and philosophy at the school and university of his native place, and also entered on the study of divinity, a desire of being acquainted with a larger circle of literati, and of improving himself in every branch of knowledge, carried him, first to the university of Glasgow, and afterwards to that of Edinburgh. The period of theological studies at the universities of Scotland is four years: but during that period, young men of ingenious minds find sufficient leisure to carry on and advance the pursuits of general knowledge. Mr Watson pursued his studies with ardour. Few men ever studied more constantly. It was a rule with him to study eight hours every day; and this law he observed during the whole course of his life. An acquaintance with the polite writers of England, after the union of the two kingdoms, became general in Scotland; and in Watson's younger years, an emulation began to prevail of writing pure and elegant English. Mr Watson applied himself with great industry to the principles of philosophical or universal grammar; and by a combination of these, with the authority of the best English writers, formed a course of lectures on style or language. He proceeded to the study of rhetoric or eloquence; the principles of which he endeavoured to trace to the nature of the human mind. He delivered a course of lectures in Edinburgh on these subjects; and met with the countenance, approbation, and friendship of Lord Kames, Mr Hume, with other men of genius and learning.

At this time he had become a preacher; and a vacancy having happened in one of the churches of St Andrew's, he offered himself a candidate for that living, but was disappointed. Soon after he was appointed professor of logic; and he obtained also a patent from the crown, constituting him professor of rhetoric and belles lettres. The study of logic in St Andrew's, as in most other places, was at this time confined to syllogisms, modes, and figures. Mr Watson, whose mind had been opened by conversation, and by reading the writings of the wits that had begun to flourish in the Scotch capital, prepared and read to his students a course of metaphysics and logics on the most enlightened plan; in which he analyzed the powers of the mind, and entered deeply into the nature of the different species of evidence of truth or knowledge. By his history of Philip II. Dr Watson attained in his lifetime a considerable degree of celebrity; and his history of Philip III. published after his death, has added to his fame. Of this last performance, however, he has only completed the first four books; the two last were written by the editor of his manuscript, at the desire of the guardians of his children.

On the death of Principal Tulideph, Dr Watson, was appointed his successor; in which station he lived only a few years. He married a lady of singular beauty and virtue, daughter to Mr Shaw, professor of divinity in St Mary's college, St Andrew's. By this lady he had five daughters, who survived him.

WATT, James, the celebrated improver of the steam engine, see Supplement.

WATTS, Dr Isaac, a learned and eminent dissenting minister, was born at Southampton in 1674, of parents eminent for piety, and considerable sufferers for conscience-sake. In 1690 he was sent up to London for academical education under the tuition of the Rev. Mr Thomas Rowe; and in 1696 was himself engaged as tutor to the son of Sir John Hartopp, Bart. at Stoke Newington. He began to preach in 1698, and met with general acceptance; and after officiating as an assistant to the Rev. Dr Isaac Chauncy, he succeeded in his pastoral charge in 1702, and continued to preside over that church as long as he lived. Though his whole income did not amount to an hundred a-year, he allotted one third of it to the poor. He died in 1748. His numerous works have rendered his name famous among people of every denomination, both in this and other countries, and have been translated into a variety of languages. His Lyric Poems, his Psalms and Hymns, and his Divine Songs for Children, have had an amazing number of editions. His logic and philosophy have been much admired. He also wrote works upon a variety of other subjects, and printed several volumes of his sermons. He was admired for the mildness and benevolence of his disposition. After his death, his works were collected, and published in six volumes quarto.

WAVE, in *Philosophy*, a cavity in the surface of water, or other fluids, with an elevation aside thereof.

The waves of the sea are of two kinds, natural and accidental. The natural waves are those which are exactly proportioned in size to the strength of the wind, whose blowing gives origin to them. The accidental waves are those occasioned by the wind's reacting upon itself by repercussion from hills and mountains, or high shores, and by the washing of the waves themselves, otherwise of the natural kind, against rocks and shoals: all these causes give the waves an elevation, which they can never have in their natural state. For the height of the waves, see Sea.

Stilling Waves by means of Oil. See Sea.

WAVED, in *Heraldry*, is said of a bordure, or any ordinary or charge, in a coat of arms, having its outlines indented in manner of the rising and falling of waves: it is used to denote, that the first of the family in whose arms it stands, acquired its honours by sea-service.

WAVING, in the sea-language, is the making signs to a vessel to come near or keep off.

WAX, or *Bees Wax*, in *Natural History*, a firm and solid substance, moderately heavy, and of a fine yellow colour, formed by the bees from the pollen of flowers. See Apis.

The

Wax.

The best sort is that of a lively yellow colour, and an agreeable smell, somewhat like that of honey: when new, it is toughish, yet easy to break; but by age it becomes harder and more brittle, loses its fine colour, and in a great measure its smell.

It appears that wax and the pollen have for their basis a fat oil, which passes to the state of resin by its combination with oxygen. If the nitric or muriatic acid be digested upon fixed oil for several months, it passes to a state resembling wax. Wax, by repeated distillations, affords an oil which possesses all the properties of volatile oils. It is reduced into water and carbonic acid by combustion. The colouring matter of wax is insoluble in water and in alcohol.

Fixed alkalies dissolve wax, and render it soluble in water. It is this saponaceous solution which forms the punic wax. It may be used as the basis of several colours; and may be made into an excellent paste for washing the hands. Ammoniac likewise dissolves it; and as this solvent is evaporable, it ought to be preferred when it is proposed to use the wax as a varnish.

From the common yellow wax, by bleaching, is formed white-wax, sometimes called, very improperly, *virgin-wax*. The greater the surface is in proportion to the quantity, the sooner and more perfectly this operation is performed. The usual way is to melt the wax in hot water; when melted, they press it through a strainer of tolerable fine linen, and pour it into round and very shallow moulds. When hardened by cooling, it is taken out and exposed to the sun and air, sprinkling it now and then with water, and often turning it: by this means it soon becomes white. The best sort is of a clear and almost transparent whiteness, dry, hard, brittle, and of an agreeable smell, like that of the yellow wax, but much weaker.

The common yellow wax is of very great use both in medicine and in many of the arts and manufactures. It has been sometimes given internally in dysenteries and erosions of the intestines; but its great use is in the making ointments and plasters, and the greater part of those of the shops owe their consistence to it. The white wax is also an ingredient in some of the cerates and ointments of the shops; and it is used in making candles, and in many of the nicer arts and manufactures where wax is required.

Sealing-Wax, or *Spanish-Wax*, is a composition of gum lac, melted and prepared with resins, and coloured with some suitable pigment.

There are two kinds of sealing-wax in use; the one hard, intended for sealing letters, and other such purposes; the other soft, designed for receiving the impressions of seals of office to charters, patents, and such written instruments. The best hard red sealing-wax is made by mixing two parts of shell lac, well powdered, and resin and vermilion, powdered, of each one part, and melting this combined powder over a gentle fire; and when the ingredients seem thoroughly incorporated, working the wax into sticks. Seed-lac may be substituted for the shell-lac; and instead of resin, boiled Venice turpentine may be used. A coarser hard red sealing-wax may be made, by mixing two parts of resin, and of shell-lac, or vermilion and red lead, mixed in the proportion of one part of the vermilion to two of the red lead, of each one part; and proceeding as in the former preparation. For a cheaper kind, the vermilion may be omitted, and the shell-lac also, for very coarse uses. Wax of other colours is made by substituting other colouring matters for vermilion, as verditer for blue, ivory black for black wax. For uncoloured soft sealing-wax, take of bees wax, one pound; of turpentine, three ounces; and of olive oil, one ounce; place them in a proper vessel over the fire, and let them boil for some time; and the wax will be then fit to be formed into rolls or cakes for use. For red, black, green, blue, yellow, and purple soft sealing-wax, add to the preceding composition an ounce or more of any ingredients directed above for colouring the hard sealing-wax, and stir the mass till the colouring ingredients be incorporated with the wax.

Wax, Way.

Wax-Work, the representation of the faces, &c. of persons living or dead; made by applying plaster of Paris in a kind of paste, and thus forming a mould containing the exact representation of the features. Into this mould melted wax is poured, and thus a kind of masks are formed; which being painted and set with glass eyes, and the figures dressed in their proper habits, they bear such a resemblance that it is difficult to distinguish between the copy and the original.

WAY, a passage or road.

The Roman ways are divided into consular, prætorian, military, and public; and of these we have four remarkable ones in England: the first, Watling-street, or Watheling-street, leading from Dover to London, Dunstable, Toucester, Atterston, and the Severn, extending as far as Anglesea in Wales. The second, called *Hikenild* or *Ikenild street*, stretches from Southampton over the river Isis at Newbridge; thence by Camden and Litchfield; then passes the Derwent near Derby, and ends at Tinmouth. The third, called *Fosse-way*, because in some places it was never perfected, but lies as a large ditch, leads from Cornwall through Devonshire, by Tethbury, near Stow in the Wolds; and beside Coventry to Leicester, Newark, and so to Lincoln. The fourth, called *Erming* or *Erminage street*, extends from St David's, in Wales, to Southampton.

Way Covert, *Gang*, *Hatch*. See Covert *Way*, *Gang*, &c.

Way of a Ship, is sometimes the same as her rake, or run forward or backward: but this term is most commonly understood of her sailing.

Way-Leaves, in the coal business. See Coalery, N° 3.

Right of Ways, in *Law*. This may be grounded on a special permission; as when the owner of the land grants to another a liberty of passing over his grounds, to go to church, to market, or the like: in which case the gift or grant is particular, and confined to the grantee alone; it dies with the person; and if the grantee leaves the country, he cannot assign over his right to any other; nor can he justify taking another person in his company. A way may be also by prescription; as if all the owners and occupiers of such a farm have immemorially used to cross another's ground; for this immemorial usage supposes an original grant, whereby a right of way thus appurtenant to land may clearly be created. A right of way may also arise by act and operation of law; for if a man grants me a piece of ground in the middle of his field, he at the same time tacitly and impliedly gives me a way to come at it; and I may cross his land for that purpose without trespass. For when the law doth give any thing to one, it giveth impliedly whatsoever is necessary for enjoying the same. By the law of the twelve tables at Rome, where a man had a right of way over another's land, and the road was out of repair, he who had the right of way might go over any part of the land he pleased; which was the established rule in public as well as private ways. And the law of England, in both cases, seems to correspond with the Roman.

WAYFARING TREE. See VIBURNUM, BOTANY *Index*.

WAYGHTES, or WAITS, a word which is used only in the plural number, and signifies *hautboys*. It is now applied to the performers on these and other musical instruments, by a transition from the instruments themselves, and particularly to those performers who parade the streets by night, about the Christmas season of the year.

WAYWODE, is a title formerly given to the governors of the chief places in the dominions of the czar of Muscovy. The palatines, or governors of provinces in Poland, also bear the quality of *waywodes* or *waiwodes*. The Poles likewise call the princes of Wallachia and Moldavia *waywodes*; as esteeming them no other than on the foot of governors; pretending that Wallachia and Moldavia are provinces of Poland. Everywhere else these are called *hospodars*. Du Cange says, that the name *waywode* is used in Dalmatia, Croatia, and Hungary, for a general of an army; and Leunclavius, in his Pandects of Turkey, tells us, it usually signifies *captain* or *commander*.

WEANING, putting a child away from the breast, and bringing it to use common food.

WEAR, or WEER, a great stank or dam in a river, fitted for the taking of fish, or for conveying the stream to a mill. New wears are not to be made, or others altered, to the nuisance of the public, under a certain penalty. See RIVER.

WEARING, or VEERING, in *Seamanship*. See SEAMANSHIP.

WEASEL. See MUSTELA, MAMMALIA *Index*.

WEATHER denotes the state of the atmosphere with regard to heat and cold, wind, rain, and other meteors. See METEOROLOGY.

WEATHER, in sea-language, is used as an adjective, and applied by mariners to every thing lying to windward of a particular situation: thus, a ship is said to have the weather-gage of another, when she is farther to windward. Thus also, when a ship under sail presents either of her sides to the wind, it is then called the *weather-side* or *weather board*; and all the rigging and furniture situated thereon are distinguished by the same epithet, as the *weather-shrouds*, the *weather-lifts*, the *weather-braces*, &c.

To WEATHER, in sea-language, is to sail to windward of some ship, bank, or head-land.

WEATHER-*Cock*, a moveable vane, in form of a cock, or other shape, placed on high, to be turned round according to the direction of the wind, and point out the quarter from whence it blows.

WEATHER *Glass*. See BAROMETER.

WEATHERING, among sailors, signifies the doubling or sailing by a head-land or other place.

WEAVING, the art of working a web of cloth, silk, or other stuff, in a loom with a shuttle. For an idea of the manner in which this is performed, see CLOTH.

WEAVING-*Loom*, a machine for weaving cloth, silk, &c. by raising the threads of the warp in order to throw in the shoot, and strike it close. Of these there are various kinds, distinguished by the different sorts of cloths, stuffs, silks, &c. in which they are employed, and which are chiefly distinguished by the number and variety of the threads they raise in order to work the warp, either plain or in figures, by making more or less of the woof or shoot appear through the warp. In order to give a general idea of weaving, we shall here describe the parts of the common weaver's loom. Fig. 1. in which *e f*, *e f* are the front posts, and *g*, *g* the back posts of the loom; *l l l*, *m m*, *m m* are the *lams* in their place at Q, or, as they are called in some parts of Scotland, the *headles*, and in others the *sleves*. They are composed of strong threads, stretched between two horizontal bars, an upper and a lower. The threads of one lam are so disposed as to pass between the upper threads of the warp, while they admit the lower threads to pass through loops or small holes in them, and the disposition of the threads of the other lam is such, that while they pass between the lower threads of the warp, they admit the upper threads to pass through the small holes just mentioned. The lams are suspended from the cross bar or *lam-bearer* HH, by means of ropes *n*, *n* passing from the upper bars of the *lams* over the pulleys at EE, and balanced by weights at the other ends. From the lower bar of each *lam* or *headle* a rope passes to the *treadles* or moveable bar at OO; so that when a foot presses a treadle, the lam fastened to it sinks, while the other rises by means of the balancing weight suspended from the pulley at E. The workman then throws in the woof by means of the shuttle, and closes it by one or two strokes of the *lay* or *batten*, of which WB, WB are called the *swords*, CC the *cap*, or in Scotland the upper *shell*, DD the *block* or under *shell*, and PP the *reed* or comb contained between these shells. LL is the bench on which the workmen sit; for the loom which our figure represents is constructed for weaving cloth of such a breadth as to require two workmen, who have their quills in a box *d* on the middle of the bench on which they sit. Between the workmen's bench and the *batten* or *lay* is the *breast-bar* I, I, a smooth square beam, in which there is an opening to let the web through as it is wove. From this opening the web SS passes to the *knee roll* or *web beam* GG, round which it is rolled by means of the spokes, visible in the figure, and kept from being unrolled by a wheel with teeth and clench, visible likewise in the figure. In some looms the web passes from the knee roll to the wooden frame X, to be dried as it is wove. Opposite to the breast-bar, and on the other side of the *batten* or *lay*, is the *cane-roll* or *yarn-beam*, on which the warp is rolled when put into the loom, and from which it is gradually unrolled as the work proceeds. TT are bobbins filled with yarn of the warp to mend such threads of it as may be broke in the weaving; and B *b*, B *b* are clues of the same kind of yarn with the borders of the warp, to mend such threads as may there be broken.

Plate DLIII. fig. 1.

Fig. 2. represents the common shuttle with the vacuity in the middle, in which the quill with the woof is placed on a spindle or axis. As this shuttle is thrown with one hand in at one side of the warp, and received with

Fig. 2.

Weaving.

with the other hand at the other side, it is obvious, that when the web is of a breadth too great for a man to reach from one side of it to the other, two workmen must be employed and much time lost. To remedy this inconveniency, a new shuttle has, in this country, been lately brought into very general use, and called the *flying shuttle*, because it flies through the warp with wonderful rapidity on two steel rollers RR (fig. 3.). This shuttle is not thrown with the hand, but moved backwards and forwards by a very simple piece of machinery, of which fig. 4. will give the reader a sufficiently accurate conception. To each end of the *batten* or *lay* L is fastened a kind of open box B, *b*, with the bottom or horizontal side exactly on a level with the threads of the warp of the intended web. In each of these boxes is a vertical piece of wood D, *d*, of considerable thickness, called a *driver*. This driver is moved easily on an iron spindle or axis from one end of the box to the other by means of a slender rope CCCD, and a handle H is seen in the figure. When the weaver is to begin his work, he lays the shuttle on its rollers in the box B with the iron tip T (fig. 3.) touching, or almost touching, the driver D (fig. 4.). Then moving the handle H, with a sudden jerk, towards the box *b*, the driver D forces the shuttle with a rapid motion through the warp till it strikes *d*, which is impelled by the stroke to the further end of the box *b*. The two drivers D and *d* have now changed their positions in their respective boxes; so that the driver which was at the front of its box before, is now at the further end of it, and *vice versa*. Then by a sudden jerk of the hand towards B the shuttle is driven back till it strike D; and thus is the work continued without the weaver having occasion ever to stretch his arms from one margin of the web to the other. That the shuttle may not, by the unsteadiness of the workman's hand, be driven *zig-zag* through the warp or out of the place in which it ought to move, the guiding or driving rope CCCD is made to pass through smooth holes or loops C, C, at the ends of the ropes EC, EC, suspended either from the cross bar on the top of the loom or from the swords of the batten.

Fig. 3. Fig 4.

This shuttle, we should think, a great improvement in every kind of weaving-loom, though some of the older tradesmen, with whom we have conversed on the subject, contend, that it is valuable only in what they call light work, such as cotton or linen cloth, or when the web, if woollen, is very broad.

But as the labour of weaving is pretty severe, Mr Robert Millar, an ingenious calico-printer in the county of Dumbarton, Scotland, wishing to lessen it, invented, some years ago, a weaving-loom, which may be wrought by water, steam, horses, or any other power, for which invention he received a patent in 1796. The following is his own description of his patent weaving-loom:

Fig. 5. Fig. 5. represents a side view of the loom, AA, BB, CC, DD, being the frame. *a* is an axis (which we shall call the spindle) across the frame. On this axis is a sheeve *b*, two inches thick, having a groove round it, two inches deep, and half an inch wide. The bottom of this groove is circular, except in one part *c*, where it is filled up to the top; a lever *d* rests on the bottom of this groove, and is lifted up by it when the elevation *c* comes round to the situation represented in the figure. By this motion, the lever *d* acts on the ratchet-wheel *e* by the catch *t*, and draws it forward one tooth, each revolution of the sheeve. This ratchet wheel is in an iron frame *g g*, which also properly carries the two catches *t* and *u*, which are connected with it at *v*. The catch *u* holds the ratchet-wheel in its position, while the lever *d* and the catch *t*, are moved by the groove *c* in the sheeve. On the arbor of the ratchet is a small pinion *h*, working in the wheel *f*; this wheel is fixed on the end of the roller *e* of fig. 7. On the side of the sheeve *b* is fixed a wiper *k*, which lifts the treadle *l*. This treadle turns on its joints in the sheeve E, which is fixed to the side of the frame A and D; it is kept pressing on the bottom of the groove in the sheeve by a spring *m*, fixed to the frame side A, and having a slender rod *n* from its extremity, joining it with the treadle at *l*. From the point of the treadle there goes a belt *o*, which passes over the pulley *p*, which is seen edgewise in this figure, and is joined to the top of the fly pin *q*, of fig. 6. At the end of the frame A is the short post F; on this rests the yarn-beam *j*, having a sheeve *r*, over which passes a cord, having a weight *s* suspended to it. The other end of this cord is fastened to the spring *v*; the weight causes the yarn-beam to stretch the web from the ratchet-wheel *e*, with its catch *u*; and the spring *v* allows the rope to slide on the sheeve as the ratchet is drawn round during the working.

Fig. 6. Fig. 6. is a front view of the loom. *a a* is the spindle which carries the sheeve *b*, and the wipers *d* and *d*, which move the treadles *w*, *w*, of fig. 5. These use the treadles of the headles, with which they are connected by cords from the shafts of the headles *s*, *s*. From the upper shaft there go two leathern belts *f*, *f*, to the roller *y*, furnished each with a buckle, for tightening them at pleasure. The two wipers *c*, *c*, on the shaft *a*, which serve for taking back the lay, have the two treadles, *x*, *x*, in fig. 7. with a belt from each passing over the roller *h* 2 of fig. 6. and fixed to the sword of the lay. From the swords of the lay forward is fixed a belt to each end of the roller *i*; from this roller there goes a cord to the spring *j*, which serves for taking forward the lay which is hinged on the rocking-tree *t*. The star-wheel *b* of fig. 3. and the sheeve *b* of fig. 1. are fixed to the opposite ends of the spindle *a* without the frame; and both the wheel and sheeve have a wiper *k* fixed to them for moving the treadles. In order to drive the shuttle, the belts *o*, *o*, go from the points of the treadles, over the pulleys *p*, *p*, to the top of the fly-pin *q*. This turns on a pin joint in a rail *r*, which goes across the loom. From its lower end there go two small cords to the shuttle drivers *g*, *g*, which slide on the iron rods *n*, *n*. A long iron rod *v* goes across the lay, and is hung on two centres at the ends. In this rod *v* are fixed two small crooked wires *w*, *w*, which are more distinctly marked in the little figure *w* above, which represents a section of the lay. The dot at the lower end of the wire *w*, in this figure, is the section of the rod *v*. The shuttle passes between these wires and the lay every shot, and lifts them up, causing the rod *v* to turn round a little. But if the shuttle should not pass these wires, nor lift them, it would be drawn home by the lay, and destroy the web. To prevent this, there is fixed on one end of the rod *v* a stout crooked wire *z*, having a broad or flat head, which naturally rests on a plate of iron, marked and fixed to the back of the lay. This plate has a slit in

its

Weaving. its middle about an inch deep. In this slit rests the rod *a* 2 of fig. 7. on which is a short stud, which is caught by the wire *z* when the wire *w* is not lifted back by the passing shuttle. This will stop the lay from coming home, and will set off the loom.

Fig. 7. Fig. 7. is another side view of the loom opposite to fig. 5. On the spindle *a* is the star wheel *b*, on the outside of the loom frame, on the arms of which wheel is fixed the wiper *k*, as the similar wiper is fixed to the sheeves on the other end of the spindle. The wipers which drive the shuttles are fixed on opposite squares of the spindle, and work alternately. Below the star-wheel is a pinion *c*, which is on a round spindle, turned by the water-wheel, by means of a wheel on this spindle. In a wheel on this spindle are two studs, on which the pinion *c* slides off and on, as the loom is set off and on by the lever *d*. At the farther end of this lever is the weight *s*, hanging by a chord which passes over a pulley *t*, fixed at the outer end of the spring-catch on which the lever *d* rest; and thus the loom is drawn in at the upper end of the lever *d*. But when the shuttle does not lift the wire *z*, it catches on the stud on the rod *a* 2, which is connected with the spring-catch, and the lever *d* flies off with the weight *s*, and the loom stops working. On the head of the post F is the yarn-beam. The rollers *e* and *f* are cylinders, pressed together by a screw-lever, and take away the cloth between them at a proper rate. In the roller *f* is a groove for a band for driving the roller *g*, on which the cloth winds itself as it is wrought. Wherever springs are mentioned to be used in the above description, weights may be used in their stead, and to the same effect, and more especially upon the treadle of fig. 5. for driving the shuttle.

Fig. 8. Fig. 8. is a representation of a ribband loom. 1. Is the frame of the loom. 2. The castle, containing 48 pulleys. 3. The branches, on which the pulleys turn. 4. The tires, or the riding-cords, which run on the pulleys, and pull up the high-lisses. 5. The list-sticks, to which the high-lisses are tied. 6. The high-lisses, or lists, are a number of long threads, with platines, or plate-leads at the bottom; and ringlets, or loops, about their middle, through which the cords or cross-threads of the ground-harness ride. 7. The plate-leads, or platines, are flat pieces of lead, of about six inches long, and three or four inches broad at the top, but round at the bottom; some use black slates instead of them: their use is to pull down those lisses which the workman had raised by the treadle, after his foot is taken off. 8. The branches or cords of the ground harness, which go through the loops in the middle of the high-lisses: on the well ordering of these cords chiefly depends the art of ribbon-weaving, because it is by means of this contrivance that the weaver draws in the thread or silk that makes the flower, and rejects or excludes the rest. 9. The batton: this is the wooden frame that holds the reed or shuttle, and beats or closes the work: where observe, that the ribbon-weaver does not beat his work; but as soon as the shuttle is passed, and his hand is taken away, the batton is forced, by a spring from the top, to beat the work close. 10. The shuttle, or reed. 11. The spring of the batton, by which it is made to close the work. 12. The long-harness are the front-reeds, by which the figure is raised. 13. The linguas are the long pieces of round or square lead, tied to the end of each thread of the long-harness to keep them tight. 14. The broad piece of wood, about a foot square, leaning somewhat forward, intended to ease the weaver as he stoops to his shuttle; it is fixed in the middle of the breast-beam. Some weavers, instead of this, have a contrivance of a cord or rope that is fastened to the front-frame, and comes across his breast; this is called a *stopfall*. 15. The seat-bench; this leans forward very much. 16. The foot-step to the treadles. 17. The breast-beam, being a cross-bar that passes from one of the standards to the other, so as to front the workman's breast: to this breast-bar is fixed a roll, upon which the ribbon passes in its way, to be rolled upon the roller, that turns a little below. 18. The clamps, or pieces of wood, in which the broaches that confine the treadles rest. 19. The treadles are long narrow pieces of wood, to the ends of which the cords that move the lisses are fastened. 20. The treadle-cords are only distinguished from the riding-cords by a board full of holes, which divide them, in order to prevent the plate-leads, which are tied to the high-lisses, from pulling them too high when the workman's foot is off the treadle: which stop is made by a knot in the treadle-cord, too big to be forced through that hole in the board. 21. The lams are two pieces of thin narrow boards only used in plain works, and then to supply the place of the long-harness. 22. The knee-roll, by which the weaver rolls up his ribbon as he sees proper, or by bit and bit as it is finished. 23. The back-rolls, on which the warp is rolled. It is to be observed, that there is always as many rolls as colours in the work to be wove. 24. The clamps, which support the rollers. 25. The returning-sticks, or, as others call them, the *returns*, or the *tumblers*, or *pulleys*, to which the tiers are tied, to clear the course of cords through the high-lisses. 26. The catch-board for the tumblers. 27. The tire-board. 28. The buttons for the knee-rolls and treadle-board, described in N° 20.

It is stated in the proceedings of the National Institute of France, that a report was presented to that body concerning a new machine for weaving ribbed stockings. The advantages which this machine possesses are said to be, that it may be erected at one half of the expence of the English stocking frame, and that its movements are much lighter. The experience of its operations for two years has confirmed these advantages. Of the nature and construction of this machine we have had no opportunity of obtaining any information; but we thought it worth while to insert this short notice, with the view of directing the attention of such of our readers as may be interested in the improvement of such manufactures.

Web. WEB, a sort of tissue or texture formed of threads interwoven with each other; some whereof are extended in length, and called the *warp*; others are drawn across, and called the *woof*.

WEBERA, a genus of plants belonging to the class and order pentandria monogynia. See BOTANY *Index*.

WEBSTER, ALEXANDER, D. D. was the son of James Webster, minister of the Tolbooth church in Edinburgh, and born in that city about the year 1707. He was only 13 years of age at the death of his father, and of course could derive little from parental instruction or example. He studied at the university of Edinburgh the several branches of learning with great approbation, particularly

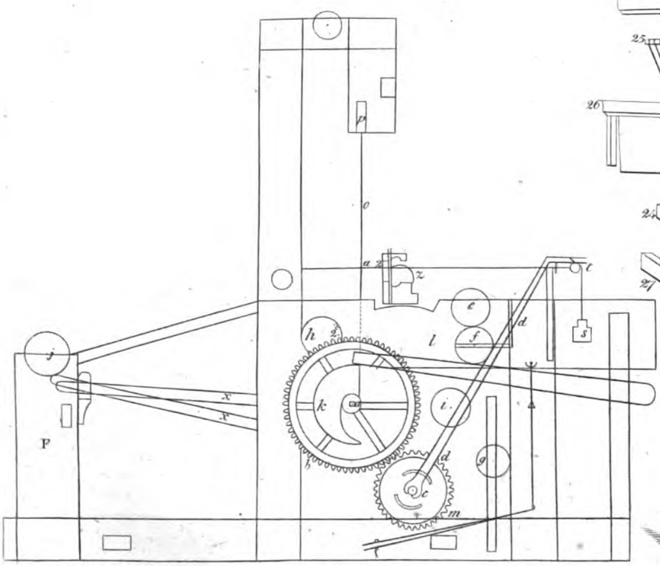

Fig. 8.

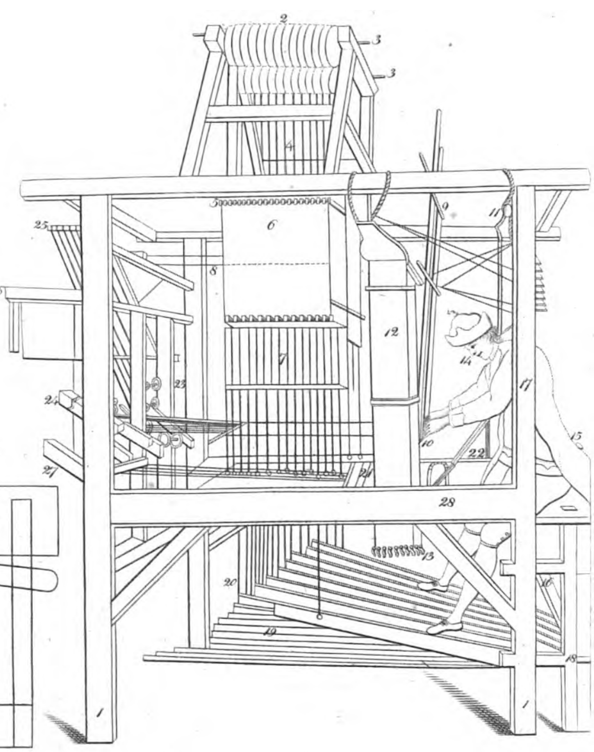

Webster. particularly those connected with the mathematics, for which he discovered an early predilection. He afterwards attended the lectures of the professor of divinity, and in the year 1733 he was ordained minister of the parish of Culross, and in June 1737, he was admitted to be one of the ministers of the Tolbooth church of Edinburgh. His eloquence was noble and manly, his piety conspicuous, and the discharge of his pastoral duties faithful and laborious. To these qualities he added an enlightened zeal for the external interests of the church, a jealousy of corruption, a hatred of false politics and tyrannical measures, which sometimes exposed him to calumny from the guilty, but secured him the esteem of all who could value independence of soul and integrity of heart.

The prosperity of fortune which placed Mr Webster in the church of his father, and restored him to the polished society of his native city, was not confined to these favours. Eleven days after his settlement in Edinburgh, he obtained the hand of Mary Erskine, a young lady of considerable fortune, and nearly related to the noble family of Dundonald. The genius of Mr Webster now began to unfold itself. Family connections extended his acquaintance with the nobility. Edinburgh then possessed a number of men, both in civil and ecclesiastical stations, who have saved or adorned their country. With these he was soon to co-operate in defending the Protestant interests from the arms and artifices of rebellion.

In the year 1733, five or six ministers seceded from the church, and being anxious to draw away as many as possible from the communion which they had renounced, they invited down to Scotland in 1741, Mr George Whitefield, a young preacher of great piety and extraordinary pulpit talents. On his way to Dunfermline, he was met and entertained at Edinburgh by Mr Webster and some of his brethren. From them he learned the state of church parties in Scotland; and though he kept his promise of preaching first in Fife, he declined connecting himself with any particular sect. Disappointed of his influence and assistance, the Seceders ascribed the effects of his preaching to sorcery and the devil, while Mr Webster, in a pamphlet which he published on the occasion, attributed them to the influence of the Holy Spirit, an opinion regarded by the Seceders as unspeakable wickedness.

In the year 1745, Mr Webster remained in the city when it was taken by the rebels, and employed his universal popularity and vigorous eloquence in retaining the minds of the people in the interests of the house of Hanover. His exertions in this were not overlooked by most of the spirited gentlemen who acted in quelling the rebellion. He became an intimate friend of Duncan Forbes of Culloden, Lord Milton, and others.

He preserved to the latest period of his career, that activity both of mind and body, which distinguished him in the prime of life, obtaining at last his frequent wish and prayer, an easy and peaceful death, after a very short indisposition, on the 25th of January 1784. His remains were deposited in the Grayfriars church-yard; and it is not a little remarkable that neither private friendship nor public generosity has yet come forward to testify its regard for two of the most eminent characters of the church of Scotland. The ashes of Webster and Blair repose in the same cemetry, undistinguished from the less illustrious dead. No monumental stone marks the place of their dust.

Webster ‖ Weeks.

Nature endowed Mr Webster with strong faculties, which were afterwards improved by a considerable share of erudition. He was a master in the knowledge of the world and of human nature; his address was engaging; his wit strong as his mind; his convivial powers, as they are called, enchanting. He had a constitutional strength against intoxication, which made it dangerous in most men to attempt bringing him into such a state. His character as a minister was popular in the extreme. His voice was harmonious, and his figure noble. To the poor he was a father and a friend, a liberal patron to poor students. In his person he was tall, and of a thin and meagre habit. His features were strongly marked, and the conformity of the whole indicated genius and independence.

To him the widows of the clergy are indebted for the establishment of the celebrated *Scheme*, the plan of which he matured in his mind soon after he was appointed a minister of the Tolbooth church. By it the widows of ministers are entitled to the annual sum of 10, 15, 20, or 25 pounds, according as the clergy pay into the fund yearly, 2l. 12s. 6d.—3l. 18s. 9d.—5l. 5s. or 6l. 11s. 3d, or to their children in sums of 100—150—200—or 250l. in favour of which an act of parliament was obtained in terms of a petition (17 Geo. II.) with liberty to employ the surplus of the annual payments and expences in loans of 30l. each among the contributors, and to put out the remainder at interest, on proper security. A second act was procured in the 22d year of the same reign (1748) granting liberty to raise the capital to 80,000l. including the sums lent to contributors. The fund is conceived to commence from the 25th March 1744. This was followed by another act in the year 1770, discontinuing the loan granted to contributors, and granting liberty to raise the capital to 100,000l.; and the whole economy of the institution was then fixed and determined, a report of the state of the fund being ordered to be made annually to the General Assembly by the trustees, which was to be afterwards printed. The success of the scheme has been complete.

WEDGE, one of the mechanical powers. See MECHANICS.

WEDNESDAY, the fourth day of the week, so called from a Saxon idol named *Woden*, supposed to be Mars, worshipped on this day.

Ash-WEDNESDAY, the first day of Lent, so called from the custom observed in the ancient Christian church of penitents expressing their humiliation at this time, by appearing in sackcloth and ashes.

WEED, a common name for all rank and wild herbs, that grow of themselves, to the detriment of other useful herbs they grow among.

WEED, in the miners language, denotes the degeneracy of a load or vein of fine metal into an useless marcasite.

WEEDS, also denote a peculiar habit, worn by the relicts of persons deceased, by way of mourning.

WEEK, in chronology, a division of time comprising seven days. See *PLANETARY Days* and SABBATH.

Passion-WEEK, or the *Holy WEEK*, is the last week in Lent, wherein the church celebrates the mystery of our Saviour's death and passion.

Weeks, Ember. See Ember.

Feast of Weeks. See Pentecost.

WEEVER. See Trachinus, Ichthyology *Index.*

WEEVIL, in *Zoology*, a species of curculio. See Curculio, Entomology *Index;* and for the method of destroying this troublesome and destructive insect, see Granary and Vermin.

WEIGELIA, a genus of plants belonging to the class and order pentandria monogynia. See Botany *Index.*

WEIGH, a weight of cheese, wood, &c. containing 256 pounds avoirdupois. Of corn, the weigh contains 40 bushels; of barley or malt, six quarters. In some places, as Essex, the weigh of cheese is 300 pounds.

WEIGHING, the act of examining a body in the balance to find its weight.

Weighing Anchor, is the drawing it out of the ground it had been cast into, in order to set sail, or quit a port, road, or the like.

WEIGHT, in *Physics*, a quality in natural bodies, whereby they tend downwards towards the centre of the earth. Or, weight may be defined in a less limited manner, to be a power inherent in all bodies, whereby they tend to some common point, called the *centre of gravity*, or, to speak more accurately, to one another: and that with a greater or less velocity, as they are more or less dense, or as the medium they pass through is more or less rare. See Mechanics.

Weight, in commerce, denotes a body of a known weight appointed to be put in the balance against other bodies whose weight is required.

The security of commerce depending, in a good measure, on the justness of weights, which are usually of lead, iron, or brass, most nations have taken care to prevent the falsification thereof, by stamping or marking them by proper officers, after being adjusted by some original standard. Thus, in England, the standard of weights is kept in the exchequer by a particular officer, called the *clerk of the market.*

Weights may be distinguished into the ancient and modern.

I. Ancient Weights.

1. Those of ancient Jews, reduced to the English troy weight, will stand as in the following table:

			lib.	oz.	dwt.	gr.
Shekel			0	0	9	$2\frac{4}{7}$
60	Maneh		2	3	6	$10\frac{2}{7}$
3000	50	Talent	113	10	1	$10\frac{2}{7}$

2. Roman weights, reduced to English troy weight, will stand as in the following table:

										oz.	dwt.	gr.
Lentes										0	0	$0\frac{85}{112}$
4	Siliquæ									0	0	$3\frac{1}{28}$
12	3	Obolus								0	0	$9\frac{3}{28}$
24	6	2	Scriptulum							0	0	$18\frac{3}{14}$
72	18	6	3	Drachma						0	2	$6\frac{9}{14}$
96	24	8	4	$1\frac{1}{3}$	Sextula					0	3	$0\frac{6}{7}$
144	36	12	6	2	$1\frac{1}{2}$	Sicilicus				0	4	$13\frac{2}{7}$
192	48	16	8	$2\frac{2}{3}$	2	$1\frac{1}{3}$	Duella			0	6	$1\frac{5}{7}$
576	144	48	24	8	6	4	3	Uncia		0	18	$5\frac{1}{7}$
6912	1728	576	288	96	72	48	36	12	Libra	10	18	$13\frac{5}{7}$

The Roman ounce is the English avoirdupois ounce, which they divided into seven denarii, as well as eight drachmas.

3. *Attic Weights.*

			English Troy Weight. lb.	oz.	dwt.	gr.
Drachma			0	0	2	16.9
100	Mina		1	1	10	10
6000	60	Talent	67	7	5	0

II. Modern Weights.

1. *English Weights.*—Mr Renardson, in a paper published in the Philosophical Transactions, has proved, that at first there was but one weight in England, and that this was the avoirdupois. Troy weight was introduced in the time of Henry VII.: At present, both the troy and avoirdupois weights are used in England. Troy weight seems to have derived its name from *Troyes*, a town in France, where a celebrated fair was kept. It is used for weighing gold, silver, jewels, silk, and all liquors. The avoirdupois is used for weighing other things.

Table of Troy Weight, as used by the

Goldsmiths, &c.

Grains.			
24	Penny-weights.		
480	20	Ounce.	
5760	240	12	Pound.

Apothecaries.

Grains.				
20	Scruple. ℈			
60	3	Dram. ʒ		
480	24	8	Ounce. ℥	
5760	288	96	12	Pound.

The troy pound in Scotland, which by statute is to be the same as the French pound, is commonly supposed equal

equal to 15 ounces and three quarters troy English weight, or 7560 grains. But by a mean of the standards kept by the dean of guild of Edinburgh, it weighs 7599$\frac{2}{31}$ or 7600 grains.

Table of Avoirdupois Weight.

Drams.					
16	An ounce.				
256	6	A pound.			
7168	448	28	A quarter.		
28672	1792	112	4	A hundred.	
573440	35840	2240	80	20	A ton.

The avoirdupois pound is equal to 7004 troy grains, the avoirdupois ounce to 437.75 grains; and it follows of consequence, that the troy pound is to the avoirdupois ounce as 88 to 107 nearly; for as 88 to 107, so is 5760 to 7003.636: that the troy ounce is to the avoirdupois ounce as 80 to 73 nearly; for as 80 to 73, so is 480 to 438. An avoirdupois pound is equal to 1 lb. 2 oz. 11 dwts. 20 gr. troy; a troy ounce is equal to 1 oz. 1.55 dr. avoirdupois; an avoirdupois dram contains 27.34375 grains; 175 troy pounds are equal to 144 avoirdupois pounds.

The moneyers have a peculiar subdivision of the grain troy: thus,

$$\text{The}\left\{\begin{array}{l}\text{Grain}\\ \text{Mite}\\ \text{Droit}\\ \text{Periot}\end{array}\right\}\text{into}\left\{\begin{array}{l}\text{20 Mites.}\\ \text{24 Droits.}\\ \text{20 Peroits.}\\ \text{24 Blanks.}\end{array}\right.$$

The English weights are used in the United Provinces of America.

2. *French Weights.*—Different weights were formerly used in most of the different provinces of France: These, however, have undergone very material alterations since the revolution in that kingdom. See **Measure**. But as a knowledge of the ancient weights of that country is of importance, on account of the books in which they are used, we insert the following tables. The Paris pound contains 16 ounces, and is divided two ways.

Grains.					
24	Penny-weight.				
72	3	Gros.			
576	24	8	Ounce.		
4608	192	64	8	Marc.	
9216	384	128	16	2	Pound.

Half ounce.						
2	Ounce.					
4	2	Half-quarter pound.				
8	4	2	Quarter-pound.			
16	8	4	2	Half-pound.		
32	16	8	4	2	Pound.	
3200	1600	800	400	200	100	Quintal.

The weights of the first division are used to weigh gold, silver, and the richer commodities; and the weights of the second division for commodities of less value.

The Paris 2 marc, or pound weight, is equal to 7560 grains troy, and the Paris ounce equal to 472.5 grains troy.

	lb.	oz.	dwt.	gr.	
The Paris pound =	1	3	15	0	troy.
The Paris ounce =	0	9	19	16.5	troy.

A grain troy = 1.2186507 of a Paris grain.

But the pound was not the same throughout France. At Lyons, *e. gr.* the city pound was only 14 ounces: so that 100 Lyons pounds, made only 86 Paris pounds. But beside the city pound, they had another at Lyons for silk, containing 15 ounces. At Thoulouse, and throughout the Upper Languedoc, the pound was 13 ounces and a half of Paris weight. At Marseilles, and throughout Provence, the pound was 13$\frac{1}{3}$ ounces of Paris weight. At Rouen, beside the common Paris pound and mark, they had the weight of the vicomte; which was 16 ounces, a half, and five-sixths of the Paris weight. The weights enumerated under the two articles of English and French weights are the same that are used throughout the greatest part of Europe; only under somewhat different names, divisions, and proportions.

French weights were formerly used in all the French American settlements.

3. *Dutch Weights.*—The weight used in Amsterdam and all over Holland is called *Troy weight*, and is exactly the same with that used at Brussels. The Dutch weights are as follows:

Deuskens.						
2	Troyken.					
4	2	Vierling.				
16	8	4	As.			
512	256	128	32	Angle.		
10240	5120	2560	640	20	Ounce.	
81920	40960	20480	5120	160	8	Marc.

The marc is equal, according to M. Tillet, to 4620 French grains.

Weight.

The Amsterdam pound used in commerce is divided into 16 ounces, 32 loots, or 128 drams. This pound contains 2 marcs troy, and ought therefore to weigh only 10240 *as*: but it weighs 10280; so that it is a little heavier than the troy pound of Amsterdam: 256lb. of commerce are equal to 257lb. troy of Holland. Two different pounds are used by apothecaries; the one containing 2 marcs, the other only $1\frac{1}{2}$. The first is called *arsenic* pound weight; it contains 16 ounces, the ounce 8 drams, the dram 8 scruples, the scruple 20 grains. The second is called the *apothecary's* pound; it is divided into 12 ounces, or 24 loots. Three arsenic pounds are equal to 4 apothecary's pounds.

The Dutch stone	=	8 commercial lb.
The Lispundt, or Ll.	=	15
The hundred weight	=	100
The Schippondt, or Sch. lb.	=	300

4. *Spanish Weights.*—The marc of Castile, used for weighing gold and silver, is divided as follows:

Grains (gold weight).	Grain (silver weight).	Tomine (gold weight).	Tomine (silver weight.)	Adarme.	Ochava.	Castellano.	Ounce.	Marc.
$1\frac{1}{24}$	Grain (silver weight).							
12	$11\frac{13}{25}$	Tomine (gold weight).						
$12\frac{1}{2}$	12	$1\frac{1}{24}$	Tomine (silver weight.)					
$37\frac{1}{2}$	36	$3\frac{1}{8}$	3	Adarme.				
75	72	$6\frac{1}{4}$	6	2	Ochava.			
96	$92\frac{4}{25}$	8	$7\frac{17}{25}$	$2\frac{14}{25}$	$1\frac{7}{25}$	Castellano.		
600	576	50	48	16	8	$6\frac{1}{4}$	Ounce.	
4800	4608	400	384	128	64	50	8	Marc.

The marc, according to Tillet, is equal to 7 oz. 4 gros, 8 grains French, which is equal to 4785 *as* of Holland. One hundred marcs of Castile = about $93\frac{1}{2}$ marcs of Holland; 100 marcs of Holland = 107 marcs of Castile. Medicines are sold by the same marc; but it is divided differently, containing 8 ounces, 64 drachms, 192 scruples, 384 obolos, 1152 caracteras, 4608 grains.

The Spanish commercial pound is divided into two marcs, called *marcs of Tejo*, each of which is equal to the marc of Castile. This pound is divided into 16 ounces, 256 adarmes, 9,216 grains.

5. *Weights of Portugal.*—The Lisbon marc for essaying silver coin of 12 deniers, and the denier of 24 grains. The marc of Portugal for weighing gold and silver is equal, according to Tillet, to 7 ounces $3\frac{1}{2}$ gros, and 34 grains French, which makes 4776 *as* of Holland; so that it is exactly the same with the Lisbon pound. It is divided into 8 ounces, 64 outavas, 192 scruples, 4608 grains.

The pound consists of 2 marcs, 16 ounces, or 96 outavas; the arroba of 32 lb.; the quintal of 4 arrobas, or 128 lb. 100 Oporto pounds make $87\frac{1}{8}$th pounds of commerce of Amsterdam.

6. *Weights of Italy.*—*Genoa.* Two kinds of weights

are used at Genoa, the *peso grosso* (heavy weight), and the *peso sottile* (light weight): the latter is used for weighing gold and silver, the former for other things. The pound of the peso sottile is equal, according to Tillet, to 1 marc, 2 ounces, $2\frac{1}{2}$ gros, 30 grains French. It is divided into 8 ounces, the ounce into 24 deniers, and the denier into 24 grains. The pound of the peso grosso is equal to 1 marc, 2 ounces, 3 gros, 5 grains, French. It is divided into 12 ounces:

The cantaro	=	100 lbs. peso grosso.
The rubbo	=	25 lbs.
The rotolo	=	$1\frac{1}{2}$ lb.
100 lbs. peso grosso	=	$64\frac{1}{7}$ lb. of commerce of Amsterdam.
100 lbs peso sottile	=	129 marcs troy of Holland.

Rome. The Roman pound consists of 12 ounces, the ounce of 24 deniers, the denier of 24 grains. The Roman pound, according to Tillet, is equal to 1 marc, 3 ounces, $\frac{1}{2}$ gros, 14 grains, French.

Venice. The marc for weighing gold and silver contains 8 ounces, 32 quarti, 1152 carati, or 4608 grani. An hundred marcs of Venice = $97\frac{1}{5}$ marcs troy of Holland, 100 marcs of Holland = 103 of Venice. In Venice they also use a *peso grosso* and *peso sottile.* 100 lbs. peso grosso = $94\frac{4}{5}$ commercial lbs of Amsterdam. 100 lbs. peso sottile = $61\frac{2}{7}$ ditto.

7. *Swedish Weights.*—The marc for weighing gold and silver is equal to 16 lods, 64 quentins, or 4384 as. The pound of 32 lods, used for weighing food, is equal, according to Tillet, to 1 marc, 5 ounces, 7 gros, 8 grains French, which makes $8848\frac{1}{2}$ as troy of Holland. This answers exactly to the weight of the different pounds, as fixed in Sweden, viz. 8848 as = the pound for weighing articles of food; $7821\frac{79}{125}$ as = marc used in the mines; $7450\frac{2}{125}$ as = marc used in towns and in the country; $7078\frac{2}{5}$ as = marc used for weighing iron; 7416 as = pound used in medicine.

The skippund	=	400 lbs. for weighing food.
The centner	=	120 lbs.
The waag	=	165 lbs.
The sten	=	32 lbs.
The Swedish as	=	1 as of Holland troy.

8. *German Weights.*—*Vienna.* The marc of Vienna for weighing gold and silver is divided into 16 loths, 64 quintals, or 256 deniers or pfenings; the loth into 4 quintals, or 16 pfenings. This marc, according to Tillet, is equal to 1 marc, 1 ounce, 1 gros, 16 grains, French, = 5831 as troy Holland. The pound of Vienna is divided into 2 marcs, or 4 viertings; the mark into 8 ounces, 16 loths, 64 quintals, or 266 pfenings.

Hamburgh. The marc for essaying gold is divided into 24 carats; the carat into 12 grains. The marc for silver is divided into 16 loths, and the loth into 18 grains. These marcs consist each of 288 grains, and are therefore equal. This marc, used in Hamburgh for gold and silver, is the marc of Cologne, which is equal, according to Tillet, to 7 ounces, 5 gros, $7\frac{1}{2}$ grains, French, = 4866 as troy of Holland. It is divided into 8 ounces, 16 loths, 64 quentins, 256 pfenings, 4352 esches, or 65536 richt pfenings theile. The apothecary pound used in Hamburgh, and almost all Germany, is divided into 12 ounces, 96 drachms, 288 scruples, or 5760 grains; an ounce is equal to 621 as of Holland.

The

Weight.

The pound of commerce is equal, according to Tillet, to 10085 as of Holland; for half a pound is equal to 7 ounces, 7 gros, 23 grains, French. This pound is divided into 16 ounces, 32 loths, 128 quentins, or 512 pfenings.

9. *Russian Weights.*—The berckowitz = 400 lbs.
The poud . - - - - = 40 lbs.

The pound is divided into 32 loths, or 96 solotnuks. One hundred Russian lbs. = $166\frac{1}{2}$ marcs, or $82\frac{4}{5}$ lbs. of Amsterdam. One hundred lbs. of commerce of Amsterdam = $120\frac{3}{4}$th lbs. of Russia.

10. *Weights used in the several parts of Asia, the East Indies, China, Persia, &c.*—In Turkey, at Smyrna, &c. they use the batman, or battemant, containing $7\frac{1}{2}$ occos; the occo contains 4 chekys or pounds, each of which, according to Tillet, is equal to 1 marc 2 oz. 3 gros. 28 gr. French. The Turkish weights are divided as follows:

Cantaras.	Batmans.	Occos.	Rotolos.	Chekis.	Mescals.	Drachms.
1 =	$7\frac{1}{2}$ =	44 =	100 =	176 =	$11733\frac{1}{3}$ =	17600
	1 =	6 =	$13\frac{1}{11}$ =	24 =	1600 =	2400
		1 =	$2\frac{1}{11}$ =	4 =	$266\frac{2}{3}$ =	400
			1 =	$1\frac{19}{28}$ =	$117\frac{1}{3}$ =	176
				1 =	$66\frac{2}{3}$ =	100
					1 =	$1\frac{1}{2}$

At Aleppo there are three sorts of rottos; the first 720 drachms, making about 7 pounds English, and serving to weigh cottons, galls, and other large commodities; the second is 680 drachms, used for all silks but white ones, which are weighed by the third rotto of 700 drachms. At Seyda the rotto is 600 drachms.

The other ports of the Levant, not named here, use some of these weights; particularly the occa, or ocqua, the rottoli, and rotto.

The Chinese weights are, the piece for large commodities: it is divided into 100 catis or cattis, though some say into 125; the cati into 16 taels or tales, each tael equivalent to $1\frac{1}{5}$ of an ounce English, or the weight of one rial and $\frac{1}{12}$, and containing 12 mas or masses, and each mas 10 condrins. So that the Chinese piece amounts to 137 pounds English avoirdupois, and the cati to 1 pound 8 ounces. The picol for silk containing 66 catis and $\frac{1}{3}$; the bahar, bakaire, or barr, containing 300 catis.

Tonquin has also the same weights, measures, &c. as China. Japan has only one weight, viz. the cati; which, however, is different from that of China, as containing 20 taels. At Surat, Agra, and throughout the states of the Great Mogul, they use the man, or maund, whereof they have two kinds; the king's maund, or king's weight; and the maund simply; the first used for the weighing of common provisions, containing 40 seers, or serres; and each seer a just Paris pound. The common maund, used in the weighing of merchandise, consists likewise of 40 seers, but each seer is only estimated at 12 Paris ounces, or $\frac{3}{4}$ of the other seer.

The maund may be looked upon as the common weight of the East Indies, though under some difference of name, or rather of pronunciation; it being called *mao* at Cambaya, and in other places *mein* and *maun*. The seer is properly the Indian pound, and of universal use; the like may be said of the bahar, tael, and catti, above mentioned.

Weight.

The weights of Siam are the piece, containing two shans or cattis; but the Siamese catti is only half the Japanese, the latter containing 20 taels and the former only 10; though some make the Chinese catti only 16 taels, and the Siamese 8. The tael contains 4 baats, or ticals, each about a Paris ounce; the baat 4 selings or mayons; the mayon 2 fouangs; the fouang 4 payes; the paye 2 clams; the sompaye half a fouang.

It is to be observed, that these are the names of their coins as well as weights; silver and gold being commodities there sold, as other things, by their weights.

In the isle of Java, and particularly at Bantam, they use the gantan, which amounts to near 3 Dutch pounds. In Golconda, at Visapour, and Goa, they have the furatelle, containing 1 pound 14 ounces English; the mangalis, or mangelin, for weighing diamonds and precious stones, weighing at Goa 5 grains, at Golconda, &c. $5\frac{1}{2}$ grains. They have also the rotolo, containing $14\frac{1}{4}$ ounces English; the metricol, containing the sixth part of an ounce; the wall for piastres and ducats, containing the 73d part of a rial.

In Persia they use two kinds of batmans or mans; the one called *cahi* or *cheray*, which is the king's weight, and the other *batman of Tauris*. The first weighs 13 pounds 10 ounces English; the second $6\frac{1}{2}$ pounds. Its divisions are the ratel, or a 16th; the derhem, or drachm, which is the 50th; the meschal, which is half the derhem; the dung, which is the sixth part of the meschal, being equivalent to 6 carat grains; and, lastly, the grain which is the fourth part of the dung. They have also the vakie, which exceeds a little our ounce; the sah-cheray, equal to the 1170th part of the derhem; and the toman, used to weigh out large payments of money without telling; its weight is that of 50 abasses.

11. *Weights at Cairo in Egypt.*—Almost every kind of goods has its own weight; these are regulated by the cantaren or principal weight.

	Rotels.
The ordinary cantaren, or hundred weight, weighs	100
The cantaren of quicksilver and tin -	102
coffee, wine, and iron -	105
ivory - - - - -	100
almonds and other fruits -	115
woods for dyeing - -	120
arsenic and other drugs -	125
minium and cinnabar -	130
gum arabic, aloes, and other aromatics - -	133

The ratel or rotoli is nearly equal to the pound of Marseilles; 108 lbs. of Marseilles are equal to 110 rotels. The Marseilles pound consists of 13 ounces of Paris; so that the 100 lbs. of Marseilles are equal to 81 lbs. Paris, and 100 lbs. Paris = 123 lbs. of Marseilles.

We shall subjoin here Mr Ferguson's table for comparing the English avoirdupois pound with foreign pounds:

London pound	1.0000	Bruges	1.0204
Antwerp	1.04	Calabria	0.73
Amsterdam	1.1111	Calais	0.9345
Abeville	1.0989	Dieppe	1.0989
Ancona	0.78	Dantzic	0.862
Avignon	0.8928	Ferrara	0.75
Bourdeaux	1.0989	Flanders	0.9433
Bologna	0.8	Geneva	1.07

Ferguson's Tables and Tracts.

Genoa

Weight.

Genoa, gross	0.7	Rochelle	0.8928
Hamburgh	1.0865	Rome	0.7874
Lisbon	1.135	Rouen	1.1089
Leghorn	0.75	Seville	0.9259
Norimberg	1.1363	Thoulouse	0.8928
Naples	0.71	Turin	0.82
Paris	1.1235	Venice	1.06
Prague	1.2048	Vienna	1.23
Placentia	0.72		

In order to show the proportion of the several weights used throughout Europe, we shall add a reduction of them to one standard, viz. the London pound.

The 100 lb. of England, Scotland, and Ireland are equal to

lb.	oz.	
91	8	of Amsterdam, Paris, &c.
96	8	of Antwerp or Brabant.
88	0	of Rouen, the viscounty weight.
106	0	of Lyons, the city weight.
90	9	of Rochelle.
107	11	of Thoulouse and Upper Languedoc.
113	0	of Marseilles or Provence.
81	7	of Geneva.
93	5	of Hamburgh.
89	7	of Francfort, &c.
96	1	of Leipsic, &c.
137	4	of Genoa.
132	11	of Leghorn.
153	11	of Milan.
152	0	of Venice.
154	10	of Naples.
97	0	of Seville, Cadiz, &c.
104	13	of Portugal.
96	5	of Liege.
112	$\frac{2}{3}$	of Russia.
107	$\frac{1}{11}$	of Sweden.
89	$\frac{1}{2}$	of Denmark.

A curious weighing machine was some time ago invented by M. Hanin of Paris, whereby the weights of the principal countries in Europe, and the relative proportions they bear to each other, are shown at one view. For this he received a bounty of 20 guineas from the Society instituted at London for the Encouragement of Arts, Manufactures, and Commerce. The following is a description of this ingenious machine.

Plate DLXXVII fig. 1. Figure 1. represents the back of the machine, which being suspended by the ring A, and a weight hung to the hook B, the spring C, C, C, made fast by strong screws at *g*, is drawn downwards; and the bar D having a rack thereon at *c*, turns the pinion *f*, in proportion to the weight of the body hanging thereto. Fig. 2. Figure 2. shows the face of the machine, on which is a number of concentric circles, and the weights of several countries of Europe engraved thereon, as expressed by the words on a line with them. In the centre of this face is a ring fixed to the small plate, turned by the pinion *f*, shown at figure 1. From this ring a hand projects, which, by the turning of the pinion, points to such part of the circle as is marked with the weight hung to the hook B; and thereby shows what weight of any of the countries mentioned, is equal to the pounds troy of London, which are engraved on the outer circle, or to the pounds avoirdupois, which are engraved on the second circle, and so of the rest. A slider moves on the hand, which may be brought to any of the circles at pleasure, in order to point out the relative weight with greater precision.

Many attempts have been made to introduce an uniformity of weights and measures into the commercial world; but hitherto they have all failed. The accomplishment of such an undertaking would be of infinite advantage to mankind, and certainly claims the most serious attention of those who by their situation can alone bring it about. The undertaking is indeed difficult, but surely not impossible. Something of this kind has been attempted and adopted in France; and, as the method is simple, and exceedingly well adapted for calculation, it surely deserves to be imitated. See MEASURE.

WEIGHT of Air. See PNEUMATICS, N° 14–19.

Regulation of WEIGHTS and Measures, is a branch of the king's prerogative. See PREROGATIVE and MEASURE.

As weight and measure are things in their nature arbitrary and uncertain, it is therefore expedient that they be reduced to some fixed rule or standard: which standard it is impossible to fix by any written law or oral proclamation; for no man can, by words only, give another an adequate idea of a foot rule, or a pound weight. It is therefore necessary to have recourse to some visible, palpable, material standard; by forming a comparison with which all weights and measures may be reduced to one uniform size; and the prerogative of fixing this standard, our ancient law vested in the crown, as in Normandy it belonged to the duke. This standard was originally kept at Winchester: and we find in the laws of King Edgar, near a century before the Conquest, an injunction that the one measure, which was kept at Winchester, should be observed throughout the realm. Most nations have regulated the standard of measures of length by comparison with the parts of the human body; as the palm, the hand, the span, the foot, the cubit, the ell (*ulna* or arm), the pace, and the fathom. But as these are of different dimensions in men of different proportions, our ancient historians inform us, that a new standard of longitudinal measure was ascertained by King Henry the First; who commanded that the *ulna*, or ancient ell, which answers to the modern yard, should be made of the exact length of his own arm. And one standard of measure of length being gained, all others are easily derived from thence; those of greater length by multiplying, those of less by dividing, that original standard. Thus, by the statute called *compositio ulnarum et perticarum*, five yards and a half make a perch; and the yard is subdivided into three feet, and each foot into 12 inches; which inches will be each of the length of three grains of barley. Superficial measures are derived by squaring those of length; and measures of capacity by cubing them. The standard of weights was originally taken from corns of wheat; whence the lowest denomination of weights we have is still called a *grain*; 32 of which are directed, by the statute called *compositio mensurarum*, to compose a pennyweight, whereof 20 make an ounce, 12 ounces a pound, and so upwards. And upon these principles the first standards were made; which, being originally so fixed by the crown, their subsequent regulations have been generally made by the king in parliament. Thus, under King Richard I. in his parliament holden at Westminster, A. D. 1197, it was ordained that there should be only one weight and one measure

measure throughout the kingdom, and that the custody of the assize, or standard of weights and measures, should be committed to certain persons in every city and borough; from whence the ancient office of the king's aulnager seems to have been derived, whose duty it was, for a certain fee, to measure all cloths made for sale, till the office was abolished by the statute 11th and 12th William III. c. 20. In King John's time this ordinance of King Richard was frequently dispensed with for money; which occasioned a provision to be made for enforcing it, in the great charters of King John and his son. These original standards were called *pondus regis* and *mensura domini regis*, and are directed by a variety of subsequent statutes to be kept in the exchequer chamber, by an officer called the *clerk of the market*, except the wine gallon, which is committed to the city of of London, and kept in Guildhall.

The *Scottish* standards are distributed among the oldest boroughs. The elwand is kept at Edinburgh, the pint at Stirling, the pound at Lanark, and the firlot at Linlithgow.

Various statutes have been enacted for regulating and enforcing an uniformity of weights and measures; and by the articles of union, the English standards are established by law over all Great Britain. But the force of custom is so strong, that these statutes have been ill observed. The Scottish standards are still universally retained for many purposes; and likewise a variety of local weights and measures are used in particular places of both countries, which differ from the general standards of either. A report was made by a committee of the House of Commons on the subject of weights and measures, 24th June, 1819, recommending alterations of a very limited nature; but nothing farther has been done.

WEINMANNIA, a genus of plants of the class *octandria*, order *monogynia*, and arranged in the natural classification with those plants the order of which is doubtful.

WELD, or WOLD. See RESEDA, BOTANY *Index*, and DYEING.

WELDING HEAT, in smithery, a degree of heat given to iron, &c. sufficient to make the surfaces of two pieces incorporate upon being beaten together with a hammer.

WELL, a hole under ground, usually of a cylindrical figure, and walled with stone and mortar: its use is to collect the water of the strata around it.

WELL, an apartment formed in the middle of a ship's hold to inclose the pumps, from the bottom to the lower decks. It is used as a barrier to preserve those machines from being damaged by the friction or compression of the materials contained in the hold, and particularly to prevent the entrance of ballast, &c. by which the tubes would presently be choked, and the pumps rendered incapable of service. By means of this inclosure, the artificers may likewise more readily descend into the hold, in order to examine the state of the pumps, and repair them as occasion requires.

WELL-Room of a Boat, the place in the bottom where the water lies between the ceiling and the platform of the stern-sheets, whence it is thrown out into the sea with a scoop.

Burning-WELL. See *BURNING-Spring*.

WELL of a Fishing-vessel, an apartment in the middle of the hold, which is entirely detached from the rest, being lined with lead on every side, and having the bottom thereof penetrated with a competent number of small holes passing also through the ship's floor; so that the salt-water running into the well is always kept as fresh as that in the sea, and yet prevented from communicating itself to the other parts of the hold.

WELL-hole, in building, is the hole left in a floor for the stairs to come up through.

WELLS, a city of Somersetshire, and see of a bishop; the bishop of Bath being also that of Wells.—It is supposed to take its name from the many springs and wells that are near it. It is not very large; but is adorned with handsome buildings, and contained 5156 inhabitants in 1811. Its cathedral is a very beautiful structure, adorned with images and carved stone work. The bishop's palace joins to the cathedral; and on the other side are the houses for the prebendaries. In the market-place is a fine market house, supported by pillars. It is governed by a mayor, and sends two members to parliament. The chief manufacture is knit hose. W. Long. 2. 40. N. Lat. 51. 12.

WEN, a tumor or excrescence arising on different parts of the body, and containing a cystus or bag filled with some peculiar kind of matter. See NÆVUS, SURGERY *Index*.

WEREGILD, the price of *homicide;* paid partly to the king for the loss of a subject, partly to the lord whose vassal he was, and partly to the next of kin of the person slain.

WERST, WURST, or *Verst*, a Russian measure equal to 3500 English feet. A degree of a great circle of the earth contains about 104 wersts and a half.

WERTURIAN or *URALIAN Mountains*, a famous chain of mountains forming part of the boundary of Asia. It begins distinctly (for it may be traced interruptedly farther south) near the town of Kungur, in the government of Kasan, in latitude 57° 20'; runs north, and ends opposite to the Waygatz strait, and rises again in the isle of *Nova Zemlja*. The Russians also call this range *Semennoi Poias*, or, *the girdle of the world;* from a supposition that it encircled the universe. These were the *Riphæi montes: Pars mundi damnata a natura rerum, et densa mersa caligine* *; of which only the southern part was known to the ancients, and that so little as to give rise to numberless fables. Beyond these were placed the happy *Hyperborei*, a fiction most beautifully related by Pomponius Mela. Moderns have not been behind-hand in exaggerating several circumstances relative to these noted hills. Ysbrand Ides, who crossed them in his embassy to China, asserts that they are 5000 toises or fathoms high; others, that they are covered with eternal snow. The last may be true in their more northern parts; but in the usual passages over them, they are free from it three or four months.

* *Plinii Hist. Nat.* lib. iv. cap. 12.

The heights of part of this chain have been taken by M. l'Abbé d'Auteroche: who, with many assurances of his accuracy, says, that the height of the mountain Kyria near Solikamskaia, in latitude 60°, does not exceed 471 toises from the level of the sea, or 286 from the ground on which it stands. But according to M. Gmelin, the mountain Pauda is much higher, being 752 toises above the sea. From Petersburgh to this chain is a vast plain, mixed with certain elevations or platforms, like islands in the midst of an ocean. The eastern side descends gradually to a great distance into the wooded and morassy Siberia, which forms an im-

Werturian, Wesley.

mense inclined plane to the Icy sea. This is evident from all the great rivers taking their rise on that side, some at the amazing distance of latitude 46°; and, after a course of about 27 degrees, falling into the Frozen ocean, in latitude 73° 30′. The Yaik alone, which rises near the southern part of the eastern side, takes a southern direction, and drops into the Caspian sea. The Dwina, the Peczora, and a few other rivers in European Russia, shew the inclined plane of that part. All of them run to the northern sea; but their course is comparatively short. Another inclination directs the Dnieper and the Don into the Euxine, and the vast Wolga into the Caspian sea.

WESLEY, John, a very extraordinary character, and founder of the sect of Methodists, was the son of the Reverend Samuel Wesley, rector of Epworth in the isle of Axholme in Lincolnshire, and was born in that village in the year 1703. His very infancy was distinguished by an extraordinary incident; for when he was only six years old, the parsonage-house at Epworth was burnt to the ground, and the flames had spread with such rapidity, that few things of value could be saved. His mother, in a letter to her son Samuel Wesley, then on the foundation at Westminster school, thanks God that no lives were lost, although for some time they gave up *Poor Jacky*, as she expresses herself; for his father had twice attempted to rescue the child, but was beaten back by the flames. Finding all his efforts ineffectual, he resigned him to Divine Providence. But parental tenderness prevailed over human fears, and Mr Wesley once more attempted to save his child. By some means equally unexpected and unaccountable, the boy got round to a window in the front of the house, and was taken out, by one man's leaping on the shoulders of another, and thus getting within his reach. Immediately on his rescue from this very perilous situation, the roof fell in. This extraordinary escape explains a certain device, in a print of Mr John Wesley, engraved by Vertue, in the year 1745, from a painting by Williams. It represents a house in flames, with this motto from the prophet, "Is he not a brand plucked out of the burning?" Many have supposed this device to be merely emblematical of his spiritual deliverance; but from this circumstance it is apparent that it has a primary as well as a secondary meaning; it is real as well as allusive.

In the year 1713 he was entered a scholar at the Charter-house in London, where he continued seven years under the tuition of the celebrated Dr Walker, and of the Rev. Andrew Tooke author of The Pantheon. Being elected to Lincoln college, Oxford, he became a fellow of that college about the year 1725, took the degree of Master of Arts in 1726, and was joint tutor with the Rev. Dr Hutchins the rector. He discovered very early an elegant turn for poetry. Some of his gayer poetical effusions are proofs of a lively fancy and a fine classical taste; and some translations from the Latin poets, while at college, are allowed to have great merit. He had early a strong impression, like Count Zinzendorff, of his designation to some extraordinary work. This impression received additional force from some domestic incidents; all which his active fancy turned to his own account. His wonderful preservation, already noticed, naturally tended to cherish the idea of his being designed by Providence to accomplish some purpose or other, that was out of the ordinary course of human events. The late Rev. Samuel Badcock, in a letter inserted in the Bibliotheca Topographica Britannica, N° XX. says, "There were some strange phenomena perceived at the parsonage at Epworth, and some uncommon noises heard there from time to time, which he was very curious in examining into, and very particular in relating. I have little doubt that he considered himself the chief object of this wonderful visitation. Indeed his father's credulity was in some degree affected by it; since he collected all the evidences that tended to confirm the story, arranged them with scrupulous exactness, in a manuscript consisting of several sheets, and which is still in being. I know not what became of the ghost of Epworth; unless, considered as the prelude to the noise Mr John Wesley made on a more ample stage, it ceased to speak when he began to act."

"The dawn of Mr Wesley's public mission (continues Mr Badcock) was clouded with mysticism; that species of it which affects silence and solitude; a certain inexplicable introversion of the mind, which abstracts the passions from all sensible objects; and as the French Quietists express it, perfects itself by an absorption of the will and intellect, and all the faculties, into the Deity." In this *palpable obscure* the excellent Fenelon led himself, when he forsook the shades of Pindus, to wander in quest of *pure love* with Madam Guyon! Mr Wesley pursued for a while the same *ignis fatuus* with Mr William Law and the Ghost of De Renty. A state, however, so torpid and ignoble, ill suited the active genius of this singular man. His elastic mind gained strength by compression; thence bursting glorious, he passed (as he himself somewhere says) "the immense chasm, upborne on an eagle's wings."

The reading of the writings of this Mr William Law, the celebrated author of Christian Perfection, and of A Serious Address to the Christian World, contributed moreover, to lead Mr John Wesley and his brother Charles with a few of their young fellow-students, into a more than common strictness of religious life. They received the sacrament of the Lord's Supper every week; observed all the fasts of the church; visited the prisons; rose at four in the morning; and refrained from all amusements. From the exact method in which they disposed of every hour, they acquired the appellation of *Methodists;* by which their followers have been ever since distinguished.

But a more particular account of the origin of this sect, we shall give from a celebrated publication. "The Methodists (says the editor of this work) form a very considerable class, principally of the lower people in this country. They sprung up about fifty years ago at Oxford, and were soon divided into two parties; the one under the direction of Mr George Whitefield, and the other under that of two brothers, John and Charles Wesley. These leaders, and, if we except Mr William Law, founders of the Methodists, were educated at Oxford, received episcopal ordination, and always professed themselves advocates for the articles and liturgy of the established church; though they more commonly practised the dissenting mode of worship. But conceiving a design of forming separate communities, superior in sanctity and perfection to all other Christian churches, and impressed to a very considerable degree by a zeal of an extravagant and enthusiastic kind, they became itinerant preachers; and, being excluded from most of our churches, exercised their ministry in private houses,

fields

Wesley.

fields, &c. not only in Great Britain and Ireland, but also in America; thus collecting a very considerable number of hearers and proselytes, both among the members of the established church and the dissenters. The theological system of Mr Whitefield and his followers is Calvinistic; that of Mr Wesley and his disciples Arminian; and the latter maintains the possibility of attaining sinless perfection in the present state. The subordinate teachers of both these classes of Methodists are generally men of no liberal education; and they pretend to derive their ministerial abilities from special communications of the Spirit. The Methodists of both parties, like other enthusiasts, make true religion to consist principally in certain affections and inward feelings which it is impossible to explain; but which, when analysed, seem to be mechanical in their spring and operation; and they generally maintain, that Christians will be most likely to succeed in the pursuit of truth, not by the dictates of reason, or the aids of learning, but by laying their minds open to the direction and influence of divine illumination; and their conduct has been directed by impulses."

Our readers will judge for themselves, according to their various modes of education, and to the different lights in which they may respectively view the doctrines of our common Christianity, whether this representation of the origin of the Methodists, and of their distinguishing tenets, be accurate and just.—Not presuming to sit in judgment on the religious opinions of any man, we shall only observe, that an appellation originally given in reproach, has been gloried in ever since by those who have distinguished themselves as the followers either of Mr Whitefield or of Mr Wesley. "After the way called *Methodists*, so worship they the God of their fathers." But the ridicule and contempt which the singularity of their conduct produced, both John and Charles Wesley were well qualified to bear. They were not to be intimidated by danger, actuated by interest, or deterred by disgrace.

The boundaries of this island were soon deemed by Mr Wesley too confined for a zeal which displayed the piety of an apostle, and of an intrepidity to which few missionaries had been superior. In 1735 he embarked for Georgia, one of our colonies, which was at that time in a state of political infancy; and the great object of this voyage was to preach the gospel to the Indian nations in the vicinity of that province. He returned to England in 1737. Of his spiritual labours, both in this country and in America, he himself has given a very copious account, in a series of Journals printed at different periods. These journals drew upon our laborious preacher and his coadjutors some severe animadversions from two right reverend prelates; Dr George Lavington bishop of Exeter, and Dr William Warburton bishop of Gloucester. The former published, in three parts, The Enthusiasm of the Methodists and Papists compared; the third part of this performance containing a personal charge of immoral conduct. Mr Wesley, in his vindication, published a letter to his lordship, which produced a reply from the latter.

Bishop Warburton's attack is contained in his celebrated treatise, entitled The Doctrine of Grace: or, The Office and Operations of the Holy Spirit vindicated from the Insults of Infidelity, and the Abuses of Fanaticism: concluding with some thoughts, humbly offered to the consideration of the Established Clergy, with regard to the Right Method of defending Religion against the Attacks of either party; 2 vols. small 8vo, 1762. There is much acute reasoning, and much poignant and sprightly wit, in his Doctrine of Grace; but there is too much levity in it for a grave bishop, and too much abuse for a candid Christian. On this occasion, Mr Wesley published a letter to the bishop, in which, with great temper and moderation, as well as with great ingenuity and address, he endeavoured to shelter himself from his lordship's attacks; not only under the authority of the Holy Scriptures, but of the church itself, as by law established.

On his return from Georgia, Mr Wesley paid a visit to Count Zinzendorf, the celebrated founder of the sect of Moravians, or Hernhutters, at Hernhut in Upper Lusatia. In the following year he appeared again in England, and with his brother Charles, at the head of the Methodists. He preached his first field-sermon at Bristol, on the 2d of April 1738, from which time his disciples have continued to increase. In 1741, a serious altercation took place between him and Mr Whitefield. In 1744, attempting to preach at an inn at Taunton, he was regularly silenced by the magistrates. Although he chiefly resided for the remainder of his life in the metropolis, he occasionally travelled through every part of Great Britain and Ireland, establishing congregations in each kingdom. In 1750 he married a lady, from whom he was afterwards separated. By this lady, who died in 1781, he had no children.

We have already mentioned Mr Wesley as a very various and voluminous writer. Divinity, both devotional and controversial, biography, history, philosophy, politics, and poetry, were all, at different times, the subjects of his pen: and, whatever opinion may be entertained of his theological sentiments, it is impossible to deny him the merit of having done very extensive good among the lower classes of people. He certainly possessed great abilities, and a fluency which was well accommodated to his hearers, and highly acceptable to them. He had been gradually declining for three years before his death; yet he still rose at four in the morning, and preached, and travelled, and wrote as usual. He preached at Leatherhead in Surrey, on the Wednesday before that event. On the Friday following, appeared the first symptoms of his approaching dissolution. The four succeeding days he spent in praising God; and he left this scene, in which his labours had been so extensive and so useful, at a quarter before ten in the morning of the 2d of March 1791, in the 88th year of his age. His remains, after lying in a kind of state at his chapel in the city-road, dressed in the sacerdotal robes which he usually wore, and on his head the old clerical cap, a bible in one hand, and a white handkerchief in the other, were, agreeably to his own directions, and after the manner of the interment of the late Mr Whitefield, deposited in the cemetry behind his chapel, on the morning of the 9th March, amid an innumerable concourse of his friends and admirers; many of whom appeared in deep mourning on the occasion. One singularity was observable in the funeral service. Instead of, "We give thee hearty thanks, for that it hath pleased thee to deliver this our brother;" it was read "our father." A sermon, previously to the funeral, had been preached by Dr Thomas Whitehead, one of the physicians to the

London

Wesley, West.

London hospital; and on the 13th the different chapels of his persuasion in London were hung with black.

It has been justly observed of Mr Wesley, that his labours were principally devoted to those who had no instructor; to the highways and hedges; to the miners in Cornwall, and the coalliers in Kingswood. These unhappy creatures married and buried among themselves, and often committed murders with impunity, before the Methodists sprung up. By the humane and active endeavours of Mr Wesley and his brother Charles, a sense of decency, morals, and religion, was introduced into the lowest classes of mankind; the ignorant were instructed, the wretched relieved, and the abandoned reclaimed. His personal influence was greater, perhaps, than that of any other private gentleman in any country.—But the limits of this article will not permit us to expatiate further on the character of this extraordinary man.

WEST, GILBERT, was the son of Dr West, prebendary of Winchester, and chaplain to King George I. but at 12 years of age lost his father. He studied at Winchester and Eton schools, and from thence was placed in Christ-church college, Oxford. His studious and serious turn inclined him to take orders; but Lord Cobham, his uncle, diverted him from that pursuit, and gave him a cornetcy in his own regiment. This profession he soon quitted, on account of an opening of another nature, which presented him with a flattering prospect of advancement in life. A number of young gentlemen were to be elected from the universities, and, at the expence of government, were to be taught foreign languages; and then sent to the secretaries office, to be initiated into business, and trained there for public services, as envoys, ambassadors, &c. Mr Gilbert West was one of the few pitched upon; and on his first introduction into that office, Lord Townsend, secretary of state, treated him with singular marks of regard, and the strongest inclinations to serve him were testified from all quarters. But his uncle Lord Cobham's strong opposition to the measures of the government, rendered these advantages entirely fruitless; and the ministers honestly told Mr West, that he must not expect them to distinguish his merit, as any favours conferred upon him would be imputed as done to his uncle Lord Cobham. Mr West now left that office, and all his views of making his fortune; and entering into marriage, retired to Wickham in Kent, where he lived in great domestic comfort and tranquil happiness. He was there visited by his valuable friends, who held the most delightful converse of wit, humour, and learning, supported upon the principles of virtue, sound reasoning, and solid friendship, which rendered the whole cheerful, animating, and instructive. Mr William Pitt, who was one of those that composed this happy society, becoming paymaster, appointed Mr West treasurer to Chelsea-hospital; and he obtained a seat at the council board, in consequence of a friendship contracted at the school with one of the duke of Devonshire's sons, who procured of his grace his being nominated one of the clerks extraordinary of that office. Towards the latter part of Mr West's life, he wholly applied himself to the study of the Scriptures; being extremely anxious to try his utmost endeavours to reconcile the seeming inconsistencies which gave the enemies to revealed religion a handle to doubt and discredit their authenticity. His observations on the resurrection, which, it has been said, were written to confirm the wavering faith of his great friends Pitt and Lyttleton, bear ample testimony to his reasoning powers and the sincerity of his religion; while his translations of Pindar show him to have been an eminent Greek scholar, and very considerable poet. He had a mind replete with virtue, and was an honour to his country; but died at 50 years of age.

WEST, one of the cardinal points of the horizon, diametrically opposite to the east; and strictly defined the intersection of the prime vertical with the horizon on that side the sun sets in.

WESTMINSTER, a city which forms the west part of the capital of Britain, but has a government distinct from the rest. This city had its name from the situation of its abbey, anciently called a *minster*, in respect of that of St Paul. That part properly called the city of Westminster, comprehending the parishes of St John and St Margaret, was once an island formed by the Thames, called *Thorney island*, from the thorns with which it was overrun; and the abbey that stood in it, Thorney abbey. The liberties of Westminster contain the several parishes of St Martin in the Fields, St James's, St Anne, St Paul, Covent-Garden, St Mary le Strand, St Clement Danes, St George, Hanover Square, and the precinct of the Savoy. The government, both of the city and liberties, is under the jurisdiction of the dean and chapter of Westminster, in civil as well as ecclesiastical affairs; and their authority extends to the precinct of St Martin le Grand, by Newgate-street, and in some towns of Essex, which are exempted from the jurisdiction of the bishop of London and the archbishop of Canterbury; but the management of the civil part has, ever since the Reformation, been in the hands of laymen, elected from time to time, and confirmed by the dean and chapter. The chief of these laymen are the high-steward, the deputy-steward, and the high-bailiff, who hold their offices for life. There are also 16 burgesses and their assistants, out of which are elected two head-burgesses, one for the city, and the other for the liberties. Another officer is the high-constable, who has all the other constables under his direction.

WESTMORELAND, a county of England, bounded on the north and north-west by Cumberland; on the south and south-east by Yorkshire; and on the south and south-west by Lancashire. Its extent from north-east to south, is 40 miles, and its breadth from the east projection to that in the west, 42. It is generally divided into the baronies of Kendal and Westmoreland: the former is very mountainous, but the latter is a large champaign country. These are the only principal divisions of this county, which contains eight market-towns, 26 parishes, and in 1811 the number of inhabitants was 45,922. It lies partly in the diocese of Chester, and partly in that of Carlisle. The earl of Thanet is hereditary sheriff of the county, which sends only four members to parliament. The air is clear, sharp, and salubrious, the natives being seldom troubled with diseases, and generally living to old age. The soil is various; that on the mountains is very barren, while that in the valleys is fertile, producing good corn and grass, especially in the meadows near the rivers. In the hilly parts on the western borders it is generally believed there are vast quantities of copper ore, and veins of gold; some mines of copper are worked, but most of the ore lies so deep that it it will not answer the expence. This county yields the finest slate, and abundance of excellent hams are cured here. The principal rivers are, the Eden, the Lone, and the Ken. It has also several fine lakes, the principal of which is Windermere. In the forest of Martindale, to the south of Ulls-water, the breed of red deer still exists in a wild state.—Appleby is the county town. See WESTMORELAND, SUPPLEMENT.

WESTPHALIA, formerly a duchy of Germany, bounded to the east by the bishopric of Paderborn, and the territories of Waldeck and Hesse; to the south by the counties of Witgenstein and Nassau, and the duchy of Berg; to the north by the bishopric of Munster and the county of Lippe. It is about 40 miles in length and 30 in breadth. The lower part of it is very fruitful, yielding plenty of corn and cattle, and some salt springs. The higher affords iron ore, calamine, lead, copper, some silver and gold, fine woods, cattle, game, fish, with a little corn. The rivers, that either pass through the duchy or along its borders, are the Rahr, the Lenne, the Bigge, the Dimel, and the Lippe. There are 28 towns in it, besides boroughs and cloisters. The provincial diets were held at Arensberg. In the year 1180, the emperor Frederic I. made a donation of this duchy to the archbishopric of Cologne, which was confirmed by succeeding emperors; and in 1638, the last duke of Arensberg ceded to it also the county of Arensberg.

WESTPHALIA, one of the circles of Germany. Anciently the people inhabiting between the Weser and the Rhine, were called *Westphalians;* and hence that tract got the name of *Westphalia:* but the circle of that name is of a larger extent, being surrounded by the circle of Burgundy, or the Austrian Netherlands, the United Provinces, and the North sea, with the circles of the Upper and Lower Rhine, and comprising a great many different states.

With respect to religion, Westphalia is partly Protestant and partly Catholic; but the Protestants predominate, and are, at least the greater part of them, Calvinists. The air of this country is not reckoned very wholesome, and towards the north is extremely cold in winter. The soil in general is marshy and barren; yet there is some good corn and pasture land; but the fruit is chiefly used to feed hogs; and hence it is that their bacon and hams are so much valued and admired.

After the peace of Tilsit in 1807, the principalities of Hanover, Brunswick, Magdeburg, Old Mark, Hesse Cassel, with some other territories, were erected into the kingdom of Westphalia, which was governed by Jerome Bonaparte. This state disappeared on the overthrow of the French power in 1814, and the territories which composed it were restored to their former princes. Jerome Bonaparte's court was kept at Cassel, the capital of the principality of Hesse.

WESTRINGIA, a genus of plants, formed from *cunila fruticosa*, which was discovered by Dr Solander in New Holland. Dr Smith describes it as approaching nearer to rosemary, and places it after *teucrium* in the class didynamia.

WET-COUCH, *Coming-heap*, a term used by the maltsters for one of the principal articles of malt-making. See BREWING, N° 4.

WETSTEIN, JOHN JAMES, a learned German divine, was born at Basil in 1693. On his admission to the ministry, he maintained a thesis *De variis Novi Testamenti Lectionibus;* in which he showed that the great variety of readings of the New Testament afford no argument against the authenticity of the text. He had made these various readings the object of his attention; and travelled into foreign countries to examine all the MSS. he could come at. In 1730, he published *Prolegomena ad Novi Testamenti Græci editionem accuratissimam*, &c. Some divines, dreading his unsettling the present text, procured a decree of the senate of Basil against his undertaking, and even got him prohibited from officiating in the ministry; on which he went to Amsterdam, where the Remonstrants named him to succeed the famous Le Clerc, then superannuated, as professor of philosophy and history. At last he published his edition of the New Testament, in 2 vols. folio, 1752; in which he left the text as he found it, placing the various readings, with a critical commentary, underneath; subjoining two epistles of Clemens Romanus, till then unknown to the learned, but discovered by him in a Syriac MS. of the New Testament. He also published some small works; and is said to have been not only an universal scholar, but to have abounded in good and amiable qualities. He died at Amsterdam in 1754.

WETTERAVIA, the southern division of the landgravate of Hesse in Germany, lying along the northern bank of the river Maine, and comprehending the counties of Hanau and Nassau.

WEXFORD, a county of Ireland, in the province of Munster, 38 miles in length, and 24 in breadth; bounded on the north by Wicklow, on the east by St George's channel, on the south by the Atlantic ocean, on the west by Waterford and Kilkenny, and on the north by Catherlough. It contains 109 parishes, and formerly sent 18 members to the Irish parliament. It is a fruitful country in corn and grass. See WEXFORD, SUPPLEMENT.

WEXFORD, a sea-port of Ireland, capital of a county of the same name. It was once reckoned the chief city in Ireland, being the first colony of the English, and is still a large handsome town, with a very commodious harbour at the mouth of the river Slana, on a bay of St George's channel, 63 miles south of Dublin. W. Long. 6. 25. N. Lat. 52. 18.

WHALE. See BALÆNA and PHYSETER, CETOLOGY *Index*.

WHALE, one of the constellations. See ASTRONOMY.

WHALE-Bone. For its natural history, see CETOLOGY *Index*.

A patent was granted in October 1806 to Robert Bowman of Leith, in Scotland, for making hats, caps, and bonnets for men and women, of whalebone; harps for harping or cleansing corn or grain; and also the bottoms of sieves and riddles, and girths for horses; and also a cloth or webbing for making into hats, caps, &c.; and for the backs and seats of chairs and sofas, gigs, coaches, and other similar carriages; and the bottoms of beds; as also reeds for weavers.

WHALE-Fishery. See CETOLOGY.

WHARF, a space on the banks of a haven, creek, or hithe, provided for the convenient loading and unloading of vessels.

WHARTON, PHILIP DUKE OF, a nobleman of the most brilliant parts, but of the most whimsical, extravagant, and inconsistent turn of mind, was educated by his father's

Wharton.

father's express order at home. He very early married a young lady, the daughter of Major-General Holmes, which disappointed his father's views of disposing of him in such a marriage as would have been a considerable addition to the fortune and grandeur of his illustrious family; yet that amiable lady deserved infinitely more felicity than she met with by this alliance. This precipitate marriage is thought to have hastened the death of his father; after which the duke, being free from paternal restraints, plunged into those excesses which rendered him, as Pope expresses it,

> " A tyrant to the wife his heart approv'd;
> " A rebel to the very king he lov'd."

In the beginning of the year 1716, he began his travels; and as he was designed to be instructed in the strictest Whig principles, Geneva was thought a proper place for his residence. He first passed through Holland, and visited several courts of Germany; and being arrived at Geneva, conceived such a disgust against his governor, that he left him, and set out post for Lyons, where he wrote a letter to the chevalier de St George, who then resided at Avignon, and presented him a very fine stout horse; which the chevalier no sooner received than he sent a man of quality to him, who took him privately to his court, where he was entertained with the greatest marks of esteem, and had the title of duke of Northumberland conferred upon him. He, however, remained there but one day, and then returned post to Lyons, whence he set out for Paris. He likewise paid a visit to the consort of James II. who then resided at St Germains, to whom he also paid his court. During his stay at Paris, his winning address and abilities gained him the esteem and admiration of all the British subjects of rank of both parties.

About the latter end of December 1716, he arrived in England, whence he soon after set out for Ireland, where, though under age, he was allowed the honour to take his seat in the house of peers, and immediately distinguished himself, notwithstanding his former conduct, as a violent partizan for the ministry; in consequence of which zeal the king created him a duke. He no sooner came of age than he was introduced to the house of lords in England with the same blaze of reputation. In a little time he opposed the court, and appeared one of the most vigorous in defence of the bishop of Rochester; and soon after printed his thoughts twice a-week, in a paper called the *True Briton*, several thousands of which were circulated.

The duke's boundless profusion had by this time so burdened his estate, that by a decree of Chancery it was vested in the hands of trustees for the payment of his debts, allowing him a provision of 1200l. per annum for his subsistence. This being insufficient to support his title with suitable dignity, he went abroad, and shone to great advantage, with respect to his personal character, at the imperial court. From thence he made a tour to Spain: the English minister was alarmed at his arrival, fearing that his grace was received in the character of an ambassador: upon which the duke received a summons under the privy seal to return home; but instead of obeying it, he endeavoured to inflame the Spanish court against that of Great Britain, for exercising an act of power, as he calls it, within the jurisdiction of his Catholic majesty. He then acted openly in the service of the Pretender, and was received at his court with the greatest marks of favour.

While his grace was thus employed, his neglected duchess died in England on the 14th of April 1726, without issue. Soon after the duke fell violently in love with M. Oberne, one of the maids of honour to the queen of Spain, the daughter of an Irish colonel, whose fortune chiefly consisted in her personal accomplishments. All his friends, and particularly the queen of Spain, opposed the match; but he falling into a lingering fever, occasioned by his disappointment, the queen gave her consent, and they were soon after married. He then spent some time at Rome, where he accepted of a blue garter, assumed the title of duke of Northumberland, and for a while enjoyed the confidence of the exiled prince. But not always keeping within the bounds of Italian gravity, it became necessary for him to remove from hence; when, going by sea to Barcelona, he wrote a letter to the king of Spain, acquainting him that he would assist at the siege of Gibraltar as a volunteer. Soon after he wrote to the chevalier de St George, expressing a desire to visit his court; but the chevalier advised him to draw near to England.

The duke seemed resolved to follow his advice; and setting out with his duchess, arrived in Paris in May 1728, whence he soon after proceeded to Rouen, where he took up his residence; and was so far from making any concession to the government of England, that he did not give himself the least trouble about his estate, or any other concern there, though, on his arrival at Rouen, he had only about 600l. in his possession, and a bill of indictment was preferred against him in England for high-treason. Soon after the chevalier sent him 2000l. which he squandered away in a course of extravagance; when, to save the charges of travelling by land, he went from Orleans to Nantz by water, and staid there till he got a remittance from Paris, which was squandered almost as soon as received. At Nantz he was joined by his ragged servants, and from hence took shipping with them for Bilboa, when the queen of Spain took the duchess to attend her person. About the beginning of the year 1731, the duke, who commanded a regiment, was at Lerida, but declined so fast that he could not move without assistance; yet when free from pain did not lose his gaiety. He, however, received benefit from some mineral waters in Catalonia; but soon after relapsed at a small village, where he was utterly destitute of all the necessaries of life, till some charitable fathers of a Bernardine convent removed him to their house, and gave him all the relief in their power. Under their hospitable roof he languished a week, and then died, without one friend or acquaintance to close his eyes; and his funeral was performed in the same manner in which the fathers inter those of their own fraternity.

Thus died Philip duke of Wharton, " who, like Buckingham and Rochester (says Mr Walpole), comforted all the grave and dull, by throwing away the brightest profusion of parts on witty fooleries, debaucheries, and scrapes, which mix graces with a great character, but never can compose one.

" With attachment to no party, though with talents to govern any party, this lively man changed the free air of Westminster for the gloom of the Escorial, the prospect of King George's garter for the Pretender's; and

Wharton, Wheat.

and with indifference to all religion, the frolic lord who had written the ballad on the archbishop of Canterbury, died in the habit of a capuchin. It is difficult to give an account of the works of a man whose library was a tavern, and women of pleasure his muses. A thousand sallies of his imagination may have been lost. There are only two volumes in 8vo, called *his Life and Writings*. These contain nothing of the latter, but 74 numbers of the True Briton, and his speech in defence of the bishop of Rochester. His other works are the ballads above mentioned; the Drinking Match at Eden hall, in imitation of the Chevy Chace, printed in a miscellany called *Whartoniana;* and a parody of a song sung at the opera house by Mrs Tofts. His lordship also began a play on the story of the queen of Scots."

WHEAT. See TRITICUM, BOTANY *Index;* and for the culture of wheat, see AGRICULTURE *Index*.

The three principal kinds of bad wheat are, the *blighted*, the *smutty*, and the *worm-eaten*. Blighted wheat is that of which the stalk is a little twisted and rickety, the blade being of a bluish green and curled up, the grain also is green and tubercled: smutty wheat appears as if great part of the ear had been burnt, some small parts only being free, and, in particular, the stem that rises in the centre of the ear, round which the grain is ranged: worm-eaten or rotten wheat is corrupted without losing much of its natural form, or external appearance; the husk is filled with a greasy black powder, that is insufferably fetid. It appeared, from the experiments of M. Tillet, that there was a kind of infectious quality in all those kinds of wheat: so that if sound wheat was sprinkled with the flower of smutty or rotten wheat, the crop produced would be rotten or smutty. It appeared also, that among the grain which was produced from ground manured with the straw of distempered wheat, there was a much greater proportion of distempered wheat than in that produced from ground manured with the straw of good wheat; the great secret then was to destroy the principle of this contagion in the wheat that was put into the ground; and M. Tillet found, as the result of a great number of experiments, that if the grain, before it is sowed, be well moistened with a solution of sea-salt, or nitre, in common water, none of the ensuing crop will be smutty, or otherwise defective, either in kind or quality; not only supposing the grain that is sowed to be sound, and the soil to be good, but even supposing the grain to be strewed with the flour of smutty wheat, and the ground manured with bad straw.

Prize Dissertation by the Academy of Bourdeaux.

The following receipt for preventing smutty wheat was published in 1769 by order of the Society for the Encouragement of Arts: they received it from Mr John Reynolds of Adisham in Kent.

A tub is to be procured that has a hole at bottom, in which a staff and tap-hose is to be fixed over a whisp of straw, to prevent any small pieces of lime passing (as in the brewing way); this done, we put 70 gallons of water, then a corn bushel heap-full of stone-lime, unslaked, stirring it well till the whole is dissolved or mixed, letting it stand about 30 hours, and then run it off into another tub as clear as we can (as practised in beer): this generally produces a hogshead of good strong lime-water; then add three pecks of salt, 42 pounds, which, with a little stirring, will soon dissolve; thus we have a proper pickle for the purpose of brining and liming our seed-wheat without any manner of obstacle, which is more than can be said in doing it the common way, and greatly facilitates the drilling.

Wheat ‖ Wheel-carriages.

Herein we steep the wheat in a broad-bottomed basket of about 24 inches in diameter, and 20 inches deep (for large sowing, made on purpose), running in the grain gradually in small quantities from 10 to 12 gallons up to 16 gallons, stirring the same. What floats, we skim off with a strainer, and is not to be sown: then draw up the basket to drain over the pickle, for a few minutes; all which may be performed within half an hour, sufficiently pickled; and so proceed as before. This done, the wheat will be fit for sowing in 24 hours, if required; but if designed for drilling, two hours pickled will be found best; and if prepared four or five days before-hand, in either case it makes no difference at all; but should the seed be clammy, and stick to the notches in the drill-box, more lime must be added to the lime-water: here the master must use his discretion, as the case requires; for some lime has much more drying or astringent qualities in it than others. If sea-water can be obtained conveniently, much less salt will suffice, but some will be found necessary even then, otherwise the light grains will not float, a thing of more consequence than is generally imagined, and it ought to be skimmed off and thrown aside for poultry, &c.

WHEEL, in *Mechanics*, a simple machine, consisting of a round piece of wood, metal, or other matter, which revolves on its axis. See MECHANICS.

Wheel-Carriages. See MECHANICS for an account of the general principles.

No kind of wheel-carriages are of more importance to a commercial and manufacturing country than stage coaches; and perhaps in no kingdom of Europe has the system of travelling in public vehicles been carried to greater perfection, as to comfort and speed, than in Britain. The danger, however, of travelling by these coaches makes considerable deduction from their accommodation otherwise: it is but too well known that this mode of travelling is liable to frequent and serious accidents. Every attempt therefore that promises to be useful in diminishing such danger should have all possible publicity. With this view we are much gratified in having an opportunity of laying before our readers the following account of an invention to render stage coaches more secure from danger, obligingly transmitted to us by the inventor, the reverend William Milton of Heckfield, Hants. For this invention that gentleman has obtained a patent.

The danger of stage coaches arises sometimes from *overturning*, and sometimes from *breaking down*. The *overturn* is, in general, occasioned *either* by taking two side-wheels into too deep a hole or ditch, or over too high a bank; *or*, secondly, by running down more quickly than the carriage is calculated to do, from the top to the sides of a rounded road; *or*, lastly, by turning a sharp corner with too great velocity. In the two first cases the danger arises from the centre of gravity of the total coach and load being placed too high; and in the last instance, of turning the sharp corner, from the same centre (but which we must now consider as the centre of the *vis inertiæ*) being also placed too high. The danger in the two first cases grows often out of the very circumstances of the road, and meets every one's

 comprehension:

Wheel-carriages.

comprehension: the last, which is less obvious, is generally owing to the mere will of the driver; and the better the road, the more is he tempted, without any intention, to go on to produce it: it requires therefore to be more generally understood than it is. It may be thus explained:—A carriage is going along a straight level road at the rate of nine miles an hour: then, though you imagine the horses or pulling power to be in an instant withdrawn, yet will the carriage continue its motion for ten, fifteen, or more yards, and at first with the same velocity, *and in the same straight line, in consequence of the acquired motion.* Supposing, now, the coach with its four horses going the nine miles an hour along a fine level road, but which has *a sharp and sudden corner to turn;*—the coachman knows it, and wishes to keep his velocity; the horses are aware of both—and by the animal dexterity with which they are gifted, *contrive to make the turn* without remitting any thing of their speed. *Not so the coach which follows them;* that has a tendency to persevere *in its straight line;* and the centre of its effort to do so is the centre of its *vis inertiæ*, the very centre of its gravity. If this centre be *low*, the turn of the corner may be made with no other inconvenience than a short awkward slide of the hind wheels, *onward in the original direction;* whereas, if it *be high*, there will be no slide, but *the coach will be overturned*, and overturned nearly at that point where its broadside is at rectangles to the straight line of road it has been thus forced to quit: for at that point the base against such an overturn will be the most disadvantageous, and the check to the onward motion the greatest. The *remedy* offered against all these *causes of the overturn*, (whether by a *ditch*, *bank*, *rounded road*, or *sharp corner*), *is to bring down this centre*, by placing as much of the luggage as possible *in a luggage-box*, *below the body of the carriage;* the body not being higher than usual.

From the *overturn*, we pass to the consideration of the *breaking-down;* this we must reckon on happening as often in these patent stage coaches as in others. Wheels will come off or fail, or axles will break, *in future, as they have done heretofore;* but against the disastrous and fatal consequences of such accidents the remedy offered may be thus described.—On each side of *the luggage-box*, with their periphery below its floor, and each as near as may be requisite to its respective *active wheel*, there is placed a *small strong idle wheel*, *ready* in case of *breaking down, on either side, to catch the falling carriage, and instantly to continue its previous velocity*, till the coachman can pull up his horses, thereby preventing *that sudden stop to rapid motion*, which at present constantly attends the *breaking-down;* and which has so frequently proved fatal to the coachman and outside passengers. In case a fore-wheel comes off, each end of the fore-carriage has its *idle wheel.* By this provision we shall be, *to all effect of safety*, continually travelling with two carriages under us. The bottom of this luggage-box is meant to be about fourteen inches from the ground; and the *idle wheels* seven, six, or five; but if at a still less distance, little inconvenience would result; for when either of them takes over an obstacle in the road, it instantly, and during the need, discharges its respective *active wheel* from the ground, and works in its stead. If these two principles of safety were applied to the description of the several stage-coach accidents we meet with, there is no doubt but a general conviction would arise, *that* the safety by these modes is (in vehicles of all kinds), *perhaps as great as can consist with rapid loco-motion; and that*, sooner or later, *legislative authority*, in some shape or other, may judge it necessary to interpose, for the purpose of controlling a prejudice against *the form essential to this mode of safety.* The trial and proof which these principles have been brought to, have not only been by public exhibition, and with preparation; but *in all the suddenness*, also, *of actual heavy work:* and the result in both cases has been so exactly the same, as to give *continual assurance* of the full effect of the remedy, as often as the casualties of the road shall bring it into action.

Wheel-carriages.

The aim in the arrangement of this *coach of safety*, has been to bring down the load, and consequently the centre of gravity, as low as possible: this is thought to make the coach *look heavy;* and this word, by the ready operation of a prejudice, has been transferred to its going; and one specific reason added withal, that, *because the load is low*, the draught *must* be heavy. This point, however, has, in the presence of 10 or 12 competent persons, been brought to the most decisive proof; and it comes out, that it is as indifferent to draught, as it is material to danger or safety, whether *a ton* be placed on the roof of a coach, or *a ton* on the floor of the patent luggage-box, about 15 or 16 inches from the ground.

It has been asked, "*What would this coach do in snow?*" The question has been thus answered by the result of actual work; for the patent coach, after being detained on the road with several other coaches, by a sudden fall of snow, when at last they started together, *came in six or seven hours before any of them.* They were bound in prudence, to go cautiously along the ground, whose unevenness was invisible; while the patent coach dashed along it with all the confidence and safety of a post-chaise. See Plate DLXXVII.

Wheel-Animal. See Animalcule, N° 16—23.

Wheel, Persian. See Agriculture.

Wheel, Potter's. See Porcelain.

Wheel is also the name of a kind of punishment to which great criminals are put in divers countries. In some, assassins, parricides, and robbers on the highway, are said to be condemned to the wheel, when they are to have their bones first broken with an iron bar on a scaffold, and then to be exposed, and left to expire on the circumference of a wheel. In Germany they break their bones on the wheel itself.—Of this cruel punishment, it is not certain who was the inventor: it was first used in Germany, and was, indeed, but rarely practised anywhere else, till the time of Francis I. of France; who, by an edict of the year 1534, appointed it to be inflicted on robbers on the highway.

WHEELER, Sir George, a learned traveller and divine, was the son of Colonel Wheeler of Charing in Kent, and was born in 1650 at Breda, where his parents as royalists were then in exile. He travelled through various parts of Greece and the East, in company with Dr James Spon of Lyons; and taking orders on his return, was installed a prebend of Durham, made vicar of Basingstoke, and afterward rector of Houghton le Spring. He published an account of his Travels in 1682 in folio; and in 1689, his Observations on Ancient Edifices of Churches yet remaining in the East, compared

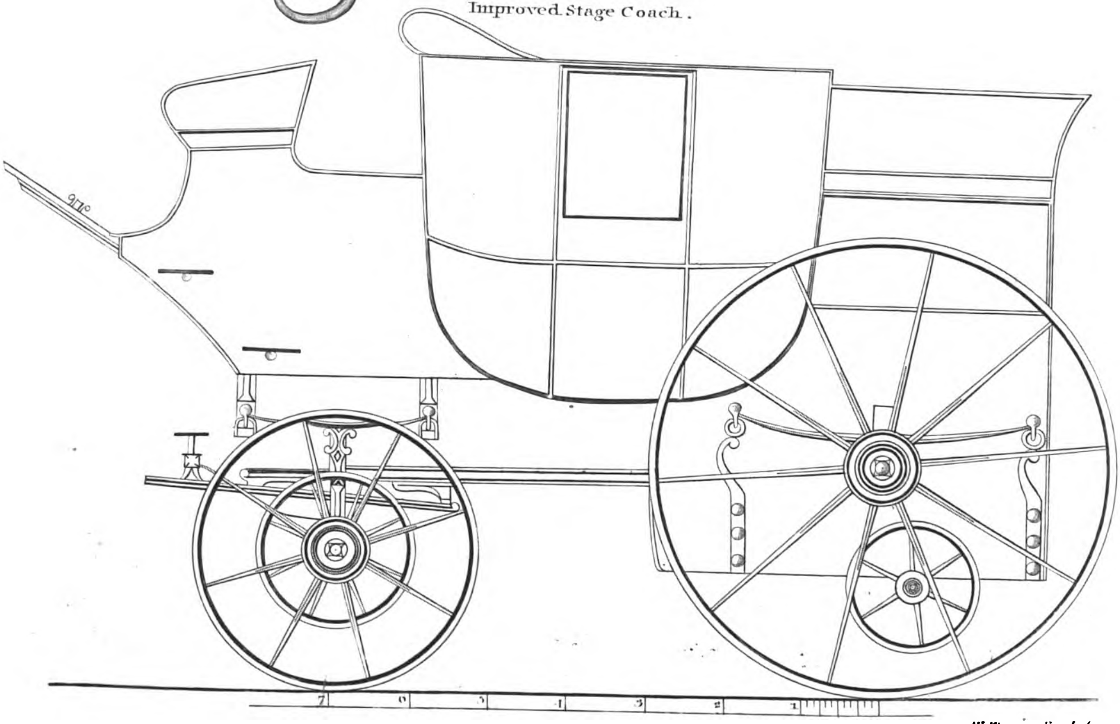
WHEEL CARRIAGES

Improved Stage Coach.



compared with Eusebius: also the Protestant Monastery, or Christian Oeconomics. He died in 1724.

WHEELINGS, in the military art, are different motions made both by horse and foot, either to the right and left, or to the right and left about.

General Rules for WHEELING.—The circle is divided into four equal points: thence, wheeling to the right or left, is only a quarter of the circle; wheeling to the right or left about, is one half of the circle.

When you wheel to the right, you are to close to the right, so near as to touch your right-hand man, but without pressing him; and to look to the left, in order to bring the rank about even.

When you wheel to the left, you are to close to the left, and look to the right as above directed. This rule will serve for all the wheeling by ranks; as when a battalion is marching by subdivisions with their ranks open, then each rank wheels distinctly by itself, when it comes to the ground on which the ranks before it wheeled, but not before.

In wheeling, the men are to take particular care neither to open nor close their ranks, and to carry their arms well.

In wheeling, the motion of each man is quicker or slower, according to the distance he is from the right or the left: thus, when you wheel to the right, each man moves quicker than his right-hand man; and wheeling to the left, each man moves quicker than his left-hand man; the circle that every man wheels being larger, according to the distance he is from the hand he wheels to; as may be seen by describing several circles within one another, at two feet distance from each, which is nearly the space every man is supposed to take up.

WHELK, a species of shell-fish. See BUCCINUM, CONCHOLOGY *Index*.

WHELP, the young of a dog, fox, lion, or any wild beast.

WHELPS, in a ship, the seaman's term for those brackets which are set up on the capstan close under the bars; they give the sweep to it, and are so contrived that the cable winding about them may not surge so much as it might otherwise do if the body of the capstan were quite round and smooth.

WHETSTONE, a stone so called, because it serves for the whetting of edge tools upon. See MINERALOGY *Index*.

WHEY, the serum or watery part of milk.

WHIDAH, a kingdom of Africa, on the coast of Guinea, and to the west of the Gold Coast; extending about 10 miles along the sea. It is a populous country, well furnished with large villages; and there are so many small ones, that they are not above a musket-shot from each other.—The houses are small, round at the top, and encompassed with mud walls or hedges, together with a great number of all sorts of beautiful and lofty trees, which afford the most beautiful prospect in the world, insomuch that those that have been here represent it as a perfect paradise. The fields are always green, and they cultivate beans, potatoes, and fruits; nor will the negroes here let a foot of ground remain uncultivated. They sow again the very next day after they have reaped. The inhabitants are greatly civilized, very respectful to each other, especially to their superiors, and very industrious. The women brew the beer, dress the victuals, and sell all sorts of commodities at the market. Those that are rich employ their wives and slaves in tilling the land, and they carry on a considerable trade with the product, as well as in slaves; for some of them are able to deliver 1000 of the latter every month. The chief men have generally 40 or 50 wives, the principal captains 300 or 400, and the king 4000 or 5000. They are extremely jealous, and, on the least suspicion, will sell them to the Europeans for slaves. If any one happen to touch one of the king's wives accidentally, he is doomed to perpetual slavery. It is no wonder then that the women are not fond of being the king's wives; and some of them will prefer a speedy death to such a miserable life. They have no distinction of hours, days, weeks, months, or years. The rite of circumcision is used here; but they are not able to tell why they use it, nor whence it is derived. They are such great gamesters, that they will stake all they have at play, not excepting their wives and children. They have a vast number of idols; and they deify the most contemptible animal that they see first in a morning, and even stocks and stones. Their principal regard is for snakes, very high trees, and the sea. An English factor, just arrived, found a snake in the house belonging to the factory, and killed it without the least scruple; which so incensed the negroes, that they were for revenging the death of the snake, not only upon him that killed it, but upon the whole factory; but by means of presents, and the interposition of the people of the other factories, the affair was made up, and the snake honourably interred. However, to prevent such accidents, they gave them warning not to do the like for the future. They have oxen, cows, goats, sheep, hogs, turkeys, ducks, and hens; which last are extremely plentiful. There are many elephants, buffaloes, tigers, several kinds of deer, and a sort of hares. The fruits are citrons, lemons, oranges, bananas, tamarinds, &c. and they have vast numbers of palm-trees, from which they obtain wine. Whidah was conquered by the king of Dahomy. Their trade consists of slaves, elephants teeth, wax, and honey. The English factory is 200 miles east of Cape Coast Castle, within land. Bows, arrows, beautiful assaguays, and clubs, are the principal weapons of the nation.

WHIDAW-BIRD. See EMBERIZA, ORNITHOLOGY *Index*.

WHIG, a person belonging to a political party in Britain, opposite to the Tories. See TORIES, and BRITAIN.

WHIMBREL. See SCOLOPAX, ORNITHOLOGY *Index*.

WHIN. See ULEX, BOTANY *Index*.

WHINCHAT. See MOTACILLA, ORNITHOLOGY *Index*.

WHIP, or *WHIP-Staff*, in a ship, a piece of timber, in form of a strong staff, fastened into the helm, for the steersman, in small ships, to hold in his hand, in order to move the rudder, and direct the ship.

WHIRLPOOL, an eddy, vortex, or gulf, where the water is continually turning round.

Those in rivers are very common, from various accidents, and are usually very trivial, and of little consequence. In the sea they are more rare, but more dangerous. Sibbald has related the effects of a very remarkable marine whirlpool among the Orcades, which would prove very dangerous to strangers, though it is

of

Whirlpool. Whirlwind.

of no consequence to the people who are used to it. This is not fixed to any particular place, but appears in various parts of the limits of the sea among these islands. Wherever it appears, it is very furious, and boats, &c. would inevitably be drawn in and perish with it; but the people who navigate them are prepared for it, and always carry an empty vessel, a log of wood, or large bundle of straw, or some such thing in the boat with them; as soon as they perceive the whirlpool, they toss this within its vortex, keeping themselves out: this substance, whatever it be, is immediately received into the centre, and carried under water; and as soon as this is done, the surface of the place where the whirlpool was becomes smooth, and they row over it with safety; and in about an hour they see the vortex begin again in some other place, usually at about a mile's distance from the first.

WHIRLWIND, a wind which moves in a spiral direction, as well as horizontally, which is exceedingly rapid and impetuous, but only of short duration.

Dr Franklin's opinion of the origin of whirlwinds has been already given in the article *Water-Spout*. If his theory be true, it will follow, that no hurricane ever can be so violent as to remove an obstacle of the size of only one cubic inch, provided that was supported by a power equivalent to 15 pounds; for this is the utmost force of the atmosphere when rushing into a perfect vacuum, which never could take place in the centre of a whirlwind or water-spout. Indeed, notwithstanding the dreadful effects sometimes observed from hurricanes and whirlwinds, we shall easily perceive, that the utmost of their power always falls very far short of this. The diminution of the specific gravity of the air by only one-fourth in the middle of the column, would produce such an afflux of air from all quarters, that an obstacle presenting a surface of one foot square, would require a force of 504 pounds to prevent it from being carried away; which the strongest walls that can be built by human art could scarce resist. Nay, even the tenth part of this, or the diminution of the gravity of the atmosphere by one-fortieth part, would produce a pressure of upwards of 50 pounds on every square foot of surface, which, it is to be doubted, whether any of our common houses could resist.

Some philosophers ascribe the vacuum in the atmosphere, to which, according to Dr Franklin's theory, whirlwinds are owing, to a stream of electric matter rushing with violence into the atmosphere out of the earth. But they do not inform us how this matter comes to be accumulated in that part of the earth; what induces it to pass out of the earth; how it passes invisibly through pure air; or what serves it for a conductor. It seems to be the fashion among certain philosophers to ascribe every phenomenon, with the cause of which we are unacquainted, to electricity. But this is merely substituting a new name, and serves rather to retard than advance our knowledge of nature.

Some kinds of whirlwinds move with a slow motion, and are injurious only by their vortex; while others seem to do mischief as well by their progressive as their whirling motion. Of this kind are those called *typhons*; which, by their frequently following the course of rivers, seem thus also to discover their electrical origin. Of the destructive effects of these, we have an instance in what happened in Charlestown in South Carolina, on the 1st of June 1761. It was first observed about noon on land, upwards of 50 miles west by south of Charlestown, and destroyed several houses, &c. as it passed along, in many places making wide avenues through the woods; from whence every tree and shrub was torn up, and great branches of trees were driven about in the column as it passed along. It directed its course to Ashley river, down which it came with surprising velocity; in its appearance resembling a column of smoke or vapour, whose motion was very irregular and tumultuous. Its momentum was so great, that Ashley river was ploughed to the bottom, and the channel laid bare. As it came down this river, it made a constant noise like thunder; its diameter being computed about 300 fathoms. It was met at White Point by another of the same kind which came down Cooper's river, but with inferior strength; however, on their meeting together, the agitation of the air was much greater, while the clouds, which were driving in all directions to the place, seemed to be precipitated, and whirled round with incredible velocity. It then fell upon the shipping in the road; entirely destroying some, and damaging others; being scarce three minutes in its passage, though the distance was near two leagues. In that short time it did damage to the amount of 20,000l.; and had not its direction been altered by that gust which came down Cooper's river, it must have totally destroyed Charlestown, as no obstacle whatever seemed capable of resisting its fury.

WHISKY, a term signifying *water*, and applied in Scotland and in Ireland to a distilled liquor drawn from barley,

WHISPERING-PLACES. See Acoustics, N° 24.

WHIST, a well known game at cards, which requires great attention and silence; hence the name.

This game is played by four persons, who cut for partners; the two highest and the two lowest are together, and the partners sit opposite to each other: the person who cuts the lowest card is to deal first, giving one at a time to each person, till he comes to the last card, which is turned up for the trump, and remains on the table till each person has played a card. The person on the left hand side of the dealer plays first, and whoever wins the trick is to play again, thus going on till the cards are played out. The ace, king, queen, and knave of trumps, are called *honours*; in case any three of these honours have been played between, or by either of the two partners, they reckon for two points towards the game; and if the four honours have been played between, or by either of the two partners, they reckon for four points towards the game, the game consisting of ten points. The honours are reckoned after the tricks; all above six tricks reckoning also towards the game.

General Rules for playing the Game of Whist.—

1. He who is to play first should lead from the strongest suit. If he has a sequence of king, queen, and knave, or queen, knave and ten, he may safely lead the highest of the sequence; but if he has five or six in number, he must begin with the lowest. He must always begin with the highest trump, by which he forces out the superior trumps, and can come in again, to make his strong suit.

2. He should never be afraid to play trumps when he has five in his hand, even of the smallest, although he may not have any good cards of any other suit.

3. With

3. With ace and king of any two suits, and only two or three small trumps, the aces and kings should be played out, in order to make as many tricks as possible; and having but two or three small trumps, he should never force his partner to trump, if he finds he cannot follow suit; but endeavour to throw the lead into his partner's hand.

4. He should in general return his partner's lead, unless he has some capital cards of his own.

5. As this game is played with the lurch, that is, to save half the stake, five points must be made before the game is out: he should not venture to play trumps when he is four of the game, unless he is very strong, having at least an honour and three trumps, or ace, king, and two small ones.

6. When the game is scored nine, at which stage the honours reckon for nothing, he should be still more cautious how he plays trumps, even if he is strong in hand, and give his partner an opportunity of trumping the adversaries suits, in case he is deficient in them.

7. If his adversaries are six or seven love of the game, he should play a forward or bold game, that he may have a chance, at the risk of a trick or two, to come up with them. If he has but three trumps and other good cards, he may play trumps, especially if he has a sequence, or queen, knave, and a small one.

8. He should always risk a trick or two when the game is much in his favour; because a new deal is of greater consequence to the adversary than one or two points are to him.

9. When the player finds there is a likelihood of either saving the game or his lurch, he should risk the odd trick; but if the game is five all, and he can make two tricks in his own hand, he should make them, in order to secure the difference of two points, which make the game near two to one in his favour.

10. A good player should begin with a small trump, when he has ace, king, and four small ones; for this reason, if his partner has a better trump than the last player, which is an equal wager but he has, he has a chance of fetching out all the trumps, by having three rounds of them.

11. The odds are always in his favour that his partner holds an honour; consequently if he has king, queen, and four small ones, he should begin with a small one.

12. When queen, knave, and four small trumps are dealt him, he should play a small one first, the odds being in his favour that his partner holds an honour; if he has knave, ten, and four small trumps, he should also begin with a small one, for the same reason.

13. If he has knave, ten, eight, and three small trumps, the knave should be played first, by which means the nine may be prevented from winning a trick, the odds being in his favour that three honours are played in two rounds.

14. If an honour is turned up against him on his left hand, and he has ten, nine, and eight, with two or three small trumps; when he is to play, he should play through the honours with the ten, which will force the dealer to play his honour to a disadvantage, if the dealer does not choose to leave it to the option of his adversary whether he will pass it or not; but if he has six trumps of a lower denomination, and not ten, nine, and eight, and no honour turned up against him, he should begin with a small one.

15. In general, when he has two capital cards in trumps, and two or three small ones, he should begin with a small one, for the reason assigned in N° 12.

16. When he has ace, king, knave, and two small trumps, or even one small trump, by first playing the king, and putting the lead into his partner's hand, who will play a trump; judging him to have ace and knave, from his beginning with the king: in this case the knave should be finessed (A), nothing being against him but the queen.

17. If he has knave, ten, eight, and two small trumps, by playing the knave first, it is odds but in two rounds of trumps the nine falls, or he may finesse the eight when his partner returns trumps.

18. With five trumps of a lower denomination, he should begin with the smallest, unless he has a sequence of ten, nine, and eight; then he should begin with the ten.

19. When he has king, queen, ten, and one small trump, he must begin with the king, and wait for his partner's return of the trumps, in order to finesse the ten, by which means he may win the knave.

20. In order to prevent the ten from winning, when he has queen, knave, nine, and one small trump, he must begin with the queen. And in case he has knave, ten, eight, and one small trump, he should begin with the knave, that the nine may not win.

21. If he has ten, nine, eight, and one small trump, he should begin with the ten; thereby he strengthens his partner's hand, leaving it at his option to take it or not.

22. He should begin with a small one, when he has the ten and three small trumps.

23. If he has a good suit, and ace, king, and four small trumps, he must play three rounds of trumps, in order to secure his strong suit from being trumped.

24. When he has king, queen, ten, and three small trumps, he should begin with the king, because he has a chance of the knaves's coming down in the second round; and to secure his strong suit, he should not wait to finesse the ten. If he should have queen, knave, and three small trumps, and some good suit to make, he must begin with a small one.

25. If he has knave, ten, eight, and two small trumps, with a strong suit, he should begin with the knave, in order to make the nine fall in the second round; but if he has knave, ten, and three small trumps, with a good suit, he should play a small one first.

26. With ten, nine, eight, and one small trump, provided he has a good suit, he should begin with the ten; by which means he may get the trumps out, and have a chance of making his strong suit.

The following observations will enable a player to know that his partner has no more of a suit which either of

(A) *Finesse*, is to play a small card which may win, keeping the superior card or cards to lay over the right-hand adversary.

Whist. of them has played. Suppose he leads from queen, ten, nine, and two small cards of any suit, the second hand puts on the knave, his partner plays the eight; in this case, he having queen, ten, and nine, it is a demonstration, if his partner plays well, that he can have no more of that suit. By that discovery, he may play his game accordingly, either by forcing his partner to trump that suit, if he is strong in trumps, or by playing another suit. If he has king, queen, and ten of a suit, and he leads his king, his partner plays the knave; this also demonstrates he has no more of that suit. If he has king, queen, and many more of a suit, and begins with the king, in some cases it is good play in a partner, when he has the ace and one small card in that suit only, to win the king with the ace; for suppose the partner to be very strong in trumps, by taking the king with the ace, he gets the lead and trumps out, and having cleared the board of trumps, his partner returns his lead; and the ace being out, there is room for him to make that whole suit, which could not have been done if the partner had kept the ace. Suppose he has no other good card in his hand besides that suit, he loses nothing by the ace's taking his king; and if it should so happen that he has a good card to bring in that suit, he gains all the tricks which he makes to that suit by this method of play: as his partner has taken his king with the ace, and trumps out upon it, he has reason to imagine that his partner has one of that suit to return him; for which reason he should not throw away any of that suit, even to keep a king or queen guarded.

Method of playing when an honour is turned up on the right hand.—Suppose the knave is turned up on his right hand, and that he has king, queen, and ten; in order to win the knave, he must begin with the king; by which means, his partner may suppose him to have queen and ten remaining, especially if he has a second lead, and he does not proceed to play the queen.

Suppose the knave turned up as before, and he has ace, queen, and ten, by playing his queen, it answers the purpose of the former rule.

When the queen is turned up on his right hand, and he has ace, king, and knave, by playing his king, it answers the same purpose of the former rule.

In case an honour is turned up on his left hand, supposing he should hold no honour, he should play trumps through the honour as soon as he gets the lead; but if he should hold an honour (except the ace), he must be cautious how he plays trumps, because, in case his partner holds no honour, his adversary will play his own game upon him.

Method of playing the sequences.—The highest in sequences of trumps should be played, unless he has ace, king, and queen; and then he should play the lowest, which informs his partner of the state of his game.

When he has king, queen, and knave, and two small ones, which are not trumps, he should begin with the knave, whether he is strong in trumps or not, as he makes way for the whole suit by getting the ace out.

If he is strong in trumps, and has a sequence of queen, knave, ten, and two small cards of a suit, he should play the highest of his sequence; for if either of the adversaries should trump that suit in the second round, being also strong in trumps, he will make the remainder of that suit, by fetching out the trumps. When he has knave, ten, and nine, and two small cards of a suit, he may play in the like manner.

If king, queen, and knave, and one small card of any suit, is the case, whether strong in trumps or not, he should play the king; and when there are only four in number, the same method of play should be observed by inferior sequences.

When weak in trumps, he should begin by the lowest of the sequence, provided he has five in number, because if his partner has the ace of that suit he will make it. If he has the ace and four small cards of a suit, and weak in trumps, leading from that suit, he should play the ace. When strong in trumps, the game may be played otherwise.

How to make a flam, or *win every trick.*—Suppose A and B partners against C and D, and C to deal, A to have the king, knave, and nine, and seven of hearts, which are trumps, a quart-major in spades, a tierce-major in diamonds, and the ace and king of clubs. Then suppose B to have nine spades, two clubs, and two diamonds. Also suppose D to have ace, queen, ten, and eight of trumps, with nine clubs, and C to have five trumps and eight diamonds. A leads a trump, which D wins, and D is to play a club, which his partner C is to trump; C leads a trump, which his partner D wins; D then will lead a club, which C will trump; and C will play a trump, which D will win; and D having the best trump will play it; after which D having seven clubs in his hand, makes them, so that he flams A and B.

How to play any hand of cards according to the nearest calculations of his partner's holding certain winning cards:

1. That he has not one certain winning card, is - - -	2 to 1
2. That he has not two certain winning cards, is - - -	17 to 2
But it is about 5 to 4 that he has one or both, or - - -	32 to 25
3. That he has one card out of any three certain winning cards, is about	5 to 2
4. That he has not three certain winning cards is about 31 to 1, or -	681 to 22
5. That he has not two of them, is about 7 to 2, or - - -	547 to 156
6. That he has not one of them, is about 7 to 6, or - - -	378 to 325
7. That he holds one or two of them, is in his favour about 13 to 6, or	481 to 222
8. And about 5 to 2, that he holds 1, 2, or all three of them.	

The use of these calculations is for a whist-player to play his cards to the most advantage. For instance,

As the first calculation is two to one that his partner does not hold one certain winning card.—Suppose then a suit is led, of which the second player has the king and a small one only, he should put on the king, because the odds are in his favour, that the third player cannot win it. For the same reason, when he is second player, and to lead, he should play a king in preference to a queen, because it is two to one the ace does not take it; but it is five to four the queen will be taken by either ace or king, which may be in the third hand.

According

Whist, Whiston.

According to the second calculation, of its being five to four that his partner holds one certain winning card out of any two: If he has two honours in any suit, he can play to an advantage, knowing it is five to four in favour of his partner's having one of the two honours; and by the same rule, if he is second player, having a queen and one small card, by playing the queen he plays five to four against himself.

It is obvious, from the third calculation, which proves it to be five to two that his partner has one card out of any three certain winning cards, that he who plays the knave second hand, having but the knave and one small card of the same suit, must play five to two against himself, and discovers his game to a great disadvantage; for which reason, he should play the lowest of any sequence which he may hold in his hand, as the knave, if he has king, queen, and knave; the ten, if he has queen, knave, and ten, &c. By so doing, his partner has an opportunity of judging what card to play in that suit, according to the odds for or against him.

The Hoyle's games improved by Beaufort.

From the above calculation, if he has ace, king, and two small trumps, he is entitled to win four tricks out of six, provided he has four winning cards of any suit; or five tricks out of seven, if he has five winning cards of any suit: by playing two rounds of trumps, and taking out eight of them, it is five to two but his partner has a third trump; and if it should be so, he makes the tricks intended.

WHISTON, William, an English divine of great parts, uncommon learning, and of singular character, was born in 1667 at Norton near Twycrosse in the county of Leicester, where his father was rector. He was admitted of Clarehall, Cambridge, where he pursued his studies, particularly in the mathematics, and commenced tutor; which his ill health at length forced him to decline. Having entered into orders, he became chaplain to Dr More bishop of Norwich in 1694; and in this station he published his first work, entitled A New Theory of the Earth, &c. in which he undertook to prove the Mosaic doctrine of the earth perfectly agreeable to reason and philosophy. This work brought no small reputation to the author. In the beginning of the 18th century he was made Sir Isaac Newton's deputy, and afterwards his successor, in the Lucasian professorship of mathematics; when he resigned a living he had in Suffolk, and went to reside at Cambridge. About this time he published several scientifical works, explanatory of the Newtonian philosophy; and he had the honour to be one of the first, if not the very first, who rendered these principles popular and intelligible to the generality of readers. About the year 1710, he was known to have adopted Arian principles, and was forming projects to support and propagate them: among other things, he had translated the Apostolic Constitutions into English, which favoured the Arian doctrine, and which he asserted to be genuine. The consequence was, that he was deprived of his professorship, and banished the university; he nevertheless pursued his scheme, by publishing the next year his Primitive Christianity Revived, 4 vols. 8vo, for which the convocation fell upon him very vehemently. On his expulsion from Cambridge, Mr Whiston settled in London; where, without suffering his zeal to be intimidated, he continued to write, and propagate his Primitive Christianity, with as much ardour as if he had been in the most flourishing circumstances. In 1721, a subscription was made for the support of his family, which amounted to 470l. For though he drew profits from reading astronomical and philosophical lectures, and also from his publications, which were very numerous, yet these of themselves would have been very insufficient: nor, when joined with the benevolence and charity of those who loved and esteemed him for his learning, integrity, and piety, did they prevent his being frequently in great distress. He continued long a member of the church of England, and regularly frequented its service, though he disapproved of many things in it: but at last he went over to the Baptists, and attended Dr Forster's meeting at Pinner's hall, Broadstreet. Among other performances not specified above, he wrote Memoirs of his own life and writings, which contain some curious particulars.

Whiston, Whitby.

He was remarkable for speaking the plainest truths on every occasion, and to persons of every degree. During the year 1725, that he, with Dr Clarke, Dr Berkeley, and others, had the honour to attend Queen Caroline on a certain day of every week, to talk of the progress of science, her majesty one evening took occasion to pay him a just compliment on his truth and integrity, requesting that he would, with his usual plainness, point out to her any fault that he might have observed in her conduct. At first he begged to be excused, adding, that few persons could bear to have their faults plainly told to them, and least of all royal personages, who, from their elevation, are necessarily surrounded by flatterers, to whose lips truth is a stranger. Her majesty replied, that he was to consider her not as a queen, but as a philosopher; and that philosophy is of very little use, if it cannot enable its professors to bear without offence truths necessary to their own improvement. Upon this he told her, that the greatest fault which he had observed in her conduct, was her indecent behaviour in the house of God, which, he assured her, had made very unfavourable impressions on the minds of many persons, who coming to town from distant parts of the country, had gone to the chapel to obtain a sight of her majesty, the king, and the royal family. The queen made no reply; but in about six weeks afterwards renewed her request, that Mr Whiston would point out the most glaring improprieties in her conduct. To this he answered, that he had laid down a maxim, from which he could not deviate, never to point out to any person more than one fault at a time, and never to give a second reproof till he had observed some good consequence to have arisen from the first (A). Much to the queen's honour, she was pleased with this plain-dealing, and continued to think favourably of Mr Whiston. This honest, but whimsical and credulous man, died in 1762, at the advanced age of 95.

WHITBY, Dr Daniel, a very learned English divine, was born in 1638, and bred at Oxford; where in 1664, he was elected perpetual fellow of his college. He afterwards became chaplain to Dr Seth Ward, bishop

(A) Bishop Berkeley was present at these conversations, and from his son we received the account we have given of them. They are likewise mentioned, but not stated so accurately, by Bishop Newton in his own Life.

Whitby ‖ Whitefield.

shop of Salisbury; who collated him in 1668 to the prebend of Yatesbury in that church, and soon after to that of Husborn and Burbach. In 1672 he was admitted chanter of the said church, on the death of Mr John South, and then, or soon after, rector of St Edmund's church in Salisbury. He was made a prebendary of Taunton Regis in 1696, and died in 1726. He was ever strangely ignorant of worldly affairs, even to a degree that is scarcely to be conceived. His writings are numerous, and well known; particularly his Commentary on the New Testament.

WHITBY, a sea-port town in the north riding of Yorkshire, seated on the river Esk, near the place where it falls into the sea. The houses are neat, strong, and convenient; the number of inhabitants in 1811 was 6969. Ship-building is their principal employment. W. Long. 0. 24. N. Lat. 54. 30.

WHITE, one of the colours of natural bodies.

White of the Eye, denotes the first tunic or coat of the eye, called *albuginea*. See ANATOMY, N° 142.

White of Egg. See ALBUMEN and EGG.

White Friars, a name common to several orders of monks, from being clothed in a white habit.

White Sea, is a bay of the Frozen ocean, so called in the north part of Muscovy, lying between Russian Lapland and Samoieda; at the bottom of which stands the city of Archangel. This was the chief port the Russians had before their conquest of Livonia.

White Colour, white lead for painting. See CHEMISTRY, N° 1856.

White Iron, or *Tin-plate*, iron-plates covered over with tin; for the method of making which, see LATTEN, CHEMISTRY, N° 1956.

In 1681 tin-plates were manufactured in England by one Andrew Yarranton, who had been sent to Bohemia to learn the method of making them. But the manufacture was soon afterwards discontinued. It was revived in 1740, and has now arrived at as great, if not greater, perfection in this country than in any other.

White Lead. See CHEMISTRY, N° 1856.

White-Throat. See MOTACILLA, ORNITHOLOGY *Index*.

WHITEFIELD, GEORGE, the celebrated preacher among the people called *Methodists*, was born in the year 1714, at the Bell in the city of Gloucester, which was then kept by his mother. At about 12 years of age he was put to a grammar-school; but his mother entering into a second marriage, which proved a disadvantageous one, he, when about 15, put on a blue apron, and served her in the capacity of a drawer or waiter. After continuing about a year in this servile employment, she turned over the business to his brother; who marrying, and George not agreeing with his sister-in-law, he left the inn. Some time after, meeting with an old school-fellow, then a servitor in Pembroke college, Oxford, he was induced to attempt getting into the same college in a like capacity, and succeeded. Here Mr Whitefield, who from his own account appears to have always had a strong tincture of enthusiasm in his constitution from his very childhood, distinguished himself by the austerity of his devotion, and acquired considerable eminence in some religious assemblies in that city. At the age of 21, the fame of his piety recommended him so effectually to Dr Benson, then bishop of Gloucester, that he made him a voluntary offer of ordination. Immediately after this regular admission into the ministry, Mr Whitefield applied himself to the most extraordinary, the most indefatigable, duties of his character, preaching daily in prisons, fields, and open streets, wherever he thought there would be a likelihood of making proselytes. Having at length made himself universally known in England, he embarked for America, where the tenets of Methodism began to spread very fast under his friends the Wesleys; and first determined upon the institution of the orphan-house at Georgia, which he afterwards effected. After a long course of peregrination, his fortune increased as his fame extended among his followers, and he erected two very extensive buildings for public worship, under the name of *Tabernacles*; one in Tottenham-Court Road, and the other in Moorfields. Here, with the help of some assistants, he continued for several years, attended by very crowded congregations, and quitting the kingdom only occasionally. Besides the two tabernacles already mentioned, Mr Whitefield, by being chaplain to the countess dowager of Huntingdon, was connected with two other religious meetings, one at Bath, and the other at Tunbridge, chiefly erected under that lady's patronage. By a lively, fertile, and penetrating genius, by the most unwearied zeal, and by a forcible and persuasive delivery, he never failed of the desired effect upon his ever crowded and admiring audiences. In America, however, which always engaged much of his attention, he was destined to finish his course; and he died at Newberry, about 40 miles from Boston in New England, in 1770.

WHITEHAVEN, a sea-port town of Cumberland, with a market on Tuesday, and containing 10,106 inhabitants in 1811. It is seated on a creek of the Irish sea, on the north end of a great hill, washed by the tide of flood on the west side, where there is a large rock or quarry of hard white stone, which gives name to the place, and which, with the help of a strong stone-wall, secures the harbour, into which small barks may enter. It is lately much improved in its buildings, and noted for its trade in pit-coal and salt, there being near it a valuable coal-mine, which runs a considerable way under the sea. They have a custom-house here; and they carry on a good trado to Ireland, Scotland, Chester, Bristol, and other parts. It is 10 miles south-west of Cockermouth, and 305 north-west of London. W. Long. 2. 55. N. Lat. 55. 30.

WHITENESS, the quality which denominates or constitutes a body white.

WHITES, or FLUOR *Albus*. See MEDICINE, N° 250.

WHITING. See GADUS, ICHTHYOLOGY *Index*.

WHITLOW, or WHITLOE. See SURGERY *Index*.

WHITSUN-FARTHINGS, otherwise called *Smoke-farthings* or *Quadrantes Pentecostales*, a composition for offerings which were anciently made in Whitsun-week by every man in England, who occupied a house with a chimney, to the cathedral church of the diocese in which he lived.

WHITSUNDAY, a solemn festival of the Christian church, observed on the fiftieth day after Easter, in memory of the descent of the Holy Ghost upon the apostles in the visible appearance of fiery cloven tongues, and of those miraculous powers which were then conferred upon them.

It

Whitsunday ‖ Whytt.

It is called *Whitsunday*, or *White Sunday;* because this being one of the stated times for baptism in the ancient church, those who were baptized put on white garments, as types of that spiritual purity they received in baptism. As the descent of the Holy Ghost upon the apostles happened upon the day which the Jews called *Pentecost*, this festival retained the name of *Pentecost* among the Christians.

Whitsunday Isle, one of the New Hebrides, which lies about four miles to the south, runs in the same direction, and is of the same length, having more sloping exposures than Aurora: it appears to be better inhabited, and to contain more plantations.

WHORTLEBERRY. See Vaccinium, Botany *Index*.

WHYTT, Dr Robert, an eminent physician, born at Edinburgh on the 6th September 1714, was the son of Robert Whytt, Esq. of Bennochy, advocate. This gentleman died six months before the birth of our author, who had also the misfortune to be deprived of his mother before he had attained the seventh year of his age. After receiving the first rudiments of school-education, he was sent to the university of St Andrew's; and after the usual course of instruction there, in classical, philosophical, and mathematical learning, he came to Edinburgh, where he entered upon the study of medicine, under those eminent medical teachers, Monro, Rutherford, Sinclair, Plummer, Alston, and Innes. After learning what was to be acquired at this university, in the prosecution of his studies he visited foreign countries; and after attending the most eminent teachers at London, Paris, and Leyden, he had the degree of Doctor of Physic conferred upon him by the university of Rheims in 1736, being then in the 22d year of his age.

Upon his return to his native country, he had the same honour also conferred upon him by the university of St Andrew's; where he had before obtained, with applause, the degree of Master of Arts.

Not long afterwards, in the year 1737, he was admitted a Licentiate of Medicine by the Royal College of Physicians of Edinburgh; and the year following he was raised to the rank of a Fellow of the College. From the time of his admission as a licentiate, he entered upon the practice of physic at Edinburgh; and the reputation which he acquired for medical learning, pointed him out as a fit successor for the first vacant chair in the university. Accordingly, when Dr Sinclair, whose eminent medical abilities, and persuasive powers of oratory, had contributed not a little to the rapid advancement of the medical school of Edinburgh, found that those conspicuous talents which he possessed could no longer be exerted in the manner which they once had been, when he enjoyed bodily vigour unimpaired by age and powers of mind unclouded by disease, he resigned his academical appointments in favour of Dr Whytt.

This admission into the college took place on the 20th of June 1746; and he began his first course of the institutions of medicine at the commencement of the next winter-session. The abilities which he displayed from his academical chair, in no particular disappointed the expectations which had been formed of his lectures. The Latin tongue was the language of the university of Edinburgh; and he both spoke and wrote in Latin with singular propriety, elegance, and perspicuity. At that time the system and sentiments of Dr Boerhaave, which, notwithstanding their errors, must challenge the admiration of latest ages, were very generally received by the most intelligent physicians in Britain. Dr Whytt had no such idle ardour for novelties as to throw them entirely aside because he could not follow them in every particular. The institutions of Dr Boerhaave, therefore, furnished him with a text for his lectures; and he was no less successful in explaining, illustrating, and establishing the sentiments of the author, when he could freely adopt them, than in refuting them by clear, connected, and decisive arguments, when he had occasion to differ from him. The opinions which he himself proposed, were delivered and enforced with such acuteness of invention, such display of facts and force of argument, as could rarely fail to gain universal assent from his numerous auditors; but free from that self-sufficiency which is ever the offspring of ignorance and conceit, he delivered his conclusions with becoming modesty and diffidence.

From the time that he first entered upon an academical appointment, till the year 1756, his prelections were confined to the institutions of medicine alone. But at that period his learned colleague Dr Rutherford, who then filled the practical chair, who had already taught medicine at Edinburgh with universal applause for more than thirty years, and who had been the first to begin the institution of clinical lectures at the Royal Infirmary, found it necessary to retire from the fatiguing duties of an office to which the progress of age rendered him unequal. On this crisis Dr Whytt, Dr Monro, sen. and Dr Cullen, each agreed to take a share in an appointment in which their united exertions promised the highest advantages to the university. By this arrangement students, who had an opportunity of daily witnessing the practice of three such teachers, and of hearing the grounds of that practice explained, could not fail to derive the most solid advantages.

In these two departments, the institutions of medicine in the university, and the clinical lectures in the Royal Infirmary, Dr Whytt's academical labours were attended with the most beneficial consequences both to the students and to the university. But not long after the period we have last mentioned, his lectures on the former of these subjects underwent a considerable change. About this time the illustrious Gaubius, who had succeeded to the chair of Boerhaave, favoured the world with his *Institutiones Pathologiæ*. This branch of medicine had indeed a place in the text which Dr Whytt formerly followed; but, without detracting from the character of Dr Boerhaave, it may justly be said, that the attention he had bestowed upon it was not equal to its importance. Dr Whytt was sensible of the improved state in which pathology now appeared in the writings of Boerhaave's successor; and he made no delay in availing himself of the advantages which were then afforded.

In the year 1762, his pathological lectures were entirely new-modelled. Following the publication of Gaubius as a text, he delivered a comment, which was read by every intelligent student with the most unfeigned satisfaction. In these lectures he collected and condensed the fruits of accurate observation and long experience. Enriched by all the opportunities of information

 which

Whytt. which had enjoyed, and by all the discernment which he was capable of exerting, they were justly considered as his most finished production.

For a period of more than twenty years, during which he was justly held in the highest esteem as a lecturer at Edinburgh, it may readily be supposed that the extent of his practice corresponded to his reputation. In fact, he received both the first emoluments, and the highest honours, which could here be obtained. With extensive practice in Edinburgh, he had numerous consultations from other places. His opinion on medical subjects was daily requested by his most eminent contemporaries in every part of Britain. Foreigners of the first distinction, and celebrated physicians in the most remote parts of the British empire, courted an intercourse with him by letter. Besides private testimonies of esteem, many public marks of honour were conferred upon him both at home and abroad. In 1752, he was elected a fellow of the Royal Society of London; in 1761, he was appointed first physician to the king of Scotland; and in 1764, he was chosen president of the Royal College of Physicians at Edinburgh.

But the fame which Dr Whytt acquired as a practitioner and teacher of medicine, were not a little increased by the information which he communicated to the medical world in different publications. His celebrity as an author was still more extensive than his reputation as a professor.

His first publication, An Essay on the Vital and other Involuntary Motions of Animals, although it had been begun soon after he had finished his academical course of medical education, did not come from the press till 1751; a period of fifteen years from the time that he had finished his academical course, and obtained a degree in medicine: but the delay of this publication was fully compensated by the matter which it contained, and the improved form under which it appeared.

The next subject which employed the pen of Dr Whytt was one of a nature more immediately practical. His Essay on the Virtues of Lime-water and Soap in the Cure of the Stone, first made its appearance in a separate volume in 1752. Part of this second work had appeared several years before in the Edinburgh Medical Essays: but it was now presented to the world as a distinct publication, with many improvements and additions.

His third work, intitled Physiological Essays, was first published in the year 1755. This treatise consisted of two parts; 1st, An Inquiry into the Causes which promote the Circulation of the Fluids in the very small Vessels of Animals; and 2dly, Observations on the Sensibility and Irritability of the Parts of Men and other Animals, occasioned by Dr Haller's treatise on that subject. The former of these may be considered as an extension and farther illustration of the sentiments which he had already delivered in his Essay on the Vital Motions, while the latter was on a subject of a controversial nature. In both he displayed that acuteness of genius and strength of judgment which appeared in his former writings.

From the time at which his Physiological Essays were published, several years were probably employed by our author in preparing for the press a larger and perhaps a more important work than any yet mentioned, his Observations on the Nature, Causes, and Cure of those Disorders which are commonly called *nervous*, *hypochondriac*, and *hysteric*. The elaborate and useful work was published in the year 1764.

The last of Dr Whytt's writings is entitled, Observations on the Dropsy in the Brain. This treatise did not appear till two years after his death; when all his other works were collected and published in one quarto volume, under the direction of his son and of his intimate friend the late Sir John Pringle.

Besides these five works, he wrote many other papers, which appeared in different periodical publications; particularly in the Philosophical Transactions, the Medical Essays, the Medical Observations, and the Physical and Literary Essays.

At an early period of life, soon after he had settled as a medical practitioner in Edinburgh, he entered into the married state. His first wife was Miss Robertson, sister to General Robertson, governor of New York. By her he had two children; both of whom died in early infancy, and their mother did not long survive them. A few years after the death of his first wife, he married as a second wife Miss Balfour, sister to James Balfour, Esq. of Pilrig. By her he had fourteen children; but in these also he was in some respects unfortunate; for six of them only survived him, three sons and three daughters, and of the former two are since dead. Although the feeling heart of Dr Whytt, amidst the distresses of his family, must have often suffered that uneasiness and anxiety which in such circumstances is the unavoidable consequence of parental affection and conjugal love; yet he enjoyed a large share of matrimonial felicity. But his course of happiness was terminated by the death of his wife, which happened in the year 1764: and it is not improbable that this event had some share in hastening his own death; for in the beginning of the year 1765 his health was so far impaired, that he became incapable of his former exertions. A tedious complication of chronical ailments, which chiefly appeared under the form of diabetes, was not to be resisted by all the medical skill which Edinburgh could afford; and at length terminated in death, on the 15th of April 1766, in the 52d of his age.

WIBURGH, a considerable town of Denmark, in North Jutland, with a bishop's see, remarkable for being the seat of the chief court of justice in the province. The hall where the council assembles has the archives of the country, and escaped the terrible fire that happened in the year 1726, and which burned the cathedral church, that of the Black Friars, the town-house, and the bishop's palace; but they have all been rebuilt more magnificent than before. It is seated on the lake Weter, in a peninsula, 25 miles north-west of Sleswick, and 110 north-by-west of Copenhagen. E. Long. 9. 50. N. Lat. 56. 20.

WICK, a royal borough on the east coast of the county of Caithness. It is small, and the streets narrow, but a few of its buildings are an ornament to the place. The present harbour is very inconvenient, but it is proposed to erect a new one, which will be of great importance to the safety of navigation along that coast. The population of the whole parish in 1793 amounted to 5000; that of the town alone, in 1811, 5080.

WICKER, signifies made of small twigs.

WICKET, a small door in the gate of a fortified place,

place, &c. or a hole in a door through which to view what passes without.

WICKLIFF, John, the first divine in Europe who had resolution to attempt a reformation of religion, was born about the year 1324, in the parish of Wycliff, near Richmond, in Yorkshire. He was educated at Oxford, first in Queen's and afterwards in Merton college, of which he was a probationer fellow. Having acquired the reputation of a man of great learning and abilities, in 1361 he was chosen master of Baliol-hall, and in 1365 constituted warden of Canterbury college, by the founder, Archbishop Simon de Islip; but in 1367, he was ejected by the regulars, together with three secular fellows. He thought their proceedings arbitrary, and therefore appealed to the pope; but instead of obtaining redress, the ejectment was confirmed in 1370. This disappointment probably contributed somewhat towards his enmity to the see of Rome, or rather to confirm that enmity; for he had long before written against the pope's exactions and corruptions of religion. However, his credit in the university continued; for having taken the degree of doctor in divinity, he read public lectures with great applause; in which he frequently exposed the impositions of the Mendicant friars. About this time he published a defence of his sovereign Edward III. against the pope, who had insisted on the homage to which his predecessor King John had agreed. This defence was the cause of Wickliff's introduction at court, and of his being sent one of the ambassadors in 1374 to Bruges, where they met the pope's nuncios, in order to settle several ecclesiastical matters relative to the pope's authority. In the mean time Wickliff was presented by the king to the rectory of Lutterworth in Leicestershire, and in 1375 he obtained a prebend in the church of Westbury in Gloucestershire. Wickliff continued hitherto, without molestation, to oppose the papal authority; but in 1377 a bull was sent over to the archbishop of Canterbury, and to Courtney bishop of London, ordering them to secure this arch-heretic, and lay him in irons; at the same time the pope wrote to the king, requesting him to favour the bishops in the prosecution; he also sent a bull to Oxford, commanding the university to give him up. Before these bulls reached England Edward III. was dead; and Wickliff, protected by John duke of Lancaster, uncle to Richard II. favoured by the queen-mother, and supported by the citizens of London, eluded the persecution of Pope Gregory IX. who died in 1378. In the following year this intrepid reformer presented to parliament a severe paper against the tyranny of Rome, wrote against the papal supremacy and infallibility, and published a book *On the Truth of the Scriptures*, intended to prepare the way for an English translation of them, in which he had made considerable progress. In 1381 he published *Sixteen Conclusions;* in the first of which he ventured to expose the grand article of transubstantiation. These conclusions being condemned by the chancellor of Oxford, Wickliff appealed to the king and parliament; but being deserted by his unsteady patron the duke of Lancaster, he was obliged to make a confession at Oxford; and by an order from the king was expelled the university. He now retired to his living of Lutterworth, where he finished his translation of the bible. This version, of which there are several manuscript copies in the libraries of the universities, British Museum, &c. is a very literal translation from the Latin vulgate. In 1383 he was suddenly struck with a palsy; a repetition of which put an end to his life in December 1384. He was buried in his own church, where his bones were suffered to rest in peace till the year 1428, when, by an order from the pope, they were taken up and burnt.—Besides a number of works that have been printed, he left a prodigious number of manuscripts; an accurate list of which may be seen in Bishop Tanner's *Bib. Brit. Hib.* Some of them are in the Bodleian Library, others in the British Museum, &c.

Wickliff was doubtless a very extraordinary man, considering the times in which he lived. His natural sagacity discovered the absurdities and impositions of the church of Rome, and he had the honesty and resolution to promulgate his opinions, which a little more support would probably have enabled him to establish: they were evidently the foundation of the subsequent reformation.

WICKLOW, a county of Ireland, in the province of Leinster; bounded on the north by the county of Dublin; on the east by the Irish sea; on the south by Wexford; and on the west by Kildare and Catherlough. It is 33 miles in length, 20 in breadth, and indifferently fruitful. It contains 54 parishes, and sends two members to parliament. See Wicklow, Supplement.

Wicklow, the capital of a county of the same name in Ireland; seated on the sea-side, with a narrow harbour, at the mouth of the river Leitrim, over which stands a rock, instead of a castle, surrounded by a strong wall, 24 miles south of Dublin. W. Long. 6. 7. N. Lat. 52. 55.

WIDGEON. See Anas, Ornithology *Index*.

WIDOW, a woman who has lost her husband.

WIFE, a married woman, or one joined with, and under the protection of, an husband. See Husband.

Isle of WIGHT, an island lying on the south coast of Hampshire, from which it is separated by a narrow channel. It is about 21 miles in length and 13 in breadth. It is nearly divided into equal parts by the river Mede or Cowes, which rising in the southern angle, enters at the northern, into the channel, opposite the mouth of Southampton bay. The south-coast is edged with very steep cliffs of chalk and freestone, hollowed into caverns in various parts. The west side is fenced with ridges of rocks, of which the most remarkable are those called, from their sharp extremities, the *Needles*. Between the island and the main are various sand-banks, especially off the eastern part, where is the safe road of St Helen's. Across the island, from east to west, runs a ridge of hills, forming a tract of fine downs, with a chalky or marly soil, which feed a great number of fine-fleeced sheep. Rabbits are also very plentiful here. To the north of this ridge the land is chiefly pasture: to the south of it is a rich arable country, producing great crops of corn. The variety of prospects which this island affords, its mild air, and the neat manner in which the fields are laid out, render it a very delightful spot. It is devoted almost solely to husbandry, and has no manufactory. It is one of the principal resources of the London market for unmalted barley. Among its products are to be reckoned a pure white pipe-clay, and a fine white crystalline sand; of the latter of which great quantities are exported for the use of the glass works in various parts. Its principal town is the

Will, William.

ment: that is called a *will* where lands or tenements are given; and when the disposition concerns goods and chattels alone, it is termed a *testament*. See TESTAMENT.

WILL-with-a-wisp, or *Jack with-a-lanthorn*, two popular names for the meteor called *ignis fatuus*. See LIGHT, N° 46.

WILLIAM *of* MALMSBURY, an history of considerable merit in the reign of King Stephen; but of whose life few particulars are known. According to Bale and Pits, he was surnamed *Somersetus*, from the county in which he was born. From his own preface to his second book *De Regibus Anglorum*, it appears that he was addicted to learning from his youth; that he applied himself to the study of logic, physic, ethics, and particularly to history. He retired to the Benedictine convent at Malmsbury, became a monk, and was made precentor and librarian; a situation which much favoured his intention of writing the history of this kingdom. In this monastery he spent the remainder of his life, and died in the year 1142. He is one of our most ancient and most faithful historians. His capital work is that intitled *De Regibus Anglorum*, in five books; with an Appendix, which he styles *Historiæ Novellæ*, in two more. It is a judicious collection of whatever he found on record relative to England, from the invasion of the Saxons to his own times.

WILLIAM of Newbury, so called from a monastery in Yorkshire, of which he was a member, wrote a history which begins at the Conquest and ends at the year 1197. His Latin style is preferred to that of Matthew Paris; and he is entitled to particular praise, for his honest regard to truth, in treating the fables of Jeffrey of Monmouth with the contempt they deserve; as well as for expressing his approbation of Henry II.'s design of reforming the clergy, by bringing them under the regulation of the secular power.

WILLIAM of Wykeham, bishop of Winchester, was born in the village of Wykeham, in the county of Southampton, in 1324. He was educated at Winchester and Oxford; and having continued near six years in the university, his patron Nicholas Wedal, governor of the province of Southampton, took him into his family, and appointed him his counsellor and secretary. He could not have made choice of a fitter person for that employment, no man in that age writing or speaking more politely than Wykeham. For this reason Edington, bishop of Winchester, lord high treasurer of the kingdom, appointed him his secretary three years after, and also recommended him to King Edward III. who took him into his service. Being skilled in geometry and architecture, he was appointed surveyor of the royal buildings, and also chief justice in eyre: he superintended the building of Windsor-castle. He was afterward chief secretary of state, a keeper of the privy seal; and in 1367 succeeded Edington in the see of Winchester. A little after he was appointed lord-high chancellor and president of the privy-council. That he might well discharge the several functions of his employments, both ecclesiastical and civil, he endeavoured on one hand, to regulate his own life according to the strictest maxims, and to promote such parish priets only as were able to give due instructions to their parishioners, and at the same time led exemplary lives: on the other hand, he did all in his power to cause justice to be impartially administered. In 1371 he resigned his chancellorship, and some time after the great seal. Edward returning to England, after having carried on a very successful war in France, found his exchequer in great disorder. The duke of Lancaster, one of his sons, at the head of several lords, having brought complaints against the clergy, who then enjoyed the chief places in the kingdom, the king removed them from their employments. But the laymen, who were raised to them, behaved so ill, that the king was forced to restore the ecclesiastics. The duke of Lancaster showed strong animosity to the clergy, and set every engine at work to ruin Wykeham. He impeached him of extortion, and of disguising things, and obliged him to appear at the King's-bench. He got such judges appointed as condemned him; and not satisfied with depriving him of all the temporalities of his bishopric, he advised Edward to banish him: but this prince rejected the proposal, and afterward restored to Wykeham all that he had been divested of. Richard II. was but 11 years old when Edward died: so that the duke of Lancaster had an easy opportunity of reviving the accusations against the bishop of Winchester; nevertheless Wykeham cleared himself. Then he founded two noble colleges, the one in Oxford, the other in Winchester. Whilst he was exerting his utmost endeavours to improve these two fine foundations, he was recalled to court, and in a manner forced to accept of the office of lord-high-chancellor in 1389.—Having excellently discharged the duties of that employment for three years, he obtained leave to resign it, foreseeing the disturbances that were going to break out. Being returned to his church, he finished his college, and built there so magnificent a cathedral, that it almost equals that of St Paul's in London. He laid out several sums in things advantageous to the public and to the poor; notwithstanding which, in 1397 he was in great danger; for he and some others were impeached of high-treason in open parliament: however, he was again fully cleared. From that time till his death he kept quiet in his diocese, and there employed himself in all the duties of a good prelate. He died in 1404, in the 81st year of his age.

WILLIAM, the name of several kings of England. See ENGLAND, N° 87—92, and BRITAIN, N° 302.

Fort-WILLIAM, a fortress in the Highlands of Scotland, erected in King William's reign, as was also a small town adjoining, called *Maryburgh*, in honour of his queen. It is situated in Inverness-shire, on a narrow arm of the sea called *Loch Eil*, which by the completion of the Caledonian canal, will be united to the Western sea. Fort-William is of a triangular form, having two bastions, and is capable of admitting a garrison of 800 men; but could not be defended against an attack, as it is commanded by several hills in the neighbourhood.

WILLIAM's Fort, is a factory of Asia belonging to the East India Company, seated on one of the branches of the river Ganges, in the kingdom of Bengal. The fort was first built in the shape of an irregular tetragon of brick and mortar; and the town has nothing regular in it, because every one built a house as he liked best, and for his own conveniency. The governor's house is within the fort, and is the best piece of architecture in these parts. Here there are also convenient lodgings for the factors and writers, with store-houses for the company's company's goods, and magazines for ammunition. About 50 yards from the fort is the church, which was originally built by the merchants. The town of *Calcutta* is contiguous, containing 500,000 inhabitants. It is governed by a mayor and aldermen, as most of the company's factories in the East Indies now are. In 1757 it was surprised by the nabob of Bengal, who took it, and put most of those that had made resistance into a place called the *Black-Hole*, where the greater number was suffocated. This nabob was afterwards killed, and another set up in his room, more friendly to the English; and the factory was re-established. E. Long. 86. 0. N. Lat. 22. 27. See CALCUTTA.

Sweet-William. See DIANTHUS, BOTANY *Index*.

WILLIAMSBURG, a town of North America, in Virginia, and formerly capital of that state. It is situated between two creeks; one falling into James and the other into York River. The distance of each landing place is about a mile from the town, which, with the disadvantage of not being able to bring up large vessels, and the want of enterprise in the inhabitants, has occasioned its decay. Here is a college, designed for the education of the Indians, but which, on account of their aversion to learning, never answered the purpose. It is 60 miles east of Richmond. W. Long. 76. 30. N. Lat. 37. 10.

WILLIAMSTADT, a sea-port town of Holland. It is a handsome strong place, and the harbour is well frequented. It was built by William prince of Orange in 1585; and in 1732 belonged to the stadtholder of Friesland. The river near which it is built is called *Butterfliet* or *Holland Diep*; and it is one of the bulwarks of the Dutch on the side of Brabant, where they always keep a garrison. This place made a gallant defence in 1793 against the French, who were obliged to raise the siege. It is 15 miles north-east of Bergen-op-Zoom, and 12 south-west of Dort. E. Long. 4. 30. N. Lat. 51. 39.

WILLIS, DR THOMAS, a celebrated English physician, was born at Great Bodwin, in Wiltshire, in 1621, and studied at Christ-church college, Oxford. When that city was garrisoned for the king, he, among other scholars, bore arms for his majesty, and devoted his leisure hours to the study of physic. The garrison of Oxford at length surrendering to the parliament, he applied himself to the practice of his profession; and soon rendered himself famous by his care and skill. He appropriated a room as an oratory for divine service according to the church of England, whither most of the loyalists in Oxford daily resorted. In 1660, he became Sedleian professor of natural philosophy, and the same year took the degree of doctor of physic. In 1664, he discovered the famous medicinal spring at Alstropp, near Brackley. He was one of the first members of the Royal Society, and soon made his name illustrious by his excellent writings. In 1666, after the fire of London, he removed to Westminster; and his practice became greater than that of any of the physicians his contemporaries. Soon after his settlement in London, his only son Thomas falling into a consumption, he sent him to Montpelier in France for the recovery of his health; and it proved successful. His wife also labouring under the same disorder, he offered to leave the town; but she, not suffering him to neglect the means

of providing for his family, died in 1670. He died at his house in St Martin's in 1675, and was buried near her in Westminster-abbey. Dr Willis was extremely modest and unambitious, and refused the honour of knighthood. He was remarkably pious: As he rose early in the morning, that he might be present at divine service, which he constantly frequented before he visited his patients, he procured prayers to be read beyond the accustomed times while he lived; and at his death settled a stipend of 20l. per annum to continue them. He was a liberal benefactor to the poor wherever he came, having from his early practice allotted part of his profits to charitable uses. He was exact and regular in all his hours: and though his table was the resort of most of the great men of London, yet he was remarkable for his plainness, and his being a man of little discourse, complaisance, or society; but he was justly admired for his deep insight into natural and experimental philosophy, anatomy, and chemistry; for his successful practice: and for the elegance and purity of his Latin style. He wrote, 1. A treatise in English, intitled *A plain and easy Method for preserving those that are well from the Infection of the Plague, and for curing such as are infected*. 2. Several Latin works, which were collected and printed at Amsterdam, in 1682, in 2 vols 4to.

WILLUGHBY, FRANCIS, a celebrated natural historian, was the only son of Sir Francis Willughby, knight. He was fond of study from his childhood, and held idleness in abhorrence; he being so great an economist with regard to his time, as not willingly to lose or misapply the least part of it, by which means he attained great skill in all branches of learning, and particularly in the mathematics. But to the history of animals, which was in a great measure neglected by his countrymen, he particularly applied himself; and for this purpose carefully read over what had been written on that subject by others. He then travelled several times over his native country; and afterwards into France, Spain, Italy, Germany, and the Low Countries, attended by his ingenious friend Mr John Ray. It is remarkable, that, notwithstanding the advantages of birth, fortune, and parts, he was as humble as any man of the meanest fortune; was sober, temperate, and chaste; scrupulously just; so true to his word and promise, that a man might venture his estate and life upon it; so faithful and constant to his friend, as never to desert him when fortune frowned upon him; and remarkably pious, patient, and submissive to the divine will. This is the character given of him by Mr Ray, whose veracity none will doubt. This ingenious and learned gentleman, died in 1672, at 37 years of age; having impaired his health by his application. He wrote, 1. *Ornithologiæ libri tres*, folio, which was afterwards translated into English, with an Appendix, by Mr Ray, in folio. 2. *Historiæ Piscium libri quatuor*, folio. 3. Letters of Francis Willughby, Esq. added to Philosophical Letters between the learned Mr Ray and several of his correspondents, published, in 8vo, by William Derham. 4. Several ingenious papers in the Philosophical Transactions.

WILMOT, JOHN, earl of Rochester, a great wit in the reign of Charles II. the son of Henry earl of Rochester, was born in 1648. He was taught grammar and classical learning at the free-school at Burford;

Wilmot. where he obtained a quick relish of the beauties of the Latin tongue, and afterwards became well versed in the authors of the Augustan age. In 1659, he was admitted a nobleman of Wadham college, where he obtained the degree of master of arts. He afterwards travelled through France and Italy; and at his return was made one of the gentlemen of the bedchamber to the king, and comptroller of Woodstock Park. In 1665, he went to sea, and was in the Revenge, commanded by Sir Thomas Tiddiman, when an attack was made on the port of Bergen in Norway: during the whole action he showed the greatest resolution, and gained a high reputation for courage; which he supported in a second expedition, but afterwards lost it in a private adventure with Lord Mulgrave.

Before the earl of Rochester travelled, he had indulged in the most disorderly and intemperate way of living; at his return, however, he seemed to have got the better of it entirely. But falling into the company of the courtiers, who continually practised these excesses, he became so sunk in debauchery, that he was for five years together so given up to drinking, that during all that time he was never cool enough to be master of himself. His violent love of pleasure, and his disposition to extravagant mirth, carried him to great excesses. The first involved him in sensuality, and the other led him into many adventures and ridiculous frolics. Once disguising himself so that he could not be known by his nearest friends, he set up in Tower-street for an Italian mountebank, and there dispersed his nostrums for some weeks. He often disguised himself as a porter, or as a beggar, sometimes to follow a mean amour; at other times, he would go about merely for diversion, in odd shapes; and acted his part so naturally, that he could not be known even by his friends. In short, by his constant indulgence in wine, women, and irregular frolics, he entirely wore out an excellent constitution before he was 30 years of age. In October 1679, when recovering from a violent disease, which ended in a consumption, he was visited by Dr Burnet, upon an intimation that such a visit would be agreeable to him. Dr Burnet published an account of his conferences with Lord Rochester; in which it appears, that though he had lived the life of a libertine and atheist, yet he died the death of a penitent Christian. His death happened in 1680; since which time his poems have been various times printed, both separately and together: but when once he obtained the character of a lewd and obscene writer, every thing in that strain was ascribed to him; and thus many pieces not of his writing have crept into the later editions of his works. The author of the Catalogue of Royal and Noble Authors says, he was "a man whom the Muses were fond to inspire, and ashamed to avow, and who practised without the least reserve that secret which can make verses more read for their defects than their merits. Lord Rochester's Poems have much more obscenity than wit, more wit than poetry, and more poetry than politeness." His writings, besides those already mentioned, are, A Satire against Mankind; Nothing, a poem; Valentinian, a tragedy; Fifty four Letters to Henry Saville, and others; Seven more to his wife and Son: a Letter on his deathbed to Dr Burnet. He also left behind him several other papers, and a History of the Intrigues of the Court of Charles II.; but his mother, a very devout lady, ordered all his papers to be burned.

WILSON, FLORENCE, known in the republic of letters by the name of *Florentius Volusinus*, was born at Elgin in the shire of Murray in Scotland, and educated in the university of Aberdeen. Travelling to England with an intention to improve his fortune, he had the felicity to be introduced to Cardinal Wolsey, who appointed him tutor to one of his nephews. In that capacity he went to Paris, and continued there till the Cardinal's death. During his residence in that city he became acquainted with the learned Cardinal Bellai, archbishop of Paris, who allowed him a pension, and meant to have appointed him royal professor of the Greek and Latin languages in the university of Paris: but Bellai being disgraced, Wilson's prospects faded with the fortunes of his patron, whom nevertheless he attended on his journey to Rome. Wilson was taken ill at Avignon, and the cardinal proceeded without him. After his recovery, he paid a visit to the celebrated Cardinal Sabolet, the Mecænas of his time, who was also bishop of Carpentras, where he then resided. The cardinal was so charmed with his erudition, that he appointed him professor of the learned languages, with a stipend of 100 pistoles per annum.

During his residence at Carpentras, he wrote his celebrated treatise *De Animi Tranquillitate*. Mackenzie says that he afterwards taught philosophy in Italy; and that, being at length desirous of returning to Scotland, he began his journey homeward, was taken ill at Vienne in Dauphiny, and died there in the year 1547. He was generally esteemed an accomplished linguist, an admirable philosopher, and an excellent Latin poet. He wrote, beside the above treatise, 1. *Poemata*, London 1619, 4to. 2. *Commentatio quædam theologica in aphorismos dissecta, per Sebast. Gryph.* 3. *Philosophiæ Aristot. Synopsis*, lib. iv.

WILSON, *Thomas*, lord bishop of Sodor and Man, was born in 1663, at Burton, in the county of Chester. He received the rudiments of his education at the county town, and from thence was removed to the university of Dublin. His allowance at the university was 20l. a-year; a sum, small as it may now appear, which was in those days sufficient for a sober youth in so cheap a country as Ireland.

His first intention was to have applied to the study of physic; but from this he was diverted by Archdeacon Hewetson, by whose advice he dedicated himself to the church. He continued at college till the year 1686, when, on the 29th of June, he was ordained deacon.

The exact time of Mr Wilson's leaving Dublin is not known: but on account of the political and religious disputes of those days, it was sooner than he intended. On the 10th of December, in the same year, he was licensed to the curacy of New Church in Winwick, of which Dr Sherlock, his maternal uncle, was rector. His stipend was no more than 30l. a-year; but being an excellent economist, and having the advantage of living with his uncle, this small income was not only sufficient to supply his own wants, but it enabled him to supply the wants of others; and for this purpose he set apart one-tenth of his income. In 1692 he was appointed domestic chaplain to William earl of Derby, and tutor to his son James Lord Strange, with a salary of

Wilson.

of 30l. a-year. He was soon after elected master of the alms-house at Latham, which brought him in 20l. a-year more. Having now an income far beyond his expectations, or his wishes, except as it increased his ability to do good, he set apart one-fifth of his income for pious uses, and particularly for the poor. In short, as his income increased, he increased the portion of it which was allotted to the purposes of charity. At first he set apart a tenth, then a fifth, afterwards a third, and lastly, when he became a bishop, he dedicated the full half of his revenues to pious and charitable uses.

He had not been long in the service of Lord Derby, before he was offered the valuable living of Buddesworth in Yorkshire; which he refused to accept, as being inconsistent with the resolves of his conscience against non-residence, Lord Derby choosing still to retain him as chaplain and tutor to his son. In 1697 he was promoted, not without some degree of compulsion on the part of his patron, to the bishopric of the Isle of Man; a preferment which he held 58 years. In 1698 he married Mary, daughter of Thomas Patten, Esq. of Warrington. By this lady who survived her marriage above six years, he had four children; none of whom survived him, except the late Dr Wilson, prebendary of Westminster.

"The annual receipts of the bishopric (says the author of his memoirs) did not exceed 300l. in money. Some necessaries in his house, as spices, sugar, wine, books, &c. must be paid for with money; distressed or shipwrecked mariners, and some other poor objects, required to be relieved with money; but the poor of the island were fed and clothed, and the house in general supplied from his demesnes, by exchange, without money. The poor, who could weave or spin, found the best market at Bishop's-court, where they bartered the produce of their labour for corn. Taylors and shoemakers were kept in the house constantly employed, to make into garments or shoes that cloth or leather which his corn had purchased; and the aged and infirm were supplied according to their several wants. Mr Moore of Douglas informed the editor, that he was once witness to a pleasing and singular instance of the Bishop's attention to some aged poor of the island. As he was distributing spectacles to some whose eyesight failed them, Mr Moore expressed his surprise, as he well knew not one of them could read a letter. "No matter (said the Bishop with a smile), they will find use enough for them; these spectacles will help them to thread a needle, to mend their clothes, or if need be, to keep themselves free from vermin."

So great was the bishop's attachment to his flock, that no temptation could seduce him from their service. He more than once refused the offer of an English bishopric. There is an anecdote of his lordship and Cardinal Fleury, which does great credit to them both. The cardinal wanted much to see him, and sent over on purpose to inquire after his health, his age, and the date of his consecration, as they were the two oldest bishops, and he believed the poorest, in Europe; at the same time inviting him to France. The bishop sent the cardinal an answer, which gave him so high an opinion of him, that the cardinal obtained an order that no French privateer should ravage the isle of Man.

This good prelate lived till the year 1755, dying at the advanced age of 93. His works have lately been published in 2 vols. 4to.

Wilson ‖ Winchelsea.

WILTON, a market town in Wiltshire, three miles west of Salisbury. It was once so considerable as to give title to the county. It had formerly 12 churches; and Odo, brother-in-law to William I. was bishop of Wilton. Only one now remains, and its inhabitants in 1811 amounted to 1963. It sends members to parliament, and is the place where the knights of the shire are chosen. It has a great manufactory of carpets, which are brought to high perfection. Wilton is famous for Lord Pembroke's seat, so well known through Europe for its containing a grand assemblage of the productions of the greatest and most ancient masters in painting and sculpture.—Two fairs are held here anually.

WILTSHIRE, a county of England, bounded on the west by Somersetshire, on the east by Berkshire and Hampshire, on the north by Gloucestershire, and on the south by Dorsetshire and part of Hampshire. The length amounts to 39 miles; its breadth to 30; and its circumference to 140. It contains 29 hundreds, 23 market-towns, 304 parishes, and in 1811 had 193,828 inhabitants. Besides two members for the shire, and two for the city of Salisbury, each of the following towns sends two members to parliament, viz. Wilton, Downton, Hindon, Heytesbury, Westbury, Calne, Devizes, Chippanham, Malmsbury, Cricklade, Great Bedwin, Ludgershall, Old Sarum, Wooton-Basset, Marlborough.

The air of this county is very healthy, not only in the more low and level parts, but also on the hills. The soil of the vales is very rich, and produces corn and grass in great plenty. The beautiful downs in the south yield the finest pasture for sheep, with which they are overspread. The greatest disadvantage the county labours under is want of fuel, as there is no coal-pits, and but little wood. This county is noted for great quantities of very fine cheese, and for its manufacture of broad cloth, to which it was invited by the great plenty and fineness of its wool. It is watered by the rivers Isis, Kennet, Upper and Lower Avon, Willy, Burne, and Nadder, which are well stored with fish. See Wiltshire, Supplement.

WINCHELSEA, a town in Sussex, which has no market, but has one fair on May 14th for cattle and pedlars ware. It was an ancient place, at least the old town, which was swallowed up by the ocean in 1250. It is now dwindled to a mean place, though it retains its privileges, and sends two members to parliament. It is seated on a rocky cliff, on an inlet of the sea; and had a haven, now choked up. It had 18 parish-churches, now reduced to one. The market-house is in the midst of the town, from whence run four paved streets, at the end of which are four ways, which had formerly buildings on each side for a considerable distance. It is 71 miles south-east of London. It is governed by a mayor and jurats, though it had but 652 inhabitants in 1811. Three of the gates are still standing, but much decayed. E. Long. 0. 44. N. Lat. 50. 58.

Winchelsea, *Anne Countess of*, a lady of excellent genius, especially in poetry, was maid of honour to the duchess of York, second wife to King James II. and was afterwards married to Heneage, second son of the earl of Winchelsea. One of the most considerable of the countess of Winchelsea's poems was that on the

Spleen. A collection of her poems was printed at London in 1713, containing a tragedy never acted, intitled *Aristomenes*. The countess died in 1720 without issue, as her husband did in 1706.

WINCHESTER, the capital of the county of Hampshire in England. It is a very ancient city, supposed to have been built several centuries before Christ. The Romans called it *Venta Belgarum*, the Britons *Caer Givent*, and the Saxons *Wittanceaster*; whence came the present name. It stands upon the river Itchin, in a bottom surrounded with chalky hills; and is generally allowed to have been a considerable place in the time of the Romans. Some of the first converts to Christianity are supposed to have lived here. In the castle, near the west gate, many of the Saxon kings anciently kept their court. The cathedral was founded by Kenegulfe, a king of the Mercians; but there were many Christians, and places for their worship here, long before that period. It is a large pile, and has a venerable look, but is not very elegant. Besides the tombs, there are many curious pieces of workmanship in it; the chief of which are, 1. The font, erected in the time of the Saxons. 2. Copper statues of James I. and Charles I. 3. The bishop's throne. 4. The stalls of the dean and prebendaries. 5. The ascent to the choir and altar. 6. The pavement inlaid with marble of diverse colours, in various figures. 7. The altar-piece, reckoned the noblest in England. 8. The paintings in the windows, especially the great east window. At the hospital of the Holy Cross, every traveller that knocks at the door may claim a manchet of white bread and a cup of beer; of which a great quantity is provided every day for that purpose. This hospital was intended for the maintenance of a master and 30 pensioner, but only 14 are now maintained in it; and the master enjoys a revenue of 800l. a-year. This city is about a mile and a half in compass, and almost surrounded with a wall of flint; has six gates, large suburbs, broad clean streets; but the private houses are in general but ordinary, many of them being very old. The city is interspersed with a great many gardens, which contribute to its beauty and healthiness. The corporation consists of a mayor, high-steward, recorder, aldermen, two coroners, two bailiffs, 24 common-council men, a town-clerk, four constables, and four serjeants at mace; and the city gives title of *marquis* to the duke of Bolton. A Roman highway leads from hence to Alton; and went formerly, as it is thought, from thence to London. The charming downs in the neighbourhood contribute greatly to the health and pleasure of the inhabitants. The river Itchin is navigable for barges from hence to Southampton. The population in 1811 amounted to 6705 persons. W. Long. 1. 16. N. Lat. 50. 57.

WINCKLEMAN, Abbe John, was born at Stendall, in the old Marche of Brandenburg, in 1718. His father was a shoemaker. This wonderful man, to all appearance destined by his birth to superintend a little school in an obscure town of Germany, raised himself to the office of president of antiquities in the Vatican. After having been seven years professor in the college of Seehausen near Salswedel, he went into Saxony, where he resided seven years more, and was librarian to Count Bunau at Nethenitz. When he left this place, 1754, he went to Dresden, where he formed an acquaintance with the ablest artists, and particularly with M. Oeser, an excellent painter, and one of the best draughtsmen of the age. In that year he abjured Lutheranism, and embraced the Roman Catholic religion. In September 1755, he set out for Italy, and arrived at Rome in December following. His principal object was to see the Vatican library, and to examine the ruins of Herculaneum.

Mr Winckleman carried with him into Italy a sense of beauty and art, which led him instantly to admire the masterpieces of the Vatican, and with which he began to study them. He soon increased his knowledge; and it was not till after he had thus purified his taste and conceived an idea of ideal beauty, which led him into the greatest secrets of art, that he began to think of the explanation of other monuments, in which his great learning could not fail to distinguish him. His erudition enabled him to fill up his principal plan of writing the "History of Art." In 1756, he planned his "Restoration of Ancient Statues," and a larger work on the Taste of the Greek Artists; and designed an account of the galleries of Rome and Italy, beginning with a volume on the Belvidere statues, in the manner of Richardson, who, he says, only ran over Rome. He also intended a history of the corruption of taste in art, the restoration of statues, and an illustration of the obscure points of mythology. All these different essays led him to his "History of Art," and his "Monumenti Inediti." It must, however, be confessed, that the first of these works has not all the clearness and precision that might be expected in its general plan and division of its parts and objects; but it has enlarged and extended the ideas both of antiquaries and collectors. The description of the gems and sulphurs of the Stosch cabinet contributed not a little to extend Mr Winckleman's knowledge. Few persons have opportunities of contemplating such vast collections. The engravings of Lippet and Count Caylus are all that many can arrive at. Mr Winckleman's Monumenti Inediti, of which he had begun the third volume 1767, seem to have secured him the esteem of antiquaries. Had he lived, we should have had a work long wished for; a complete collection of the bas-reliefs discovered from the time of Bartoli to the present, the greater part of which are in the possession of Cardinal Albani.

When Cardinal Albani succeeded to the place of librarian of the Vatican, he endeavoured to get a place for the Hebrew language for Winckleman, who refused a canonry. because he would not take the tonsure. The elector of Saxony gave him, 1761, unsolicited, the place of Counsellor Richter, the direction of the royal cabinet of medals and antiquities at Dresden. Upon the death of the abbé Venuti, 1762, he was appointed president of the antiquities of the apostolic-chamber, with power over all discoveries and exportations of antiquities and pictures. This is a post of honour, with an income of 160 scudi per annum. He had a prospect of the place of president of antiquities in the Vatican going to be created at 16 scudi per month, and was named corresponding member of the Academy of Inscriptions. The king of Prussia offered him, by Col. Quintus Icilius, the place of librarian and director of his cabinet of medals and antiquities, void by the death of M. Gautier de la Croze, with a handsome appointment. He made no scruple of accepting the offer; but when it came to the pope's ears, he added an appointment out of his own purse, and kept him at Rome.

In

In April 1786, he left Rome to go with M. Cavaceppi over Germany and Switzerland. When he came to Vienna, he was so pleased with the reception he met with, that he made a longer stay there than he had intended. But, being suddenly seized with a secret uneasiness and extraordinary desire to return to Rome, he set out for Italy, putting off his visits to his friends in Germany to a future opportunity. As he passed through Trieste, he was assassinated, June 8. 1786, by a wretch named Arcangeli, a native of Campiglio, a town in the territory of Pistoia, with whom he had made an acquaintance on the road. This miscreant had been condemned for a robbery to work in fetters four years, and then to be banished the Austrian territories, on an oath never to return. He had obtained a mitigation of one of his sentences, and retired to Venice; but, changing his quarters backwards and forwards, he was so reduced in circumstances that he at length took up his lodgings at the inn to which the Abbé happened to come. Arcangeli paid such assiduous court to him, that he entirely gained his confidence; and having been favoured with a sight of the valuable presents which he had received at Vienna, formed a design to murder and rob him. He bought a new sharp knife on purpose; and as the Abbé (who had in the most friendly manner invited him to Rome) was sitting down in his chair, early in the morning, he threw a rope over his head, and before he could disengage himself, stabbed him in five different places. The Abbé had still strength to get down to the ground floor, and call for help; and being laid on a bed in the midst of the most violent pain, he had composure sufficient to receive the last sacraments, and to make his will, in which he appointed Cardinal Alexander Albani his residuary legatee, and expired in the afternoon. The murderer was soon after apprehended; and executed on the wheel opposite the inn, June 26.

Abbé Winckleman was a middle-sized man; he had a very low forehead, sharp nose, and little black hollow eyes, which gave him an aspect rather gloomy than otherwise. If he had any thing graceful in his physiognomy, it was his mouth. A fiery and impetuous disposition often threw him into extremes. Naturally enthusiastic, he often indulged an extravagant imagination; but as he possessed a strong and solid judgment, he knew how to give things a just and intrinsic value. In consequence of this turn of mind, as well as a neglected education, a cautious reserve was a quality he little knew. If he was bold in his decisions as an author, he was still more so in his conversation, and has often made his friends tremble for his temerity. If ever man knew what friendship was, that man was Mr Winckleman, who regularly practised all his duties; and for this reason he could boast of having friends among persons of every rank and condition.

WIND is a sensible agitation of the atmosphere, occasioned by a quantity of air flowing from one place to another. See METEOROLOGY.

Hot WINDS. See SAMIEL.

WIND-Flower. See ANEMONY, BOTANY *Index*.

WIND-Mill, a kind of mill, the internal parts of which are much the same with those of a water mill: from which, however, it differs, in being moved by the impulse of the wind upon its sails or vanes, which are to be considered as a wheel in axis. See MECHANICS *Index*.

WIND Gage. See *Wind-GAGE*.

WIND-Galls. See FARRIERY *Index*.

WIND-Gun. See *AIR GUN*, under *SCIENCE, Amusements of*.

Instruments for measuring the strength, velocity, &c. *of the WIND*. See *Wind-GAGE*, ANEMOMETER and ANEMOSCOPE.

WIND-Hatch, in mining, a term used to express the place at which the ore is taken out of the mines.

WIND-Shock, a name given by our farmers to a distemper to which fruit trees, and sometimes timber trees, are subject. It is a sort of bruise and shiver throughout the whole substance of the tree; but the bark being often not affected by it, it is not seen on the outside, while the inside is twisted round, and greatly injured. It is by some supposed to be occasioned by high winds; but others attribute it to lightning. Those trees are most usually affected by it whose boughs grow more out on one side than on the other. The best way of preventing this in valuable trees, is to take care in the plantation that they are sheltered well, and to cut them frequently in a regular manner while young.

WIND-Taught, in sea language, denotes the same as stiff in the wind. Too much rigging, high masts, or any thing catching or holding wind aloft, is said to hold a ship wind-taught; by which they mean, that she stoops too much in her sailing in a stiff gale of wind. Again, when a ship rides in a main stress of wind and weather, they strike down her top masts, and bring her yards down, which else would hold too much wind, or be too much distended and wind-taught.

WIND-Sails, a sort of wide tube or funnel of canvas, employed to convey a stream of fresh air downward into the lower apartments of a ship.

This machine is usually extended by large hoops situated in different parts of its height. It is let down perpendicularly through the hatches, being expanded at the lower end like the base of a cone; and having its upper side open on the side which is placed to windward, so as to receive the full current of wind; which entering the cavity, fills the tube, and rushes downwards into the lower regions of the ship. There are generally three or four of these in our capital ships of war, which, together with the ventilators, contribute greatly to preserve the health of the crew.

WINDAGE *of a GUN*, is the difference between the diameter of the bore and the diameter of the ball.

WINDLASS, a machine used for raising huge weights, as guns, stones, anchors, &c.

It is very simple, consisting only of an axis or roller, supported horizontally at the two ends by two pieces of wood and a pulley; the two pieces of wood meet at top, being placed diagonally so as to prop each other; the axis or roller goes through the two pieces, and turns in them. The pulley is fastened at top where the pieces join. Lastly, there are two staves or handspikes which go through the roller, whereby it is turned, and the rope which comes over the pulley is wound off and on the same.

WINDLASS, in a ship, is an instrument in small ships, placed upon the deck, just abaft the fore mast. It is made of a piece of timber six or eight feet square, in form

Windlass ‖ Wine.

form of an axletree, whose length is placed horizontally upon two pieces of wood at the ends thereof, and upon which it is turned about by the help of hand-spikes put into holes made for that purpose. This instrument serves for weighing anchors, or hoisting of any weight in or out of the ship, and will purchase much more than any capstan, and that without any danger to those that heave; for if in heaving the windlass about, any of the handspikes should happen to break, the windlass would pall of itself.

WINDOW, an aperture or open place in the wall of a house to let in the light. See ARCHITECTURE, N° 78.

The word is Welch, *uynt dor*, signifying the passage for the wind. Window is yet provincially denominated *windor* in Lancashire; i. e. *wind-door*, or the passage for air, as that for people was peculiarly called the *door*.

Before the use of glass became general, which was not till towards the end of the 12th century, the windows in Britain seem generally to have been composed of paper. Properly prepared with oil, this forms no contemptible defence against the intrusions of the weather, and makes no incompetent opening for the admission of the light. It is still used by our architects for the temporary windows of unfinished houses, and not unfrequently for the regular ones of our work shops. But some of the principal buildings we may reasonably suppose to have been windowed in a superior manner. They could, however, be furnished merely with lattices of wood or sheets of linen, as these two remained the only furniture of our cathedrals nearly to the eighth century; and the lattices continued in some of the meaner towns of Lancashire to the 18th; and in many districts of Wales, and many of the adjoining parts of England, are in use even to the present moment. These seem all to have been fixed in frames that were called *capsamenta*, and now therefore *casements* in Wales and Lancashire.

WINDSOR, a borough town of Berkshire, 22 miles west of London, most remarkable for the magnificent royal palace or castle situated there on an eminence, which commands the adjacent country for many miles, the river Thames running at the foot of the hill. The knights of the Garter are installed in the royal chapel here. It sends two members to parliament. The number of inhabitants in 1811 was 6155. W. Long. 0. 36. N. Lat. 51. 30.

WINDWARD, in the sea language, denotes any thing towards that point from whence the wind blows, in respect of a ship: thus windward-tide, is the tide which runs against the wind.

WINE, an agreeable spirituous liquor, produced by fermentation from those vegetable substances that contain saccharine matter. A very great number of vegetable substances may be made to afford wine, as grapes, currants, mulberries, elders, cherries, apples, pulse, beans, pease, turnips, radishes, and even grass itself. Hence, under the class of wines or vinous liquors, come not only wines, absolutely so called, but also ale, cyder, &c.

Chaptal's Chemistry, part iv. sect. v. chap. 6.

1 Method of making wine.

Wine, however, is in a more particular manner appropriated to the liquor drawn from the fruit of the vine. The process of making wine is as follows: When the grapes are ripe, and the saccharine principle is developed, they are then pressed, and the juice which flows out is received in vessels of a proper capacity, in which the fermentation appears, and proceeds in the following manner: At the end of several days, and frequently after a few hours, according to the heat of the atmosphere, the nature of the grapes, the quantity of the liquid, and temperature of the place in which the operation is performed, a movement is produced in the liquor, which continually increases; the volume of the fluid increases; it becomes turbid and oily; carbonic acid is disengaged, which fills all the unoccupied part of the vessel, and the temperature rises to the 72.5th degree. At the end of several days these tumultuous motions subside, the mass falls, the liquid becomes clearer, and is found to be less saccharine, more odorant, and of a red colour, from the reaction of the ardent spirit upon the colouring matter of the pellicle of the grape.

The wine is usually taken out of the fermenting vessels at the period when all the phenomena of fermentation have subsided. When the mass is settled, the colour of the liquor is well developed, when it has become clear, and its heat has disappeared; it is put into casks, where, by a second insensible fermentation, the wine is clarified, its principles combine more perfectly together, and its taste and smell become more and more developed. If this fermentation be stopped or suffocated, the gaseous principles are retained, and the wine is brisker, and more of the nature of must.

It appears, from the interesting experiments of the Marquis de Bullion, that the vinous fermentation does not take place unless tartar be present.

1 Causes of imperfect fermentation.

The causes of an imperfect fermentation are the following: 1. If the heat be too little, the fermentation languishes, the saccharine and oily matters are not sufficiently elaborated, and the wine is unctuous and sweet. 2. If the saccharine body be not sufficiently abundant, as happens in rainy seasons, the wine is weak, and the mucilage which predominates, causes it to become sour by its decomposition. 3. If the juice be too watery, concentrated and boiling must is added. 4. If the saccharine principle be not sufficiently abundant, the defect may be remedied by the addition of sugar. Macquer has proved that excellent wine may be made of verjuice and sugar; and M. de Bullion has made wine at Bellejames, with the verjuice of his vine rows and moist sugar.

There have been many disputes to determine whether grapes should be pressed with the stalks or without. This depends on the nature of the fruit. When they are highly charged with saccharine and mucilaginous matter, the stalk corrects the insipidity of the wine by its bitter principle: but when, on the contrary, the juice is not too sweet, the stalk renders it drier, and very rough.

Colouring matter of wine.

The colouring principle of wine is of a resinous nature, and is contained in the pellicle of the grape; and the fluid is not coloured until the wine is formed; for until then there is nothing which can dissolve it: and hence it is that white wine may be made of red grapes, when the juice of the grape is expressed, and the husk thrown away. If wine be evaporated, the colouring principle remains in the residue, and may be extracted by spirit of wine. Old wines lose their colour; a pellicle being precipitated, which is either deposited on the sides of the bottles, or falls to the bottom. If wine be exposed to the heat of the sun during the summer, the colouring matter is detached in a pellicle, which falls to the bottom: when the vessel is opened, the discolouring

is

Wine.

is more speedy, and it is effected in two or three days during the summer. The wine thus deprived of its colour is not perceptibly weakened.

4 Vinous fermentation explained.

The vinous fermentation has been examined with great accuracy by M. Lavoisier. According to him, the vegetable juice of which wine is to be made consists of oxygen, hydrogen, and carbone, combined with one another in different proportions, so as to form chiefly water and sugar. The fermentation produces a separation of the elements, and a new combination of them; a quantity of the oxygen and carbone combine and fly off in the state of carbonic acid; part of the carbone, oxygen, and hydrogen, combine first with each other, and then all together, to form alcohol; another part forms acetous acid; the water still remains, and a residuum falls to the bottom composed of the three elements combined in other proportions.

5 Ingredients of different wines.

The different kinds of wines produced in Europe and other parts of the world are many; the principal of them and their qualities are well known: a catalogue of them would serve no purpose here. We shall, however, subjoin a table of the quantities of the ingredients of the principal kinds from Neumann's Chemistry.

A quart of	Highly rectified Spirit.			Thick, oily, unctuous, resinous matter.			Gummy and tartarous matter.			Water.

The colour of wine is frequently artificial; a deep red is almost always the effect of artificial additions, as of the red woods, elder berries, bilberries, &c. In France no secret is made of these practices, the colouring matters being publicly thrown out after they have been used.

6 Adulteration of wine.

It is well known to be a common practice among wine-coopers, innkeepers, and other dealers in wines, to adulterate bad wine in order to conceal its defects: if, for instance, the wine be sour, they throw into it a quantity of sugar of lead, which entirely takes away the sour taste. For similar purposes alum is often mixed with wine. Such substances, however, are well known to be extremely pernicious to the human constitution; it becomes of importance therefore to be able to detect them whenever they happen to be contained in wine. Several chemists who have turned their attention to this subject, have furnished us with tests for this purpose.

7 To detect lead in wine. *Watson's Chemical Essays*, vol. iii. p. 371.

To discover lead dissolved in wine, boil together in a pint of water an ounce of quicklime and half an ounce of flour of brimstone; and when the liquor, which will be of a yellow colour, is cold, pour it into a bottle, and cork it up for use. A few drops of this liquor being dropt into a glass of wine or cyder containing *lead*, will change the whole into a colour more or less *brown*, according to the quantity of lead which it contains. If the wine be wholly free from lead, it will be rendered turbid by the liquor, but the colour will be rather a dirty white than a black brown.

By this test, however, iron is also precipitated when dissolved in wine, and is apt to be taken for lead; a mistake which has ruined several honest merchants. The following test is therefore preferable, as not liable to the same inconvenience.

8 Another method.

Take equal parts of calcined oyster-shells and crude sulphur in fine powder, and put them in a crucible, which put into a fire, and raise the heat suddenly till it has been exposed to a white heat for 15 minutes. Then take it out, let it cool, beat the ingredients to powder, and put them into a well corked bottle. To prepare the test liquor, take 20 grains of this powder together with 120 grains of cream of tartar, and put them into a strong bottle, fill it up with water, boil it for an hour, and let it cool. Cork the bottle immediately, and shake it from time to time. After some hours repose, decant off the clear liquor into an ounce vial, having first put 22 drops of muriatic acid into each vial. Cork these vials accurately with a little wax mixed up with a little turpentine. One part of this liquor, mixed with three parts of suspected wine, will discover the presence of the smallest quantity of lead or copper, by a very sensible black precipitate, and of arsenic by an orange precipitate: but will have no effect on iron, if there be any; the presence of which, however, may be ascertained by adding a little potash, which will turn the liquor black if there be any iron. Pure wine remains limpid after the addition of this liquor*.

* *Journal de Physique*, October 1791.

9 State of lead in wine.

As this subject is of importance, we shall add M. Fourcroy's observations on the state in which lead exists in wine, and on the methods of discovering its presence: "Of the different principles which compose wine, there was no doubt (says he) but that acids were the only ones which were capable of dissolving oxide (*calx*) of lead. But was it the tartareous acid always contained in larger or smaller quantity in wine, or the acetous acid developed in those which have become sharp, and which there is a greater temptation to sweeten? Experience

Wine. rience had proved to me that the acidulous tartrate of potash, or the cream of tartar, takes oxide of lead from the acetous acid, and a precipitate of tartrate of lead is formed; the pure tartareous acid prepared in Scheele's method produces the same effect. In order to understand how the sharp wine which contains these two acids can hold the oxide of lead in solution, I made the experiments which gave me the following results: 1. The acidulous tartrate (*crem. tart.*) has no sensible action upon the oxides of lead. 2. The pure tartareous acid has a slight action upon the oxides, and forms on their surface a little tartrate of lead (*tartarised lead*), in a white powder. 3. Wine which only contains the tartareous acidule, would not have any action upon the semi-vitrous oxide of lead or litharge. 4. Sharp wine which we attempt to sweeten by this oxide of lead, acts first upon it by the acetous acid it contains. 5. When this acetite of lead is formed, the tartareous acid precipitates it in the form of tartrite of lead; this is proved by the precipitate which the solution of the acetite of lead or sugar of lead forms in the wine. 6. But the acetous acid, if it be in large enough quantity, redissolves the tartrate of lead in the wine just as distilled water would. Bergman has pointed out this solution of tartrite of lead in acetous acid for distinguishing the tartareous salt from the sulphate of lead (*vitriol of lead*). 7. As this solution of tartrate of lead in the acetous acid is much quicker, and more easy in sharp wines than in distilled water and vinegar, it is probable that the cause of this difference depends upon the citric and malic acids which I have found in wine, and which I shall take notice of again on another occasion. 8. Litharged wine then, or wine sweetened with lead, contains tartrite dissolved in the acetous acid, and perhaps at the same time in the malic and citric acids.

10 It forms an aceto-tartrite of lead.

"It was necessary afterwards to know the properties of this combination. What experience has taught me is as follows: I particularly examined the tartrite of lead and its solution in acetous acid. The tartrite of lead is scarcely at all soluble in water; it is in the form of powder, or of small white grains which have no sensible taste; when it is dissolved in vinegar, the vinegar is softened, its sharpness is diminished remarkably, and the solution takes a slight sweetish taste, much less strong than that of the pure acetite of lead. This taste proves that the union of the tartrite of lead with vinegar is not only a solution like that of salt in water, by which the properties of the salt are not changed, but a combination which gives occasion to new properties. It is a kind of a triple salt, different from those we have hitherto known, formed of two acids and of one base; whereas the other triple salts described hitherto are composed of one acid and two bases. I name this new triple salt *aceto-tartrite of lead*. The acetous acid adheres to it more than water in a common solution: what is remarkable in this combination is, that the two acids appear to adhere to the base with an equal force, although they have a different attraction for it: nothing is necessary to produce this equilibrium, but to unite first the oxide of lead with the acid to which it adheres the most strongly, and afterwards to put this first compound in contact with the weaker acid.

11 Other methods of detecting this salt.

"It was necessary, in order to discover easy and certain methods of ascertaining the presence of lead in wine, to examine with care the properties and phenomena of the decompositions of the aceto-tartrite of lead. Fixed alkalies and ammoniac (*volatile alkali*) precipitate from this salt an oxide of lead, which is of a grayish white colour; but as they occasion a precipitate in pure wine, they cannot be of any use. The sulphuric (*vitriolic*) acid decomposes the aceto-tartrite of lead, and forms with it instantly sulphate of lead; which being very little soluble, and very heavy, is precipitated. The oxalic, or pure saccharine acid, and the acidulous oxalate, or the salt of sorrel of the shops, likewise decompose this salt, and take from it the lead. The oxalate of lead is precipitated in great abundance: these two acids, the suphuric and oxalic acids, not producing any precipitate in pure wine, are very proper to show the presence of lead in wine. The sulphate and oxalate of lead, when they are precipitated from wine, are coloured, whereas they are very white when they are formed in distilled water; but their red or brown colour does not prevent us from discovering them by a very simple method. If the precipitates be collected with care, and are cautiously heated upon a coal with a blow-pipe, they smoke, become white, exhale vapours, pass successively through the states of the red and yellow oxides of lead, and at length are reduced into metallic globules at the instant they are perceived to be agitated by a very evident effervescence: if we cease to blow at this instant, we obtain globules upon the charcoal. In order to this, it is necessary, however, that the charcoal be solid, and be not cracked, and that we should not have blowed too strongly; otherwise the globules would be absorbed, and would disappear. The sulphate of lead requires a longer time to be reduced than the oxalate of the same metal, and there is a greater hazard of losing the metallic particles, which, beside, are in small quantity.

"To these two first processes, already sufficiently certain of themselves, I wished to be able to add one which might be capable of pointing out instantly the presence of lead, by an appearance belonging exclusively to this metal, and which might unite to this advantage that of manifesting very small quantities of it. Distilled water impregnated with sulphurated hydrogenous gas, or hepatic gas, extricated from solid alkaline sulphurets (*livers of sulphur*) by acids, presented me with these properties. This solution blackens very deeply that of the aceto-tartrite of lead, and renders $\frac{1}{1000}$ of this salt in water or in wine very sensible. The sensibility of this reactive is such, that we may dilute litharged wine with a sufficient quantity of water to take away almost entirely the colour of the wine, and this reactive will still produce a very manifest alteration. The sulphurated water has, besides, the advantage not to occasion any change in the wines which do not contain a metallic substance, and it is not precipitated by the acids of wine, like the solutions of alkaline sulphurets. In order to procure this reactive pure, it is necessary to prepare it at the instant of the experiment, by receiving in a vial full of distilled water, and inverted upon a shelf of a small hydro-pneumatic apparatus, filled with distilled water, the sulphurated hydrogenous gas, separated from the solid sulphuret of potash by the sulphuric or muriatic acid, and first filtrated through water in another vial; when the second vial contains the third of its volume of the sulphurated hydrogenous gas, the gas is shaken strongly with the water, which fills the two-thirds of the

the vial; and when the absorption is over, the test liquor is prepared. This re-active changes very quickly in the air: it is necessary to make it the moment it is to be employed, and to keep it in a vessel quite full and well corked. If there were any fear that the black colour and the precipitation by the gaseous sulphurated water should not be sufficient to prove the presence of lead in spirituous liquors, I would observe, that this fear would be diminished by employing the three re-actives mentioned in this memoir, and by depending only on the correspondent effects of these three re-actives: but all suspicion would be removed, by reducing the three precipitates by the blow-pipe, and obtaining globules of lead from each of them."

12 Method of detecting alum dissolved in wine.

Some years ago, the Academy of Lyons proposed the following prize-question: What is the best method of ascertaining the presence and the quantity of *alum* dissolved in wine, especially in very deep coloured red wine? The prize was gained by M. J. S. Beraud. From his experiments, it appears that a mixture of lime-water and wine in any proportion whatever, will at the end of 12 or 15 hours furnish a quantity of crystals, which may be separated by filtration, and that these crystals will be easiest discovered when the quantities of wine and lime-water are equal; but that wine containing alum dissolved in it, will not form crystals, when mixed with lime-water, but merely deposits a muddy sediment. To know therefore whether any wine contains alum or not, we have only to mix a small quantity of it with lime-water: if crystals are formed, it contains no alum; if not, it does. Again, if wine contains alum, the residuum that remains after filtration will, as it dries, split into quadrilateral segments, which will detach themselves from the paper which contains them; but if the wine contains no alum, the residuum, after it is dry, will remain united and attached to the paper. If one measure of wine and two-thirds of a measure of lime-water deposit crystals, we are certain that if the wine contains alum, the proportion of that alum to the wine will be less than 1 to 1152; if, when equal parts of wine and lime-water are mixed, no crystals be deposited, we may be sure that more than $\frac{1}{400}$th part of the mass of wine consists of alum.

A great proportion of the wine consumed in this country is brought from Spain and Portugal; government has always discouraged the importation of French wines by heavy taxes. We are not sure how far such conduct is founded on good policy, as the French wines are confessedly the best, and might be the cheapest; but such is the jealousy and enmity that has always subsisted between Britain and France, that both nations have been contented to injure themselves, provided they could do a greater injury to their neighbours. Besides, the advantages which Britain derives from the Portugal trade are very great, and it would not be easy perhaps to secure them on any other terms.

13 Directions for the treatment of imported wines.

It may be worth while to insert here a few directions about the treatment of wines after they have been imported into this country.—On landing, the less they are exposed the better; for they are affected by the seasons, and more or less by climate. March and April are the proper times for shipping wines from France, and they will be landed in England and Ireland in the same degree of temperature. The great art in keeping wines is to prevent their fretting, which is done by keeping them in the same degree of heat. In spring and fall, the wines in Bourdeaux are subject to changes that may be dangerous, if not prevented by necessary rackings: these changes are solely the effects of the seasons. If wines are chilled, and of course turn foul, from being shipped and landed in cold weather, they will soon recover by putting them in a warm vault, well covered with saw-dust. As soon as they are in the vault, they ought to be covered up. But if shipped and landed in summer, if the smallest degree of fermentation be found on them, it will be requisite to dip the bung cloths in brandy, and leave the bungs loose for some days, to give it time to cool; and if in a fortnight or three weeks the fermentation do not cease, and the wine become bright, it will be proper to rack it (matching the hogsheads well with brimstone), and force it with the white of eight eggs. If it then becomes fine, bung it tight, and let it remain so until it is bottled. If wines new landed are wanted soon for the bottle, it will be necessary to force them immediately, and let them remain bunged close for at least a month, to recover from the forcing, or if two months the better; for wines bottled in high order come much sooner into drinking than if bottled when flat, which all wines are after forcing. Wine must never be bottled the least foul, which produces a tendency to fret; and if bottled in this state, will never come in order, but may possibly be lost; for this there is no remedy but repeated rackings; and care must be taken (after rinsing the hogsheads well and drawing them) to burn a good piece of match in them. This cools the wine, and there is no danger of hurting the colour, for it recovers it in a little time: but if it did, it is absolutely necessary; for if wine is suffered to continue on the fret, it will wear itself to nothing. Wines bottled in good order may be fit to drink in six months; but they are not in perfection before twelve: from that to two years they may continue so; but it would be improper to keep them longer, for wines in general have not the body they had formerly, from the vines being too much forced.

It sometimes happens that wines scuddy and stubborn will not fall with one or even two forcings. It will then be proper to give them five or six gallons of good strong wine, and force them with the whites of a dozen eggs, with a tea-spoonful of sand produced from sawing-marble, or a small spoonful of fine salt. Bottled wine in winter should be well covered with saw-dust, and if the vaults are cold and damp, strew it deep on the floor; if saw-dust is thrown upon the hogsheads, and their sides are bedded some inches thick, it will keep them from the fret.

The same treatment is to be regarded with white wines, except that they require to be higher matched, particularly Muscat wines; such as Frontignac, Beziers, &c. which being often sweetened with honey, are very subject to fret; and these only frequent rackings, with a great deal of brimstone, can cool. Hermitage, from not being sufficiently dried, and possessing more richness than claret, is also very liable to come on the fret, and will require much the same treatment as the Muscat wines. Attention should be had to bottle in fine weather, when the wind is north; but to avoid cold or frosty weather. The months of April and October are favourable. The best time to bottle port wine is four years

Wine.

years after the vintage, and to keep them two years in bottle when you begin to use them. When wines are racked, and the lees immediately passed through flannel bags into close-necked jars, and directly bottled, there will be very little loss by rackings, as the wine when fine may serve for filling up.

When wines are destined for warm climates, it may be proper to rinse the hogsheads with brandy; and in bottling many rinse the bottles and corks with it. Wines that have remained a certain time (three or four months) in a vault, and made fine by their lees, ought never to be sent into the country without first racking them, otherwise they may be liable to fret; and if bottled in that state, may not bring well.

When wines may be ordered for immediate drinking will be forced in the ordinary way, and in a few weeks after they are forced will be fit for the bottle. The forcings proper for claret are the whites of a dozen eggs, beat up with a tea-spoonful of fine salt, and well worked with a forcing rod. Take care to use no bad egg. This is for one hogshead.

The forcing for white wine is isinglass dissolved in wine. One ounce is sufficient for two hogsheads. No salt is to be used in forcing the white wines. See *Croft on Wines*, 8vo, 1788.

14 Receipt for making raisin wine.

We shall insert here the following receipt for making *raisin wine.*—To a 20 gallon vessel take 100 pounds of raisins; pick off the stalks, chop them grossly, and put them into an open tub more wide than deep. Add two parts in three of the water of them, and let them stand 15 days, stirring them well every day. Then strain and press them, putting aside the liquor that runs from them. Add the remainder of the water to the raisins that have thus been pressed, and let it stand upon them one week, frequently stirring them as before. Then press off the liquor, and add it to what you first collected; putting both runnings together into your vessel, together with one quart of brandy. To colour it, burn three-fourths of a pound of sugar into a small quantity of the liquor, and add this to the wine. When the liquor in the barrel has done singing, stop the vessel close, and let it stand till fit to be bottled. The greater the quantity which the vessel holds, and the longer it is kept in the wood, the better will it be.

As some of the hints for making wines in Champagne may be useful in the manufacture of the wines of this country, we insert the following abridged account of the different processes that are followed in making white and red champagne.

Great care is necessary for making white wine. The ripest bunches must be carefully gathered, freed from rotten, dry, and bruised grapes, put into large baskets covered with a cloth to keep them from the sun, carried to the shade, and kept there till the evening, when they are to be speedily pressed. The grapes being laid on the bed of the press, they are covered with three or four layers of flat stones, and the press turned. The juice having run for four or five minutes, the press is turned backward, the stones removed, the grapes which have protruded thrust into the heap, the stones replaced, and the press turned again. The juice from three of such pressures, which will not require an hour, is put by itself for the best wine into a vat, where it is left all night to settle.

The next morning the juice is poured off from the sediment, and put into new well rinsed casks. In these it ferments violently at first, but afterwards imperceptibly, till about the end of December it becomes fine, having gone through all the stages of fermentation. It is then racked off in dry weather, on a clear frosty day, and fined with isinglass. About a pound is sufficient for [illegible] puncheons. The isinglass being dissolved is well mixed, diluted with wine taken from the cask, then poured into it, and the whole well stirred by an instrument introduced at the bung-hole. The wine then enters into fermentation slightly again, till it be stopped by the cold weather, or by time. In a month or six weeks it is racked off again, and has another fining with half the quantity of isinglass.

For making red wine, the grapes are gathered with the same precautions as for making white, taking only the black grapes. These are bruised in particular vessels, by men treading on them with strong wooden shoes; part of the stalks are thrown away, and the must is left in covered vessels to ferment sufficiently to extract the colouring matter from the pellicles. In some years, three or four days are sufficient; in others it requires 10, 15, or even 20. When the fermentation begins, the husks and stalks are forced down so as to be covered with the must, either by means of strong poles furnished with cross pieces, or, which is better, by a couple of strong men going into the vat, and well treading and mixing its contents. When the air above the vat extinguishes a candle, the stalks and husks rise forcibly, whatever pains be taken frequently to sink them, that the must may not acquire a disagreeable taste; the contents of the vat experience a degree of ebullition, and the colouring matter is decomposed. The fermentation must be made to stop here, that the wine may not acquire a hard taste, which even time cannot destroy.

About the end of December, when the fermentation has ceased, the wine is racked off from the lees; about the middle of May it is racked off again; the barrels are fresh hooped, and the wine is put into the cellar. When it is to be sent to the consumer, it is racked a third time; the whites of five or six fresh eggs are well beaten up in a pint of water, for every puncheon holding 240 bottles. Good red champagne will keep in bottles from six to twelve years.

Wine-Press, a machine contrived to squeeze the juice out of grapes, and consisting of several pieces of timber, variously disposed, which compose three bodies of timber-work, closely united to the axis, which serves as a swing whereby it may be moved by the vice. Of these there are different sizes as well as different constructions; for an account of which, illustrated by figures, see Miller's Gardener's Dictionary, article *Wine-Press*.

Spirit of Wine, or *Alcohol*, a name given by chemists to every ardent spirit produced by distillation. See Chemistry *Index*.

WING, that part of a bird, insect, &c. whereby it is enabled to fly. See Bird and Ornithology.

Wings, in military affairs, are the two flanks or extremes of an army, ranged in form of a battle; being the right and left sides thereof.

WINTER, one of the four seasons or quarters of the year. See Season, &c.

Winter commences on the day when the sun's distance from the zenith of the place is greatest, and ends on the day

day when its distance is at a mean between the greatest and least.

Under the equator, the winter as well as other seasons returns twice every year; but all other places have only one winter in the year: which in the northern hemisphere begins when the sun is in the tropic of Capricorn, and in the southern hemisphere when in the tropic of Cancer; so that all places in the same hemisphere have their winter at the same time.

Winter-Berry. See Physalis, Botany *Index*.

WINTERA, a genus of plants of the class of polyandria, and in the natural system arranged under the 12th order, *Holoraceæ*. See Botany and Materia Medica *Index*.

WINTON, Andrew, a Scottish poet and historian of the 14th century; but very little is known of his life. He was a canon regular of St Andrews, and was prior of the monastery of St Serf in the island of Loch Leven in Kinross-shire; for in the chartulary of the priory of St Andrews there are several public instruments of Andrew Winton, as prior of Loch Leven. They are dated between the years 1395 and 1413, so that Winton must have been cotemporary with Barbour, whose merits are on several occasions celebrated by him. Winton is best known as the author of the *Orygynale Cronykill of Scotland.* This work was undertaken at the request of Sir John Wemyss, the ancestor of the noble family of that name. It remained neglected for several centuries, but in 1795 a splendid edition of that part of it relative to Scottish affairs, was published by Mr Macpherson. The time of Winton's death is unknown; but, as he mentions the death of Robert duke of Albany, which happened in 1420, the historian must have been alive at that time.

WIRE, a piece of metal drawn through the hole of an iron into a thread of a fineness answerable to the hole it passed through.

Wires are frequently drawn so fine as to be wrought along with other threads of silk, wool, flax, &c.

The metals most commonly drawn into wire are gold, silver, copper, and iron. Gold-wire is made of cylindrical ingots of silver, covered over with a skin of gold, and thus drawn successively through a vast number of holes, each smaller and smaller, till at last it is brought to a fineness exceeding that of a hair. That admirable ductility which makes one of the distinguishing characters of gold, is nowhere more conspicuous than in this gilt wire. A cylinder of 48 ounces of silver, covered with a coat of gold, only weighing one ounce, as Dr Halley informs us, is usually drawn into a wire, two yards of which weigh no more than one grain; whence 98 yards of the wire weigh no more than 49 grains, and one single grain of gold covers the 98 yards; so that the ten-thousandth part of a grain is above one-eighth of an inch long.

In 1784, Mr Roswag of Strasbourg presented to the board of trade some gauze made of iron wire, for which he received a reward; and the loom he invented for making it was lodged in the collection of machines at Vaucanson. In 1799 Mr Rochon made others, and coated them with a transparent glue, to be substituted instead of horn for ship lanterns, to be used between decks, and in engagements by night. He has since conceived, that with a thin coating of plaster they might be employed to preserve ships from fire, and buildings on shore still more easily; or at least that they might render the ravages of fire less frequent, and less terrible. These gauzes might be very useful too for theatrical decorations, which would not be liable to take fire. Their only inconvenience is their being so little flexible; but Mr Rochon does not despair of means being found by chemistry to remedy this imperfection, and it was with a view of calling attention to this subject, that he read a paper on it to the class.

Wire of Lapland. The inhabitants of Lapland have a sort of shining slender substance in use among them on several occasions, which is much of the thickness and appearance of our silver wire, and is therefore called, by those who do not examine its structure or substance, *Lapland wire.* It is made of the sinews of the rein deer, which being carefully separated in the eating, are, by the women, after soaking in water and beating, spun into a sort of thread, of admirable fineness and strength, when wrought to the smallest filaments; but when larger, is very strong, and fit for the purposes of strength and force. Their wire, as it is called, is made of the finest of these threads covered with tin. The women do this business; and the way they take is to melt a piece of tin, and placing at the edge of it a horn, with a hole through it, they draw these sinewy threads, covered with the tin, through the hole, which prevents their coming out too thick covered. This drawing is performed with their teeth; and there is a small piece of bone placed at the top of the hole, where the wire is made flat; so that we always find it rounded on all sides but one, where it is flat.

This wire they use in embroidering their clothes, as we do gold and silver; they often sell it to strangers, under the notion of its having certain magical virtues.

WISDOM, usually denotes a higher and more refined notion of things immediately presented to the mind, as it were, by intuition, without the assistance of ratiocination.

Sometimes the word is more immediately used, in a moral sense, for what we call *prudence*, or *discretion*, which consists in the soundness of the judgment, and a conduct answerable thereto.

Wisdom of Solomon, one of the books of the Apocrypha. It abounds with Platonic language, and was probably written after the Cabalistic philosophy was introduced among the Jews.

WIT, is a quality of certain thoughts and expressions, much easier perceived than defined. According to Mr Locke, wit lies in the assemblage of ideas, and putting those together with quickness and variety, wherein can be found any resemblance or congruity, thereby to make up pleasant pictures and agreeable visions to the fancy. Mr Addison limited this definition considerably, by observing, that every resemblance of ideas does not constitute wit, but those only which produce delight and surprise. Mr Pope defined wit to be a quick conception and an easy delivery: while, according to a late writer, it consists in an assimilation of distant ideas.

The word *wit* originally signified *wisdom.* A *witte* was anciently a *wise man:* the *wittenagemot*, or Saxon parliament, an assemblage of wise men. So late as the reign of Elizabeth, a man of pregnant *wit*, of great *wit*,

Wit.

wit, was a man of vast *judgment*. We still say, *in his wits, out of his wits*, for in or out of sound mind. The word, however, is now applied in a more limited sense.

Without attempting to expose the inaccuracy of the definitions above mentioned, or hazarding a definition of our own where so many eminent men have failed, we shall endeavour to show in what true wit consists.

It is evident that wit excites in the mind an agreeable surprise, and that this is owing entirely to the strange assemblage of related ideas presented to the mind. This end is effected, 1. By debasing things pompous or *seemingly* grave; 2. By aggrandizing things little or frivolous; 3. By setting ordinary objects in a particular and uncommon point of view, by means not only remote but apparently contrary. Of so much consequence are surprise and novelty, that, nothing is more tasteless, and sometimes disgusting, than a joke that has become stale by frequent repetition. For the same reason, even a pun or happy allusion will appear excellent when thrown out extempore in conversation, which would be deemed execrable in print. In like manner, a witty repartee is infinitely more pleasing than a witty attack: for though, in both cases, the thing may be equally new to the reader or hearer, the effect on him is greatly injured, when there is access to suppose that it may be the slow production of study and premeditation. This, however, holds most with regard to the inferior tribes of witticism, of which their readiness is the best recommendation.

Campbell's Philosophy of Rhetoric, vol. i.

We shall illustrate these observations by subjoining a specimen or two of each of these sorts of wit:

Of the first sort, which consists in the debasement of things great and eminent, Butler, amongst a thousand other instances, hath given us those which follow:

And now had Phœbus in the lap
Of Thetis taken out his nap:
And, like a lobster boil'd, the morn
From black to red began to turn.
Hudibras, part ii. canto 2.

Here the low allegorical style of the first couplet, and the simile used in the second, afford us a just notion of this lowest species, which is distinguished by the name of the *ludicrous*. Another specimen from the same author you have in these lines:

Great on the bench, great in the saddle,
That could as well bind o'er as swaddle,
Mighty he was at both of these,
And styl'd of *war*, as well as *peace*:
So some rats of amphibious nature,
Are either for the *land* or *water*.
Ibid. part i. canto 1.

In this coarse kind of drollery, those laughable translations or paraphrases of heroic and other serious poems, wherein the authors are said to be travestied, chiefly abound.

The second kind, consisting in the aggrandisement of little things, which is by far the most splendid, and displays a soaring imagination, these lines of Pope will serve to illustrate:

As Berecynthia, while her offspring vie
In homage to the mother of the sky,
Surveys around her in the blest abode,
An hundred sons, and every son a god:
Not with less glory mighty Dulness crown'd,
Shall take thro' Grubstreet her triumphant round;
And her Parnassus glancing o'er at once,
Behold a hundred sons, and each a dunce.

This whole similitude is spirited. The parent of the celestials is contrasted by the daughter of night and chaos; heaven by Grubstreet; gods by dunces. Besides, the parody it contains on a beautiful passage in Virgil adds a particular lustre to it. This species we may term *thrasonical*, or *the mock-majestic*. It affects the most pompous language, and sonorous phraseology, as much as the other affects the reverse, the vilest and most grovelling dialect.

To this class also we must refer the application of grave reflections to mere trifles. For that *great* and *serious* are naturally associated by the mind, and likewise little and trifling, is sufficiently evinced by the common modes of expression on these subjects used in every tongue. An apposite instance of such an application we have from Philips:

My galligaskins, that have long withstood
The winter's fury and encroaching frosts,
By time subdu'd, (*What will not time subdue!*)
An horrid chasm disclose. *Splendid Shilling.*

Of the third species of wit, which is by far the most multifarious, and which results from what may be called the queerness or singularity of the imagery, we shall give a few specimens that will serve to mark some of its principal varieties. To illustrate all would be impossible. The first shall be where there is an apparent contrariety in the things she exhibits as connected. This kind of contrast we have in these lines of Garth:

Then Hydrops next appears amongst the throng;
Bloated and big she slowly sails along:
But like a miser in excess she's poor,
And pines for thirst amidst her wat'ry store.
Dispensary.

A second sort is, where the things compared are what with dialecticians would come under the denomination of *disparates*, being such as can be ranked under no common genus. Of this we shall subjoin an example from Young.

Health chiefly keeps an Atheist in the dark;
A fever argues better than a *Clarke*:
Let but the logic in his pulse decay,
The Grecian he'll renounce, and learn to pray.
Universal Passion.

A third variety in this species springs from confounding artfully the proper and the metaphorical sense of an expression. In this way, one will assign as a motive what is discovered to be perfectly absurd, when but ever so little attended to; and yet from the ordinary meaning of the words, hath a specious appearance on a single glance. Of this kind we have an instance in the subsequent lines:

While thus the lady talk'd, the knight
Turn'd th' outside of his eyes to white,

As

As men of inward light are wont
To turn their optics in upon't.
Hudibras, part iii. canto 1.

For whither can they turn their eyes more properly than to the light?

A fourth variety, much resembling the former, is when the argument or comparison (for all argument is a kind of comparison) is founded on the supposal of corporeal or personal attributes in what is strictly not susceptible of them; as in this,

But Hudibras gave him a twitch
As quick as lightning in the breech,
Just in the place where honour's lodg'd,
As wise philosophers have judg'd:
Because a kick in that place more
Hurts honour than deep wounds before.
Ibid. part ii. canto 3.

The fifth, and only other variety which we shall mention, is that which arises from a relation, not in the things signified, but in the signs of all relations, no doubt the slightest. Identity here gives rise to puns and clinches; resemblance to quibbles, cranks, and rhimes: Of these it is quite unnecessary to exhibit specimens.

Wit, *John de*, a celebrated pensionary of Holland, and one of the greatest politicians of his time, was the son of Jacob de Wit, burgomaster of Dort, and was born in 1625. He became well skilled in civil law, politics, mathematics, and other sciences; and wrote a treatise on the Elements of Curved lines, published by Francis Schooten. Having taken his degree of doctor of law, he travelled into foreign courts, where he became esteemed for his genius and prudence. At his return to his native country in 1650, he became pensionary of Dort, then counsellor-pensionary of Holland and West Friesland, intendant and register of the fiefs, and keeper of the great seal. He was thus at the head of affairs in Holland; but his opposition to the re-establishment of the office of stadtholder, which he thought a violation of the freedom and independence of the republic, cost him his life, when the prince of Orange's party prevailed. He and his brother Cornelius were assassinated by the populace at the Hague in 1674, aged 47.

WITCH a person guilty of witchcraft.

WITCHCRAFT, a supernatural power which persons were formerly supposed to obtain the possession of by entering into a compact with the devil. They gave themselves up to him body and soul; and he engaged, that they should want for nothing, and that he would avenge them upon all their enemies. As soon as the bargain was concluded, the devil delivered to the witch an imp, or familiar spirit, to be ready at a call, and do whatever it was directed. By the assistance of this imp and the devil together, the witch, who was almost always an old woman, was enabled to transport herself in the air on a broomstick or a spit to distant places to attend the meetings of the witches. At these meetings the devil always presided. They were enabled also to transform themselves into various shapes, particularly to assume the forms of cats and hares, in which they most delighted; to inflict diseases on whomsoever they thought proper; and to punish their enemies in a variety of ways. Witchcraft.

The belief that certain persons were endowed with supernatural power, and that they were assisted by invisible spirits, is very ancient. The *sagæ* of the Romans seem rather to have been sorcerers than witches; indeed the idea of a witch, as above described, could not have been prevalent till after the propagation of Christianity, as the heathens had no knowledge of the Christian *devil*.

Witchcraft was universally believed in Europe till the 16th century, and even maintained its ground with tolerable firmness till the middle of the 17th. Vast numbers of reputed witches were convicted and condemned to be burnt every year. The methods of discovering them were various. One was, to weigh the supposed criminal against the church bible, which, if she was guilty, would preponderate: another, by making her attempt to say the Lord's Prayer; this no witch was able to repeat entirely, but would omit some part or sentence thereof. It is remarkable, that all witches did not hesitate at the same place; some leaving out one part, and some another. Teats, through which the imps sucked, were indubitable marks of a witch: these were always raw, and also insensible; and if squeezed, sometimes yielded a drop of blood. A witch could not weep more than three tears, and that only out of the left eye. This want of tears was, by the witch-finders, and even by some judges, considered as a very substantial proof of guilt. Swimming a witch was another kind of popular ordeal generally practised; for this she was stripped naked, and cross-bound, the right thumb to the left toe, and the left thumb to the right toe. Thus prepared, she was thrown into a pond or river, in which, if guilty, she could not sink; for having, by her compact with the devil, renounced the benefit of the water of baptism, that element, in its turn, renounced her, and refused to receive her into its bosom. Sir Robert Filmer mentions two others by fire: the first, by burning the thatch of the house of the suspected witch; the other, burning any animal supposed to be bewitched by her, as a hog or ox. These, it was held, would force a witch to confess. *Provincial Glossary.*

The trial by the stool was another method used for the discovery of witches. It was thus managed: Having taken the suspected witch, she was placed in the middle of a room upon a stool or table, cross-legged, or in some other uneasy posture; to which if she submitted not, she was then bound with cords; there she was watched, and kept without meat or sleep for the space of 24 hours (for, they said, within that time they should see her imp come and suck). A little hole was likewise made in the door for imps to come in at; and lest it should come in some less discernible shape, they that watched were taught to be ever and anon sweeping the room, and if they saw any spiders or flies, to kill them: if they could not kill them, then they might be sure they were imps. If witches, under examination or torture, would not confess, all their apparel was changed, and every hair of their body shaven off with a sharp rasor, lest they should secrete magical charms to prevent their confessing. Witches were most apt to confess on Fridays.

By such trials as these, and by the accusation of children, Witchcraft.

dren, old women, and fools, were thousands of unhappy women condemned for witchcraft, and burnt at the stake. In the 18th volume of the Statistical Account of Scotland there is the trial of two witches, William Coke and Alison Dick, in Kirkaldy, in 1636. The evidence on which they were condemned is absolutely ridiculous: they were, however, burnt for witchcraft. The expences which the town and kirk-session were put to on this occasion were as follows:

	L.	s.
In primis.—To Mr James Miller, when he went to Prestowne for a man to try them, 47s. - -	L.2	7
Item.—To the man of Culross, (the executioner), when he went away the first time, 12s. - -	0	12
Item.—For coals for the witches, 24s.	1	4
Item.—In purchasing the commission,	9	3
Item.—For one to go to Finmouth for the laird to sit upon their assize as judge, - - -	0	6
Item.—For harden to be jumps to them,	3	10
Item.—For making of them, -	0	8
Summa for the kirk's part	L.17	10 Scots.

The town's part of expences debursed extraordinarily upon William Coke and Alison Dick.

	L.	s.	d.
In primis.—For 10 loads of coals to burn them, 5 merks, -	L.3	6	8
Item. For a tar barrel, 14s. -	0	14	0
Item.—For towes, - -	0	6	0
Item.—To him that brought the executioner, - -	2	18	0
Item.—To the executioner for his pains, - - -	8	14	0
Item.—For his expences here,	0	16	4
Item.—For one to go to Finmouth for the laird, - -	0	6	0
Summa town part,	L.17	1	0 Scots.
Both,	L.34	11	0
Or	L. 2	17	7 Ster.

Dr Ferriar, Manchester Trans. vol. iii.

For a considerable time after the inquisition was erected, the trials of witches (as heretics) were confined to that tribunal; but the goods of those who were condemned being confiscated to the holy office, its ministers were so active in discovering sorcerers, that the different governments found it necessary to deprive them of the cognisance of this crime. On the continent, commissioners were then appointed for the discovery and conviction of witches, who, though less active than the inquisitors, were but too zealous in prosecuting their function. In 1494, Sprenger and Institor, two persons employed in this commission, published a collection of trials, most of which had come before themselves, under the title of *Malleus Maleficarum:* this served as a kind of institute for their successors.

The first writers against witchcraft were stigmatized as Atheists, though they only endeavoured to prove the imbecility of the persons accused, and the infatuation or the knavery of their accusers. Such were the epithets bestowed by Dr Henry More, and even by Cudworth himself. Wierus, the disciple of the celebrated Agrippa, gave rise to the first great controversy on this subject. His master had taught him humanity; and he endeavoured, but with too feeble a hand, to stop the bloody proceedings of the judges. Wierus appears to have been a well-disposed, weak man, with extensive reading on his subject, but too narrow-minded to comprehend it thoroughly. He involved himself in unspeakable difficulties, by admitting the action of supernatural powers in certain diseases, and in possessions, while he denied that witches had any concurrence in them. These appearances (said he) are illusions of the devil, who persuades simple and melancholy persons that the mischief he himself performs, is done by them, and at their pleasure. He was weak enough to attempt the explanation of every story alleged by his antagonists, without questioning the truth of the facts.

Bodinus, a French lawyer of eminence, who had assisted at several trials of witches, wrote against Wierus, in his *Demonomania.* He urged the concurrent testimonies of sufficient witnesses, and the confessions of the witches themselves, to establish the existence of sorcery. Wierus owned that the unhappy persons believed themselves to be guilty of the crimes alleged against them, but that they were deceived by the devil. But what do you make of the witches meetings, cried Bodinus? The witches (replied his antagonist) are atrabilious. This explanation was so unsatisfactory that Wierus passed for a magician, whom the devil had furnished with specious arguments to save others from punishment. Lercheimer Godelmann, Ewichius, Ewaldus, and some others, followed him, notwithstanding this stigma; but they were opposed by men of more acuteness and consistency than themselves; by Remigius, who had condemned several hundreds of sorcerers to the flames; Delrio, whose book is a complete Corpus Magiæ; Cujas, Erastus, Scribonius, Camerarius, and a crowd of others.

In this country, while the belief in witchcraft was supported by royal authority (for James I. is universally known to have written on demonology) countenanced by Bacon, and generally adopted among the people, only one writer was hardy enough to oppose it. This was Reginald Scott, who published a collection of impostures detected, under the title of Discoveries of Witchcraft. James ordered the book to be burnt by the common executioner, and the judges continued to burn witches as usual. During the civil wars, upwards of eighty were hanged in Suffolk, on the accusations of Hopkins the witch-finder. Webster was the next writer against witchcraft; but he had a different fate from that of Scott, for most of his arguments were refuted by Glanville. This very acute writer was induced to publish his Philosophical Considerations about Witchcraft, by the apprehension, that the increasing disbelief of witches and apparitions tended to affect the evidences of religion, and even of a Deity. In respect of argument, he was certainly superior to his adversaries; his reasoning is perspicuous, though sometimes subtle, rested on the most specious foundations of evidence, and arranged with great skill.

On the continent, this controversy seemed almost forgotten, till Bekker published his *Monde Enchanté,* in which he denied the existence of witches, on the Cartesian principle, that the Deity is the source of all action, consequently actions so opposite to his nature and attributes cannot be supposed to exist. He was answered by Frederick

Frederick Hoffman, the father of the modern theory and practice of medicine, in his dissertation *De Diaboli Potentia in Corpora*.

The latest witchcraft frenzy was in New England, about 1692, when the execution of witches became a calamity more dreadful than the sword or the pestilence. The accusers became so daring, that neither civil nor religious authority would have proved a security against their attacks, if all the prosecutions had not been suddenly dropped, and the prisoners set at liberty. So far did those wretches proceed in absurdity, that a dog was accused of throwing persons into fits by looking at them. As soon as the prosecutions were stopped, all reports of witchcraft ceased.

It would be ridiculous to attempt a serious refutation of the existence of witches; and at present, luckily, the task is unnecessary. In this country, at least, the discouragement long given to all suspicion of witchcraft, and the repeal of the statutes against that crime, have very much weakened, though perhaps they have not entirely eradicated, the persuasion. On the continent, too, it is evidently on the decline; and notwithstanding the exertions of Dr De Haen, and of the celebrated Lavater, we have little doubt but that in a short time posterity will wonder at the credulity of their ancestors. That there ever were witches, is an opinion that cannot for a moment be believed by a thinking man. The actions imputed to them were either absurd or impossible; the witnesses by whose evidence they were condemned, either weak enthusiasts or downright villains: and the confessions ascribed to the witches themselves, effects of a disordered imagination produced by cruel treatment and excessive watchings. As to the nightly meetings, demonologists themselves have been obliged to confess, that they were nothing else but uneasy dreams, often produced by soporific compositions. The facts which have been brought forward by the advocates for witchcraft bear in their front the most evident marks of trick and imposture; and this has constantly been found out whenever these facts have been properly examined. See SORCERY.

WITENA MOT, or WITENA *Gemot*, among the Anglo-Saxons, was a term which literally signified the assembly of the wise men; and was applied to the great council of the nation, of latter days called the *parliament*.

WITHERS *of a* HORSE, the juncture of the shoulder-bones at the bottom of the neck and mane, towards the upper part of the shoulder.

WITNESS, in *Law*, a person who gives evidence in any cause, and is sworn to speak the truth, the whole truth, and nothing but the truth.

Trial by WITNESS, a species of trial without the intervention of a jury. This is the only method of trial known to the civil law, in which the judge is left to form in his own breast his sentence upon the credit of the witnesses examined: but it is very rarely used in the English law, which prefers the trial by jury before it in almost every instance. Save only that when a widow brings a writ of dower, and the tenant pleads that the husband is not dead; this being looked upon as a dilatory plea, is in favour of the widow, and for greater expedition allowed to be tried by witnesses examined before the judges: and so, saith Finch, shall no other case in our law. But Sir Edward Coke mentions some others; as, to try whether the tenant in a real action was duly summoned, or the validity of a challenge to a juror: so that Finch's observation must be confined to the trial of direct and not collateral issues. And in every case Sir Edward Coke lays it down, that the affirmative must be proved by two witnesses at the least.

WITTENBERG, a city of Germany, capital of the circle of Upper Saxony, 50 miles north of Dresden. The town is not large; but is well fortified, and contains a famous university, in which Melancthon was a professor. In this place Martin Luther first began to preach against the pope's indulgences; and in the cathedral of All Saints he is said to have been buried. In the old citadel of this town the ancient Saxon electors used to reside. Besides the university, there is a Latin school in the town, with six masters. The library belonging to the university is said to be very valuable. In 1756, the Prussians being masters of the town, destroyed a part of its fortifications. This town belonged to the elector, now king of Saxony, but was included in the country which he was compelled to cede to Prussia in 1814. E. Long. 12. 47. N. Lat. 51. 49.

WOAD. See ISATIS, BOTANY *Index*; see also DYEING.

The preparation of woad for dyeing, as practised in France, is minutely described by Astruc, in his Memoirs for a Natural History of Languedoc. The plant puts forth at first five or six upright leaves, about a foot long and six inches broad: when these hang downwards, and turn yellow, they are fit for gathering: five crops are gathered in one year. The leaves are carried directly to a mill, much resembling the oil or tan mills, and ground into a smooth paste. If this process was deferred for some time, they would putrefy, and send forth an insupportable stench. The paste is laid in heaps, pressed close and smooth, and the blackish crust, which forms on the outside, reunited if it happens to crack: if this was neglected, little worms would be produced in the cracks, and the woad would lose a part of its strength. After lying for fifteen days, the heaps are opened, the crust rubbed and mixed with the inside, and the matter formed into oval balls, which are pressed close and solid in wooden moulds. These are dried upon hurdles: in the sun, they turn black on the outside; in a close place, yellowish, especially if the weather be rainy. The dealers in this commodity prefer the first, though it is said the workmen find no considerable difference betwixt the two. The good balls are distinguished by their being weighty, of an agreeable smell, and when rubbed, of a violet colour within. For the use of the dyer, these balls require a farther preparation: they are beat with wooden mallets, on a brick or stone floor, into a gross powder; which is heaped up in the middle of the room to the height of four feet, a space being left for passing round the sides. The powder, moistened with water, ferments, grows hot, and throws out a thick fetid fume. It is shovelled backwards and forwards, and moistened every day for twelve days; after which it is stirred less frequently, without watering, and at length made into a heap for the dyer.

WOAHOO, one of the Sandwich islands, lying to the north-west of Morotoi, at the distance of seven leagues. From the appearance of the north-east and north-west parts, it is the finest island of the group. Nothing can exceed the verdure of the hills, the variety of of wood and lawn, and rich cultivated valleys, which the whole face of the country displays. A bay is formed by the north and west extremities, into which a fine river empties itself, through a deep valley; but as the water is brackish for 200 yards from the entrance, watering in it is not convenient. It contains about 60,000 inhabitants. Lieutenant Hergest, commander of the Dædalus store-ship, who had been sent from England, in 1791, to New South Wales, and thence to the Southern Pacific ocean, with a supply of provisions for the Discovery sloop, Captain Vancouver, then on a voyage of discovery, was here surprised and murdered by the natives, together with Mr Gooch, the astronomer. W. Long. 157. 51. N. Lat. 21. 43.

WODEN. See ODIN, and MYTHOLOGY, N° 40.

WODEVILLE, ANTHONY, earl of Rivers, brother to the queen of Edward IV. was born in the end of 1442, or in the beginning of 1443. Though one of the most accomplished men of his age, very little is known of his private history. He was early and constantly employed either in the tumults of those turbulent times, or in discharging the duties of some of the highest offices of the state, with which he was invested. Yet he found leisure to cultivate letters, and to be the author of works which, though of little value now, made some noise in that age, when learning was at a low ebb in England. These consisted chiefly of translations from the French; and his lordship and his printer Caxton, were the first English writers who had the pleasure to see their works published from the press. This accomplished, brave, and amiable nobleman was treacherously imprisoned by Richard III. in Pomfret castle, where, during his confinement, he composed a short poem, which has been preserved by John Rous of Warwick, and breathes, says Dr Henry, a noble spirit of pious resignation to his approaching fate. He was beheaded on the 23d of June 1483, in the 41st year of his age.

WODROW, ROBERT, a clergyman of the west of Scotland, who lived in the beginning of the 18th century, well known as the author of an Ecclesiastical History of that kingdom during the latter part of the preceding century. His father, Mr James Wodrow, was a man of learning and piety. He preached occasionally to the persecuted presbyterians, and taught a little academy of their students of philosophy and theology at Glasgow, before the Revolution. About that time he was ordained one of the ministers of that city, continuing his connexion with the academy till he was elected professor of theology by the university in the year 1692. He taught with reputation and success till his death in 1708.

His son Robert was born in the year 1679; his mother being then in the 51st year of her age. Her death (though it did not happen till several years after), was then fully expected; and his father, obnoxious to a tyrannical government, narrowly escaped imprisonment, or something worse, by attempting to obtain a last short interview with her. As he passed the town guard-house, he was marked, and soon followed by the soldiers into his own house, and even into his wife's bedchamber, where he was concealed. Their officer checked this violence; sent them out of the room, and left the house himself; placing, however, centinels both within and without, till the birth should be over. In half an hour after, Mr Wodrow at his wife's suggestion assumed the bonnet and great-coat of the servant of the physician then in attendance; and carrying the lantern before him, made an easy escape through the midst of the guards. They soon renewed their search with marks of irritation, thrusting their swords into the very bed where the lady lay; who pleasantly desired them to desist, "for the bird (said she) is now flown."

His son Robert went through the usual course of literary education at Glasgow, entered the university in 1691; and prosecuted the study of the languages and the different branches of philosophy, till he became a student of theology under the tuition of his father. He was chosen librarian to the university in the year 1698, and continued in that office four years. There he began his researches into every thing connected with the ecclesiastical history of his country, which he continued to pursue to the end of his life; and also imbibed his taste for medals, inscriptions, and whatever seemed curious or illustrative of Roman, Celtic, and British antiquities.

He was among the first in Scotland who attended to the study of natural history. From a great number of letters in his own hand-writing, begun about this time, it appears that he was in habits of the utmost intimacy with a select number of literary gentlemen, animated with the same ardour of research; that they corresponded regularly with one another, made collections of singular stones, of fossils, petrified plants, fishes, &c. and exchanged what they could spare from their respective stores. Among his correspondents were Mr William Nicolson, archdeacon, afterwards bishop of Carlisle, and at last of Derry, author of the Historical Libraries; Mr Edward Lhwyd keeper of the Ashmolean closet at Oxford; Sir Robert Sibbald, physician in Edinburgh, author of a natural history of Scotland, and another of Fife; Lord Pitmedan; Messrs James Sutherland, Laughlan Campbell minister of Campbelton, and others. In a letter to Mr Lhwyd, dated August 1709, Mr Wodrow tells him his manse was but at a little distance from a place where they had been lithoscoping together, during a visit of Mr Lhwyd to Scotland. "My parochial charge (he continues) does not allow me the same time I had then for those subterranean studies; but my inclination is equally strong, perhaps stronger. I take it to be one of the best diversions from serious study, and in itself a great duty, to admire my Maker's works. I have gotten some store of fossils here from our marle, limestone, &c. and heartily wish I had the knowing Mr Lhwyd here to pick out what he wants, and help me to class a great many species which I know not what to make of." He informs him, in the end of the letter, that he had 500 or 600 species of one thing or another relative to natural history.

Mr Wodrow, when he left Glasgow, resided a short time in the neighbourhood, in the house of a very distant relation, Sir ——— Maxwell of Nether Pollock, then one of the Scots judges. It being within the bounds of the presbytery of Paisley, he offered himself to them for probationary trials, and obtained their licence to preach the gospel in March 1703. In the summer following, the parish of Eastwood, where Lord Pollock lived, becoming vacant, by the death of Mr Matthew Crawford (another Scots historian), a petition, with an unanimous *call* or invitation from the parish to Mr Wodrow to be their minister, was presented to the presbytery;

Wodrow. presbytery; and they, waving part of the usual second trials, in order to expedite the business, ordained Mr Wodrow to be minister of Eastwood on the 28th of October 1703. In this charge he continued to the end of his life. Notwithstanding his ministerial duty, he still found some time to gratify the early bent of his mind towards natural history, and his curiosity to learn every thing in his power, not only at home, but concerning the natural productions of other countries, and the opinions, customs, manners, and way of living of their inhabitants. In his farewell letters to his friends, about to sail to the Scottish settlement of Darien or to the coast of Africa, &c. he directed their attention and enquiries to these subjects; and something similar he suggested to other friends going to reside in remote places of the Highlands, or even on the continent of Europe. The collection of his MS. letters bound up in five or six thick 8vo volumes, though reaching nearly to the end of his life, seems to consist only of the first draught of his own letters to his friends, not a single scrap is now to be found of their answers to him.

After his ordination, however, this worthy man, considering the duties of his office as his principal and only proper business, rose into distinguished reputation and usefulness as a preacher, and was looked upon as one of the first clergymen in the west of Scotland. Humble and unambitious of public notice, he was well entitled to it, by his conscientious and exemplary piety, his learning, not only in professional, but in other branches of knowledge, his natural good sense and solid judgment, his benevolent obliging spirit to all, his warm attachment to his friends, who formed a wide circle around him, and especially his deep concern for the best interests of his people, and active exertions for their instruction and improvement. His weekly sermons were all distinctly written out in long hand, and even his lectures in short-hand. Accustomed to regular composition, he had acquired an uncommon facility in it. His countenance and appearance in the pulpit was manly and dignified; his voice clear and commanding, his manner serious and animated: these things, joined with the general prejudice in his favour, added to the impression of the plain edifying discourses he delivered, without papers, to his hearers; and living in the near neighbourhood of Glasgow, his little church was often crowded, especially when he dispensed the Lord's Supper, considered in Scotland as the principal religious solemnity.

Yet these talents, and this merited popularity which followed them, made little impression on his own modest conscientious mind; for he chose to continue in the obscure country parish with which he was first connected, resisting all the attempts made by his friends or by strangers to get him translated into several other more honourable and opulent parishes, who were desirous of the benefit of his ministry, however convenient the change might have proved for the education of his family. In the year 1712, the magistrates of Glasgow invited him to be one of the ministers of that city; and in January 1717, a deputation from the town of Stirling did the same. On the other hand, the patron, heritors, and elders of his own parish, strenuously opposed the translation. The presbytery, who had it in their power to have appointed it, found great difficulties in both cases on the plea of the *majus bonum ecclesiæ*; referred the decision in the first case to the synod, and in the last to the commission of the General Assembly, and these courts thought proper to put no restraint on the minister's judgment or inclination, as he himself was certainly the best judge of his comparative usefulness in two different situations.

Mr Wodrow was equally conscientious and assiduous in the business of the ecclesiastical courts, as in his parochial duty. Notwithstanding his studious turn, he punctually attended the meetings of Presbytery, Synod, and General Assembly, when elected, as he often was, a member of that court; and also the commissions in November and March, which regularly met during that period of the church. His connexion with Lord Pollock made his journeys to Edinburgh easy: and after he began to collect materials for his voluminous history, his personal inspection of the public records and of the various MSS. accumulated in the Edinburgh libraries, made his visits to that capital frequent and necessary.

In common with the great body of the Presbyterians, he had strongly imbibed what are called Whig principles; in other words, he was warmly attached to the constitutional liberties of the people, as established by the revolution settlement. No wonder! The dreadful persecution and oppression they had suffered during the two preceding reigns were still fresh and galling to their minds: they considered the elevation of King William to the throne, and the Hanover succession, as the two chief bulwarks raised up by Providence, for the security both of their religion and liberty. They trembled at every dark appearance threatening to this security, such as the death of King William. That cloud, however, was soon dissipated by the perseverance of the queen's ministers in his views and measures, and the splendid victories of Marlborough and his allies over the armies of Louis XIV. But the elevation of the Tory ministry in the latter part of the queen's reign was a severe trial to the Scottish Presbyterians, and involved the conscientious part of the clergy in very serious difficulties and dangers. The oath of abjuration required at that time from clergymen, and enforced by civil penalties, and even the royal proclamation for a national thanksgiving, after the peace of Utrecht, pressed hard upon the scrupulous consciences of many of the clergy. The very language of the *oath* seemed to them dubious and jesuitical, hostile to the elector of Hanover's newly acquired right to the crown, conferred on him by the parliament and the people; and, as to the other point, they had not freedom to lead their people, in a solemn thanksgiving to Heaven for a peace, termed safe and honourable, which they and the generality of their hearers considered as dangerous and disgraceful. Mr Wodrow, as might be expected, was one of the recusants of the oath: for nothing could move him to shuffle with his conscience. At the same time the liberality and equity of his mind led him to judge candidly of the consciences of others. Accordingly, he made every effort in his power to reconcile his clerical brethren, and his own people, to such of the clergy as had the freedom to take it, and by so doing, had rendered themselves obnoxious to popular prejudice and odium. With such, this good man still continued to live, not only in Christian, but ministerial communion; endeavouring to soften and remove the prejudices against them, and, in as far as his influence reached, to revive and cherish a spirit of mutual forbearance. Many proposals be made, and private meetings

Wodrow. meetings and conferences he held with his brethren, to prevent their differences from rising, as they threatened to do, into a schism; to prevent them especially from entering at all into the church courts; justly afraid of the sparks of animosity too apt to be kindled there. His endeavours and those of his friends were seconded by the prudence of the superior courts, especially the commission of the General Assembly. Whatever passed there in the way of admonition to the rest of the church, breathed the spirit of mutual forbearance and love. How he managed the other difficult and delicate point, *the Thanksgiving*, in a consistency with his duty, does not appear in his letters; nor is it now worth while to investigate this as a trait of his character, which might be done, perhaps, from his MS. sermons preached at the time. Only it is pleasing to remark from the letters, that the same spirit of wisdom and mild forbearance which animated the majority of the clergy in the west, seems also to have pervaded the officers of the crown, justices of the peace, and other civil magistrates in Scotland at the time. The oath was not pressed on the recusants, and the execution of the legal penalties incurred by the neglect of it avoided; for their general loyalty was undoubted.

A more severe stroke was inflicted on their adversaries by the Tory ministry in the year 1710, by an act of the British parliament which restored patronage to its former full force. An act of the Scotch parliament passed after the Revolution had extracted the chief sting of that grievance, by placing the election of the minister of every parish in the hands of the landed proprietors, called heritors, in conjunction with the elders, or members of the kirk-session. A majority of that joint body, at a meeting appointed for the purpose, drew up a *call* or written invitation, which they subscribed, to a particular candidate to be their minister. This was presented to the presbytery of the bounds, the proper judges of his learning and moral character; and if these were found unexceptionable, he was ordained, or solemnly consecrated and installed into the office. This Scotch act having continued in force for twenty years, and being conceived to have become perpetual by the articles of the Union, was now repealed; and the choice of a minister to every parish was in effect placed in the power of a single person, a patron, because he had in fact the sole power of nominating the only candidate who could enjoy the benefice.

Mr Wodrow was exceedingly averse from the revival of the power of patronage; and in this he was influenced both by his political and religious principles. In his letters, he seems to have looked upon a patron of a parish, as a kind of hereditary despot; or at least like a prince, who had no restraints laid on his prerogative, to prevent or check the abuse of it. The paramount power or trust committed to a patron, this conscientious minister could not reconcile with the apostolical counsels, *to commit the keeping of religious truth to faithful men, able also to instruct others*. He thought it very improper to leave the choice of a religious instructor, in the first instance, to any single person whatever, especially to one generally a stranger to the circumstances of the parishioners; one who had little knowledge, and therefore little sympathy with them in their religious sentiments and feelings. He was persuaded that the purposes of edification, and the peace of the country, circumstanced as Scotland then was, were much better secured by the restraints laid on a patron in the act 1690, that is, by admitting the two principal bodies of the parish to a participation with him in his choice, than by trusting it wholly to himself; and he threw out many judicious hints in his letters, and even schemes or proposals to his brethren, on this difficult and important subject.

On the other hand, he wished nothing to be attempted but in a constitutional way, in harmony with the civil power. Few men were so sensible as he was of the abuses incident to popular government, either in church or state, and of the danger of resisting, even unjust and oppressive laws, in a tumultuous or disorderly manner. The Presbyterian church, in the outward order or form of it, he viewed as a well regulated republic. He did not consider the people in their individual capacity, as qualified to vote even on the choice of their own minister. The elders of the parish he looked upon as the representatives of the people in the ecclesiastical courts; and their number, in his own congregation, he restricted to a very few, four or five at most, fit to assist him in the exercise of church discipline within the parish. The rest of his session were deacons, whose jurisdiction was confined to the care of the poor, visiting the sick, and distributing the bread and wine at the communion, but could not, like the former, be chosen to represent the parish in the presbytery and superior courts. In this sense of the necessity of order and subordination, he persevered to the end of his life. When, contrary to *his* judgment or vote, an unpopular brother was to be ordained in a parish within twelve or fifteen miles distant from Eastwood, in consequence of a sentence of the General Assembly, to be executed, perhaps with military assistance; this aged minister thought it his duty, regardless of personal danger or odium, to countenance the young brother, by joining with the rest of the clergy in laying their hands on him, inviting him afterwards to his pulpit, and exerting any influence he had to conciliate the irritated minds of that parish.

The only publication for which the world is indebted to Mr Wodrow, is The History of the Singular Sufferings of the Church of Scotland during the twenty-eight years immediately preceding the Revolution. It was written at a proper distance of time from the events it records; and printed at Edinburgh in the year 1721, in two large folio volumes, with two appendixes consisting of copies of the public records, and of many private, family, and personal papers, letters, &c. inserted as vouchers of the historical facts. In collecting this great body of information, the author was assisted by his friends, who cheerfully seconded his own almost incredible industry and patience of research. In consequence of this, the book has more the appearance of a biographical, than of a historical work. It has, however, the form, and all the essentials of a regular history, divided into books, chapters, and sections, with proper margins and indexes; written in a plain, rather too familiar style, unavoidably interspersed with Scoticisms, yet these sufficiently intelligible to an English reader. It exhibits a distinct sketch of the characters both of the principal sufferers, and of their persecutors; of the springs of the persecution, in the unjustifiable plans and measures of an arbitrary government; with the motives of the advisers and executors of them. The unfortunate and innocent

Wodrow. innocent sufferers, our author viewed in the light, not of a set of wild fanatics, as they were called by their contemporaries, and frequently too by later historians; many of them were most respectable for their rank in their country, as well as for their talents and virtues; but even those in the lower ranks of society, our author thought worthy of some public notice, as confessors and martyrs in the noble cause which they had espoused, the support of the rights of conscience, and of national liberty.

The subject of the history is the most melancholy that could be chosen; a long and severe persecution of a people, who had been guilty of nothing undutiful to their civil or ecclesiastical rulers; a series of open acts of injustice and tyranny, perpetrated under the colour of law, and this with such an increasing and merciless violence, as to sink the usual spirit of a free people, and easily quash one or two feeble ill-timed attempts to resist their oppressors. No wonder that the continued view of such a wretched and melancholy scene, without any thing joyful to interrupt it, should give a melancholy tinge to the mind of the writer, easily communicated to his readers. On the other hand, some things have happily an opposite tendency. The mass of biographical intelligence, though it must be confessed it is much too voluminous, and too minute for the management of any historian whatsoever, yet furnishes a variety of anecdotes, which give some needful relaxation or relief to the sympathy of the reader. These indeed are in part the *simple annals of the poor*, without the varnish or easy elegance of polished life; but even in this shape they are not destitute, both of entertainment and instruction; and then the minuteness in the detail of names, of persons, places, and other particular circumstances, adds to the impression of the facts, by placing their certainty beyond all reasonable doubt.

If faithfully to record past facts, and transmit the knowledge of them to posterity, be the principal duty of a historian, this Wodrow has certainly aimed at; and also to repress any feelings hostile to his fidelity and impartiality; in short, to come as near as he was able to the motto prefixed to his volumes, *Nec studio, nec odio.* Doubtless, like all other men, he had some political, and many theological prejudices, the last chiefly imbibed from education, and confirmed by too high a veneration for the characters of our first reformers;—prejudices which warped his personal opinions and feelings on both subjects. But he seems to have made a considerable effort to prevent his party prejudices from warping or perverting his judgment of the truth or falsehood of stubborn historical facts. Nothing almost oratorial enters into his narratives, though there is room for admiration, and much scope for just indignation; no exaggerated encomiums on his friends, or strong opprobrious language in speaking of his and their enemies, the unprovoked persecutors of his church. He allows the facts which he has recorded to speak for both, and transmit to posterity a memorial to their honour or their infamy.

The chief fault of this historical collection already hinted at, is its minuteness, and excessive copiousness. The prodigious multitude of facts it embraces, though different from one another in their circumstances, are in other respects somewhat similar. This must necessarily occasion some repetition and satiety, especially to a fastidious reader, who has it, however, in his power to gratify his taste by selecting what is most agreeable to it. Nevertheless a candid and patient reader can be at no loss to form a proper judgment of the principal transactions of the period, from the authentic accounts of them before him, to appreciate the true characters of the actors, or of the motives and views from which they acted. And an inquisitive and penetrating reader will be gratified by seeing not a little of the peculiar principles, opinions, sentiments, habits, and manners of that age, as distinguished from the present; and may thus estimate the gradual progress towards much noble and useful improvement; and on the other hand, the progress towards a very hurtful corruption and degeneracy of manners, which have both taken place during the last hundred and twenty years.

Wodrow. At the time of its first publication, the book met with less general attention than might have been expected in Scotland, and scarcely any attention in England, except from professed readers. As it came to be more studied, it was the more valued, except where there was an evident bias on the opposite side. Few can be at a loss to see why such historians as Hume, Macpherson, and Dalrymple should neglect or undervalue such a book. Our later Scotch historians, Somerville and Laing, have done it more justice. In truth, there is a very near coincidence in their estimates of the characters they draw, and their accounts of the facts they relate, in common with Wodrow. But especially our late illustrious patriot Charles Fox, whose high abilities, uncommon candour, and sweetness of disposition, almost remove the suspected bias of his party spirit—Mr Fox has, in the historical fragment published since his death, given a very honourable testimony to the fidelity and accuracy of our historian. After mentioning the execution of three females, he adds, page 131. "To relate all the instances of cruelty which occurred would be endless. But it may be necessary to remark, that no historical facts are better ascertained, than the accounts of them which are to be found in Wodrow. In every instance, where there has been an opportunity of comparing these accounts with the records, and other authentic monuments, they appear to be quite correct."

The collection of the materials for writing the church history from the public records, and many other authentic sources, must have cost the author a prodigious labour and time. The pecuniary expence incurred was considerable, and scarcely refunded from the sale of the book. The only neat profit, he has been heard to say, which accrued from it, was one or two hundred pounds that he received from the king, to whom it was dedicated.

The last twelve years of Mr Wodrow's life were chiefly occupied in drawing up a biography of the principal persons concerned in introducing the reformation of religion into Scotland, and settling the different forms or modes of ecclesiastical government attempted to be established there from the beginning to the end of that period, namely from about the year 1560 to 1660, when the printed history of the sufferings commences. Had it pleased God to continue his useful life till this larger work was finished, public curiosity would have been much gratified; for it contains the lives, not only of John Knox, George Buchanan, and others already well known, but the lives of a great number more, very learned, ingenious, respectable, and worthy men, scarce-

Wodrow. ly at all known to the literary world; besides a variety of anecdotes naturally entering into such a work, illustrative of the history and the living manners of that age. Happily these manuscript lives are still preserved, all written with his own pen, and some of the longest of them copied, probably during his last long illness, in a more legible hand. Whatever important or curious information they may contain, they are not fit for the press in their present state. They are now deposited in the library of the university of Glasgow.

Besides writing the history and the biography, both extended by himself for publication, and two days every week regularly appropriated to his preparation for the pulpit, much of his time must have been occasionally spent in writing letters, some of them like dissertations, on theological and other literary subjects; for he corresponded with a very wide circle of acquaintances and friends in Scotland, England, and Ireland, and with a few on the continent and in North America.

His constitution in the first part of life was robust and strong, his health in general good; but his studious habits or constant reading, and especially incessant writing, it is supposed, may have brought on the bodily complaint which occasioned his death. In the latter end of the year 1731, a swelling about the size of a small chesnut appeared on his breast, near the collar bone. It was on the same place where a spark of fire had fallen when he was a child, and had then left a little lump and hardness like a large pea. About a month after the swelling began, it had increased to the size of a plumb, and in April 1732 was as large as a man's fist. It was attempted to be removed by caustic; the attempt failed. His body became greatly emaciated, and he gradually declined till his death, which happened on the 21st of March 1734. Supported by the testimony of a good conscience, joined with the strong consolation and well-founded hope of the gospel, he bore this long continued severe distress with admirable fortitude, unabated piety and resignation; never uttering a murmur, but behaving to his friends who came to see him, and to all about him, with much ease and affection; thus leaving, both in the active exertions of a useful life, and in his patient sufferings at the close of it, a very edifying example to his family and his flock. The day before his death, he gathered his children around his bed, gave each of them his dying blessing, with counsels suitable to their ages and circumstances; last of all two boys, neither of them four years old, too young to understand and feel these marks of his affection, yet, after the example of the venerable patriarch, Gen. xlviii. 15. even them he drew to him, laid his hands upon their heads, and devoutly prayed, *that the God of his fathers, the angel who had redeemed him from all evil, would bless the lads.*

Mr Wodrow was married in the end of 1708, to Margaret Warner, grand-daughter of the reverend Mr William Guthrie of Fenwick, well known in Scotland by his writings, and daughter of the reverend Patrick Warner, then living on his estate of Ardeer in Ayrshire. Mr Warner, in the early part of his life, had been chaplain to the East India Company at Madras. After his return home, he was driven from his ministry and from the kingdom, by the persecution of the privy council; but returned in consequence of King James's indulgence, and became minister of Irvine. He had a personal interview on his last return with the prince of Orange at the Hague, a short time before the Revolution, an account of which appears in the history, vol. ii. p. 604. Mr Wodrow had a family of 16 children, nine of whom, with his widow, survived him in decent circumstances, without any breach among them for above 25 years. Three of his sons were clergymen of the church of Scotland; one was minister of the parish of Cumbray, another of Tarbolton; and the third, the late Dr James Wodrow, author of the life of Dr Leechman of Glasgow, was minister of Stevenston in Ayrshire.

Besides his collection of fossils, and a few Roman and British medals, Mr Wodrow left a valuable library of books, many volumes of pamphlets and also of manuscripts written by others, sent to him in presents, or copied by his orders. The most valuable part of them is now in the advocates library, and in the repositories of the church at Edinburgh. His own manuscript biography, as has been already said, is in the library of the university of Glasgow.

WOLAW, a town in Germany, in Prussian Silesia, and capital of a duchy of the same name. It is surrounded with strong walls and a morass, and one part of the houses are built with stone. The castle is also encompassed with deep ditches, and the greatest part of the inhabitants are employed in a woollen manufactory. In 1709 a Protestant church was allowed to be built here. It is seated on the river Oder, 20 miles north-west of Breslau, and 32 south-east of Glogau. E. Long. 16. 54. N. Lat. 51. 18.

WOLFE, MAJOR-GENERAL JAMES, was born at Westerham in the county of Kent, about the beginning of the year 1726. His father was Lieutenant-general Edward Wolfe. He went into the army when very young; and applying himself with unwearied assiduity to the study of his profession, soon became remarkable for his knowledge and his genius. He distinguished himself at the battle of Lafelt when little more than 20, and received the highest encomiums from the commander in chief. After the peace he still continued to cultivate the art of war. He contrived to introduce the greatest regularity and the exactest discipline into his corps, and at the same time to preserve the affection of every soldier. In 1758 he was present as a brigadier-general at the siege of Louisbourg. He landed first on the island at the head of division; and in spite of the violence of the surf, and the force and well directed fire of the enemy, drove them from their post with great precipitation. The surrender of the town which happened soon after, was in a great measure owing to his activity, bravery, and skill. The fame which he acquired during this siege pointed him out to Mr Pitt, who was then minister, as the properest person to command the army destined to attack Quebec. This was the most difficult and the most arduous undertaking of the whole war. Quebec was the capital of the French dominions in North America; it was well fortified, situated in the midst of a hostile country, and defended by an army of 20,000 men, regulars and militia, besides a considerable number of Indian allies. The troops destined for this expedition consisted of ten battalions, making up altogether about 7000 men. Such was the army

Wolfe.

army destined to oppose three times their own number, defended by fortifications, in a country altogether unknown, and in a late season in that climate for military operations. But this little army, says an officer who was present at that expedition, and who has been so obliging as to communicate all the information we desired, was always sanguine of success; for they were commanded by General Wolfe, who, by a very uncommon magnanimity and nobleness of behaviour, had attached the troops so much to his person, and inspired them with such resolution and steadiness in the execution of their duty, that nothing seemed too difficult for them to accomplish. The admirable skill with which his measures were planned, and the prudence and vigour with which they were executed, are well known. He landed his army on the northern shore of the river St Lawrence in spite of the enemy, and forced them to a battle, in which they were completely defeated. The consequence of this battle was the reduction of Quebec, and the conquest of Canada. In the beginning of the battle General Wolfe was wounded in the wrist by a musket-ball: he wrapt his handkerchief round it, continued to give his orders with his usual calmness and perspicuity, and informed the soldiers that the advanced parties on the front had his orders to retire, and that they need not be surprised when it happened. Towards the end of the battle he received a new wound in the breast; he immediately retired behind the rear-rank supported by a grenadier, and laid himself down on the ground. Soon after a shout was heard; and one of the officers who stood by him exclaimed, "See how they run!" The dying hero asked with some emotion, "Who run?" "The enemy (replied the officer); they give way every where." The general then said, "Pray, do one of you run to Colonel Burton, and tell him to march Webb's regiment with all speed down to Charles river, to cut off the retreat of the fugitives from the bridge. Now, God be praised, I shall die happy!" He then turned on his side, closed his eyes, and expired.

The death of General Wolfe was a national loss universally lamented. He inherited from nature an animating fervour of sentiment, an intuitive perception, an extensive capacity, and a passion for glory, which stimulated him to acquire every species of military knowledge that study could comprehend, that actual service could illustrate and confirm. This noble warmth of disposition seldom fails to call forth and unfold all the liberal virtues of the soul. Brave above all estimation of danger; generous, gentle, complacent, and humane; the pattern of the officer, the darling of the soldier. There was a sublimity in his genius which soared above the pitch of ordinary minds; and had his faculties been exercised to their full extent by opportunity and action, had his judgment been fully matured by age and experience, he would, without doubt, have rivalled in reputation the most celebrated captains of antiquity. His body was brought to England, and buried with military honours in Westminster abbey, where a magnificent monument is erected to his memory.

Wolfe, *Christian*, a celebrated German philosopher, was born at Breslau in 1679. After having been well instructed in the rudiments of learning and science in his own country, Wolfe prosecuted his studies successively in the universities of Jena, Hamburgh, and Leipsic. At the age of 26 he had acquired so much distinction, that he was appointed professor of mathematics, and soon afterwards of philosophy in general, in the university of Hall. After Leibnitz had published his *Theodicea*, Wolfe, struck with the novelty of the edifice which that philosopher had raised, assiduously laboured in the investigation of new metaphysical truths. He also digested the Elements of Mathematics in a new method, and attempted an improvement of the art of reasoning, in a treatise On the Powers of the Human Understanding. Upon the foundation of Leibnitz's doctrine of Monads, he formed a new system of Cosmology and Pneumatology, digested and demonstrated in a mathematical method. His work, entitled Thoughts on God, the World, and the Human Soul, was published in the year 1719; to which were added, in a subsequent edition, Heads of Ethics and Policy.

Enfield's History of Philosophy, vol. ii.

Wolfe, Wolfenbuttle.

Wolfe was now rising towards the summit of philosophical reputation, when the opinion which he entertained on the doctrine of necessity being deemed by his colleagues inimical to religion, and an oration which he delivered in praise of the morality of the Chinese having given much offence, an accusation of heresy was publicly brought against him; and, though he attempted to justify himself in a treatise which he wrote on the subject of fatality, a royal mandate was issued in November 1723, requiring him to leave the Prussian dominions. Having been formerly invited by the landgrave of Hesse-Cassel to fill a professor's chair in the university of Cassel, Wolfe now put himself under the patronage of that prince, who had the liberality to afford him a secure asylum, and appointed him professor of mathematics and philosophy. The question concerning the grounds of the censure which had been passed upon Wolfe was now every where freely canvassed; almost every German university was inflamed with disputes on the subject of liberty and necessity; and the names of Wolfians and Anti-Wolfians were every where heard. After an interval of nine years, the king of Prussia reversed his sentence of exile, and appointed him vice-chancellor of the university of Hall; where his return was welcomed with every expression of triumph. From this time he was employed in completing his Institutes of Philosophy, which he lived to accomplish in every branch except policy. In 1745 he was created a baron by the elector of Bavaria, and succeeded Ludowig in the office of chancellor of the university. He continued to enjoy these honours till the year 1754, when he expired. He possessed a clear and methodical understanding; which, by long exercise in mathematical investigations, was particularly fitted for the employment of digesting the several branches of knowledge into regular systems; and his fertile powers of invention enabled him to enrich almost every field of science in which he laboured, with some valuable additions. The lucid order which appears in all his writings enables his reader to follow his conceptions with ease and certainty, through the longest trains of reasoning.

WOLFENBUTTLE, a considerable town of Germany, in the circle of Lower Saxony, and duchy of Brunswick, with a castle, where the duke of Brunswick Wolfenbuttle resides. It is one of the strongest places in Germany, though the fortifications want repairing in several places. There is an excellent library, kept in a building lately erected for that purpose, consisting of 116,000 printed books, and 2000 uncommon books, with

with a cabinet of curiosities, relating to natural history. It is seated on the river Ocker, five miles south of Brunswick, and 30 west of Halberstadt. E. Long. 10. 25. N. Lat. 52. 10.

WOLFRAM, or TUNGSTEN. See TUNGSTEN, CHEMISTRY and MINERALOGY *Index*.

WOLFSPERG, a town of Germany, in Lower Carinthia, with a castle, on which the district about it depends, which is 20 miles in length, and 10 in breadth. It is seated on the river Lavand, at the foot of a mountain covered with wood, and full of wolves, from whence the town took its name. It is 36 miles east of Clagenfurt. E. Long. 15. 0. N. Lat. 46. 56.

WOLGAST, a considerable town of Germany, in the circle of Upper Saxony, and in Pomerania, capital of a territory of the same name, with a castle, and one of the best and largest harbours on the Baltic sea. It is a well built place, subject to Prussia, and seated on the river Psin. E. Long. 13. 42. N. Lat. 54. 4.

WOLLASTON, WILLIAM, descended of an ancient family in Staffordshire, was born in 1659. He was in 1674 admitted a pensioner in Sidney college, Cambridge, where, notwithstanding several disadvantages, he acquired a great degree of reputation. In 1682, seeing no prospect of preferment, he became assistant to the head master of Birmingham school. Some time after, he got a small lecture about two miles distant, but did the duty the whole Sunday; which, together with the business of a great free-school for about four years, began to break his constitution. During this space he likewise underwent a great deal of trouble and uneasiness, in order to extricate two of his brothers from some inconveniences, to which their own imprudence had subjected them. In 1688 affairs took a new turn. He found himself by a cousin's will entitled to a very ample estate: and came to London that same year, where he settled; choosing a private, retired, and studious life. Not long before his death, he published his treatise, entitled The Religion of Nature Delineated; a work for which so great a demand was made, that more than 10,000 were sold in a very few years. He had scarcely completed the publication of it, when he unfortunately broke an arm; and this adding strength to distempers that had been growing upon him for some time, accelerated his death; which happened upon the 29th of October 1724. He was a tender, humane, and in all respects worthy man; but is represented to have had something of the irascible in his constitution and temperament. His Religion of Nature Delineated exposed him to some censure, as if he had put a slight upon Christianity, by laying so much stress, as he does in this work upon the obligations of truth, reason, and virtue; and by making no mention of revealed religion. But this censure must have been the offspring of ignorance or envy, since it appears from the introduction to his work, that he intended to treat of revealed religion in a second part, which he lived not to finish.

WOLSEY, THOMAS, a famous cardinal and archbishop of York, is said to have been the son of a butcher at Ipswich. He studied at Magdalen college, Oxford, where he became acquainted with the learned Erasmus; and in the year 1500 became rector of Lymington in Somersetshire: he was afterwards made chaplain to King Henry VIII. and obtained several preferments. Having gradually acquired an entire ascendency over the mind of Henry VIII. he successively obtained several bishoprics, and at length was made archbishop of York, lord high-chancellor of England, and prime minister; and was for several years the arbiter of Europe. Pope Leo X. created him cardinal in 1515, and made him *legate à latere;* and the emperor Charles V. and the French king Francis I. loaded him with favours, in order to gain him over to their interest; but after having first sided with the emperor, he deserted him to espouse the interest of France. As his revenues were immense, his pride and ostentation were carried to the greatest height. He had 500 servants; among whom were 9 or 10 lords, 15 knights, and 40 esquires. His ambition to be pope, his pride, his exactions, and his political delay of Henry's divorce, occasioned his disgrace. In the earlier part of his life he seems to have been licentious in his manners; it was reported, that soon after his preferment to the living of Lymington in Somersetshire, he was put into the stocks by Sir Amias Paulet, a neighbouring justice of the peace, for getting drunk and making a riot at a fair. This treatment Wolsey did not forget when he arrived at the high station of lord-chancellor of England; but summoned his corrector up to London, and, after a severe reprimand, enjoined him six years close confinement in the Temple. Whatever may have been his faults, there can be no doubt of their having been aggravated both by the zealous reformers and by the creatures of Henry VIII. who was himself neither Papist nor Protestant; for there is every reason to believe that the cardinal was sincere in his religion; and sincerity, or at least consistency, was then a crime. Wolsey was the patron of learned men; a judge and munificent encourager of the polite arts; and ought to be considered as the founder of Christchurch college, Oxford; where, as well as in other places, many remains of his magnificent ideas in architecture still exist. He died in 1530.

WOOD, ANTHONY, an eminent biographer and antiquarian, was the son of Thomas Wood, bachelor of arts and of the civil law, and was born at Oxford in 1632. He studied at Merton college, and in 1655 took the degree of master of arts. He wrote, 1. The History and Antiquities of the University of Oxford; which was afterwards translated into Latin by Mr Wase and Mr Peers, under the title of *Historia et Antiquitates Universitatis Oxoniensis*, 2 vols folio. 2. *Athenæ Oxonienses;* or an exact Account of all the Writers and Bishops who have had their education in the University of Oxford, from the Year 1500 to 1600, 2 vols folio; which was greatly enlarged in a second edition published in 1721 by Bishop Tanner. Upon the first publication of this work the author was attacked by the university, in defence of Edward earl of Clarendon, lord high chancellor of England, and chancellor of the university, and was likewise animadverted upon by Bishop Burnet; upon which he published a Vindication of the Historiographer of the University of Oxford. He died at Oxford in 1695.

WOOD, a substance whereof the trunks and branches of trees consists. It is composed of a number of concentric circles or zones, one of which is formed every year; consequently their number corresponds to the age of the tree. These zones vary in thickness according to the degree of vegetation that took place the year of their formation. They are also of different degrees of thickness in different parts, that part of the tree which is most exposed to the sun and best sheltered growing fastest; hence in this country that part of the zone which looked towards the south while the tree was growing is generally thickest. The innermost circle or zone is the one which was first formed, the outermost was formed the year before the tree was cut down. These zones are at first very soft and tender, and harden by degrees as the tree becomes older: this is the reason that the middle of a tree is so often much better wood than the outside of it.

The proper ligneous part of the wood consists of longitudinal fibres, disposed in fasciculi, and possessed of considerable hardness. It is this longitudinal direction of the fibres that renders it so much easier to cleave wood lengthwise, than across the tree, or in any other direction. See PLANT and VEGETABLE PHYSIOLOGY.

For an account of the ingredients which enter into the composition of wood, see CHEMISTRY *Index*.

For the *Method of Staining or Dyeing Wood*, see TURNING.

For more complete information concerning wood, see also TREE, and *STRENGTH of Materials*.

Fossil WOOD. Fossil wood, or whole trees, or parts of them, are very frequently found buried in the earth, and that in different strata; sometimes in stone, but more usually in earth; and sometimes in small pieces loose among the gravel. These, according to the time they have lain in the earth, or the matter they have lain among, are found differently altered from their original state; some of them having suffered very little change; and others being so highly impregnated with crystalline, sparry, pyritical, or other extraneous matter, as to appear mere masses of stone, or lumps of the common matter of the pyrites, &c. of the dimensions, and, more or less, of the internal figure, of the vegetable bodies into the pores of which they have made their way.

The fossil woods have been arranged by Dr Hill into three kinds: 1. The less altered; 2. The pyritical; and, 3. The petrified.

Of the trees, or parts of them, less altered from their original state, the greatest store is found in digging to small depths in bogs, and among what is called *peat* or *turf earth*, a substance used in many parts of the kingdom for fuel. In digging among this, usually very near the surface, immense quantities of vegetable matter of various kinds are found buried; in some places there are whole trees scarce altered, except in colour; the oaks in particular being usually turned to a jetty black; the pines and firs, which are also very frequent, are less altered, and are as inflammable as ever, and often contain between the bark and wood a black resin. Large parts of trees have also been not unfrequently met with unaltered in beds of another kind, and at much greater depths, as in strata of clay and loam, among gravel, and sometimes even in solid stone.

Besides these harder parts of trees, there are frequently found also in the peat earth vast quantities of the leaves and fruit and catkins of the hazel and similar trees; these are usually mixed with sedge and roots of grass, and are scarce at all altered from their usual texture. The most common of these are hazel nuts; but there are frequently found also the twigs and leaves of the white poplar; and a little deeper usually there lies a cracked and shattered wood, the crevices of which are full of a bituminous black matter: and among this the stones of plums and other stone-fruits are sometimes found, but more rarely.

In this state the fruits and larger parts of trees are usually found: what we find of them more altered, are sometimes large and long, sometimes smaller and shorter branches of trees; sometimes small fragments of branches, and more frequently small shapeless pieces of wood. The larger and longer branches are usually found bedded in the strata of stone, and are more or less altered into the nature of the stratum they lie in. The shorter and smaller branches are found in vast variety in the strata of blue clay used for making tiles in the neighbourhood of London. These are prodigiously plentiful in all the clay-pits of this kind, and usually carry the whole external resemblance of what they once were, but nothing of the inner structure; their pores being wholly filled, and undistinguishably closed, by the matter of the common pyrites, so as to appear mere simple masses of that matter. These fall to pieces on being long exposed to moisture; and are so impregnated with vitriol that they are what is principally used for making the green vitriol or copperas at Deptford and other places.

The irregular masses or fragments of petrified wood are principally of oak, and are most usually found among gravel; though sometimes in other strata. These are variously altered by the insinuation of crystalline and stony particles; and make a very beautiful figure when cut and polished, as they usually keep the regular grain of the wood, and show exactly the several circles which mark the different years growth. These, according to the different matter which has filled their pores, assume various colours, and the appearance of the various fossils that have impregnated them; some are perfectly white, and but moderately hard; others of a brownish black, or perfectly black, and much harder; others of a reddish black, others yellowish, and others grayish, and some of a ferruginous colour. They are of different weights also and hardnesses, according to the nature and quantity of the stony particles they contain: of these some pieces have been found with every pore filled with pure pellucid crystal; and others in large masses, part of which is wholly petrified and seems mere stone, while the rest is crumbly and is unaltered wood. That this alteration is made in wood, even at this time, is also abundantly proved by the instances of wood being put into the hollows of mines, as props and supports to the roofs, which is found after a number of years as truly petrified as that which is dug up from the natural strata of the earth. In the pieces of petrified wood found in Germany, there are frequently veins of spar or of pure crystal, sometimes of earthy substances, and often of the matter of the common pebbles: these fragments of wood sometimes have the appearance of parts of the branches of trees in their natural state, but more frequently they resemble pieces of broken boards; these are usually capable of a high and elegant polish.

Many

Wood.

Many substances, it is certain, have been preserved in the cabinets of collectors, under the title of *petrified wood*, which have very little right to that name. But where the whole outer figure of the wood, the exact lineaments of the bark, or the fibrous and fistular texture of the striæ, and the vestiges of the utriculi and tracheæ or air-vessels, are yet remaining, and the several circles yet visible which denoted the several years growth of the tree, none can deny these substances to be real fossil wood. See PETRIFACTION.

Dr Parry of Bath has recently investigated the causes of the decay of wood, and the means of preventing it. For this purpose he recommends the application of a preparation of the resinous kind, mixed with a certain portion of bees-wax. The proportion of the ingredients and the mode of mixing them are as follows: Take 12 ounces of rosin and 8 ounces of roll brimstone, each coarsely powdered, and 3 gallons of train oil; beat them slowly, gradually adding 4 ounces of bees-wax, cut into small bits. Frequently stir the liquor, which, as soon as the solid ingredients are dissolved, will be fit for use. It is recommended to dress every part of the wood-work with this composition twice over before the parts are put together, and once afterwards; and a higher state of preservation is promised from its use than has yet been attained. It should be observed, that in preparing this varnish, it is advisable, in order to prevent accidents, to use an earthen vessel, and to make the fire in the open air.

WOOD (*sylva*), in *Ancient Geography*, a multitude of trees extended over a large continued tract of land, and propagated without culture. The generality of woods only consist of trees of one kind.—The ancient Saxons had such a veneration for woods, that they made them sanctuaries.—It is ordained, that none shall destroy any wood, by turning it into tillage or pasture, &c. where there are two acres or more in quantity, on pain of forfeiting 40s. an acre, by 35 Henry VIII. c. 17. All woods that are felled at 14 years growth, are to be preserved from destruction for eight years; and no cattle put into the ground till five years after the felling thereof, &c. 13 Eliz. c. 25. The burning of woods or underwood is declared to be felony; also those persons that maliciously cut or spoil timber-trees, or any fruit-trees, &c. shall be sent to the house of correction, there to be kept three months, and whipt once a month.

WOOD, *Engraving on*, is commonly executed on box; and in many cases, engravings of this kind are used with advantage instead of copperplates. The art of cutting or engraving on wood is of very high antiquity; for Chinese printing is a specimen of it. Even in Europe, if credit be due to Papillon, this art was practised at a very remote period; for he mentions eight engravings on wood, entitled, "A representation of the warlike actions of the great and magnanimous Macedonian king, the bold and valiant Alexander; dedicated, presented, and humbly offered, to the most holy father, Pope Honorius IV. by us Alexander Arberic Cunio Chevalier, and Isabella Cunio, &c." This anecdote, if true, carries the art of cutting in wood back to 1284 or 1285; for Honorius occupied the papal throne only during these two years. But this is not the remotest period to which some have carried the art in Europe: for the use of seals or signets being of very high antiquity, they imagine that the invention of wood-cuts must be coeval with them. The supposition is certainly plausible, but it is not supported by proof. The earliest impression of a wooden-cut, of which there is any certain account, is that of St Christopher carrying an infant Jesus through the sea, in which a hermit is seen holding up a lanthorn to shew him the way; and a peasant, with a sack on his back, climbing a hill, is exhibited in the back ground. The date of this impression is 1423. In the year 1430 was printed at Haerlem, "The history of St John the evangelist and his revelation, represented in 48 figures in wood, by Lowrent Janson Coster;" and, in 1438, Jorg Schappf of Augsburg cut in wood the history of the Apocalypse, and what was called *The poor man's bible*.

A folio chronicle, published 1493 by Shedal, was adorned with a great number of wooden-cuts by William Plydenwurff and Michael Wolgemut, whose engravings were greatly superior to any thing of the kind which had appeared before them. The latter was the preceptor of Albert Durer, whose admirable performances in this department of art are justly held in the highest esteem even at the present day.

About this period it became the practice of almost all the German engravers on copper to engrave likewise on wood; and many of their wood cuts surpass in beauty the impressions of their copperplates. Such are the wood-cuts of Albert Aldtorfer, Hisbel Pen, Virgil Soles, Lucas Van Cranach, and Lucas Van Leyden, the friend and imitator of Albert Durer, with several others.

The Germans carried this art to a great degree of perfection. Hans or John Holbein, who flourished in 1500, engraved the *Dance of Death*, in a series of wooden-cuts, which, for the freedom and delicacy of execution, have scarcely been equalled, and never surpassed. Italy, France, and Holland, have produced capital artists of this kind. Joan. Tornæsiom printed a bible at Leyden, in 1554, with wooden-cuts of excellent workmanship. Christopher Jegher of Antwerp, from his eminence in the art, was employed by Rubens to work under his inspection, and he executed several pieces which are held in much estimation; they are particularly distinguished for boldness and spirit.

The next attempt at improvement in this art was by Hugo da Carpi, to whom is attributed the invention of the *chiaro scuro*. Carpi was an Italian, and of the 16th century; but the Germans elaim the invention also, and produce in evidence several engravings by Mair, a disciple of Martin Schoen, of date 1499. His mode of performing this was very simple. He first engraved the subject upon copper, and finished it as much as the artists of his time usually did. He then prepared a block of wood upon which he cut out the extreme lights, and then impressed it upon the print; by which means a faint tint was added to all the rest of the piece, excepting only in those parts where the lights were meant to predominate, which appear on the specimens extant to be coloured with white paint. The drawings for this species of engraving were made on tinted paper with a pen, and the lights were drawn upon the paper with white paint.

But there is a material difference between the chiaro scuro of the old German masters and that of the Italians. Mair and Cranach engraved the outlines and deep

deep shadows upon copper. The impression taken in this state was tinted over by means of a single block of wood, with those parts hollowed out which were designed to be left white upon the print. On the contrary, the mode of engraving by Hugo da Carpi was, to cut the outline on one block of wood, the dark shadows upon a second, and the light shadows, or half-tint, upon a third. The first being impressed upon the paper, the outlines only appeared: this block being taken away, the second was put in its place, and being also impressed on the paper, the dark shadows were added to the outlines; and the third block being put in the same place upon the removal of the second, and also impressed upon the paper, made the dim tints, when the print was completed. In some instances, the number of blocks was increased, but the operation was still the same, the print receiving an impression from every block.

In 1698, John Baptist Michael Papillon practised engraving on wood with much success, particularly in ornamental foliage and flowers, shells, &c. In the opinion, however, of some of the most eminent artists, his performances are stiff and cramped. From that period the art of engraving on wood gradually degenerated, and may be said to have been wholly lost, when it was lately re-invented by Mr Bewick of Newcastle. This eminent artist was apprentice to Mr Bielby, a respectable engraver on metal. Mr Bielby, who was accustomed to employ his apprentices in engraving on wood, was much gratified with the performance of Thomas Bewick, and therefore advised him to prosecute engraving in that line. The advice was followed; and young Bewick inventing tools, even making them with his own hands, and sawing the wood on which he was to work into the requisite thickness, proceeded to improve upon his own discoveries, without assistance or instruction of any kind. When his apprenticeship expired, he went to London, where the obscure wood engravers of the time wished to avail themselves of his abilities, while they were determined to give him no insight into their art. During his apprenticeship, he received from the Society for the Encouragement of Arts, &c. a premium of considerable value for the best engraving on wood. The cut which obtained the premium was one of a series for an edition of Gay's Fables. Having remained some years in London, he returned to Newcastle, and entered into copartnership with his old master; and established his reputation as an artist by the publication of his admirable History of Quadrupeds. This was followed by his History of Birds, in 2 vols. The greater part of the volume on Quadrupeds, and the whole of the first volume of the work on Birds, was composed by Mr Bielby.

John Bewick, brother to Thomas, learned the art of him, and practised it for several years in London with great applause. His abilities, however, though respectable, were not, by the best judges, deemed so brilliant as his brother's; and owing to bad health, and the nature of his connection with the booksellers and others, he seems not to have advanced the art beyond the stage at which he received it. He died, some years ago, at Newcastle.

Mr Nesbit, who executed the admirable cuts from designs by Thornton, for an edition of Hudibras, as well as the cuts for editions of Shakespeare and Thomson's Seasons, and Mr Anderson, whose beautiful cuts adorn the poem entitled *Grove Hill*, have been the most successful of Thomas Bewick's pupils, who have appeared before the public as artists. It appears, that the method practised by the ancient engravers on wood, whose works are still admired, must have been different from that of Bewick and his pupils. What that method was seems to be altogether unknown. Papillon, who writes the best history extant of the art, guesses indeed in what manner the old engravers proceeded, so as to give to their works the spirit and freedom for which they are famed; but that his guesses are erroneous seems evident from the stiffness of his own works. The principal characteristic in the mechanical department of the productions of the ancient masters is the crossing of the black lines, which Papillon has attempted with the greatest awkwardness, though it seems to have been accomplished by them with so much ease, that they introduced it at random, even where it could add nothing to the beauty of the piece. In Bewick's method of working, this cross hatching is so difficult and unnatural, that it may be considered as impracticable. Mr Nesbit has indeed introduced something of it into two or three of his pieces; but so great was the labour, and so little the advantage of this improvement, if such it can be called, that probably it will not be attempted again.

The engravers of Bewick's school work on the end of the wood, which is cut across the trunk of the tree, in pieces of the proper thickness. As wood cuts are generally employed in the printer's press amidst a form of types, this thickness must be regulated by the height of the types with which they are to be used. The tools employed are nearly the same with those used in copperplate engraving, being only a little more deep, or lozenge, as engravers call it. They must have points of various degrees of fineness for the different purposes to which they are applied, some of them being so much rounded off at the bottom as to approach to the nature of a goodge, whilst others are in fact little chissels of various sizes. These chissels and goodges, to which every artist gives the shape which he deems most convenient, are held in the hand in a manner somewhat different from the tool of the engraver on copper, it being necessary to have the power of lifting the chips upwards with ease. To attempt a description of this in writing would be in vain; but it is easily acquired, we are told, by practice.

The pupils of the school of Bewick consider it as quite improper to speak of his invention as a revival of the ancient art. Some old prints, it is true, have the appearance of being executed in the same way with his; but others have certainly been done by a method very different. It is therefore not fair to appreciate the present art by what has been done, but by what may be done; and that remains yet to be shewn. The art is in its infancy; and those who are disposed to compare it with the art of engraving on copper, ought to look back to the period when copperplate engraving was of as recent invention as Bewick's method of engraving on wood. Marc Antonio, who engraved under the direction of the great painter Raphael, thought it no mean proof of his proficiency in his art, that he was able to imitate on copperplates the wood-cuts of Albert Durer; and Papillon is highly indignant that there should have been persons so very blind as to mistake the copies for the originals. If copper has its advantages over wood in point of delicacy and minuteness, wood has, in its turn, advantages not inferior in regard to strength and richness. Those prints which were executed under the auspices of Titian and Rubens, will always remain a monument of the spirit and vigour natural to wood-engraving; and if there be not found in them all the attention to chiaro scuro, which the present age demands, it must not be attributed either to defect in the art, or to want of abilities in the artists, but to the taste of the times, when chiaro scuro was little understood. It remains for some enterprising artist to shew that the vigour of the ancient art may be attained by the present one, and at the same time to add to that vigour those gradations of shade which are so much admired in good copperplates. As there seems to be a more perfect, or at least a more pleasant black produced by wood than by copperplate printing, and certainly a more perfect white (A), who will say that any intermediate shade whatever may not be produced by wood cuts? To attempt this on a small scale would indeed be vain, because the slightest variation, produced by a little more or less ink, or a harder pressure in printing, bears such a proportion to a very short line, as must necessarily render the attempt abortive.

Wood-engraving, therefore, must always appear to disadvantage while it is confined to small subjects, and will never reach its station *as a fine art*, till those who are engaged in its cultivation improve upon the discoveries of one another, and apply to subjects to which it is properly adapted. As an *economical art* for illustrating mechanics, various branches of natural history, and other subjects of science, it is too little employed even in its present state.

The works of Bewick and his pupils, which have hitherto been published, are not numerous. Besides his quadrupeds and birds, the Hudibras, and the cuts for some editions of Shakespeare and Thomson's Seasons, by Nesbit, and the Grove Hill by Anderson, already noticed, there are also some others of less note.—Goldsmith's Traveller and Deserted Village with elegant plates, are all executed by Thomas Bewick, except one or two which were executed by John; Somerville's Chace by the same artists, executed in a style of elegance which perhaps has never been surpassed; a View of St Nicholas's Church, Newcastle, 15 inches long, by Mr Nesbit, who received for it a silver medal from the Society for the Encouragement of Arts.

Wood, Rotten, Illumination of. This is a subject which has often been discussed by naturalists. Spallanzani maintained, that there is a perfect analogy between the illumination of rotten wood, and artificial phosphorus; and he imagines, that in the putrid fermentation, the hydrogen and the carbone of the wood come more easily in contact with the oxygen of the atmosphere, by which combination a slow combustion, and the illumination of the wood, is produced; and he thinks that this process cannot proceed in the irrespirable kinds of gases. Rotten wood also, in which the necessary quantity of hydrogen and carbone is not at the same time disengaged, does not obtain the property of illuminating. Mr Corradori, however, objects to this theory, that the slow combustion does not take place according to the above theory, as the wood, at the time when it begins to illuminate, is mostly deprived of its resinous particles, and consequently contains but very little hydrogen and carbone; and it appears to him more probable, that the more it loses of combustible matter, the more it obtains the property of illuminating. There is, he thinks, a very great difference between this natural and the artificial phosphorus. Mr Humboldt concludes, from his experiments, that the illumination of rotten wood takes place only when it gets into contact with oxygen; and when it has lost the property of emitting light in irrespirable gases, it recovers it again by exposing it to oxygen gas. Dr Gartner, however, is of opinion, that, according to his experiments, a certain degree of humidity is always requisite, and he thinks that oxygen gas is not quite necessary though the illumination be increased by it. This phenomenon, however, being so very different from all known processes of combustion, where light is disengaged, Dr Gartner asks, whether it be not more agreeing with the animal process of respiration, than with a true combustion, or whether the illumination of the wood be produced by phosphorus and carbone in a proportion hitherto unknown. Dr Gartner is, on the whole, inclined to think, that it is at present impossible to give a satisfactory explanation of all the phenomena that occur in this process. Beckmann has made numerous experiments on the illumination of rotten wood, in different gases and fluids, in order to throw some light on the ideas of the above naturalists. The results of these experiments differ in some points from what the experiments of those gentlemen have shewn, which, however, Beckmann ascribes to the nature of rotten wood, as a substance that is not always of the same kind, and has not always an equal degree of putrefaction and humidity. It seems also to differ materially from the artificial phosphorus in the following particulars. 1. It shines in oxygen gas at a very low temperature. 2. It emits light in all irrespirable gases, at least for a short time. 3. In muriatic acid gas its light is suddenly extinguished. 4. It shines in a less degree in air rarefied by the air-pump. 5. According to Mr Corradori, it even shines in the torricellian vacuum. 6. Its illumination is extinguished in oxygen gas, as well as in other kinds of gases, when they are heated. 7. By its illumination in oxygen gas, carbonic acid gas is produced. 8. One may suffer the rotten wood to be extinguished several times, one after another, in irrespirable gases, without depriving them of the property of making new pieces of rotten wood shine again. 9. Humidity greatly promotes the illumination, and even seems to be necessary in producing it. 10. The rotten wood continues to shine under water, oil, and other fluids, and in some of them its light is even increased. All this seems to shew, that the extinction of rotten wood, in different media, does not immediately depend on a want of oxygen, but rather on a particular change, to which the wood itself has been exposed.

WOODSTOCK, a town of Oxfordshire, in England, pleasantly seated on a rising ground, and on a rivulet; a well compacted borough-town, and sends two members to parliament; but is chiefly noted for Blenheim-house, a fine palace, built in memory of the victory obtained by the duke of Marlborough over the French and Bavarians in August 1704. It was erected at the public expence, and is one of the noblest seats in Europe. One of the passages to it is over a bridge with one arch, 190 feet in diameter, resembling the Rialto at Venice. The gardens take up 100 acres of ground; and the offices, which are very grand, have room enough to accommodate 300 people. The apartments of the palace are magnificently furnished; and the staircases, statues, paintings, and tapestry, surprisingly fine. The town is about half a mile from the palace, having several good inns; and a manufacture of steel chains for watches, and excellent gloves. A steel chain has been made at this place which sold for 170l.—The population in 1811 was 1419 persons. It is eight miles north of Oxford, and 60 west-north-west of London. W. Long. 1. 30. N. Lat. 51. 52.

WOODWARD, Dr John, was born in 1665, and educated at a country school, where he learned the Latin and Greek languages, and was afterwards sent to London, where he is said to have been put apprentice to a linen-draper. He was not long in that station, till he became acquainted with Dr Peter Barwick, an eminent physician, who took him under his tuition and into his family. Here he prosecuted with great vigour and success the study of philosophy, anatomy, and physic. In 1692, Dr Stillingfleet quitting the place of professor of physic in Gresham college, our author was chosen to succeed him, and the year following was elected F. R. S. In 1695 he obtained the degree of M. D. by patent from Archbishop Tennison; and the same year he published his Essay towards a Natural History of the Earth. He afterwards wrote many other pieces, which have been well received by the learned world. He founded a lecture in the university of Cambridge, to be read there upon his Essay, &c. and handsomely endowed it. He died in 1728.

WOOKEY or *Okey Hole*, a remarkable cavern two miles from the city of Wells in Somersetshire; for an account of which, see the article Grotto.

WOOL, the covering of sheep. See Ovis and Sheep.

Wool resembles hair in a great many particulars; but besides its fineness, which constitutes an obvious difference, there are other particulars which may serve also to distinguish them from one another. Wool, like the hair of horses, cattle, and most other animals, completes its growth in a year, and then falls off as hair does, and is succeeded by a fresh crop. It differs from hair, however, in the uniformity of its growth, and the regularity of its shedding. Every filament of wool seems to keep exact pace with another in the same part of the body of the animal; the whole crop springs up at once; the whole advances uniformly together; the whole loosens from the skin nearly at the same period, and thus falls off, if not

See, vol. viii. p. 57.

Wool.

previously shorn, leaving the animal covered with a short coat of young wool, which in its turn undergoes the same regular mutations.

Hairs are commonly of the same thickness in every part; but wool constantly varies in thickness in different parts, being generally thicker at the points than at the roots. That part of the fleece of sheep which grows during the winter is finer than what grows in summer. This was first observed by Dr Anderson, the editor of the Bee, and published in his *Observations on the Means of exciting a Spirit of National Industry*.

While the wool remains in the state it was first shorn off the sheep's back, and not sorted into its different kinds, it is called *fleece*. Each fleece consists of wool of divers qualities and degrees of fineness, which the dealers therein take care to separate. The French and English usually separate each fleece into three sorts, viz. 1. Mother-wool, which is that of the back and neck. 2. The wool of the tails and legs. 3. That of the breast and under the belly. The Spaniards make the like division into three sorts, which they call *prime*, *second*, and *third*; and for the greater ease, mark each bale or pack with a capital letter, denoting the sort. If the triage or separation be well made, in 15 bales there will be 12 marked R, that is, refine, or prime; two marked F, for fine, or second; and one S, for thirds.

The wools most esteemed are the English, chiefly those about Leominster, Cotswold, and the isle of Wight; the Spanish, principally those about Segovia; and the French, about Berry: which last are said to have this peculiar property, that they will knot or bind with any other sort; whereas the rest will only knot with their own kind.

Among the ancients, the wools of Attica, Megara, Laodicea, Apulia, and especially those of Tarentum, Parma, and Altino, were most valued. Varro assures us, that the people there used to clothe their sheep with skins, to secure the wool from being damaged.

Of late a great deal of attention has been paid to wool in this country, as well as several others. Several very spirited attempts have been made to improve it, by introducing superior breeds of sheep, and better methods of managing them. For this purpose has been formed the

British Wool Society, an association formed for the purpose of obtaining the best breeds of fine-woolled sheep, with a view of ascertaining, by actual experiments, how far each species or variety is calculated for the climate of Great Britain; the qualities of their wool respectively; the uses to which each kind of wool could be most profitably employed in different manufactures; and the comparative value of each species of sheep, so far as the same can be determined.

Attention had for some time been paid by the Highland Society to a famous breed of fine-woolled sheep in Shetland; but it occurred to Sir John Sinclair of Ulbster, baronet, and to Dr James Anderson, well known as the author of many useful publications, that the improvement of British wool was a matter of too much importance to be entrusted to a society which is obliged to devote its attention to such a variety of objects as the general improvement of the Highlands of Scotland. The latter of these gentlemen, therefore, in an Appendix to the Report of the Committee of the Highland

 Society

Wool. Society of Scotland, for the year 1790, proposed *the plan of a patriotic association for the improvement of British wool;* and the former, who was convener of the committee to whom the subject of Shetland wool had been referred, wrote circular letters, recommending the plan. The consequence of which was, that on the 31st of January 1791, several noblemen and gentlemen of the highest respectability met in Edinburgh, and constituted themselves into a *Society for the Improvement of British Wool.* Of this society Sir John Sinclair was elected president; after which, in an excellent speech, he pointed out to the members the objects of the institution, the means by which those objects could be attained, and the advantages which would result from their united labours. This address was afterwards printed by order of the society.

The particular breeds of sheep to which the society proposed to direct its attention, were sheep for the hilly parts of Scotland; sheep for the plains, or the Lowland breed; and sheep for the islands. They were to try experiments also with sheep from foreign countries, distinguished by any particular property.

The principal objects which the members had in view, during the first year of their association, were, 1. To collect specimens of the best breeds which Great Britain at that period afforded, in order to ascertain the degree of perfection to which sheep had already been brought in this kingdom. 2. To procure from every country, distinguished for the quality of its sheep and wool, specimens of the different breeds it possessed, in order to ascertain how far the original breed, or a mixed breed from it and the native sheep of the country, could thrive in Scotland. 3. To disperse as much as possible all these breeds, both foreign and domestic, over the whole kingdom, wherever proper persons could be found to take charge of them, in order to try experiments on a more extensive scale than the society itself could do; to spread information, and to excite a spirit for the improvement of sheep and wool in every part of the country.

Sir John Sinclair had previously collected a flock, consisting of sheep of the Spanish, Herefordshire, Southdown, Cheviot, Lomond hills, and Shetland breeds, and of a mixed breed from these different sheep. This flock amounted to 110 rams, ewes, and lambs. M. d'Aubenton, in consequence of a correspondence with Sir John Sinclair, sent over to the society ten rams and five ewes, of real Spanish breed, which had been originally entrusted to his care by the late king of France: these, after encountering a number of obstacles, and after being stopped and threatened to be slaughtered at the customhouse of Brighthelmstone for the use of the poor, arrived safe at Leith. Lord Sheffield, at the same time, sent to the society four rams and six ewes of the Southdown and Spanish breeds. Mr Bishton of Kilsall, in Shropshire, presented them with three Hereford rams, reckoned by many the best breed in England; the society at the same time ordered 150 ewes of the same breed, and two ewes of the Long Mountain breed, reckoned the best in Wales, to be sent along with them. They purchased 57 rams and 173 ewes of the Cheviot breed, reckoned the best in Scotland, for the hilly parts of the country. Lord Daer sent them 20 ewes of an excellent breed, which existed at Mochrum in Galloway. The late earl of Oxford sent them in a present three rams of the Norfolk crossed by the Cape of Good Hope breed. Mr Isaac Grant junior of Leghorn, in conjunction with Mr Sibbald, merchant at Leith, presented them an Apulian ram and ewe; the ram arrived in safety, but the ewe unfortunately died on the passage. Mr Baron Seton of Preston, in Linlithgowshire, sent them a ram and two ewes of a Spanish breed, which had been for some time kept in Sweden unmixed with any other. They purchased 100 ewes of a small breed existing in the parish of Leuchars in Fife, much resembling the Shetland. The Right Honourable William Conynghame of Ireland sent them 11 Spanish rams, seven Spanish ewes, 15 three-fourth breed and 16 one-half breed Spanish and Irish ewes. Lord Sheffield sent them eight rams and 18 ewes; and his majesty made them a present of two rams.

Thus, in the course of one year, the society acquired by donation or purchase about 800 sheep of different sorts and ages, and many of them from foreign countries: about 500 of these were distributed over different parts of Scotland, the greater number of which were sold to gentlemen anxious to promote the views of the society, and well qualified to make experiments on the different breeds which they had obtained. The greatest part of the remainder were taken by different gentlemen, who kept them for the society, and according to their directions, without any expence.

It is impossible to produce an instance of so much having been accomplished by a society of private individuals in so short a time. Nor was this all; the same year Mr Andrew Kerr, a very intelligent sheep-farmer on the borders of England, was sent, at the expence of the society, to examine the state of sheep-farming along the east coast of Scotland and the interior parts of the Highlands. His tour was printed by order of the society, and contains the first intimation of the possibility of the Cheviot breed thriving in the north of Scotland.

In the year 1792, Messrs Redhead, Laing, and Marshall were sent by the society, to make a survey of the state of sheep-farming through some of the principal counties of England; the result of which was also published by the society, and contains more information on the subject of the different breeds of England than any work hitherto published; and in 1794, Mr John Naismyth was sent on a tour through the southern districts of Scotland, which completed the circuit of almost the whole kingdom.

Thus a few private individuals, unaided by the public purse, had boldness enough to undertake ascertaining the comparative value of the different kinds of sheep in their own country, and to introduce some of the most celebrated breeds of other countries, and succeeded in the spirited attempt. It is impossible in this place to state more minutely the various other transactions of the society; to enter into any detail of the premiums given by this respectable institution for the improvement of the celebrated Shetland breed; or to explain how, as if it were by magic, in a country where the manufacture of wool was little known, articles manufactured of that material were made, rivalling, and in some cases surpassing, the most celebrated fabrics of other countries. A war having unfortunately arisen, it became impossible to pay the same attention, or to carry on with the same success, novel enterprises; even old

Wool, Wool-combing.

old establishments often fall a sacrifice amidst the horrors of war. The utmost that the British Wool Society could expect to do, was to preserve the institution in such a state, that when peace shall be happily restored it may revive with double energy and spirit.

It is a curious fact that the Romans, during their residence in Britain, established a manufactory of woollen cloth at Winchester, which was so extensive as to supply their army; and there is reason to believe that the trade which they introduced into Britain, was not neglected by the native inhabitants, for the first 900 years of the Christian era. The long Spanish wool was imported into this country so early as the 12th century, and we find that since the days of Edward III. British fleeces were admirably adapted to the kind of cloth which was in greatest request, though now they are generally unequal to the production of that which is sought after.

Wool-Combing, a well known operation, which, when performed by the hand, is laborious, tedious, and expensive. The expence of it through all England has been calculated at no less a sum than 800,000l.; and to lessen this expence, the Rev. Edmund Cartwright of Doncaster in Yorkshire bethought himself, some years ago, of carding wool by machinery. After repeated attempts and improvements, for which he took out three patents, he found that wool can be combed in perfection by machinery, of which he gives the following description.

Plate DLXXVIII. fig. 1.

Fig. 1. is the crank lasher. A is a tube through which the material, being formed into a sliver, and slightly twisted, is drawn forward by the delivering rollers; B, a wheel fast upon the cross bar of the crank; C, a wheel, on the opposite end of whose axis is a pinion working in a wheel upon the axis of one of the delivering rollers.

Note. When two or more slivers are required, the cans or baskets, in which they are contained, are placed upon a table under the lasher (as represented at D), which, by having a slow motion, twists them together as they go up.

Fig. 2. Fig. 3.

Fig. 2. is the circular clearing comb, for giving work in the head, carried in a frame by two cranks. Fig. 3. the comb-table, having the teeth pointing towards the centre, moved by cogs upon the rim, and carried round upon trucks like the head of a windmill. *a*, *b*, The drawing rollers. *c*, *d*, Callendar, or conducting rollers.

Note. Underneath the table is another pair of rollers, for drawing out the backings.

In the above specification, we have omitted the frame in which the machine stands, the wheels, shafts, &c. Had these been introduced, the drawing would have been crowded and confused; besides, as matters of information, they would have been unnecessary, every mechanic, when he knows the principles of a machine, being competent to apply the movements to it.

The wool, if for particularly nice work, goes through three operations, otherwise two are sufficient: the first operation opens the wool, and makes it connect together into a rough sliver, but does not clear it. The clearing is performed by the second, and, if necessary, a third operation. A set of machinery, consisting of three machines, will require the attendance of an overlooker and ten children, and will comb a pack, or 240lb. in twelve hours. As neither fire nor oil is necessary for machine-combing, the saving of those articles, even the fire alone, will, in general, pay the wages of the overlooker and children; so that the actual saving to the manufacturer is the *whole* of what the combing costs, by the old imperfect mode of hand-combing. Machine-combed wool is better, especially for machine-spinning, by at least 12 per cent. being all equally mixed, and the slivers uniform, and of any required length.

Wool-combing ‖ Worcester.

WOOLSTON, Thomas, an English divine, was born at Northampton in 1669, and educated at Cambridge. His first appearance in the learned world was in 1705, in a work entitled, The Old Apology for the Truth of the Christian Religion, against the Jews and Gentiles, revived. He afterwards wrote many pieces: but what made the most noise, were his six Discourses on the Miracles of Christ; which occasioned a great number of books and pamphlets upon the subject, and raised a prosecution against him. At his trial in Guildhall, before the lord chief justice Raymond, he spoke several times himself; and urged, that "he thought it very hard that he should be tried by a set of men who, though otherwise very learned and worthy persons, were no more judges of the subjects on which he wrote, than himself was a judge of the most crabbed points of the law." He was sentenced to a year's imprisonment, an to pay a fine of 100l. He purchased the liberty of the rules of the King's bench, where he continued after the expiration of the year, being unable to pay the fine. The greatest obstruction to his deliverance from confinement was, the obligation of giving security not to offend by any future writings, he being resolved to write again as freely as before. Whilst some supposed that this author wrote with the settled intention of subverting Christianity under the pretence of defending it, others believed him disordered in his mind; and many circumstances concurred which gave countenance to this opinion. He died, January 27. 1732-3, after an illness of four days; and, a few minutes before his death, uttered these words: "This is a struggle which all men must go through, and which I bear not only patiently, but with willingness." His body was interred in St George's church-yard, Southwark.

WOOLWICH, a town in Kent, with a market on Fridays. It is seated on the river Thames, and of great note for its fine docks and yards, where men of war are built; as also for its vast magazines of great guns, mortars, bombs, cannon-balls, powder, and other warlike stores. It has likewise an academy, where young officers are instructed in the military art; the population in 1801 exceeded 9000. It is nine miles east of London. E. Long. 0. 10. N. Lat. 51. 30.

WORCESTER, in Latin *Wigornia*, the capital of a county of England of the same name, stands on the river Severn, but so low that it can hardly be seen till one is close upon it. It is supposed to be the Branonium of Antoninus, the Branogenium of Ptolemy, and to have been built by the Romans to awe the Britons on the other side of the Severn. It was made an episcopal see about the year 680 by Sexulphus bishop of the Mercians; but the present cathedral was begun by Wulston in the year 1084. The town hath been several times burnt down; first, in 1041, by Hardicanute, who also massacred the citizens; secondly, not long after William Rufus's time; and a third time, when King Stephen besieged and took it. Here, in latter times, was

Worcester. was fought that battle, in which Charles II. with his Scots army, was defeated by Cromwell. In a garden near the south gate of the city, where the action was hottest, the bones of the slain are often dug up. It had formerly strong walls and a castle; but these have been demolished long ago. It is now a large city, the streets broad and well paved, and some of them very regular and well built, particularly Foregate-street; so that in general it is a very agreeable place. The cathedral is a stately edifice, and among other monuments in it are those of King John, of Arthur, elder brother to Henry VIII. and of the countess of Salisbury, who gave occasion to the institution of the order of the Garter. There are seven or eight hospitals in and about the city; of which that built and endowed by Robert Berkley of Spetchley, Esq. is a very noble one. There is a school founded by Henry VIII. three other schools, and six charity-schools. The churches, St Nicholas and All-Saints, have been lately rebuilt, and are handsome edifices. The city carries on a great trade; for which it is chiefly indebted to its situation upon the Severn. The population in 1801 was estimated at 11,000, a large proportion of which is employed in the manufacture of broad cloth and gloves. The Welch inhabit a part of it, and speak their own language. Its market is well supplied with provisions and cattle, and its quay is much frequented by ships. By a charter from James I. it is governed by a mayor, six aldermen who are justices of the peace, and chosen out of 24 capital citizens; a sheriff, the city being a county of itself; a common council, consisting of 48 other citizens, out of which two chamberlains are yearly chosen; a recorder, town-clerk, two coroners, a sword-bearer, 13 constables and four serjeants at mace. Of the bishops of this see, there have been, it is said, one pope, four saints, seven lord high chancellors, 11 archbishops, two lord treasurers, one chancellor to the queen, one lord president of Wales, and one vice-president. The city at present gives title of earl and marquis to the duke of Beaufort. W. Long. 1. 55. N. Lat. 52. 10.

WORCESTER, *Edward Somerset, Marquis of*, was a distinguished political character in the time of Charles I. by whom he was created earl of Glamorgan, while heir apparent to the marquis of Worcester. This nobleman flourished chiefly in the reign of Charles I. and seems to have been a most zealous adherent to the cause of that unfortunate monarch, on whose account it is said that he and his father wasted an immense sum. Of this the king was so sensible, that he granted to the earl a most extraordinary patent, the chief powers of which were, to make him generalissimo of three armies, and admiral with nomination of his officers; to enable him to raise money by selling his majesty's woods, wardships, customs, and prerogatives; and to create by blank patents, to be filled up at Glamorgan's pleasure, from the rank of marquis to baronet. If any thing, says Lord Orford, could justify the delegation of such authority, besides his majesty having lost all authority, when he conferred it, it was the promise with which the king concluded, of bestowing the princess Elizabeth on Glamorgan's son. This patent was given up by the marquis to the house of peers after the restoration. He died not long after that era, in 1667, after he had published what Lord Orford calls the following amazing piece of folly.

"A century of the names and scantlings of such inventions, as at present I can call to mind to have tried and perfected, which (my former notes being lost) I have, at the instance of a powerful friend, endeavoured now in the year 1655, to set these down in such a way as may sufficiently instruct me to put any of them in practice."

Some of the inventions referred to in this work are the following. A ship-destroying engine, a coach-stopping engine, a balance water-work, a bucket fountain, an ebbing and flowing castle clock, a tinder-box pistol, a pocket ladder, a most admirable way to raise weights, a stupendous water-work. For the last contrivance the marquis procured an act of parliament in 1663, for the sole benefit arising from it, one-tenth of it being appropriated to Charles II. and his successors.

In a manuscript addition to a copy of the Century of Inventions, the stupendous or water-commanding engine is described as boundless for height or quantity, requiring no external, or even additional help or force to be set or continued in motion, but what intrinsically is afforded from its own operation, nor yet the twentieth part thereof, and the engine consisteth of the following particulars. 1. A perfect counterpoise for what quantity soever of water. 2. A perfect countervail, for what height soever it is to be brought unto. 3. A primum mobile, commanding both height and quantity, regulator-wise. 4. A vicegerent or countervail, supplying the place, and performing the full force of man, wind, beast, or mill. 5. A helm or stern, with bit and reins, wherewith any child may guide, order, and controul the whole operation. 6. A particular magazine for water, according to the intended quantity or height of water. 7. A place for the original fountain, or even river to run into, and naturally of its own accord incorporate itself with the rising water and at the very bottom of the same aqueduct, though never so big or high.

Various and very opposite opinions have been held with regard to the title of this nobleman to be considered as a mechanical genius. Lord Orford has pronounced his work an amazing piece of folly; and Mr Hume, speaking of his political conduct, says, "That the king judged aright of this nobleman's character, appears from his Century of Arts, or Scantling of inventions, which is a ridiculous compound of lies, chimeras, and impossibilities, and shows what might be expected from such a man." *Hist. of England.* It may be fairly presumed from the quotations now made, that neither Lord Orford nor Mr Hume was qualified to judge of the marquis's work, otherwise a more temperate or a more modified opinion would have been given. By others, the author of the inventions has been regarded as one of the greatest mechanical geniuses, and is to be considered as the inventor of the steam-engine, which he denominates a stupendous water-work. There seems to be no reason to suppose that any steam-engine was erected by the marquis himself; but it is said that Captain Savary, after reading the marquis's books, tried many experiments upon the power and force of steam, and at last fell upon a method of applying it to raise water; and having bought up and destroyed all the marquis's books that could be got, claimed the honour of the invention to himself, and obtained a patent for it.

The

The marquis of Worcester is sometimes confounded with John Tiptoft, earl of Worcester, a very accomplished literary character, who lived in the times of Henry VI. and Edward IV. Being attached to Edward, he absconded during the short restoration of Henry, and being taken concealed in a tree in Waybridge forest in Huntingdonshire, he was brought to London, accused of cruelty in his administration of Ireland, and condemned and beheaded at the Tower in the year 1470. This nobleman translated Cicero de Amicitia, some parts of Cæsar's Commentaries, and was the author of several other works.

WORCESTERSHIRE, a county of England, bounded by Warwickshire on the east, by Gloucestershire on the south, by the counties of Hereford and Salop on the west, and on the north by Staffordshire. According to Templeman, it is 36 miles in length, 28 in breadth, and about 130 in circumference, within which it contains seven hundreds, and a part of two others, 11 market towns, of which three are boroughs, one city, namely *Worcester*, 152 parishes, about 540,000 acres, and in 1811, 160,546 inhabitants.

This being an inland county, well cultivated, and free from lakes, marshes, or stagnant waters, the air is very sweet and wholesome all over it. The soil in general is very rich, producing corn, fruit, especially pears, of which they make a great deal of perry; hops and pasture. The hills are covered with sheep, and the meadows with cattle. Hence they have wool, cloth, stuffs, butter, and cheese in abundance. They are also well supplied with fuel, either wood or coal, and salt from their brine pits and salt springs. Of the last they have not only enough for themselves, but export large quantities by the Severn; which noble river, to the great convenience and emolument of the inhabitants, runs from north to south through the very middle of the county, enriching the soil, and yielding it plenty of fish, and an easy expeditious conveyance of goods to and from it. It is also watered by the Stour, Avon, Teme, &c. It sends nine members to parliament, viz. two for the county, two for the city of Worcester, two for Droitwich, two for Evesham, and one for Bewdley; and lies in the diocese of Worcester, and Oxford circuit. See WORCESTERSHIRE, SUPPLEMENT.

WORD, in language, an articulate sound designed to represent some idea or notion. See GRAMMAR and LANGUAGE. See also LOGIC, Part I. chap. i.

WORD, or *Watch-word*, in military affairs, is some peculiar word or sentence, by which the soldiers know and distinguish one another in the night, &c. and by which spies and designing persons are discovered. It is used also to prevent surprises. The word is given out in an army every night to the lieutenant or major-general of the day, who gives it to the majors of the brigades, and they to the adjutants; who give it first to the field-officers, and afterwards to a serjeant of each company, who carry it to the subalterns. In garrisons it is given after the gate is shut to the town-major, who gives it to the adjutants, and they to the serjeants.

WORDS of Command. See EXERCISE and MANUAL.

Signals by the Drum, made use of in exercising of the Army, instead of the WORD of Command, viz.

Signals by the drum.	*Operations.*
A short roll,	To caution.
A flam,	To perform any distinct thing.
To arms,	To form the line or battalion.
The march,	To advance, except when intended for a salute.
The quick march,	To advance quick.
The point of war,	To march and charge.
The retreat,	To retreat.
Drum ceasing,	To halt.
Two short rolls,	To perform the flank firing.
The dragoon march,	To open the battalion.
The grenadier march,	To form the column.
The troop,	To double divisions.
The long roll,	To form the square.
The grenadier march,	To reduce the square to the column.
The preparative,	To make ready and fire.
The general,	To cease firing.
Two long rolls,	To bring or lodge the colours.

WORK, in the manege. To work a horse, is to exercise him at pace, trot, or gallop, and ride him at the manege. To work a horse upon volts, or head and haunches in or between two heels, is to passage him, or make him go sideways upon parallel lines.

To WORK, in sea language, is to direct the movements of a ship, by adapting the sails to the force and direction of the wind. See SEAMANSHIP.

WORK, Carpenters, Clock, Crown, Field, Fire, Fret, Grotesque, Horn, Mosaic. See the several articles, together with FORTIFICATION and PYROTECHNY.

WORK-House, a place where indigent, vagrant, and idle people, are set to work, and supplied with food and clothing.

Work-houses are of two kinds, or at least are employed for two different purposes. Some are used as prisons for vagrants or sturdy beggars, who are there confined and compelled to labour for the benefit of the society which maintains them; whilst others, sometimes called *poor-houses*, are charitable asylums for such indigent persons as through age or infirmity are unable to support themselves by their own labour. The former kind of work-house, when under proper management, may be made to serve the best of purposes; of the latter we are acquainted with none which entirely commands our approbation.

To make confinement in a work-house operate to the correction of vagrants and disorderly persons (and if it produce not this effect it can hardly be considered as a beneficial institution), the prisoners should be shut up in separate cells, and compelled to labour for their own subsistence. A crew of thieves and vagabonds associating with each other is a hell upon earth, in which every individual is hardened in his crimes by the countenance and conversation of his companions; and wretches who, when at liberty, choose to beg or steal rather than to earn a comfortable livelihood by honest industry, will submit to any punishment which a humane overseer can inflict rather than work for the benefit of others. No punishment indeed will compel a vagrant to labour. He may assume the appearance of it, but he will make no progress; and the pretext of sickness or weakness is ever at hand for an excuse. Hence it is that thieves and

Work-house.

strumpets are too often dismised from work-houses and bridewells ten times more the children of the devil than when they entered them.

To remedy these evils, we can think of no better method than to confine each prisoner in a cell by himself, and to furnish him daily with such an allowance of bread and water as may preserve him from *immediate* death; for the only compulsion to make such men work seriously is the fear of want, and the only way to reform them is to leave them to their own meditations on the consequences of their past conduct. There are surely very few persons, if any, whose aversion from labour would not be conquered by the pinchings of hunger and the certain prospect of perishing by famine; and it is to be hoped that there are not many so totally divested of every latent principle of virtue, as not to be brought by such solitude to a due sense of their former wickedness. Should one or two, however, be occasionally found so very obdurate as to suffer themselves to perish rather than work, their deaths would prove a salutary beacon to others, and their blood would be on their own heads; for we have the express command of St Paul himself, that "if any will not work, neither should he eat."

No doubt it would be proper that the meditations of vagabonds confined in a work-house should be directed by the private admonitions of a pious and intelligent clergyman; but it is not every clergyman who is qualified to discharge such a duty. If he be actuated by a zeal not according to knowledge, or if he have not with equal care studied human nature and the word of God, his admonitions will be more likely to provoke the profane ridicule of his auditor, and harden him in his wickedness, than to excite in his breast such sorrow for his sins as shall "bring forth fruits meet for repentance." To render the instruction of thieves and vagrants of any use, it must be accurately adapted to the case of each individual; and however excellent it may be in itself, it will not be listened to unless offered at seasons of uncommon seriousness, which the instructor should therefore carefully observe.

That such wholesome severity as this would often reform the inhabitants of work-houses, appears extremely probable from the effects of a similar treatment of common prostitutes mentioned by Lord Kames in his Sketches of the History of Man: "A number of those wretches were in Edinburgh confined in a house of correction, on a daily allowance of threepence, of which part was embezzled by the servants of the house. Pinching hunger did not reform their manners; for being absolutely idle, they encouraged each other in vice, waiting impatiently for the hour of deliverance. Mr Stirling the superintendant, with the consent of the magistrates, removed them to a clean house; and, instead of money, appointed for each a pound of oatmeal daily, with salt, water, and fire for cooking. Relieved now from distress, they longed for comfort. What would they not give for milk or ale? Work (says he) will procure you plenty. To some who offered to spin, he gave flax and wheels, engaging to pay them half the price of their yarn, retaining the other half for the materials furnished. The spinners earned about ninepence weekly; a comfortable addition to what they had before. The rest undertook to spin, one after another; and before the end of the first quarter they were all of them intent upon work. It was a branch of his plan to set free such as merited that favour; and some of them appeared to be so thoroughly reformed as to be in no danger of a relapse."

Work-houses erected as charitable asylums appear to us, in every view that we can take of them, as institutions which can serve no good purpose. Economy is the great motive which inclines people to this mode of providing for the poor. There is comparatively but a very small number of mankind in any country so aged and infirm as not to be able to contribute, in some degree, to their subsistence by their own labour; and in such houses it is thought that proper work may be provided for them, so that the public shall have nothing to give in charity but what the poor are absolutely unable to procure for themselves. It is imagined likewise, that numbers collected at a common table, can be maintained at less expence than in separate houses; and foot soldiers are given for an example, who could not live on their pay if they did not mess together. But the cases are not parallel. "Soldiers having the management of their pay, can club for a bit of meat; but as the inhabitants of the poor-house are maintained by the public, the same quantity of provisions must be allotted to each. The consequence is what might be expected: the bulk of them reserve part of their victuals for purchasing ale or spirits. It is vain to expect work from them: poor wretches void of shame will never work seriously, where the profit accrues to the public, not to themselves. Hunger is the only effectual means for compelling such persons to work *."

* Lord Sketches

The poor, therefore should be supported in their own houses; and to support them properly, the first thing to be done is, to estimate what each can earn by his own labour; for as far only as that falls short of maintenance, is there room for charity. In repairing those evils which society did not or could not prevent, it ought to be careful not to counteract the wise purposes of nature, nor to do more than to give the poor a fair chance to work for themselves. The present distress must be relieved, the sick and the aged provided for; but the children must be instructed; and labour, not alms, offered to those who have some ability to work, however small that ability may be. They will be as industrious as possible, because they work for themselves; and a weekly sum of charity under their own management will turn to better account than in a poor-house under the direction of mercenaries. Not a penny of it will be laid out on fermented liquors, unless perhaps as a medicine in sickness. Nor does such low fare call for pity to those who can afford no better. Ale makes no part of the maintenance of those who, in many parts of Scotland, live by the sweat of their brows; and yet the person who should banish ale from a charity work-house, would be exclaimed against as hard-hearted, and even void of humanity.

That such a mode of supporting the poor in their own houses is practicable, will hardly admit of a dispute; for it has been actually put in practice in the city of Hamburgh ever since the year 1788. At that period such revenues as had till then been expended in alms by the several church-wardens, and those of which the administration had been connected with the work-house, were united under one administration with such sums as were collected from private benevolence. The city was divided into sixty districts, containing each an equal

equal number of poor; and over these 180 overseers were appointed. Actual relief was the first object; but at the very moment that this provision was secured, measures were taken to prevent any man from receiving a shilling which he could have been able to earn for himself. By these methods, which our limits will not permit us to state, the overseers were able to make a calculation tolerably exact of what each pauper wanted for bare subsistence, in addition to the fruits of his own labour. A flax-yarn-spinning manufacture was established, in which the yarn is paid for, not by its weight, but by its measure. The clean flax is sold to the poor at a low price, and a certain measure of yarn again bought from them at 30 per cent. above the usual price; so that the overseers are sure that all the yarn spun by the poor will be brought into their office. Every pauper brings with him a book in which the quantity delivered is carefully noted down, which furnishes the overseers with a continual average of the state of industry among their poor.

As soon as this institution was established, the overseers went through their districts, and asked, in all such mansions as could be supposed to harbour want, if the inhabitants stood in need of support? The question to all such poor as wished for relief, and were able to spin, was, Whether they did earn by their work 1s. 6d. a-week? for experience had taught the inhabitants of Hamburgh, that many poor live upon that sum; and they knew enough of their poor to suppose, that 1s. 6d. avowed earning was equal to something more. If the answer was affirmative, the pauper stood not in need of weekly assistance. If it was negative, work was given him, which, by being paid 30 per cent. above its value, afforded him 1s. 6d. a-week easily, if he was even an indifferent hand. The far more frequent cases were partial inability by age, or weakness, or want of skill. For poor of the latter description a school was opened, and in three months time the business was easily learnt. During that time, the pauper got first 2s. a-week, and every week afterward 2d. less, till in the twelfth week he got nothing at all but his earnings, and was dismissed, with a wheel and a pound of flax gratis.

The quantity of work which disabled poor were capable of doing in a week was easily and accurately ascertained by a week's trial in the spinning-school. The result was produced weekly before appointed members of the committee, and the sum which the poor could earn was noted down in their small books. The overseer was directed to pay them weekly what their earnings fell short of 1s. 6d. in every such week, when it appeared from their books that they had earned to the known extent of their abilities. From that moment applications became less frequent; and the committee had an infallible standard for distinguishing real want: for whenever the pauper, if in health (if not, he was peculiarly provided for), had not earned what he could, then he had either been lazy, or had found more lucrative work; in either case, he was not entitled to a relief for that week, whatever he might be for the following.

This mode of providing for the poor, which attracted the notice and obtained the eulogium of the minister and the British house of commons, has for six years been in Hamburgh attended with the happiest consequences. In the streets of that city a beggar is rarely to be seen, whilst those who stand in need of the charitable contributions of the rich, are much more comfortably, as well as at much less expence, maintained at home, with their children about them, than they could be in work-houses, under the management of mercenary overseers. For a fuller account of this judicious institution, we must refer our readers to Voght's Account of the Management of the Poor in Hamburgh, since the year 1788, in a Letter to some Friends of the Poor in Great Britain.

WORLD, the assemblage of parts which compose the globe of the earth. See GEOGRAPHY and ASTRONOMY.

WORM, in *Gunnery*, a screw of iron, to be fixed on the end of a rammer, to pull out the wad of a firelock, carabine, or pistol, being the same with the wad-hook, only the one is more proper for small arms, and the other for cannon.

WORM, in *Chemistry*, is a long winding pipe, placed in a tub of water, to cool and condense the vapours in the distillation of spirits.

Blind-Worm, or *Slow-Worm*. See ANGUIS, ERPETOLOGY *Index*.

Earth-Worm. See LUMBRICUS, HELMINTHOLOGY *Index*.

Glow-Worm. See LAMPYRUS, ENTOMOLOGY *Index*.

Silk Worm. See SILK, N° 5.

WORMS, in horses. } See FARRIERY.
WORMS, in dogs. }

WORMS for bait. See FISHING.

WORMS, an ancient and famous city of Germany, with a bishop's see, whose bishop was formerly a sovereign and prince of the empire. It is a free and imperial city, and the inhabitants are Protestants. It is famous for a diet held here in 1521, at which Luther assisted in person, in memory of which the Protestants built a handsome church, where Luther is represented as appearing at the diet. It is noted for the excellent wine that grows in the neighbourhood, which they call *our Lady's milk*. In the campaign of 1743, King Geo. II. took up his quarters in this city, and lodged at the bishop's palace after the battle of Dettingen. Worms fell into the hands of the French in 1794, and was included in the department of Mont Tonnere. It continued in their possession till 1814, when it was united to the territories of the duke of Hesse Darmstadt. It is seated on the western bank of the Rhine, 20 miles south-east of Mentz, and 32 south-west of Frankfort. E. Long. 8. 15. N. Lat. 49. 32.

WORMING OF DOGS. All dogs have certain strings under their tongues, by most called *a worm*; this must be taken out when they are about two months old, with the help of a sharp knife to slit it, and a shoemaker's awl to raise it up; you must be careful to take all out, or else your pains is to little purpose; for till then he will be hardly ever fat and right, in regard the worm or string will grow foul and troublesome, and hinder his rest and eating. This cruel operation is generally recommended as a preventive of madness in dogs, or at least as disabling them, if mad, from biting in that condition.

In this operation, of which the vulgar account is given,

ven above, which we have justly denominated a cruel one, it is not a string that is removed, but the duct by which the saliva is conveyed from the gland in which it is secreted to the mouth, for the purpose of mixing with the food and promoting its deglutition and digestion. Now this operation by no means prevents the animal from biting, nor can it, in our opinion, obstruct the flow of the saliva by which the dreadful disease hydrophobia is communicated.

WORMIUS, Olaus, a learned Danish physician, born in 1588 at Arhusen in Jutland. After beginning his studies at home, he studied at several foreign universities, and travelled to various parts of Europe for improvement. He returned to his native country in 1613, and was made professor of the belles lettres in the university of Copenhagen. In 1615, he was translated to the chair of the Greek professor; and in 1624 to the professorship of physic, which he held to his death. These occupations did not hinder him from practising in his profession, and from being the fashionable physician: the king and court of Denmark always employed him; and Christian IV. as a recompense for his services, conferred on him a canonry of Lunden. He published some pieces on subjects relating to his profession, several works in defence of Aristotle's philosophy, and several concerning the antiquities of Denmark and Norway; for which latter he is principally regarded, as they are very learned, and contain many curious particulars. He died in 1654.

WORMWOOD. See Artemisia, Botany *Index*.

WORSHIP of God (*cultus Dei*), amounts to the same with what we otherwise call *religion*. This worship consists in paying a due respect, veneration, and homage to the Deity, under a certain expectation of reward. And this internal respect, &c. is to be shown and testified by external acts; as prayers, sacrifices, thanksgivings, &c.

The Quietists, and some other mystic divines, set aside not only all use of external worship, but even the consideration of rewards and punishments. Yet even the heathens had a notion that God did not require us to serve him for nought: "Dii quamobrem colendi sint (says Cicero), non intelligo, nullo nec accepto ab illis nec sperato bono."

The school-divines divide worship into divers kinds, viz. *latria*, that rendered to God; and *idololatria*, that rendered to idols or images. To which the Romanists add, *dulia*, that rendered to saints; and *hyperdulia*, that to the Virgin. Some theological writers have observed, that the Greek word, προσκυνειν, *to worship*, is not descriptive only of the honour which is appropriated to God, but is indifferently used to signify the honour and respect which are paid to superiors of all kinds in heaven or on earth. Accordingly, they have distinguished between civil and religious worship.

That it is the duty of man to worship his Maker, has been sufficiently proved under other articles (see Prayer; and Theology, N° 40—45.). It is not indeed easily to be conceived how any one who has tolerably just notions of the attributes and providence of God, can possibly neglect the duty of *private* worship; and though we have admitted in the last of the two articles referred to, that *public* worship does not seem to be enjoined in that system which is called the religion of *nature*, yet it is most expressly commanded by the religion of Christ, and will be regularly performed by every one who reflects on its great utility.

As the illiterate vulgar cannot form to themselves correct notions of the divine providence and attributes, it is obvious, that without the institution of public worship, they would never think of worshipping God at all, unless perhaps occasionally, when under the pressure of some severe calamity; but occasional worship, the offspring of compulsion, could have little of the resigned spirit of true devotion. Ignorant, however, as the lowest of the vulgar are, and necessarily must be, it cannot be denied, that in most Christian countries, perhaps in all, they are more accurately acquainted with the first principles of religion, and the laws of morality, than even the leaders of barbarous nations. This superiority is doubtless owing in some measure to their access to the Sacred Scriptures, but much more, we are persuaded, to the instruction which they receive in the assemblies which they frequent for public worship. If this be admitted, public worship may be easily proved to be the duty of every individual of the community: For were those, who may be supposed to stand in no need either of the contagion of society to kindle their own devotion, or of the preaching of a clergyman to instruct them in the doctrines and precepts of the gospel, "to forsake, on these accounts, the assembling themselves together, as the manner of some is," religious assemblies and public worship would very quickly fall into universal disuse. Man is an animal prone to imitation; and every order in society is ambitious of treading in the footsteps of the order immediately above it. Were the wise and the good, therefore, permitted to absent themselves from the assemblies instituted for the public worship of the Creator and Redeemer of the world, others would quickly follow their example; impelled to it not only by this universal propensity, but by the additional motive of wishing to appear both to the world and to themselves as wise and as good as their privileged neighbours. The consequence is obvious: one man would stay from church with the serious intention perhaps of employing the Lord's day in private devotion and religious study; another, following his example, would absent himself upon the same pretence, but would in reality waste the day in dozing indolence or in secret sensuality. For these and other reasons which might be easily assigned, no sincere Christian will think himself at liberty to dispute a practice enjoined by the inspired preachers of his religion, coeval with the institution, and retained by every sect into which it has since been unhappily divided.

As Christian worship consists of prayers and praises, it has been a matter of some debate whether it is most properly performed by preconcerted forms or liturgies, or by extemporaneous addresses to the Almighty. Both these modes have their advantages and disadvantages; and by the sacred writers neither of them is prescribed in opposition to the other.

The advantages of a liturgy are, that it prevents absurd, extravagant, or impious addresses to God, which the folly or enthusiasm of individuals must always be in danger of producing; it gives the congregation an opportunity of *joining* in the prayers which are put up for them, which they cannot possibly do in a series of extemporaneous petitions, since before they can assent to any

any one of these and make it their own, their attention is necessarily called away to that which succeeds it; and it relieves the clergyman from the labour of composition, which seems incompatible with that fervour which constitutes the spirit of devotion.

The disadvantages of a fixed liturgy, which are the recommendations of extemporary prayer, are principally two. The forms composed in one age must, by the unavoidable change of language, circumstances, and opinions, become in some degree unfit for another; and the perpetual repetition of the same form of words is very apt to produce inattentive lassitude in the congregation. Would the clergy of the church of England take that liberty which is allowed them in the bidding prayer before sermon, perhaps the service of that church would unite in itself all the advantages both of liturgic and extemporary worship. We have only to add on this subject, that public prayers, whether precomposed or not, ought to be compendious; that they ought to express just conceptions of the Divine attributes; recite such wants as the congregation are likely to feel, and no other; that they ought to contain as few controverted propositions as possible; and that, if it can be done without offence, the pompous style of *the state* should be laid aside in our prayers for the king, and all that are in authority; because in every act which carries the mind to God, human greatness must be annihilated.

WORT, the infusion of malt, of which beer is made. See BREWING. The uses of this infusion in common affairs are well known. By Dr M'Bride it has lately been found to have a strong antiseptic virtue, and to be useful in preventing the scurvy and other diseases to which sailors are liable; this was confirmed by Captain Cook in his voyages. See *Means of Preserving the Health of SEAMEN*.

It is of great importance to the manufacturer to be able to ascertain with facility and precision the real strength of worts, or the quantity of saccharine matter contained in the infusion. This is accomplished by determining the specific gravity by means of instruments, which, from the purpose to which they are applied, have obtained the name of *saccharometers*. But as these instruments, from the very nature of the material of which they are constructed, are liable to considerable change, the results which they afford cannot always be depended on. With the view of obviating these inconveniences, the patent areometrical beads have been invented by Mrs Lovi of Edinburgh. We have already noticed these beads on account of their accuracy, simplicity, and facility of application for ascertaining the specific gravity, or the real strength and value of spirituous liquors. See vol. xix. p. 599.; and we now recommend them with greater confidence, from having had opportunities of knowing that they are capable of a more extended application, as in the manufacture of acids, and salts of different kinds; to ascertain the strength of acids, or that of saline solutions in bleaching; to determine the strength of liquids employed in the different processes of calico printing and dyeing, and not only for the purpose of examining the strength of the acids employed, but also particularly to ascertain the density or specific gravity of the colouring matters which are used in these arts, so that the same degree of shade required may be always obtained. It has been suggested, that these beads might be conveniently employed in determining the strength of mineral waters, which, it is well known, vary considerably at different seasons of the year.

As the patent beads are constructed on the same principle from 800, the specific gravity of alcohol, to 2000, which is double the specific gravity of water; and as they are divided into different series, each of which includes a range of specific gravities applicable to the particular fluids, the density or strength of which is required, we have no hesitation in asserting that they will be found extremely convenient and useful to all manufacturers and dealers, who wish to ascertain with accuracy the real strength and value of liquids.

It has been objected to the use of these beads, that they require a longer time than other instruments in using them. The same objection has been made to the introduction of other new instruments, the application of which frequent use has afterwards rendered familiar and easy. We have had opportunities of knowing that this objection is completely obviated by those who have been accustomed to use the beads. They find that they can determine the specific gravity of a liquid by means of the beads with the same facility, and in as short a time, as with any other instrument.

WOTTON, SIR HENRY, an eminent writer, was the son of Thomas Wotton, Esq. and was born in 1568. He studied for some time at New-college, Oxford, whence he removed to Queen's-college, where he made a great progress in logic and philosophy; wrote a tragedy for the use of that college, called *Tancredo;* and afterwards received the degree of master of arts. After this, leaving the university, he travelled into France, Germany, and Italy; and having spent about nine years abroad, he returned to England, and became secretary to Robert earl of Essex, with whom he continued till that earl was apprehended for high treason. He then retired to Florence, where he became known to the grand duke of Tuscany, who sent him privately with letters to James VI. king of Scotland, under the name of *Octavio Baldi*, to inform that king of a design against his life. Some months after he went back to Florence; but King James coming to the possession of the crown of England, Mr Wotton returned home, was knighted by his majesty, and sent ambassador to the republic of Venice; and afterwards was employed in many other embassies to that and other courts; but the only reward he obtained for these services was his having the provostship of Eton conferred upon him about the year 1623, which he kept till his death, which happened in 1639. After his decease some of his manuscripts and printed tracts were published together in a volume, intitled *Reliquiæ Wottonianæ*.

WOTTON, *Dr William*, a learned divine and writer, was the son of Mr Henry Wotton, B. D. rector of Wrentham in Suffolk, where he was born in 1666. He was educated by his father, a gentleman well skilled in the learned languages; under whom he made such amazing proficiency, that at five years of age it is said he could render several chapters of the gospels out of Latin and Greek, and many psalms in Hebrew, into his mother tongue. When he was very young, he remembered the whole of almost every discourse he had heard; and often surprised a preacher by repeating his sermon to him. He was admitted into Catharine-hall in Cambridge some months before he was ten years old; when the progress he made in learning in that university engaged

gaged Dr Duport, then master of Magdalen college, and dean of Peterborough, to write an elegant copy of Latin verses in his praise. In 1679 he took the degree of bachelor of arts when he was but twelve years and five months old; and the winter following he was invited to London by Dr Gilbert Burnet, then preacher at the Rolls, who introduced him to most of the learned men in that city, and particularly to Dr William Lloyd, bishop of St Asaph; to whom he recommended himself by repeating to him one of his sermons, as Dr Burnet had engaged he should. In 1691 he commenced bachelor of divinity. The same year Bishop Lloyd gave him the sinecure of Llandrillo, in Denbighshire. He was afterwards made chaplain to the earl of Nottingham, then secretary of state, who presented him to the rectory of Middleton Keynes, in Bucks, and to whom he dedicated his Reflections upon Ancient and Modern Learning. In 1705, Bishop Burnet gave him a prebend in the church of Salisbury; and in 1707, Archbishop Tenison presented him with the degree of doctor of divinity; but in 1714, the difficulties he laboured under with respect to his private fortune, obliged him to retire into South Wales, where he was treated with great kindness and humanity by the gentlemen of that country; and wrote there the "Memoirs of the Cathedral Churches of St David's and Landaff," and his "Miscellaneous Discourses relating to the Traditions and Usages of the Scribes and Pharisees;" which were afterwards printed. He died in 1726. This great man was remarkable for his humanity and friendliness of temper; the narrowness of a party spirit never broke in upon any of his friendships; and his time and abilities were at the service of any person who was making advances in real learning. He wrote, besides the above works, 1. A History of Rome. 2. A Defence of his Reflections upon Ancient and Modern Learning. 3. A Discourse concerning the Languages of Babel. 4. Advice to a young Student, with a Method of Study for the first four Years; and other learned pieces.

WOUNDS, in *Surgery*, have been divided into *simple*, *contused* or *lacerated*, and *gun-shot*.

Of Simple Wounds.—The first thing to be considered in the inspection of a wound is, whether it be likely to prove mortal or not. This knowledge can only be had from anatomy, by which the surgeon will be able to determine what parts are injured; and, from the offices which these parts are calculated to perform, whether the human frame can subsist under such injuries. It is not, however, easy for the most expert anatomist always to prognosticate the event with certainty; but this rule he ought always to lay down to himself, to draw the most favourable prognosis the case will bear, or even more than the rules of his art will allow. This is particularly incumbent on him in sea-engagements, where the sentence of death is executed as soon as pronounced, and the miserable patient is thrown alive into the sea, upon the surgeon's declaring his wound to be mortal. There are, besides, many instances on record, where wounds have healed, which the most skilful surgeons have deemed mortal. The following wounds may be reckoned mortal.

1 Wounds which are necessarily mortal.

1. Those which penetrate the cavities of the heart, and all those wounds of the viscera where the large blood-vessels are opened; because their situation will not admit of proper applications to restrain the flux of blood.

2. Those which entirely cut off the passage of the nervous influence through the body. Such are wounds of the brain, cerebellum, medulla oblongata, and spinal marrow. Wounds likewise of the small blood-vessels within the brain are attended with great danger, from the effused fluids pressing upon the brain. Nor is there less danger where the nerves which tend to the heart are wounded, or entirely divided; for, after this, it is impossible for the heart to continue its motion.

3. All wounds which entirely deprive the animal of the faculty of breathing.

4. Those wounds which interrupt the course of the chyle to the heart; such are wounds of the receptacle of the chyle, thoracic duct, and larger lacteals, &c.

5. There are other wounds which prove fatal if neglected and left to nature: such are wounds of the larger external blood-vessels, which might be remedied by ligature. Wounds of such parts generally prove fatal; and though a few instances may have occurred where people have recovered after them, yet they are always to be considered as extremely dangerous. Portions of the brain have been destroyed, and wounds have been made into it, and the patients have lived. It is possible, too, that the thoracic duct might be wounded and the patient live; Mr A. Cooper having shown, in a very ingenious paper in the Medical Records and Researches, that it may become obstructed, and the chyle conveyed into the system by anastomosing lymphatics.

In examining wounds, the next consideration is, whether the parts injured are such as may be supposed to induce dangerous symptoms, either immediately or at some period during the course of the cure. In order to proceed with any degree of certainty, it is necessary to be well acquainted with those symptoms which attend injuries of the different parts of the body. If the skin and part of the cellular substance are only divided, the first effects are an effusion of blood; the lips of the wound retract, become tumefied, red and inflamed, leaving a gap of considerable wideness according to the length and deepness of the wound. If a very considerable portion of skin and cellular substance is divided, a slight fever seizes the patient; the effusion of blood in the mean time stops, and the wound is partly filled up with a cake of coagulated blood. Below this cake, the small vessels pour forth a clear liquor, which in a short time is converted into pus (see the articles Pus and Mucus). Below this pus granulations of new flesh arise, the cake of coagulated blood loosens, a new skin covers the place where the wound was, and the whole is healed up; and there only remains a mark, called a *cicatrix* or *scar*, showing where the injury had been received.

All wounds are accompanied with a considerable degree of pain, especially when the inflammation comes on, though the division reaches no farther than the skin and cellular substance. If the muscular fibres are divided, the pain is much greater, because the sound part of the muscle is stretched by the contraction of the divided part and the action of the antagonist muscle, which it is now less fitted to bear. The wound also gapes much more than where the cellular substance is alone

alone divided, insomuch that, if left to itself, the skin will cover the muscular fibres, without any intervention of cellular substance; and not only a very unsightly cicatrix remains, but the use of the muscle is in some measure lost.—If the muscle happens to be totally divided, its fibres retract to a very considerable distance; and unless proper methods be taken to bring them into contact, the use of it is ever afterwards lost.

5 Of the arteries.

If by a wound any considerable artery happens to be divided, the blood flows out with great velocity, and by starts; the patient soon becomes faint with loss of blood; nor does the hæmorrhagy stop until he faints away altogether; and if as much *vis vitæ* still remains as is sufficient to renew the operations of life, he recovers after some time, and the wound heals up as usual. The part of the artery which is below the wound in the mean time becomes useless, so that all the inferior part of the limb would be deprived of blood, were it not that the small branches sent off from the artery above the wounded place become enlarged, and capable of carrying on the circulation. Nature also, after a wonderful manner, often produces new vessels from the superior extremity of the divided artery, by which the circulation is carried on as formerly. The consequences of such a profuse hæmorrhagy may be, however, very dangerous to the patient, by inducing extreme debility, or an universal dropsy. This great hæmorrhagy happens especially where the artery is partially divided; because then the vessel cannot contract in such a manner as to close the orifice: however, if the wound is but small, the blood gets into the cellular substance, swelling up the member to an extreme degree, forming what is called a *diffused aneurism*. Thus the hæmorrhagy soon stops externally, but great mischief is apt to flow from the confinement of the extravasated blood, from bringing on exterior suppuration among the muscles and bones; and thus not only the use of the limb is entirely lost, but the patient is brought into great danger of his life.

6 Of the ligaments, nerves, and tendons.

Wounds of the ligaments, nerves, and tendons, are likewise attended with bad consequences. When a nerve is entirely divided, the pain is but trifling, though the consequences are often dangerous. If the nerve is large, all the parts to which it is distributed below the wound immediately lose the power of motion and sensation. This, however, takes place only when all or the greatest part of the nerves belonging to a particular part are divided. If the spinal marrow, for instance, be divided near the head, the parts below soon lose their sensation irrecoverably; or if the bundle of nerves passing out of the axilla be divided, or tied, sensation in the greatest part of the arm below will be lost. But though a nerve should be divided, and a temporary palsy be produced, it may reunite, and perform its former functions. If a nerve be wounded only, instead of being divided, the worst symptoms frequently ensue.

7 Of the thorax, and the viscera which it contains.

Wounds which penetrate the cavities of the thorax are always exceedingly dangerous, because there is scarce a possibility of all the viscera escaping unhurt. A wound is known to have penetrated the cavity of the thorax principally by the discharge of air from it at each inspiration, by an extreme difficulty of breathing, and by coughing up blood. Such wounds, however, are not always mortal: the lungs have frequently been wounded, and yet the patient has recovered.—Wounds of the diaphragm are almost always mortal, either by inducing fatal convulsions immediately, or by the ascent of the stomach, which the pressure of the abdominal muscles forces up through the wound into the cavity of the thorax; of this Van Swieten gives several instances.—Even though the wound do not penetrate into the cavity of the thorax, the very worst symptoms may follow. For if the wound descends deeply among the external muscles, and its orifice lies higher, the extravasated blood will be therein collected, stagnate, and form various sinuses; which after having eroded the pleura, may at length pass into the cavity of the thorax. The matter having once found a vent into this cavity, will be continually augmenting from the discharge of the sinuous ulcer, and the lungs will at last suffer by the surrounding matter. If, in cases of wounds in the thorax, the ribs or sternum happen to become carious, the cure will be extremely tedious and difficult. Galen relates the case of a lad who received a blow upon his sternum in the field of exercise: it was first neglected, and afterwards badly healed; but, four months afterwards, matter appeared at the place which had received the blow. A physician made an incision into the part, and it was soon after cicatrized: but in a short time a new collection made its appearance, and upon a second incision the wound refused to heal. Galen found the sternum carious; and having cut off the diseased part, the pericardium itself was observed to be corroded, so that the heart could be seen quite naked; notwithstanding which, the wound was cured in no very long time.

There is sometimes difficulty in determining whether the wound has really penetrated into the thorax or into the abdomen; for the former descends much farther towards the sides than at the middle. But as the lungs are almost always wounded when the cavity of the thorax is penetrated, the symptoms arising from thence can scarcely be mistaken.—Another symptom which frequently, though not always, attends wounds of the thorax, is an emphysema. This is occasioned by the air escaping from the wounded lungs, and insinuating itself into the cellular substance; which being pervious to it over the whole body, the tumor passes from one part to another, till at last every part is inflated to a surprising degree. An instance is given in the Memoirs of the Royal Academy, of a tumour of this kind, which on the thorax was eleven inches thick, on the abdomen nine, on the neck six, and on the rest of the body four; the eyes were in a great measure thrust out of their orbits by the inflation of the cellular substance; and the patient died the fifth day. This was occasioned by a stab with a sword.

8 Of the abdomen and its viscera.

Wounds of the abdomen are not less dangerous than those of the thorax, on account of the importance of the viscera which it contains. When the wound does not penetrate the cavity, there is some danger of a hernia being formed by the protrusion of the peritonæum through the weakened integuments, and the danger is greater the larger the wound is. Those wounds which run obliquely betwixt the interstices of the muscles often produce sinuous ulcers of a bad kind. For as there is a large quantity of fat interposed everywhere betwixt the muscles of the abdomen, if a wound happens to run between them, the matter there collected, not meeting with free egress through the mouth of the wound, often makes its way in a surprising manner through the cellu-

lar

Wounds. lar substance, and forms deep sinuosities between the muscles; in which case the cure is always difficult, and sometimes impossible.

If a large wound penetrate the cavity of the abdomen, some of the viscera will certainly be protruded through it; or if the wound is but small, and closed up with fat so that none of the intestines can be protruded, we may know that the cavity of the abdomen is pierced, and probably some of the viscera wounded, by the acute pain and fever, paleness, anxiety, faintings, hiccough, cold sweats, and weakened pulse, all of which accompany injuries of the internal parts. The mischiefs which attend wounds of this kind proceed not only from the injury done to the viscera themselves, but from the extravasation of blood and the discharge of the contents of the intestines into the cavity of the abdomen; which, being of a very putrescent nature, soon bring on the most violent disorders. Hence wounds of the abdominal viscera are very often mortal. This, however, is not always the case, for the small intestines have been totally divided, and yet the patient has recovered. Wounds both of the small and large intestines have healed spontaneously, even when they were of such magnitude that the contents of the intestine were freely discharged through the wound into the abdomen, and after part of the intestines itself has been protruded through the wound of the integuments.

When the mesentery is injured, the danger is extreme, on account of its numerous vessels and nerves. Wounds of the liver, spleen, and pancreas, are also exceedingly dangerous, although there are some instances of the spleen being cut out of living animals without any considerable injury.

From the preceding account of the symptoms attending wounds in the different parts of the body, the surgeon may be enabled to judge in some measure of the event; though it must always be remembered, that wounds, even those which seemed at first to be of the slightest nature, have, contrary to all expectation, proved mortal, chiefly by inducing convulsions, or a locked jaw; so that no certain prognostic can be drawn on sight of recent wounds. We shall now, however, proceed to consider their treatment.

9
Treatment of wounds.

For the cure of wounds, it has been already observed, that the ancients imagined balsams, the juice of herbs, &c. to be specifics. In after-ages, and in countries where balsams are not easily to be procured, salves were substituted in their place; and even at this day there are many who reckon a salve or ointment essentially necessary for healing the slightest cut. It is certain, however, that the cure of wounds cannot be effected, nay, not even forwarded in the least, by ointments, unless in particular cases. That power which the human frame has of repairing the injuries done to itself, which by physicians is called *vis medicatrix naturæ*, is the sole agent in curing external injuries; and without this the most celebrated balsams would prove ineffectual. When a wound has been made with a sharp instrument, and is not extensive, if it be immediately cleaned and all the extravasated blood sucked (A) out or washed away, it will almost always heal by *adhesion*. When a wound does not heal by this process, there are three stages to be observed in its cure; the first, called suppuration, which takes place when the ends of the wounded vessels contract themselves, and pour out the liquor which is converted into pus. As soon as this appears, the second, or granulating stage, in which the flesh begins to grow up, takes place; and as this proceeds, the edges of the wound acquire a fine bluish or pearl colour, which is that of the new skin beginning to cover the wound as far as the granulations have filled it up. This process continues, and the skin advances from all sides towards the centre, which is called the *cicatrizing* of the wound. For the promoting of each of these processes, several ointments were formerly much in vogue. But it is now found, that no ointment whatever is capable of promoting them; and that it is only necessary to keep the wound clean, and to prevent the air from having access to it. This, indeed, nature takes care to do, by covering the wound with a cake of coagulated blood; but if a wound of any considerable magnitude should be left entirely to nature, the pus would form below the crust of coagulated blood in such quantity, that it would most probably corrupt, and the wound degenerate into a corroding ulcer. It is necessary, therefore, to cleanse the wound frequently; for this purpose it will be proper to apply a little ointment spread on soft scraped lint. And, in a healthy body, the wound will heal without farther trouble. As to the ointment employed, it is almost indifferent what it be, provided it has no acrid or stimulating ingredient in its composition; hogs lard or the simple ointment of the Pharmacopeia will answer perfectly.

But though, in general, wounds thus easily admit of a cure, there are several circumstances which require a different treatment, even in simple divisions of the fleshy parts, when neither the membranous nor tendinous parts are injured. These are, 1. Where the wound is large, and gapes very much, so that, if allowed to heal in the natural way, the patient might be greatly disfigured by the scar. It is proper to bring the lips of the wound near to each other, and to join them either by adhesive plaster or by suture, according as the wound is superficial, or deep. 2. When foreign bodies are lodged in the wound, as when a cut is given by glass, &c. it is necessary to extract them, before the wound is dressed: for it will never heal until they are discharged. When these bodies are situated in such a manner as not to be capable of being extracted without lacerating the adjacent parts, which would occasion violent pain and other bad symptoms, it is necessary to enlarge the wound, so that these offending bodies may be easily removed. This treatment, however, is chiefly necessary in gunshot wounds, of which we shall afterwards speak. 3. When the wound is made in such a manner that it runs for some length below the skin, and the bottom is much lower than the orifice, the matter collected from all parts of the wound will be lodged in the bottom of it, where, corrupting by the heat, it will degenerate into a fistulous ulcer. To prevent this, we must

(A) See an account of the method of sucking wounds, in Mr John Bell's *Discourses on Wounds*, Part I. discourse v. p. 215.

Wounds. must use compresses, applied so that the bottom of the wound may suffer a more considerable pressure than the upper part of it. Thus the matter formed at the bottom will be gradually forced upwards, and that formed at the upper part will be incapable of descending by its weight; the divided parts, in the mean time, easily uniting when brought close together. Indeed, the power which nature has of uniting different parts of the human body is very surprising; for, according to authors of credit, even if a piece of flesh be totally cut out, and applied in a short time afterwards to the place from whence it was cut, it will unite. That a part cut out of a living body does not entirely lose its vital power for some time, is evident from the modern practice of transplanting teeth; and from an experiment of Mr John Hunter's, where he put the testicle of a cock into the belly of a living hen, and the testicle adhered to the liver, and became connected to it by means of blood vessels*. We have therefore the greatest reason to hope, that the divided parts of the human body, when closely applied to each other, will cohere without leaving any sinus or cavity between them. However, if this method should fail, and matter be collected in the depending part of the wound, it will be necessary to make an opening in that part in order to let it out; after which the wound may be cured in the common way. 4. During the course of the cure, it sometimes happens that the wound, instead of filling up with granulations of a florid colour, shoots up into a glassy-like substance which rises above the level of the surrounding skin, while, at the same time, instead of laudable pus, a thin ill-coloured and fetid ichor is discharged. In this case the lips of the wound lose their beautiful pearl colour, and became callous and white, nor does the cicatrizing of the wound at all advance. When this happens in a healthy patient, it generally proceeds from some improper management, especially the making use of too many emollient and relaxing medicines, an immoderate use of balsams and ointments. Frequently nothing more is requisite for taking down this fungus than dressing with dry lint: at other times desiccative powders, such as calamine, tutty, calcined alum, &c. will be necessary; and sometimes red precipitate mercury must be used. This last, however, is apt to give great pain, if sprinkled in its dry state upon the wound; it is therefore most proper to grind it with some yellow basilicon ointment, which makes a much more gentle, though at the same time an efficacious escharotic. Touching the overgrown parts with blue vitriol is also found very effectual.

* See ...ood, ... 19.

10 Of the regimen of patients in wounds.

Hitherto we have considered the wounded patient as otherwise in a state of perfect health; but it must be observed, that a large wound is capable of disordering the system to a great degree. If the patient is strong and vigorous, and the pain and inflammation of the wound great, considerable degree of fever may arise, which it will be necessary to check by bleeding, low diet, and other parts of the antiphlogistic regimen, at the same time the inflamed lips of the wound and parts adjacent are to be treated with emollient fomentations or cataplasms till the pain and swelling abate. On the other hand, it may happen, when the patient is of a weak and lax habit, that the *vis vitæ* may not be sufficient to excite such an inflammation in the wound as is absolutely necessary for its cure. In this case, the edges of the wound look pale and soft; the wound itself ichorous and bloody, without any signs or granulations; or if any granulations shoot up, they are of the fungous glassy kind above mentioned. To such wounds all external applications are vain; it is necessary to strengthen the patient by proper internal remedies, among which the bark has a principal place, until the wound begins to alter its appearance. In such persons, too, there is some danger of a hectic fever by the absorption of matter; and this will take place during the course of the cure, even when the appearances have been at first as favourable as could be wished. This happens generally when the wound is large, and a great quantity of matter formed; for by this discharge the patient is weakened; so that the pus is no sooner formed, than it is reconveyed into the body by the absorbent vessels, and immediately affects the patient with feverish heat. When this takes place, the best remedy is to exhibit the bark copiously, at the same time to support the patient by proper cordials and nourishing diet. Indeed, in general, it will be found, that, in the case of wounds of any considerable magnitude, a more full and nourishing regimen is required than the patient, even in health, has been accustomed to; for the discharge of pus alone, where the quantity is considerable, proves very debilitating. And it is constantly found, that the cure of such sores goes on much more easily when the patient is kept in his usual habit of body, than when his system is much emaciated by a very low allowance; and, for the same reason, purgatives, taken more freely than what is necessary to keep the bowels open, and whatever else tends to weaken the constitution, are improper in the cure of wounds.

11 Of hæmorrhagies from wounds.

Hæmorrhagies very frequently happen in wounds, either from a division of a large artery, or of a number of small ones. In this case, the first step to be taken by the surgeon is to effect a temporary stoppage of the blood by means of compression, and he is then to tie up all the larger vessels according to the methods usually directed.

When the principal arteries of a wound have been tied, and a little blood continues to be discharged, which appears to come from sundry small vessels only, an experienced surgeon is induced to think, that the compression of the bandages will in all probability effect a total stoppage of the hæmorrhagy. In a general oozing from the whole surface of a sore, and when no particular vessel can be distinguished, there is a necessity for trusting to the bandage or compression; but whenever an artery can be discovered, of whatever size it may be, it ought to be secured by a ligature. But it frequently happens, that considerable quantities of blood are discharged, not from any particular vessel, but from all the small arteries over the surface of the wound; and in wounds of great extent, particularly after the extirpation of cancerous breasts, and in other operations where extensive sores are left, this species of hæmorrhagy often proves very troublesome by being exceedingly difficult to suppress.

In constitutions perfectly healthy, on the occurrence of wounds even of the most extensive nature, as soon as the larger arteries are secured, all the small vessels which have been divided are diminished, not only in their diameters, but also in their length; in consequence of which, they recede considerably within the surface of the

Wounds.

the surrounding parts. This cause of itself would probably, in the greatest number of instances, prove sufficient for restraining all loss of blood from the smaller arteries. Another very powerful agent however is provided by nature for producing the same effect. From the extremities of the divided vessels which at first discharged red blood, there now, in their contracted state, oozes out a more thin, though viscid fluid, containing a great proportion of the coagulable parts of the blood; and this being equally distributed over the surface of the wound, by its agglutinating powers has a very considerable influence in restraining all such hæmorrhagies.

When a tedious oozing occurs in a patient young and vigorous, and where the tone of the muscular fibres is evidently great, the most effectual means of putting a stop to the discharge is to relax the vascular system, either by opening a vein in some other part, or, what gives still more immediate relief, by untying the ligature on one of the principal arteries of the part, so as to allow it to bleed freely: those violent spasmodic twitchings too, so frequent after operations in any of the extremities, when they do not depend on a nerve being included in the ligature with the artery, are in this manner more effectually relieved than by any other means.

By the same means the patient, from being in a febrile heat and much confused, soon becomes very tranquil: the violent pulsation of the heart and larger arteries abates, and the blood not being propelled with such impetuosity into the smaller vessels of the part, they are left at more liberty to retract.

The patient ought to be kept exceedingly cool; wine and other cordials should be rigidly avoided; cold water, acidulated either with the mineral or vegetable acids, ought to be the only drink; motion of every kind, particularly of the part affected, should be guarded against; and the lip of the wound being drawn together by adhesive plaster, and gently covered with soft charpie, it ought to be tied up with a bandage so applied as to produce a moderate degree of pressure on the extremities of the divided parts.

As soon as a sufficient quantity of blood has been discharged, the wound dressed, and the patient laid to rest, a dose of opium proportioned to the violence of the symptoms ought to be immediately exhibited. It ought to be remarked, however, that in all such circumstances, much larger doses of this medicine are necessary than in ordinary cases requiring the use of opiates. Small doses, instead of answering any good purpose, seem frequently rather to aggravate the various symptoms; so that whenever they are had recourse to in such cases, they ought always to be given in quantities sufficient for the intended effect.

But hæmorrhagies of this nature happen much more frequently in relaxed enfeebled habits, where the solids have lost part of their natural firmness, and the fluids have acquired a morbid tenuity. In this case a moderate use of generous wine ought to be immediately prescribed; for nothing tends so much, in such circumstances, to restrain hæmorrhagies, as a well directed use of proper cordials. By tending to invigorate and brace the solids, they enable the arterial system to give a due resistance to the contained fluids; and have also a considerable influence in restoring to the fluids that viscidity of texture, of which in all such instances we suppose them to be deprived.

A nourishing diet also becomes proper; the patient ought to be kept cool; and the mineral acids, from their known utility in every species of hæmorrhagy, ought also to be prescribed. Rest of body is here also proper; and opiates, when indicated either by pain or spasmodic affections of the muscles, ought never to be omitted.

Together with these remedies adapted to the general system, particular dressings, appropriated to the state of the parts to which they are to be applied, have been found very beneficial. In healthy constitutions, soon after the discharge of blood is over, the parts are covered with a viscid coagulable effusion from the mouths of the now retracted arteries; but in constitutions of an opposite nature, where the solids are much relaxed, the blood in general is found in such an attenuated state as to afford no secretion of this nature.

To supply as much as possible the deficiency of this natural balsam, different artificial applications have been invented. Dusting the part with starch or wheat-flour has sometimes been found of use, and gum arabic in fine powder has been known to answer when these failed.

Applications of this kind, indeed, have been used with success in all such hæmorrhagies, with whatever habit of body they happen to be connected; but they have always proved more particularly serviceable in relaxed constitutions, attended with an attenuated state of the blood and an enfeebled muscular system. Alcohol, or any other ardent spirits, impregnated with as great a quantity as they can dissolve of myrrh, or any other of the heating viscid gums, may be here used with freedom, though in constitutions of an opposite nature they ought never to be employed. The *balsamum traumaticum* of the shops, a remedy of this nature, has long been famous for its influence in such cases: but that indiscriminate use of this and similar applications which has long prevailed with some practitioners, has undoubtedly done much harm; for as they are all possessed of very stimulating powers, they of course tend to aggravate every symptom in wounds connected with a tense state of fibres, or much pain, especially when spasmodic muscular affections prevail.

By a due perseverance in one or other of the plans here pointed out, it will seldom happen that hæmorrhagies are not at last put a stop to: but when the contrary does occur, when, notwithstanding the use of the remedies recommended, a discharge of blood still continues; in addition to the means already advised, an equal moderate pressure ought to be applied over the whole surface of the sore, to be continued as long as the necessity of the case seems to indicate.

In finishing the dressings of such wounds, after the adhesive plaster and compresses have been applied, a bandage properly adapted to the part ought to be employed, and in such a manner as to produce as equal a degree of pressure over the surface of the wound as possible. But it now and then happens that no bandage can be applied so as to produce the desired effect; and in such cases the hand of an assistant is the only resource; which being firmly pressed over the dressings, will commonly succeed when no other means is found to have much influence.

l-let-

Wounds of the nerves, tendons, and ligaments, are attended with much more violent symptoms than those where even considerable arteries are divided, and they frequently resist every method of cure proposed by the most skilful practitioners. In the simple process of blood-letting, it frequently happens that the tendinous expansion called the *aponeurosis* of the biceps muscle is wounded, or even the tendon of that muscle itself is punctured, by the point of the lancet; or sometimes a nerve which happens to lie in the neighbourhood is partially divided. Any one of these wounds, though they are the smallest we can well suppose to be given, are frequently very dangerous and difficult of cure. It sometimes immediately happens on the introduction of the lancet, that the patient complains of a most exquisite degree of pain; and when this occurs, we may rest assured that either a tendon or a nerve has been wounded. On some occasions, by proper management, such as evacuating a considerable quantity of blood at the orifice newly made, by keeping the part at perfect rest, and preserving the patient in as cool a state as possible, the pain at first complained of will gradually abate, and at last go off entirely without any bad consequence. At other times, however, this pain which occurs instantaneously on the introduction of the lancet, instead of abating, begins soon to increase; a fullness, or small degree of swelling, takes place in the parts contiguous to the wound; the lips of the sore become somewhat hard and inflamed; and, in the course of about 24 hours from the operation, a thin watery serum begins to be discharged at the orifice.

If, by the means employed, relief is not soon obtained, these symptoms generally continue in nearly the same state for two or perhaps three days longer. At this time the violent pain which at first took place becomes still more distressing; but instead of being sharp and acute as before, it is now attended with the sensation of a burning heat, which goes on to increase, and proves, during the whole course of the ailment, a source of constant distress to the patient. The fullness and hardness in the lips of the wound begin to increase, and the swelling in the neighbouring parts gradually extends over the whole members. The parts at last become exceedingly tense and hard; an erysipelatous inflammatory colour frequently appears over the whole member; the pulse by this time is generally very hard and quick; the pain is now intense, the patient exceedingly restless; twitchings of the tendons occur to a greater or less degree; on some occasions, a locked jaw and other convulsive affections supervene; and all these symptoms continuing to increase, it most frequently happens that the torture under which the patient has been groaning is at last terminated by death.

13
pinions
bout the
auses of
hese symp-
oms.

Different opinions have prevailed respecting the cause of these symptoms. By some they have been imputed to wounds of the tendons. By others the tendons are supposed to be so entirely destitute of sensibility, as to be quite incapable of producing so much distress; so that wounds of the nerves they consider, on all such occasions, as the true cause of the various symptoms we have mentioned.

One or other of these ideas continued to be the only source for explaining the various phenomena found to occur in this malady, till a different opinion was suggested by the late ingenious Mr John Hunter of London. Mr Hunter supposed, that all the dreadful symptoms found now and then to be induced by the operation of blood-letting, might be more readily accounted for from an inflamed state of the internal surface of the vein, than from any other cause. Such a state of the vein he has often traced in horses that have died of such symptoms from venesection, and the same appearances have sometimes occurred also in the human body. And on other occasions, inflammation having in this manner been once excited, has been known to terminate in suppuration; and the matter thus produced being in the course of circulation carried to the heart, Mr Hunter supposes that in such cases death may have been induced by that cause alone.

Wounds.
14
Mr John
Hunter's
opinion

There can be no reason to doubt the fact held forth by Mr Hunter, that in such instances the vein in which the orifice has been made, has frequently after death been found greatly inflamed: but however ingenious his arguments may be for concluding that the state of the vein is the original cause of all the bad symptoms enumerated, and although we must allow that such an inflammatory affection of a vein must have a considerable influence in aggravating the various symptoms previously induced by other causes; yet we may very fairly conclude, that it could not probably in any one instance be able to account with satisfaction for their first production.

In many cases the patient, at the very instant of the operation, feels a very unusual degree of pain. In some cases, the violence of the pain is almost unsupportable. Now this we can never suppose to have been produced by the mere puncture of a vein; for although the coats of veins are not perhaps entirely destitute of feeling, yet we know well that they are not endowed with such a degree of sensibility as to render it probable that such intense pain could ever be induced by their 15
being punctured in any way whatever. This inflamed not just.
state of the veins therefore, as detected by Mr Hunter after death, must be considered rather as being produced by, than as being productive of, such affections; and that such ailments should frequently produce an inflammation of the contiguous veins, is a very probable conjecture. In the course of 48 hours from the operation, when the febrile symptoms are just commencing, such a degree of hardness and evident inflammation is induced over all the parts contiguous to the orifice, that it would be surprising indeed if the vein, which is thus perhaps entirely surrounded with parts highly inflamed, 16
should escape altogether. We shall therefore proceed Really ow-
upon the supposition of this inflamed state of the veins ing to the
being a consequence rather than the cause of such ail- partial
ments; and of course we now revert to one or other of wounding of a nerve
the opinions long ago adopted on this subject, that all or tendon.
the train of bad symptoms found on some occasions to succeed venesection, proceeds either from the wound of a nerve or of a tendon.

That a partial wound of a nerve will now and then produce very distressing symptoms, no practitioner will deny: but it has been attempted to be shown, that tendons are almost totally destitute of sensibility; and it has therefore been supposed, that their being wounded can never account for the various symptoms known to occur in such cases. There is great reason however to think, that in different instances the same train of symptoms have been induced by different causes; that in one instance

Wounds. instance a wounded nerve, and in others pricks of the tendons, have given rise to them, as we have already supposed.

17 Method of obviating these symptoms, and curing the wound.

In order to prevent as much as possible the consequent inflammation and other symptoms which usually ensue, a considerable quantity of blood should be immediately discharged at the orifice just made: the limb, for several days at least, ought to be kept in a state of perfect rest, care being at the same time taken to keep the muscles of the part in as relaxed a state as possible: the patient should be also kept cool, on a low diet; and, if necessary, gentle laxatives ought to be administered.

When, notwithstanding these means, the symptoms, instead of diminishing, rather become more violent; if the lips of the orifice turn hard and more inflamed, if the pain become more considerable, and especially if the swelling begin to spread, other remedies come to be indicated. In this state of the complaint, topical bloodletting, by means of leeches applied as near as possible to the lips of the wound, frequently affords much relief; and when the pulse is full and quick, it even becomes necessary to evacuate large quantities of blood by opening a vein in some other part.

The external applications usually employed in this state of the complaint are warm emollient fomentations and poultices. In similar affections of other parts no remedies with which we are acquainted would probably be found more successful; but in the complaint now under consideration, all such applications, instead of being productive of any advantage, rather do harm. The heat of the part is here one of the most distressing symptoms; and warm emollient applications rather tend to augment this source of uneasiness. The lips of the wound also are rendered still more hard, swelled, and of course more painful; and the swelling of the contiguous parts is increased. The best external remedies are cooling astringents, especially the saturnine applications. The parts chiefly affected being alternately covered over with cloths wet with a solution of saccharum saturni, and pledgets spread with Goulard's cerate, are kept more cool and easy than by any other remedy hitherto used. The febrile symptoms which occur must at the same time be attended to, by keeping the patient cool, on a low diet, preserving a lax state of the bowels; and, if necessary, farther quantities of blood ought to be evacuated.

On account of the violence of the pain, which is sometimes so excessive as to destroy entirely the patient's rest, opiates ought to be freely exhibited; and when twitchings of the tendons and other convulsive symptoms supervene, medicines of this kind become still more necessary. In order, however, to have a proper influence in this state of the complaint, opiates ought to be given in very full doses; otherwise, instead of answering any good purpose, they constantly tend to aggravate the different symptoms, not only by increasing the heat and restlessness, but by having an evident influence in rendering the system more susceptible than it was before of the pain and other distressing effects produced upon it by the wound.

It often happens, however, either from neglecting the wound or from improper treatment, that all these remedies are had recourse to without any advantage whatever: the fever, pain, and swelling of the parts continue, and convulsive affections of the muscles at last occur, all tending to indicate the most imminent danger. In this situation of matters, if we have not immediate recourse to some effectual means, the patient will soon fall a victim to the disorder; and the only remedy from which much real advantage is to be expected, is a free and extensive division of the parts in which the orifice producing all the mischief was at first made. We know well, from the experience of ages, that much more pain and distress of every kind are commonly produced by the partial division either of a nerve or of a tendon, than from any of these parts being at once cut entirely across. Now the intention of the operation here recommended, is to produce a complete division of the nerve or tendon we suppose to have been wounded by the point of the lance, and which we consider as the sole cause of all the subsequent distress.

This operation being attended with a good deal of pain, and being put in practice for the removal of symptoms from which it is perhaps difficult to persuade the patient that much danger can occur, all the remedies we have mentioned should be made trial of before it is proposed: but at the same time, care ought to be taken that the disorder is not allowed to proceed too far before we have recourse to it; for if the patient should be previously much weakened by the feverish symptoms having continued violent for any length of time, neither this remedy nor any other with which we are acquainted would probably have much influence. As soon, therefore, as the course already prescribed has been fairly tried, and is found to be inadequate to the effects expected from it, we ought immediately to have recourse to a free division of the parts affected.

Wherever a wounded or ruptured tendon may be situated, the limb should be placed in such a manner as will most readily admit of the retracted ends of the tendon being brought together; and when in this situation, the muscles of the whole limb in which the injury has happened must be tied down with a roller, so as to prevent them from all kinds of exertion during the cure, endeavouring at the same time to keep the parts easy and relaxed. Thus, in a wound or rupture of the tendon of the rectus muscle of the thigh, the patient's *leg* should be kept as much as possible stretched out during the cure, while the thigh should be in some degree bent, to relax the muscle itself as far as possible.

In similar affections of the tendo achillis, the *knee* should be kept constantly bent to relax the muscles of the leg, and the foot should be stretched out to admit of the ends of the ruptured tendon being brought into contact. A roller should be applied with a firmness quite sufficient for securing the muscles and tendons in this situation; but care must be taken to prevent it from impeding the circulation. With this view, soft fine flannel should be preferred either to linen or cotton; for being more elastic, it more readily yields to any swelling with which the limb may be attacked.

The late Dr Monro was the first who gave any accurate directions for the treatment of rupture in the large tendons; and it is perhaps given with more precision, from his having himself experienced the effects of this misfortune in the tendo achillis.

He used a foot-sock or slipper, made of double quilted ticking, and left open at the toe; from the heel of which a strap went up above the calf of the leg. A strong

Wounds.

strong piece of the same materials went round the calf, and was fastened with a lace. On the back part of this was a buckle, through which the strap of the foot-sock was passed, by which the calf could be brought down, and the foot extended at pleasure. Besides there was a piece of tin applied to the fore part of the leg, to prevent the foot from getting into any improper posture during sleep. After proposing to walk, he put on a shoe with a heel two inches deep; and it was not till the expiration of five months that he ventured to lay aside the tin-plate; and he continued the use of the high-heeled shoe for two years.

From this treatment a knowledge may be formed of the treatment necessary to be followed in the laceration of tendons of other parts of the body.

19
Wounds of thorax.

In wounds of the thorax, even though none of the viscera should be wounded, we may yet reasonably expect that a considerable quantity of blood will be extravasated; and this, if very large, must be evacuated if possible. However, it ought to be particularly observed, that this extravasated blood should not be discharged before we are assured that the wounded vessels have done bleeding. When the pulse appears sufficiently strong and equal, the extremities warm, no hickup or convulsion, and the patient's strength continues, we may then know that the internal hæmorrhagy has ceased, and that the means for discharging the blood may now be safely used. Matter, water, and blood have sometimes vanished from the cavities of the thorax, and been afterwards discharged by sweat, urine, &c. Yet this but seldom happens; and if we were to trust to nature alone in these cases, it is certain that many would perish from a destruction of the vital viscera by the extravasated blood, who by an artificial extraction of the same blood might have been saved.

20
Wounds of the abdomen.

Wounds of the abdomen must be closed as soon as possible, and then treated as simple wounds; only they ought to be dressed as seldom and expeditiously as possible. Copious bleeding and a spare diet, with other parts of the antiphlogistic regimen, are here absolutely necessary.

It sometimes happens, that, through a large wound of the abdominal integuments, the intestine comes out without being injured. The most certain method, in all such cases, is to return the protruded part as soon as possible; for although writers in general formerly recommended warm fomentations, &c. to be previously applied, the latest authors upon this subject consider the most natural and proper fomentation to be that which is produced by the heat and moisture of the patient's belly, and that therefore the intestines, if no mortification has taken place, are to be cleared from extraneous matter, and immediately returned.

When the wound of the abdomen is large, the intestines easily prolapse, and they are as easily returned. But when part of an intestine has been forced through a narrow wound, it is much more dangerous. For the prolapsed intestine being distended by flatus, or the ingested aliments driven thither by the peristaltic motion, it will become inflamed, tumefied, and incapable of being returned through the stricture of the wound; whence gangrene will soon follow. In this case the utmost care is to be taken to reduce the intestine to its natural size. When this cannot be accomplished by other means, some practitioners of great eminence have even advised the puncturing of the intestine in different places in order to discharge the flatus. This practice has also been recommended in an incarcerated hernia, but is exceedingly disapproved of by Mr Pott and later writers; and it seems to be very dubious whether any good can possibly arise from it. To puncture any part that is already inflamed, must undoubtedly add to the inflammation; and it is very improbable that the discharge of flatus procured by the punctures would be at all a recompense for the bad consequences produced by the increased inflammation. The method of Celsus is much more eligible: It is to dilate the wound so as to reduce the intestine with ease.

Sometimes part of the intestine is lost either by suppuration or gangrene. In this case, all that can be done is to put a single stitch through the wounded bowel, and to fix it to the external wound by passing the suture also through the sides of the wound. The ends of the intestine may perhaps adhere; or at any rate the wound will continue to perform the office of an anus, out of which the fæces will continue to be discharged during life. The directions given by some surgeons about inserting the upper end of the gut into the lower, and stitching them together, are perfectly impracticable; and even if they were practicable, would certainly produce new mortification, which could not but be fatal.

When the omentum appears prolapsed, the same general treatment is to be observed; only that, when it is mortified, the dead part may be safely extirpated.—We shall conclude the article of abdominal wounds with a case from the memoirs of the academy of sciences for the year 1705, which shows that we ought not to despair, even though the most desperate symptoms should take place. A madman wounded himself in 18 different places of the abdomen. Eight of these penetrated the cavity, and injured the contained viscera; he had a diarrhœa, nausea, and vomiting, tension of the abdomen, with difficult respiration and violent fever, so that his life was despaired of. During the first four days he was blooded seven times; and during the greatest part of the cure his diet consisted almost entirely of flesh-broths, with the addition of some mild vegetables. By these means he was not only cured of his wounds, but restored to his right senses. Seventeen months after, he went mad again, and threw himself over a precipice, by which he was instantly killed. On opening the body, the wounds were found to have penetrated the middle lobe of the liver, the intestinum jejunum, and the colon.

Such extraordinary cures are to be imputed, according to the satisfactory explanation of Mr J. Bell, to the abdomen being perfectly full, and constantly subjected to strong pressure between the diaphragm and abdominal muscles; which keeps the parts contiguous to a wound closely applied to it, also in some measure prevents the discharge of fæces or even of blood, and gives an opportunity for a very speedy adhesion between the parts.

21
Wounds of the head.

In wounds of the head, where the cellular membrane only is affected, and the aponeurosis and pericranium are untouched, phlebotomy, lenient purges, and the use of the common febrifuge medicines, particularly those of the neutral kind, generally remove all the threatening symptoms. When the inflammation is gone off, it leaves on the skin a yellowish tint and a dry scurf, which continue until perspiration takes them away; and upon the

Wounds.

removal of the disease, the wound immediately recovers a healthy aspect, and soon heals without further trouble. But in the worst kind of these wounds, that is, where a small wound passes through the tela cellulosa and aponeurosis to the pericranium, the patient will admit of more free evacuations by phlebotomy than in the former. In both, the use of warm fomentations is required; but an emollient cataplasm, which is generally forbid in the erysipelatous swellings, may in this latter case be used to great advantage. Where the symptoms are not very pressing, nor the habit very inflammable, this method will prove sufficient; but it sometimes happens that the scalp is so tense, the pain so great, and the symptomatic fever so high, that by waiting for the slow effect of such means the patient runs a risk from the continuance of the fever; or else the injured aponeurosis and pericranium become sloughy, produce an abscess, and render the case both tedious and troublesome. A division of the wounded part, by a simple incision down to the bone, about half an inch or an inch in length, will most commonly remove all the bad symptoms; and if it be done in time, will render every thing else unnecessary.

22
Wounds of the joints.

The wounds penetrating into the cavities of the joints do not seem at first alarming; yet, by exposure to the air, the lining membrane of such cavities acquires such a degree of sensibility as to endanger life when they are large. As soon therefore as any extraneous body, pushed into the joint, is removed, the admission of the external air is to be guarded against as much as possible. If the wound be not too large, this may be done by pulling the skin over the wound of the joint; and, to prevent its retraction, rather adhesive plaster, with proper bandaging, is to be used. But when inflammation has come on, repeated and copious blood-letting, together with fomentations, becomes necessary; and as the pain, in these cases, is apt to be violent, opiates must be administered; but should matter be formed in the cavity of the joint, free vent must be given to it.

Of contused and lacerated Wounds.—When the small vessels are ruptured by a blow with any hard instrument without penetrating the skin, at the same time that the solid fibres of the part are crushed, the injury is termed a *contusion:* and when at the same time the skin is broken, it is termed a *contused and lacerated wound.*

23
Symptoms and effects of contusions.

Every contusion therefore, whether the skin is broken or not, may be properly reckoned a wound; where the injury is so slight that none of the contents of the small vessels are extravasated, it scarcely deserves to be mentioned. The immediate consequence of a contusion, therefore, is a swelling, by reason of the extravasation just mentioned; and the skin becomes discoloured by the blood stagnating under it; but as this fluid, even though covered by the skin, cannot long remain in the natural state, it thence happens, that the contused part soon loses its florid red colour, and becomes blue or black; the thinner parts being in the mean time gradually taken up by the absorbent vessels. This at last happens to the blood itself; the blue disappears, and is succeeded by a yellowish colour, showing that the blood is now dissolved; after which, the part recovers its former appearance, and the ruptured vessels appear to have united as if no injury had happened.

These are the symptoms which attend the slightest kind of contusions; but it is evident, that where the blow is so violent as to rupture the blood-vessels or end some of the large nerves, all the bad consequences which attend simple wounds of those parts will ensue, and they will not be at all alleviated by the circumstance of the skin remaining whole. Hence it is easy to see how a contusion may produce ulcers of the worst kind, gangrene, sphacelus, carious bones, &c.; and if it happen to be on a glandular part, a schirrus or cancer is very frequently found to ensue. Even the viscera themselves, especially of the abdomen, may be injured by contusions to such a degree as to produce an inflammation, gangrene, or schirrus, nay instant death, without rupturing the skin.

Of Gun-shot Wounds.—Gun-shot wounds can be considered in no other light than contused wounds. In those made by a musket or pistol ball, the first things to be done are, to extract the ball, or any other extraneous body which may have lodged in the wounded part; and to stop the hemorrhagy, if there be an effusion of blood from the rupture of some considerable artery.

It is frequently necessary to enlarge the wound in order to extract the ball; and if it has gone quite through (provided the situation of the part wounded will admit of its being done with safety), the wound is to be laid freely open through its whole length; by which means any extraneous body will be more readily removed, and the cure facilitated.

In order to get at the ball, or any foreign matter, the probe is to be used as sparingly as possible: and this must appear evident to any one who will only consider the nature of the symptoms attendant on penetrating wounds of the breast or belly, either from a bullet or sharp instrument; the thrusting in a probe to parts under such circumstances being unavoidably a fresh stab on every repetition. Wherever probing is necessary, the finger is to be preferred as the best and truest probe, where it can be used.

If a ball, or any other foreign body, happen to be lodged near the orifice, or can be perceived by the finger to lie under the skin, though at some distance from the mouth of the wound, we should cut upon it and take it out: but when it is sunk deep, and lies absolutely beyond the reach of the finger, it must appear evident on the least reflection, that thrusting, first a long probe in quest of the bullet, and then, as has been likewise practised, a long pair of forceps, either with or without teeth, into a wound of that kind, though with some certainty to extract it, must either contuse, or irritate and inflame the parts to a great degree; and consequently do as much, or more, mischief as the ball did at first in forcing its passage to such a length. And should they at the same time lay hold of any considerable artery or nerve along with the ball (which can scarce ever fail of being the case), what shocking consequences would attend such a proceeding! Nor would attempts of this sort be less injurious, if a bullet should happen to be lodged in the cavity of the belly or breast. Such attempts are the less necessary, because a great number of instances have occurred, where balls have been quietly lodged in several parts of the body, till after many years they have worked themselves a passage towards the surface, and were very easily extracted; and many cases also where balls have been entirely left behind.

In case the wound be occasioned by a musket or pistol

Wounds. 25 Dilatation of the wound.

stol shot, and of course be small, it will be necessary to dilate the wound without delay, provided the nature of the part will permit of this with safety: for in wounds near a joint, or in very membranous or tendinous parts, the knife, as well as forceps, should be put under some restraint; nor should any more opening be made than what is absolutely requisite for the free discharge of the matter lodged within.

26 Advantage of bleeding.

Where the wounded person has not suffered any great loss of blood, and this is generally the case, it will be advisable to open a vein immediately, and take from the arm a large quantity; and to repeat bleeding as circumstances may require, the second, and even the third day. Repeated bleedings in the beginning are followed by many advantages. They prevent pain and a good deal of inflammation, lessen any feverish assaults, and seldom fail to obviate imposthumations, and a long train of complicated symptoms which are wont otherwise to interrupt the cure, miserably harass the poor patient, and too often endanger his life. Even where the feverish symptoms run high, and there is almost a certainty that matter is forming, bleeding, in such a state, is very frequently of great advantage.

27 Regimen.

For the first twelve days after the wound has been received, it will be proper to observe a cooling regimen, both in respect of the medicines that may be prescribed, and the diet requisite for the support of the patient. It is likewise absolutely necessary that the body be constantly kept open. Unless, therefore, nature does this office of herself, a stool should be every day procured, either by emollient clysters, or some gentle laxative taken at the mouth; and whenever there is much pain in the wounded parts, immediate recourse must be had to opium.

28 External application.

As to external applications, whatever is of a hot spirituous nature is remarkably injurious on these occasions, and what no wounded part can in any degree bear. The wound may be dressed with pledgits of any emollient ointment; the whole being covered with a common poultice, or, in some cases, the preparations of lead may be used. An opiate should now be administered; and the part affected being placed in the easiest and most convenient posture, the patient should be laid to rest. The formation of matter, in every contused wound, is an object of the first importance; for, till this takes place, there is often reason to suspect that gangrene may happen. With a view to hasten suppuration, the warm poultices should be frequently renewed, and they should be continued till the tension and swelling, with which wounds of this kind are usually attended, be removed, and till the sore has acquired a red, healthy, granulating appearance, and then it is to be treated like a common ulcer.

Gun-shot wounds are commonly covered from the beginning with deep sloughs, and various remedies are recommended for removing these. Every appearance, however, of this kind with which they are attended proceeds entirely from contusion; and, excepting the injury be extensive, the slough is not often perceptible, or it is so thin as to come away along with the matter at the first or second dressing. Although emollient poultices be extremely useful, they ought to be no longer continued than till the effects already mentioned are produced; otherwise they will not only relax the parts, but also produce too copious a discharge of matter, which is sometimes attended with great danger. A too copious flow of matter may proceed from different causes; but in whatever way it may have been produced, the practice to be adopted must be nearly the same. Every collection which appears must have a free outlet, and the limb laid in that posture which will most readily admit of its running off. In such circumstances, nourishing diet and Peruvian bark in considerable quantities are highly useful. When the discharge continues copious, in spite of every effort to check it, detached pieces of bone or some extraneous matter are probably the cause. In such a situation nothing will lessen the quantity of matter till such substances be removed. The wound ought therefore again to be examined, and any loose bodies taken away. Pieces of cloth have been known to be removed by setons, when that method was practicable, after every other method had failed. Opium is frequently used in checking an excessive discharge when it happens to be kept up by irritation.

Although no considerable hemorrhagy may happen on first receiving a gun-shot wound; yet after the sloughs commonly produced upon such occasions have come off, some considerable arteries may be exposed, and then a dangerous hemorrhagy may ensue. The hemorrhagy is often preceded by a great heat in the injured parts, and with a throbbing pulsatory pain. At this period it may frequently be prevented by plentiful blood-letting, particularly local. But if the hemorrhagy has fairly taken place, and from arteries of considerable size, nothing will restrain it but the proper application of ligatures. As the discharge in these cases would often prove dangerous before the surgeon could be procured, the attendants should be furnished with a tourniquet, with directions to apply it, upon the first appearance of blood.

Till of late years the scarifying of gun-shot wounds was a practice which prevailed very universally among surgeons; and it was expected by this, that the sloughs with which wounds are sometimes covered would sooner separate, and that the cure would thereby be more readily performed. It is now, however, known, that this practice, instead of being useful, very generally does harm by increasing the inflammation. It should therefore be laid entirely aside. 29 Scarifying improper.

When a gun-shot wound cannot easily or safely be laid open from one end to the other, perhaps it may be proper to introduce a cord through the sinus. This, however, should not be attempted till the first or inflammatory state of the wound is over: but when a cord cannot be properly introduced, on account of the situation or direction of the wound, compression may prove equally useful here as in cases of punctured wounds.

Mortification happening after gun-shot wounds, is to be treated in the same manner as if it had arisen from any other cause, only bark is not to be promiscuously used; as, in plethoric habits, it may prove hurtful, though in debilitated relaxed habits it will be extremely useful; but even in such it should never be given while much pain and tension continue. 30 Mortification.

Of Wounds and Injuries of the Head producing Fractures and Depressions.—When the brain is compressed, a set of symptoms ensue, extremely dangerous, though sometimes they do not make their appearance till after a considerable interval. But at whatever time they appear, they are uniformly of the same kind, and 31 Symptoms of compression of the brain.

are

Wounds.

are in general as follows: drowsiness, giddiness, and stupefaction, dimness of sight, dilatation of the pupil; and, where the injury done to the head is great, there is commonly a discharge of blood from the eyes, nose, or ears. Sometimes the fractured bone can be discovered through the integuments, at other times it cannot. There is an irregular and oppressed pulse, and snoring or apoplectic stertor in breathing. There is likewise nausea and vomiting, with an involuntary discharge of fæces and urine. Among the muscles of the extremities and other parts, there is loss of voluntary motion, convulsive tremors is some parts of the body, and palsy in others, especially in that side of the body which is opposite to the injured part of the head.

Some of the milder of these symptoms, as vertigo, stupefaction, and a temporary loss of sensibility, are frequently induced by slight blows upon the head, but commonly soon disappear, either by rest alone, or by the means to be afterwards pointed out. But when any other symptoms ensue, such as dilatation of the pupils, and especially when much blood is discharged from the eyes, nose, and ears, and that there is an involuntary discharge of fæces and urine, it may be reasonably concluded that compression of the brain is induced.

The cavity of the cranium, in the healthy and natural state, is everywhere completely filled by the brain; whatever therefore diminishes that cavity, will produce a compression of the brain.

32 Causes of these.

The causes producing such a diminution may be of various kinds, as fracture and depression of the bones of the cranium; the forcible introduction of any extraneous body into the cavity of the cranium; effusion of blood, serum, pus, or any other fluid; the thickness and irregularity of the bones of the cranium in certain diseases, as in lues venerea, rickets, or spina ventosa; or water collected in hydrocephalous cases. The first set of causes shall be considered in their order. The four last mentioned belong to the province of the physician, and have been considered in a former part of this work.

Fractures of the cranium have been differently distinguished by different authors; but it seems sufficient to divide them into those attended with depression, and those which are not.

In fracture and depression of the cranium, the treatment ought to be,—to discover the situation and extent of the fracture; and to obviate the effects of the injury done to the brain, by raising or removing all the depressed parts of the bone.

33 Method of discovering the situation of fractures of the cranium.

When the teguments corresponding to the injury done to the bone are cut or lacerated, and, as is sometimes the case, entirely removed, the state of the fracture is immediately discovered; but when the integuments of the skull remain entire, even though the general symptoms of fracture be present, there is sometimes much difficulty in ascertaining it. When, however, any external injury appears, particularly a tumor from a recent contusion, attended by the symptoms already described, there can be no doubt of the existence of a fracture. But it sometimes happens that compression exists without the smallest appearance of tumor. In such cases, the whole head ought to be shaved, when an inflammatory spot may frequently be observed. Sometimes the place of the fracture has been discovered by the patient applying the hand frequently on or near some particular part of the head.

When the symptoms of a compressed brain are evidently marked, no time ought to be lost in setting about an examination of the state of the cranium, wherever appearances point out, or even lead us to conjecture, in what part a fracture may be situated. For this purpose an incision is to be made upon the spot through the integuments to the surface of the bone, which must be sufficiently exposed to admit of a free examination.

Some authors have recommended a crucial incision; others one in form of the letter T; while many advise a considerable part of the integuments to be entirely removed. But as it is more agreeable to the present mode of practice to save as much of the skin as possible, a simple incision is generally preferred, unless the fracture run in different directions, and then the incision must vary accordingly. It will frequently happen, that a considerable part of the integuments must be separated from the skull, in order to obtain a distinct view of the full extent of the fracture; but no part of the integuments is to be entirely removed.

When blood-vessels of any considerable size are divided, either before or in time of the examination, they ought to be allowed to bleed freely, as in no case whatever is the loss of blood attended with more advantage than the present. When, however, it appears that the patient has lost a sufficient quantity, the vessels ought to be secured.

After the integuments have been divided, if the skull be found to be fractured and depressed, the nature of the case is rendered evident; but even where there is no external appearance of fracture, tumor, discoloration, or other injury, if the patient continne to labour under symptoms of a compressed brain, if the pericranium has been separated from the bone, and especially if the bone has lost its natural appearance, and has acquired a pale white or dusky yellow hue, the trepan ought to be applied without hesitation at the place where these appearances mark the principal seat of the injury.

Again, although no mark either of fracture or of any diseases underneath should appear on the outer table of the bone, yet there is a possibility that the inner table may be fractured and depressed. This indeed is not a common occurrence, but it happens probably more frequently than surgeons have been aware of; and where it does happen, the injury done to the brain is as great, and attended with as much danger, as where the whole thickness of the bone is beat in. The application of the trepan is therefore necessary.

But if, after the application of the trepan, it happens that no mark of injury appears either in the outer or inner table in that part, or in the dura mater below it, and that the symptoms of a compressed brain still continue, a fracture in some other part is to be suspected; or that kind of fracture termed by practitioners *counter fissure*, where the skull is fractured and sometimes depressed on the opposite side to, or at a distance from, the part where the injury was received. This is fortunately not a very frequent occurrence, and has even been doubted by some; but different instances of it have, beyond all question, been found. If therefore the operation of the trepan has been performed, and no fracture is

Wounds.

is discovered, no extravasation appears on the surface of the brain; and if blood-letting and other means usually employed do not remove the symptoms of compression, the operator is to search for a fracture on some other part. The whole head should again be examined with much accuracy; and, by pressing deliberately but firmly over every part of it, if the smallest degree of sensibility remains, the patient will show signs of pain, either by moans or by raising his hands, when pressure is made over the fractured part. In this way fractures have been frequently detected, which might otherwise have been concealed.

34 Method of removing and elevating depressed portions of the cranium.

Having now considered every thing preparatory to the operation of the trepan, we shall next point out the means best adapted for the removal or elevation of a depressed portion of the bone.

The first thing to be done is, after shaving the head, to make an incision as deep as the bone, and directly upon the course of the fracture.

The patient ought to be laid on a table, with a mattress under him, while his head is placed upon a pillow, and secured by an assistant. When the extent of the fracture has been determined, and the bleeding from the incision stopped, the depressed bone is now to be elevated; but previous to this it is necessary to search for detached pieces. Should any be found, they ought to be removed by a pair of forceps adapted to this purpose. By the same instrument any splinters of bone which may have been beaten in may be removed; but when a part of the bone is beaten in beyond the level of the rest of the cranium, as much of the pericranium is then to be removed by a raspatory, as will allow the trephine to be applied; or, if the operator incline, for the sake of dispatch, he may use the trepan; or the operation may be begun and finished with the trephine, while the trepan may perform the middle and principal part of the work. This part of the work is begun by making a hole with the perforator, deep enough to fix the central pin of the trephine, in order to prevent the saw from slipping out of its central course, till it has formed a groove sufficiently deep to be worked steadily in; and then the pin is to be removed. If the bone be thick, the teeth of the saw must be cleaned now and then by the brush during the perforation, and dipped in oil as often as it is cleaned, which will considerably facilitate the motion, and render it more expeditious: making it at the same time much less disagreeable to the patient, if he possess his senses. That no time may be lost, the operator ought to be provided with two instruments of the same size, or at least to have two heads which can be readily fitted to the same handle.

After having made some progress in the operation, the groove ought to be frequently examined with a pick-tooth, or some such instrument, in order to discover its depth; and if one side happen to be deeper than the other, the operator ought to press more on that side which is shallowest. Precautions are more particularly necessary when the operation is performed upon a part of the skull which is of an unequal thickness, especially after the instrument has passed the diploe. And though it be said by writers in general that the instrument may be worked boldly till it comes at the diploe (which is generally known by the appearance of blood), yet the operator should be upon his guard in this point, examining from time to time if the piece be loose, lest through inadvertence the dura mater be wounded; for in some parts of the skull there is naturally very little diploe, and in old subjects scarcely any. It ought likewise to be remembered, that the skulls of children are very thin. When the piece begins to vacillate, it ought to be snapped off with the forceps or levator; for the sawing ought by no means to be continued till the bone be cut quite through, otherwise the instrument may plunge in upon the brain, or at least injure the dura mater (B). If the inner edge of the perforation be left ragged, it is to be smoothed with the lenticular, to prevent it from irritating the dura mater. Particular care is to be taken in using the instrument, lest it should press too much upon the brain.

The next step is to raise the depressed part of the bone with the levator, or to extract the fragments of the bone, grumous blood, or any extraneous body. After this, if there appear reason to apprehend that blood, lymph, or matter, is contained under the dura mater, it ought to be cautiously opened with a lancet, endeavouring to avoid the blood-vessels running upon it, or lying immediately under it.

When the trepan is to be used on account of a fissure in which the bone will not yield, the instrument should be applied so as to include part of it, if not directly over it, as it is most probable that the extravasated fluid will be found directly under it. And when the fissure is of great extent, it may be proper to make a perforation at each end, if the whole can be conveniently brought into view; and in some cases several perforations may become necessary.

When it is proposed to make several perforations to remove depressed fragments of the bone which are firmly fixed, and having the internal surface larger than the external, or to raise them sufficiently, it is necessary to apply the trepan as near the fractured parts as possible; making the perforations join each other, to prevent the trouble of cutting the intermediate spaces.

When the skull is injured over a suture, and it is not thought advisable to use the trepan, a perforation ought to be made on each side of the suture, especially in young subjects, in which the dura mater adheres more strongly than in adults; because there cannot be a free communication between the one side and the other, on account of the attachment of that membrane to the suture.

35 Treatment of the patient after the operation.

After the elevation of the depressed pieces, or the removal of those which are quite loose, the extraction of extraneous bodies, and the evacuation of extravasated fluids, &c. the sore is to be dressed in the lightest and easiest manner; all that is necessary being to apply a pledget of fine scraped lint, covered with simple ointment, to that part of the dura mater which is laid bare by

(B) A trepanning instrument has been invented by Mr Rodman, surgeon, Paisley, which has no central pin, and it is so contrived that any given thickness of bone may be cut, so that the danger from other instruments is by the use of this entirely avoided. See a more detailed account of this instrument under ABAPTISTON.

Wounds. by the trepan, or otherwise; after which the edges of the scalp are to be brought together or nearly so, and another pledget laid along the whole course of the wound; a piece of fine soft linen is to be laid over all, and the dressings may be retained in their place by a common night-cap applied close to the head, and properly fixed.

The patient is to be placed in as easy a position in bed as possible, with his head and shoulders elevated a little more than ordinary. If the operation be attended with success, the patient will soon begin to show favourable symptoms; he will soon show signs of increasing sensibility, and the original bad symptoms will gradually disappear. After this he ought to be kept as quiet as possible; proper laxatives are to be administered, and such as may be least of a nauseating nature. His food ought to be simple and easy of digestion, and his drink of the most diluent kind. If he complain of the wound being uneasy, an emollient poultice should be immediately applied, and renewed three or four times in the twenty-four hours. By these means there will commonly be a free suppuration from the whole surface of the sore.

Every time the wound is dressed, the purulent matter ought to be wiped off from it with a fine warm sponge; and if any degree of sloughiness take place on the dura mater or parts adjacent, it will then be completely separated. Granulations will begin to form, which will continue to increase till the whole arise to a level with the surface of the cranium. The edges of the sore are now to be dressed with cerate straps, and the rest of it covered with fine soft lint, kept gently pressed on by the nightcap properly tied. In this way the cure will go on favourably; luxuriance of granulations will commonly be prevented; the parts will cicatrize kindly; and as the skin has been preserved in making the first incision, the cicatrix will be but little observed.

But things do not always proceed in this favourable manner. Sometimes in a few hours after the operation the patient is seized with a kind of restlessness, tossing his arms, and endeavouring to move himself in bed, while the symptoms of a compressed brain remain nearly the same as formerly. In this case, especially if the pulse be quick and strong, the patient ought to be bled freely, as there will be reason to suspect some tendency to inflammation in the brain. Sometimes, though the trepan has been properly applied, the symptoms are not relieved, on account of extravasated fluids collected internally under the dura mater, or between the pia mater and brain, or in the cavity of the ventricles. The danger in these cases will be in proportion to the depth of the collection. Particular attention therefore ought always to be paid to the state of the dura mater after the perforation has been made. If blood be collected below the dura mater, this membrane will be found tense, dark coloured, elastic, and even livid; in which case, an opening becomes absolutely necessary to discharge the extravasated fluid. Gentle scratches are to be made with a scalpel, till a probe or directory can be introduced; upon which the membrane is to be sufficiently divided in a longitudinal, and sometimes even in a crucial direction, till an outlet to the fluid be given.

After the dura mater has been cut in this manner, there is some danger of the brain protruding at the opening; but the danger from this is not equal to the bad effects arising from effused fluids compressing the brain.

A troublesome and an alarming appearance now and then follows the operation of the trepan; namely, the excrescences called *fungi*, formerly supposed to grow immediately from the surface of the brain, but which, in general, originate from the surface of the dura mater or cut edge of the bone granulating too luxuriantly.

It often happens that they possess little sensibility; and then the best method to prevent their rising to any great height is to touch them frequently with lunar caustic: but some cases occur where their sensibility is so great that they cannot be touched, unless they hang by a small neck; and then a ligature may be put round them, and tightened from time to time till they drop off, which will commonly be in the course of a few days. It seldom happens, however, that there is any occasion for applying such means for the removal of these tumours, for they generally fall off as the perforations of the bone fill up.

If they do not, as the connection between them and the brain will be then in a great measure intercepted, they may be with more safety removed, either by excision, by caustic, or by ligature.

The cure being thus far completed, only a small cicatrix will remain, and in general the parts will be nearly as firm as at first: but when much of the integuments have been separated or destroyed, as they are never regenerated, the bone will be left covered only by a thin cuticle, with some small quantity of cellular substance. When this is the case, the person ought to wear a piece of lead or tin, properly fitted and lined with flannel, to protect it from the cold and other external injuries.

This is the method now commonly practised in cases of compression; but it frequently happens, that instead of compression, such a degree of concussion takes place that no assistance from the trepan can be attended with any advantage; for the effects of concussion are totally different from those of compression, and therefore to be removed in a different manner.

WOUNDS, in *Farriery*. See FARRIERY *Index*.

WRASSE, or OLD WIFE. See LABRUS, ICHTHYOLOGY *Index*.

WREATH, in *Heraldry*, a roll of fine linen or silk (like that of a Turkish turban), consisting of the colours borne in the escutcheon, placed in an achievement between the helmet and the crest, and immediately supporting the crest.

WRECK, or SHIPWRECK, the destruction of a ship by rocks or shallows at sea.

By the ancient common law, where any ship was lost at sea, and the goods or cargo were thrown upon the land, these goods, so wrecked, were judged to belong to the king: for it was held, that, by the loss of the ship, all property was gone out of the original owner. But this was undoubtedly adding sorrow to sorrow, and was consonant neither to reason nor humanity. Wherefore it was first ordained by King Henry I. that if any person escaped alive out of the ship, it should be no wreck; and afterwards King Henry II. by his charter, declared, that if on the coasts of either England, Poictou, Oleron, or Gascony, any ship should be distressed, and

Wreck.

and either man or beast should escape or be found therein alive, the goods should remain to the owners, if they claimed them within three months; but otherwise should be esteemed a wreck, and should belong to the king, or other lord of the franchise. This was again confirmed with improvements by King Richard I.; who, in the second year of his reign, not only established these concessions, by ordaining that the owner, if he was shipwrecked and escaped, *omnes res suas liberas et quietas haberet*, but also, that if he perished, his children, or, in default of them, his brethren and sisters, should retain the property: and in default of brother or sister, then the goods should remain to the king (A). And the law, as laid down by Bracton in the reign of Henry III. seems still to have improved in its equity. For then, if not only a dog (for instance) escaped, by which the owner might be discovered, but if any certain mark were set on the goods, by which they might be known again, it was held to be no wreck. And this is certainly most agreeable to reason; the rational claim of the king being only founded upon this, that the true owner cannot be ascertained. Afterwards, in the first statute of Westminster, the time of limitation of claims, given by the charter of Henry II. is extended to a year and a day, according to the usage of Normandy: and it enacts, that if any man, a dog, or a cat, escape alive, the vessel shall not be adjudged a wreck. These animals, as in Bracton, are only put for examples; for it is now held, that not only if any live thing escape, but if proof can be made of the property of any of the goods or lading which come to shore, they shall not be forfeited as wreck. The statute further ordains, that the sheriff of the county shall be bound to keep the goods a year and a day (as in France for one year, agreeable to the maritime laws of Oleron, and in Holland for a year and a half), that if any man can prove a property in them, either in his own right or by right of representation, they shall be restored to him without delay; but if no such property be proved within that time, they then shall be the king's. If the goods are of a perishable nature, the sheriff may sell them, and the money shall be liable in their stead. This revenue of wrecks is frequently granted out to lords of manors as a royal franchise; and if any one be thus intitled to wrecks in his own land, and the king's goods are wrecked thereon, the king may claim them at any time, even after the year and day.

It is to be observed, that, in order to constitute a legal wreck, the goods must come to land. If they continue at sea, the law distinguishes them by the barbarous and uncouth appellations of *jetsam*, *flotsam*, and *ligan*. Jetsam is where goods are cast into the sea, and there sink and remain under water: flotsam is where they continue swimming on the surface of the waves: ligan is where they are sunk in the sea, but tied to a cork or buoy, in order to be found again. These are also the king's, if no owner appears to claim them; but if any owner appears, he is intitled to recover the possession. For even if they be cast overboard, without any mark or buoy, in order to lighten the ship, the owner is not by this act of necessity construed to have renounced his property: much less can things ligan be supposed to be abandoned, since the owner has done all in his power to assert and retain his property. These three are therefore accounted so far a distinct thing from the former, that by the king's grant to a man of wrecks, things jetsam, flotsam, and ligan, will not pass.

Wrecks, in their legal acceptation, are at present not very frequent; for if any goods come to land, it rarely happens, since the improvement of commerce, navigation, and correspondence, that the owner is not able to assert his property within the year and day limited by law. And in order to preserve this property entire for him, and if possible to prevent wrecks at all, our laws have made many very humane regulations; in a spirit quite opposite to these savage laws which formerly prevailed in all the northern regions of Europe, and a few years ago were still said to subsist on the coasts of the Baltic sea, permitting the inhabitants to seize on whatever they could get as lawful prize; or, as an author of their own expresses it, "*in naufragorum miseria et calamitate tanquam vultures ad prædam currere.*" For by the statute 27 Edw. III. c. 13. if any ship be lost on the shore, and the goods come to land (which cannot, says the statute, be called *wreck*), they shall be presently delivered to the merchants, paying only a reasonable reward to those that saved and preserved them, which is intitled *salvage*. Also by the common law, if any persons (other than the sheriff) take any goods so cast on shore, which are not legal wreck, the owners might have a commission to inquire and find them out, and compel them to make restitution. And by 12 Ann. stat. 2. c. 18. confirmed by 4 Geo. I. c. 12. in order to assist the distressed, and prevent the scandalous illegal practices on some of our sea-coasts (too similar to those on the Baltic), it is enacted, that all head-officers and others of towns near the sea, shall, upon application made to them, summon as many hands as are necessary, and send them to the relief of any ship in distress, on forfeiture of 100l.; and in case of assistance given, salvage shall be paid by the owners, to be assessed by three neighbouring justices. All persons that secrete any goods shall forfeit their treble value; and if they wilfully do any act whereby the ship is lost or destroyed, by making holes in her, stealing her pumps, or otherwise, they are guilty of felony without benefit of clergy. Lastly, by the statute of 26 Geo. II. c. 19. plundering any vessel, either in distress or wrecked, and whether any living creature be on board or not (for whether wreck or otherwise, it is clearly not the property of the populace), such plundering or preventing the escape of any person that endeavours to save his life, or wounding him with intent to destroy him, or putting out false lights in order to bring any vessel into danger, are all declared to be capital felonies; in like manner as the destroying of trees, steeples, or other stated sea-marks, is

(A) In like manner Constantine the Great, finding that by the imperial law the revenue of wrecks was given to the prince's treasury or fiscus, restrained it by an edict (Cod. 11. 5. 1.) and ordered them to remain to the owners; adding this humane expostulation: "Quod enim jus habet fiscus in aliena calamitate, ut de re tam luctuosa compendium sectetur."

Wreck ‖ Wrestling.

is punished by the statute 8 Eliz. c. 13. with a forfeiture of 100l. or outlawry. Moreover, by the statute of Geo. II. pilfering any goods cast ashore is declared to be petty larceny; and many other salutary regulations are made, for the more effectually preserving ships of any nation in distress.

By the civil law, to destroy persons shipwrecked, or prevent their saving the ship, is capital. And to steal even a plank from a vessel in distress or wrecked, makes the party liable to answer for the whole ship and cargo. The laws also of the Wisigoths, and the most early Neapolitan constitutions, punished with the utmost severity all those who neglected to assist any ship in distress, or plundered any goods cast on shore.

WREN. See Motacilla, Ornithology *Index*.

Wren, *Sir Christopher*, a great philosopher, and one of the most learned and most eminent architects of his age, was the son of Christopher Wren dean of Windsor, and was born in 1632. He studied at Wadham college in Oxford; where he took the degree of master of arts in 1653, and was chosen fellow of All-Souls college. When very young he discovered a surprising genius for the mathematics; in which science he made great advances before he was sixteen years old. In 1657, he was made professor of astronomy at Gresham college, London; which he resigned in 1660, on his being chosen to the Savilian professorship of astronomy in Oxford: he was next year created doctor of laws, and in 1663 was elected fellow of the Royal Society. He was one of the commissioners for the reparation of St Paul's; and in 1665 travelled into France, to examine the most beautiful edifices there, when he made many curious observations. At his return to England, he drew a noble plan for rebuilding the city of London after the fire, which he presented to parliament; and upon the decease of Sir John Denham in 1668, was made surveyor-general of his majesty's works; and from that time had the direction of a great number of public edifices, by which he acquired the highest reputation. He built the magnificent theatre at Oxford, St Paul's cathedral, the churches of St Stephen Walbrook, and St Mary-le-Bow, the Monument, the modern part of the palace of Hampton Court, Chelsea college, one of the wings of Greenwich hospital, and many other beautiful edifices. He was president of the Royal Society, one of the commissioners of Chelsea college, and twice member of parliament; first for Plymouth in Devonshire, and then for Melcomb Regis in the same county; but in 1718 was removed from his place of surveyor-general. He died in 1723, and was interred in the vault under St Paul's.

This great man also distinguished himself by many curious inventions and discoveries in natural philosophy; and, among many others, contrived an instrument for measuring the quantity of rain that falls on any space of land for a year; he invented many ways of making astronomical observations more accurate and easy; and was the first author of the anatomical experiment of injecting liquors into the veins of animals, &c. He translated into Latin Mr Oughtred's *Horologiographia Geometrica*; and wrote a Survey of the cathedral church of Salisbury, and other pieces. After his death his posthumous works and draughts were published by his son.

WRESTLING, a kind of combat or engagement between two persons unarmed, body to body, to prove their strength and dexterity, and try which can throw his opponent to the ground.

Wrestling is an exercise of very great antiquity and fame. It was in use in the heroic age; witness Hercules, who wrestled with Antæus.

It continued a long time in the highest repute, and had considerable rewards and honours assigned to it at the Olympic games. It was the custom for the athletæ to anoint their bodies with oil, to give the less hold to their antagonists.

Lycurgus ordered the Spartan maids to wrestle in public quite naked, in order, as it is observed, to break them of their too much delicacy and niceness, to make them appear more robust, and to familiarize the people, &c. to such nudities.

WRIST, in *Anatomy*. See there, N° 53.

WRIT, in *Law*, signifies, in general, the king's precept in writing under seal, issuing out of some court, directed to the sheriff or other officer, and commanding something to be done in relation to a suit or action, or giving commission to have the same done. And, according to Fitzherbert, a writ is said to be a formal letter of the king in parchment, sealed with his seal, and directed to some judge, officer, or minister, &c. at the suit of a subject, for the cause briefly expressed, which is to be determined in the proper court according to law.

Writs, in civil actions, are either original or judicial: original, are such as are issued out of the court of chancery for the summoning of a defendant to appear, and are granted before the suit is commenced, in order to begin the same; and judicial writs issue out of the court where the original is returned, after the suit is begun. See Process.

The original writ is the foundation of the suit. See Suit.

When a person hath received an injury, and thinks it worth his while to demand a satisfaction for it, he is to consider with himself, or take advice, what redress the law has given for that injury; and thereupon is to make application or suit to the crown, the fountain of all justice, for that particular specific remedy which he is determined or advised to pursue. As for money due on bond, an action of debt; for goods detained without force, an action of *detenue* or *trover*; or, if taken with force, an action of *trespass vi et armis*; or, to try the title of lands, a writ of entry or action of trespass in ejectment; or for any consequential injury received, a special action on the case. To this end he is to sue out, or purchase by paying the stated fees, an *original* or original writ from the court of chancery, which is the *officina justitiæ*, the shop or mint of justice, wherein all the king's writs are framed. It is a mandatory letter from the king in parchment, sealed with his great seal, and directed to the sheriff of the county wherein the injury is committed, or supposed so to be, requiring him to command the wrong-doer, or party accused, either to do justice to the complainant, or else to appear in court, and answer the accusation against him. Whatever the sheriff does in pursuance of this writ, he must return or certify to the court of common pleas, together with the writ itself: which is the foundation of the jurisdiction of that court, being the king's warrant for the judges to proceed to the determination of the cause. For it was a maxim introduced by the Normans, that there should be

Writs. be no proceedings in common-pleas before the king's justices without his original writ; because they held it unfit that those justices, being only the substitutes of the crown, should take cognizance of any thing but what was thus expressly referred to their judgment. However, in small actions, below the value of forty shillings, which are brought in the court-baron or county-court, no royal writ is necessary; but the foundation of such suits continue to be (as in the times of the Saxons), not by original writ, but by plaint; that is, by a private memorial tendered in open court to the judge, wherein the party injured sets forth his cause of action: and the judge is bound of common right to administer justice therein, without any special mandate from the king. Now indeed even the royal writs are held to be demandable of common right, on paying the usual fees: for any delay in the granting them, or setting an unusual or exorbitant price upon them, would be a breach of magna charta, c. 29. "nulli vendemus, nulli negabimus, aut differemus justitiam vel rectum."

Original writs are either optional or peremptory; or, in the language of our law, they are either a *præcipe* or a *si te fecerit securum*. The *præcipe* is in the alternative, commanding the defendant to do the thing required, or show the reason wherefore he hath not done it. The use of this writ is where something certain is demanded by the plaintiff, which is in the power of the defendant himself to perform; as, to restore the possession of land, to pay a certain liquidated debt, to perform a specific covenant, to render an account, and the like; in all which cases the writ is drawn up in the form of a *præcipe* or command, to do thus, or show cause to the contrary; giving the defendant his choice to redress the injury or stand the suit. The other species of original writs is called a *si fecerit te securum*, from the words of the writ; which directs the sheriff to cause the defendant to appear in court, without any option given him, provided the plaintiff gives the sheriff security effectually to prosecute his claim. This writ is in use where nothing is specifically demanded, but only a satisfaction in general; to obtain which, and minister complete redress, the intervention of some judicature is necessary. Such are writs of trespass, or on the case, wherein no debt or other specific thing is sued for in certain, but only damages to be assessed by a jury. For this end the defendant is immediately called upon to appear in court, provided the plaintiff gives good security of prosecuting his claim. Both species of writs are tested or witnessed, in the king's own name; "witness ourself at Westminster", or wherever the chancery may be held.

The security here spoken of, to be given by the plaintiff for prosecuting his claim is common to both writs, though it gives denomination only to the latter. The whole of it is at present become a mere matter of form; and John Doe and Richard Roe are always returned as the standing pledges for this purpose.—The ancient use of them was to answer for the plaintiff, who in case he brought an action without cause, or failed in the prosecution of it when brought, was liable to an amercement from the crown for raising a false accusation; and so the form of the judgment still is. In like manner, as by the Gothic constitutions no person was permitted to lay a complaint against another *nisi sub scriptura aut specificatione trium testium, quod actionem vellet persequi*: and, as by the laws of Sancho I. king of Portugal, damages were given against a plaintiff who prosecuted a groundless action.

Writs, Writing.

The day on which the defendant is ordered to appear in court, and on which the sheriff is to bring in the writ, and report how far he has obeyed it, is called the *return of the writ*; it being then returned by him to the king's justices at Westminster. And it is always made returnable at the distance of at least 15 days from the date or test, that the defendant may have time to come up to Westminster, even from the most remote parts of the kingdom; and upon some day in one of the four terms, in which the court sits for the dispatch of business.

WRITING, the art or act of signifying and conveying our ideas to others, by letters or characters visible to the eye. See COMPOSITION, GRAMMAR, and LANGUAGE.

The most ancient remains of writing, which have been transmitted to us, are upon hard substances, such as stones and metals, which were used by the ancients for edicts and matters of public notoriety; the decalogue was written on two tables of stone; but this practice was not peculiar to the Jews, for it was used by most of the eastern nations, as well as by the Greeks and Romans; and therefore the ridicule which Voltaire attempts to cast upon that part of the book of Genesis, where the people are commanded to write the law on stones, is absurd; for what is there said by no means implies, that other materials might not be used on common occasions. The laws penal, civil, and ceremonial, among the Greeks, were engraven on tables of brass which were called *cyrbes*.

We find that wood was also used for writing on in different countries. In the Sloanian library (N° 4852.) are six specimens of Kufic writings, on boards about two feet in length, and six inches in depth. The Chinese, before the invention of paper, wrote or engraved with an iron tool upon thin boards or on bamboo. Pliny says, that table books of wood were in use before the time of Homer. These table books were called by the Romans *pugillares*. The wood was cut into thin slices, and finely plained and polished. The writing was at first upon the bare wood, with an iron instrument called a *style*. In latter times these tables were usually waxed over, and written upon with that instrument. The matter written upon the tables which were thus waxed over was easily effaced, and by smoothing the wax new matter might be substituted in the place of what had been written before. The Greeks and Romans continued the use of waxed table-books long after the use of papyrus, leaves, and skins, became common, because they were so convenient for correcting extemporary compositions.

Table books of ivory are still used for memorandums, but they are commonly written upon with black lead pencils. The practice of writing on table-books covered with wax was not entirely laid aside till the commencement of the 14th century.

The bark of trees was also used for writing by the ancients, and is so still in several parts of Asia. The same thing may be said of the leaves of trees. It is needless to observe the use of parchment and vellum, papyrus and paper, for writing; it is too well known.

The method of fabricating these substances has been already described as they occurred in the order of the alphabet.

It is obvious, that when men wrote, or rather engraved, on hard substances, instruments of metal were necessary, such as the chisel and the stylus; but the latter was chiefly used for writing upon boards, waxed tablets, or on bark.

When the ancients wrote on softer materials than wood or metal, other instruments were used for writing with, of which reeds and canes seem to have been the first. Reeds and canes are still used as instruments for writing with by the Tartars, the Indians, the Persians, the Turks, and the Greeks. Pencils made of hair are used by the Chinese for their writing: they first liquefy their ink, and dip their pencils into it. Hair-pencils have likewise been used for writing in Europe. Large capital letters were made with them from the time of the Roman emperors till the 16th century. After the invention of printing they were drawn by the illuminators. Quills of geese, swans, peacocks, crows, and other birds, have been used in these western parts for writing with, but how long is not easy to ascertain. St Isidore of Seville, who lived about the middle of the 7th century, describes a pen made of a quill as used in his time.

Method of restoring decayed WRITINGS. In the 77th volume of the Phil. Trans. there is a paper on this subject by Sir Charles Blagden. One of the best methods he found upon experiment to be, covering the letters with phlogisticated or prussic alkali, with the addition of a diluted mineral acid; upon the application of which, the letters changed very speedily to a deep blue colour, of great beauty and intensity. To prevent the spreading of the colour, which, by blotting the parchment, detracts greatly from the legibility, the alkali should be put on first, and the diluted acid added upon it. The method found to answer best has been, to spread the alkali thin with a feather over the traces of the letters, and then to touch it gently, as nearly upon or over the letters as can be done with the diluted acid, by means of a feather or a bit of stick cut to a blunt point. Though the alkali should occasion no sensible change of colour, yet the moment the acid comes upon it, every trace of a letter turns at once to a fine blue, which soon acquires its full intensity, and is beyond comparison stronger than the colour of the original trace had been. If, then, the corner of a bit of blotting paper be carefully and dexterously applied near the letters, so as to imbibe the superfluous liquor, the staining of the parchment may be in a great measure avoided; for it is this superfluous liquor which, absorbing part of the colouring matter from the letters, becomes a dye to whatever it touches. Care must be taken not to bring the blotting paper in contact with the letters, because the colouring matter is soft whilst wet, and may easily be rubbed off. The acid chiefly employed was the marine; but both the vitriolic and nitrous succeed very well. They should be so far diluted as not to be in danger of corroding the parchment, after which the degree of strength does not seem to be a matter of much nicety.

WRITTEN MOUNTAINS. See MOUNTAINS.

WRY-NECK. See JYNX, ORNITHOLOGY *Index*.

WURTEMBERG, or WIRTEMBERG, formerly a duchy, now a kingdom in Germany. It is surrounded on all sides by the territories of Baden and Bavaria, except at the point where it touches the lake of Constance. It consists chiefly of the basin or valley of the Neckar, but a small part of it extends across the Danube. Its greatest length from south to north is 145 miles, its breadth from east to west 90, and its area amounts to 8,200 square English miles. Wurtemberg is one of the most populous countries in Germany, the number of inhabitants in 1818 being 1,395,463, or 170 on an average to each square mile.

Great numbers of emigrants leave this state annually for America or Russia. The country is hilly in the south, where it embraces part of a low range of mountains called the Black-forest, and some subordinate branches of the Alps, but presents generally an undulating surface in the north. It is, upon the whole, one of the most fertile districts of Germany. Besides wheat, oats, barley, maize, rye, hemp, and potatoes, it produces tobacco, fruits of many kinds, and vines, which are cultivated to a great extent, and yield a wine of superior quality. A considerable number of sheep, and a still greater proportion of black cattle are fed in the Black forest, and other hilly districts. These districts also furnish abundance of wood. There are mines of silver, copper, cobalt and iron, but not so productive as to supply the internal consumption. There are also manufactures of linens and woollens; a few of cotton, with some of leather and iron.

The inhabitants are Lutherans, with a small intermixture of Catholics. They are said to be distinguished from the other Germans by a greater share of vivacity, frankness, and good humour, but not by greater sobriety or industry. Their dialect is taxed with rudeness, but they can boast of having produced many writers of acknowledged merit. There is no part of Germany so well supplied with schools, not only for elementary instruction, but also for the learned languages. The people are in short extremely well informed; and the effects of their superior intelligence have been lately seen in the manly struggle they maintained, since the year 1815, for the restoration of their ancient privileges, which were abolished during the ascendancy of Bonaparte. Under their ancient constitution, the diet consisted of a house of prelates (for there were no nobles) representing certain abbeys, provostships, and Lutheran convents; and a house of deputies chosen by the towns. This diet met only on extraordinary occasions, but it appointed a great and a little committee, which held two or three sessions in the year; and through these committees it not only decided upon all taxes proposed, but controlled every branch of the administration, and even nominated one-third of the judges. The king offered his subjects a new constitution in 1816, but this was considered less liberal than their old one, and it experienced so much opposition that he was obliged to withdraw it. During the present year (1819) the differences between the contending parties have been adjusted by another constitution proposed by the king and accepted by the people; and which may therefore be presumed to be more favourable to popular rights, though we have not seen the specific articles of which it consists.

Wurtemberg has been greatly enlarged during the recent changes in Germany. In 1796 its surface was estimated at 3200 square English miles, and its inhabitants at 608,697; which is less than one half of its present

Wurtzburg, Wycherley.

present extent and population. It was indebted for the greater part of its acquisitions to Bonaparte; who also bestowed the title of king upon the duke in 1806. Stutgard is the chief town.

WURTSBURG, a large bishopric in Germany, situated on the Maine, erected into a dukedom in 1806, and given to Bavaria in 1814 as a compensation for Salzburg.

WURTZBURG, a large and handsome city of Germany, containing about 21,000 inhabitants. It is defended with good fortifications, and has a magnificent palace. There is a handsome hospital, in which are generally 400 poor men and women. The castle is at a small distance from the city, and commands it, as it stands upon an eminence. It communicates with the city by a stone bridge, on which are 12 statues, representing as many saints. There are manufactures of woollens, glass, leather, chemical substances, &c. There is also an university, founded in 1403. It is seated on the river Maine, in E. Long. 9. 48. N. Lat. 49. 40.

WYCHERLEY, William, an eminent English comic poet, was born about 1640. A little before the restoration of King Charles II. he became a gentleman commoner of Queen's college Oxford, where he was reconciled by Dr Barlow to the Protestant religion, which he had a little before abandoned in his travels. He afterwards entered himself in the Middle-temple, but soon quitted the study of the law for pursuits more agreeable to his own genius, as well as to the taste of the age. Upon writing his first play, entitled, Love in a Wood, or St James's Park, which was acted in 1672, he became acquainted with several of the celebrated wits both of the court and town, and likewise with the duchess of Cleveland. Some time after appeared his comedies, called The Gentleman Dancing Master, the Plain Dealer, and the Country Wife; all which were acted with applause. George duke of Buckingham had a very high esteem for him, and bestowed on him several advantageous posts. King Charles also showed him signal marks of favour; and once gave him a proof of his esteem, which perhaps never any sovereign prince before had given to a private gentleman. Mr Wycherley being ill of a fever, at his lodgings in Bow-street, the king did him the honour of a visit. Finding him extremely weakened, he commanded him to take a journey to the south of France, and assured him, at the same time, that he would order him 500l. to defray the charges of the journey. Mr Wycherley accordingly went into France; and having spent the winter there, returned to England entirely restored to his former vigour. The king, shortly after his arrival, told him, that he had a son, who he was resolved should be educated like the son of a king, and that he could not choose a more proper man for his governor than Mr Wycherley; for which service 1500l. *per annum* should be settled upon him.

Immediately after this offer he went to Tunbridge, where walking one day upon the Well's walk with his friend Mr Fairbeard of Gray's Inn, just as he came up to the bookseller's shop, the countess of Drogheda, a young widow, rich, noble, and beautiful, came there to inquire for the Plain Dealer; "Madam," says Mr Fairbeard, "since you are for the Plain Dealer, there he is for you;" pushing Mr Wycherley towards her. "Yes," says Mr Wycherley, "this lady can bear plain dealing; for she appears to be so accomplished, that what would be a compliment to others, would be plain dealing to her." "No, truly, Sir," said the countess "I am not without my faults, any more than the rest of my sex; and yet notwithstanding, I love plain dealing, and am never more fond of it than when it tells me of them." "Then, madam," says Mr Fairbeard, "you and the Plain Dealer seem designed by Heaven for each other."—In short, Mr Wycherley walked a turn or two with the countess, waited upon her home, visited her daily while she staid at Tunbridge, and married her soon after without acquainting the king. By this step, which was looked upon as a contempt of his majesty's orders, he forfeited the royal favour. The countess of Drogheda settled her whole fortune upon him; but his title being disputed after her death, he was so reduced by the expences of the law and other incumbrances, as to be unable to satisfy the impatience of his creditors, who threw him into prison; and the bookseller who printed his Plain Dealer, by which he got almost as much money as the other gained reputation, was so ungrateful as to refuse to lend him 20l. in his extreme necessity. In that confinement he languished seven years; but at length King James going to see the above play, was so charmed with it, that he gave immediate orders for the payment of his debts, and even granted him a pension of 200l. *per annum*. But the prince's bountiful intentions were in a great measure defeated merely through Mr Wycherley's modesty; he being ashamed to tell the earl of Mulgrave, whom the king had sent to demand it, a true state of his debts. He laboured under the weight of these difficulties till his father died, who left him 600l. a-year. But this estate was under limitations, he being only a tenant for life, and not being allowed to raise any money for the payment of his debts. However, he took a method of doing it which few suspected to be his choice; and this was making a jointure. He had often declared, that he was resolved to die married, though he could not bear the thoughts of living in that state again: accordingly, just at the eve of his death, he married a young gentlewoman with 1500l. fortune, part of which he applied to the uses he wanted it for. Eleven days after the celebration of these nuptials, in December 1715, he died, and was interred in the vault of Covent-garden church.

Wycherley ‖ Wye.

Besides his plays above mentioned, he published a volume of poems in folio. In 1728 his posthumous works in prose and verse were published by Mr Theobald.

WYNDHAM, Sir William, descended of an ancient family, was born about the year 1687, and succeeded young to the title and estate of his father. On his return from his travels, he was chosen member for the county of Somerset; in which station he served in the three last parliaments of Queen Anne, and as long as he lived: after the change of the ministry in 1710, he was appointed secretary at war; and in 1713 was raised to be chancellor of the exchequer. Upon the breach between the earl of Oxford and Lord Bolingbroke, he adhered to the interests of the latter. He was removed from his employment on the accession of George I. and falling under suspicion on the breaking-out of the rebellion in 1715, was apprehended. He made his escape; a reward was published for apprehending him; he surrendered, was committed to the Tower, but never brought to a trial. After he regained his liberty, he continued in opposition to the several administrations under which he lived; and died in 1740.

WYE,

Wye.

WYE, a river of South Wales, which issuing out of Plinlymmon Hill, very near the source of the Severn, crosses the north-east corner of Radnorshire, giving name to the town of Rhyadergowy (Fall of the Wye), where it is precipitated in a cataract: then flowing between this county and Brecknockshire, it crosses Herefordshire, and dividing the counties of Gloucester and Monmouth, falls into the mouth of the Severn, below Chepstow. The romantic beauties of the Wye, which flows in a deep bed, between lofty rocks clothed with hanging woods, and here and there crowned by ruined castles, have employed the descriptive powers of the pen and pencil.

WYE is also the name of a river in Derbyshire, which rises in the north-west part, above Buxton; and, flowing south-east, falls into the Derwent, below Bakewell.

WYE, the name of a town in Kent, with a market on Thursday, seated on the Stour, 10 miles south of Canterbury, and 59 south-east of London. E. Long. 1. 4. N. Lat. 51. 10.

WYE, a town of Switzerland, in a territory of the abbey of St Gallen, with a palace. It is built on an eminence, 16 miles south-south-west of Constance. E. Long. 9. 4. N. Lat. 47. 34.

X.

X
||
Xebec.

X, or x, is the 22d letter of our alphabet, and a double consonant. It was not used by the Hebrews or ancient Greeks; for, as it is a compound letter, the ancients, who used great simplicity in their writings, expressed this letter by its component letters *cs*. Neither have the Italians this letter, but express it by *ss*. X begins no word in our language but such as are of Greek original; and is in few others but what are of Latin derivation; as *perplex*, *reflexion*, *defluxion*, &c. We often express this sound by single letters, as *cks*, in *backs*, *necks*; by *ks*, in *books*, *breaks*; by *cc*, in *access*, *accident*; by *ct*, in *action*, *unction*, &c. The English and French pronounce it like *cs* or *ks*; the Spaniards like *c* before *a*, viz. *Alexandro*, as it were *Alecandro*. In numerals it expresseth 10, whence in old Roman manuscripts it is used for *denarius*; and as such seems to be made of two V's placed one over the other. When a dash is added over it, thus $\bar{X}$, it signifies 10,000.

XANTHIUM, a genus of plants of the class *monoecia*, and arranged in the natural classification under the 49th order, *Compositæ*. See BOTANY *Index*.

XANTHOXYLUM. See ZANTHOXYLUM.

XEBEC, or ZEBEC, a small three-masted vessel, navigated in the Mediterranean sea, and on the coasts of Spain, Portugal, and Barbary. See Plate. CCCCLXXXII. fig. 10.

The sails of the xebec are in general similar to those of the poleacre, but the hull is extremely different from that and almost every other vessel. It is furnished with a strong prow: and the extremity of the stern, which is nothing more than a sort of railed platform or galley, projects farther behind the counter and buttock than that of any European ship.

Being generally equipped as a corsair, the xebec is constructed with a narrow floor, to be more swift in pursuit of the enemy; and of a great breadth, to enable her to carry a greater force of sail for this purpose without danger of overturning. As these vessels are usually very low built, their decks are formed with a great convexity, from the middle of their breadth towards the sides in order to carry off the water which falls aboard more readily by their scuppers. But as this extreme convexity would render it very difficult to walk thereon at sea, particularly when the vessel rocks by the agitation of the waves, there is a platform of grating extending along the deck from the sides of the vessel towards the middle, whereon the crew may walk dry-footed whilst the water is conveyed through the grating to the scuppers.

The xebecs, which are generally armed as vessels of war by the Algerines, mount from 16 to 24 cannon, and carry from 300 to 450 men, two-thirds of whom are generally soldiers.

By the very complicated and inconvenient method of working these vessels, what one of their captains of Algiers told Mr Falconer will be readily believed, viz. that every xebec requires at least the labour of three square-rigged ships, wherein the standing sails are calculated to answer every situation of the wind.

XENOCRATES, a celebrated ancient Grecian philosopher, was born at Chalcedon in the 95th Olympiad. At first he attached himself to Æschines, but afterwards became a disciple of Plato, who took much pains in cultivating his genius, which was naturally heavy. His temper was gloomy, his aspect severe, and his manners little tinctured with urbanity. These material defects his master took great pains to correct; frequently advising him to sacrifice to the Graces: and the pupil was patient of instruction, and knew how to value the kindness of his preceptor. As long as Plato lived, Xenocrates was one of his most esteemed disciples; after his death he closely adhered to his doctrine; and in the second year of the 110th Olympiad, he took the chair in the academy, as the successor of Speusippus.

Xenocrates was celebrated among the Athenians, not only for his wisdom, but for his virtues. So eminent was his reputation for integrity, that when he was called upon to give evidence in a judicial transaction, in which an oath was usually required, the judges unanimously agreed, that his simple asseveration should be taken, as a public testimony to his merit. Even Philip of Macedon found it impossible to corrupt him. So abstemious was he with respect to food, that his provision was frequently spoiled before it was consumed. He chastity was invincible. Phryne, a celebrated Athenian courtezan, attempted without success to seduce him. Of his humanity the following pathetic incident is a sufficient proof: A sparrow, which was pursued by a hawk, flew into his bosom; he afforded it protection till its enemy was out of sight, and then let it go, saying, that he would never betray a suppliant. He was fond of retirement, and was seldom seen in the city. He was discreet in the use of his time, and carefully allotted a certain portion of each day

day to its proper business. One of these he employed in silent meditation. He was an admirer of the mathematical sciences; and was so fully convinced of their utility, that when a young man, who was unacquainted with geometry and astronomy, desired admission into the academy, he refused his request, saying, that he was not yet possessed of the handles of philosophy. In fine, Xenocrates was eminent both for the purity of his morals and for his acquaintance with science, and supported the credit of the Platonic school, by his lectures, his writings, and his conduct. He lived to the first year of the 116th Olympiad, or the 82d of his age, when he lost his life by accidentally falling, in the dark, into a reservoir of water.

XENOPHANES, the founder of the Eleaic sect of philosophy among the Greeks, was born at Colophon probably about the 65th Olympiad. From some cause or other he left his country early, and took refuge in Sicily, where he supported himself by reciting, in the court of Hiero, elegiac and iambic verses, which he had written in reprehension of the theogonies of Hesiod and Homer. From Sicily he passed over into Magna Græcia, where he took up the profession of philosophy, and became a celebrated preceptor in the Pythagorean school. Indulging, however, a greater freedom of thought than was usual among the disciples of Pythagoras, he ventured to introduce new opinions of his own, and in many particulars to oppose the doctrines of Epimenides, Thales, and Pythagoras. Xenophanes possessed the Pythagorean chair of philosophy about seventy years, and lived to the extreme age of an hundred years, that is, according to Eusebius, till the 81st Olympiad. The doctrine of Xenophanes concerning nature is so imperfectly preserved, and obscurely expressed, that it is no wonder that it has been differently represented by different writers. Perhaps the truth is, that he held the universe to be one in nature and substance, but distinguished in his conception between the matter of which all things consist, and that latent divine force which, though not a distinct substance but an attribute, is necessarily inherent in the universe, and is the cause of all its perfection.

XENOPHON, an illustrious philosopher, general, and historian, was born at Athens in the third year of the 82d Olympiad. When he was a youth, Socrates, struck with his external appearance, determined to admit him into the number of his pupils. Meeting him by accident in a narrow passage, the philosopher put his staff across the path, and stopping him, asked, where those things were to be purchased which are necessary to human life? Xenophon appearing at a loss for a reply to this unexpected salutation, Socrates proceeded to ask him, where honest and good men were to be found? Xenophon still hesitating, Socrates said to him, "Follow me, and learn." From that time Xenophon became a disciple of Socrates, and made a rapid progress in that moral wisdom for which his master was so eminent. Xenophon accompanied Socrates in the Peloponnesian war, and fought courageously in defence of his country. He afterwards entered into the army of Cyrus as a private volunteer in his expedition against his brother. This enterprise proving unfortunate, Xenophon, after the death of Cyrus, advised his fellow soldiers to attempt a retreat into their own country. They listened to his advice; and having had many proofs of his wisdom as well as courage, they gave him the command of the army, in the room of Proxenus who had fallen in battle. In this command he acquired great glory by the prudence and firmness with which he conducted them back, through the midst of innumerable dangers, into their own country. The particulars of this memorable adventure are related by Xenophon himself in his Retreat of the Ten Thousand. After his return into Greece, he joined Agesilaus, king of Sparta, and fought with him against the Thebans in the celebrated battle of Chæronea. The Athenians, displeased at this alliance, brought a public accusation against him for his former conduct in engaging in the service of Cyrus, and condemned him to exile. The Spartans, upon this, took Xenophon, as an injured man, under their protection, and provided him a comfortable retreat at Scilluntes in Elea. Here, with his wife and two children, he remained several years, and passed his time in the society of his friends, and in writing those historical works which have rendered his name immortal. A war at length arose between the Spartans and Eleans; and Xenophon was obliged to retire to Lepreus, where his eldest son had settled. He afterwards removed, with his whole family, to Corinth, where, in the first year of the hundred and fifth Olympiad, he finished his days.

XENOPHON the *Younger*, a Greek writer, so called to distinguish him from the celebrated Xenophon, was born at Ephesus, and lived, according to some authors, before Heliodorus, that is, about the beginning of the 4th century. He is only known by his *Ephesiaca*, a Greek romance in five books, which is esteemed, and contains the amours or adventures of Abracomes and Anthia. This romance was printed at London, in Greek and Latin, in 1724, 4to.

XERXES I. the fifth king of Persia, memorable for the vast army he is said to have carried into the field against Leonidas king of Sparta; consisting, according to some historians, of 800,000 men, while others make it amount to 3,000,000, exclusive of attendants. The fleet that attended this prodigious land force is likewise made to consist of 2000 sail; and all the success they met with was the taking and burning the city of Athens; for the army was shamefully repulsed near the straits of Thermopylæ by Leonidas, and the fleet was dispersed and partly destroyed by Themistocles at the straits of Salamis, who had only 380 sail under his command. Xerxes was assassinated by Artabanes, chief captain of his guards, and his distinguished favourite. See SPARTA.

XIMENES, FRANCIS, a justly celebrated cardinal, bishop of Toledo, and prime minister of Spain, was born at Torrelaguna, in Old Castile, in 1437, and studied at Alcala and Salamanca. He then went to Rome; and being robbed on the road, brought nothing back but a bull for obtaining the first vacant prebend: but the archbishop of Toledo refused it him, and threw him into prison. Being at length restored to liberty, he obtained a benefice in the diocese of Siguença, where Cardinal Gonzales de Mendoza, who was the bishop, made him his grand vicar. Ximenes some time after entered among the Franciscans of Toledo; but being there troubled with visits, he retired to a solitude named *Castanel*, and applied himself to the study of divinity and the oriental tongues. At his return to Toledo, Queen Isabella of Castile chose him for her confessor, and afterwards nominated him archbishop of Toledo; which, next to the papacy, is the richest dignity in the church of Rome. "This honour (says Dr Robertson) he declined with a firmness

Ximenes.

firmness which nothing but the authoritative injunction of the pope was able to overcome. Nor did this height of promotion change his manners. Though obliged to display in public that magnificence which became his station, he himself retained his monastic severity. Under his pontifical robes he constantly wore the coarse frock of St Francis, the rents of which he used to patch with his own hands. He at no time used linen, but was commonly clad in hair-cloth. He slept always in his habit; most frequently on the floor or on boards, and rarely in a bed. He did not taste any of the delicacies which appeared at his table, but satisfied himself with that simple diet which the rule of his order prescribed. Notwithstanding these peculiarities, so opposite to the manner of the world, he possessed a thorough knowledge of its affairs, and discovered talents for business which rendered the fame of his wisdom equal to that of his sanctity." His first care was to provide for the necessities of the poor; to visit the churches and hospitals; to purge his diocese of usurers and places of debauchery; to degrade corrupt judges, and place in their room persons whom he knew to be distinguished by their probity and disinterestedness. He erected a famous university at Alcala; and in 1499 founded the college of St Ildephonso. Three years after he undertook the Polyglot Bible; and for that purpose sent for many learned men to come to him at Toledo, purchased seven copies in Hebrew for 4000 crowns, and gave a great price for Latin and Greek manuscripts. At this Bible they laboured above 12 years. It contains the Hebrew text of the Bible; the version of the Septuagint, with a literal translation; that of St Jerom, and the Chaldee paraphrases of Onkelos; and Ximenes added to it a dictionary of the Hebrew and Chaldee words contained in the Bible. This work is called *Ximenes's Polyglot*. In 1507 Pope Julius II. gave him the cardinal's hat, and King Ferdinand the Catholic entrusted him with the administration of affairs. Cardinal Ximenes was from this moment the soul of every thing that passed in Spain. He distinguished himself at the beginning of his ministry by discharging the people from the burdensome tax called *acavale*, which had been continued on account of the war against Granada; and laboured with such zeal and success in the conversion of the Mahometans, that he made 3000 converts, among whom was a prince of the blood of the kings of Grenada. In 1509 Cardinal Ximenes extended the dominions of Ferdinand, by taking the city of Oran in the kingdom of Algiers. He undertook this conquest at his own expence, and marched in person at the head of the Spanish army clothed in his pontifical ornaments, and accompanied by a great number of ecclesiastics and monks. Some time after, foreseeing an extraordinary scarcity, he erected public granaries at Toledo, Alcala, and Torrelaguna, and had them filled with corn at his own expence; which gained the people's hearts to such a degree, that to preserve the memory of this noble action they had an eulogium upon it cut on marble, in the hall of the senate-house at Toledo, and in the market-place. King Ferdinand dying in 1516, left Cardinal Ximenes regent of his dominions; and the archduke Charles, who was afterwards the emperor Charles V. confirmed that nomination. The cardinal immediately made a reform of the officers of the supreme council and of the court, and put a stop to the oppression of the grandees. He vindicated the rights of the people against the nobility; and as by the feudal constitution the military power was lodged in the hands of the nobles, and men of inferior condition were called into the field only as their vassals, a king with scanty revenues depended on them in all his operations. From this state Ximenes resolved to deliver the crown; and issued a proclamation, commanding every city in Castile to inrol a certain number of its burgesses, and teach them military discipline; he himself engaging to provide officers to command them at the public expence. This was vigorously opposed by the nobles; but by his intrepidity and superior address he carried his point. He then endeavoured to diminish the possessions of the nobility, by reclaiming all the crown-lands, and putting a stop to the pensions granted by the late king Ferdinand. This addition made to the revenues enabled him to discharge all the debts of Ferdinand, and to establish magazines of warlike stores. The nobles, alarmed at these repeated attacks, uttered loud complaints; but before they proceeded to extremities, appointed some grandees of the first rank to examine the powers in consequence of which he exercised acts of such high authority. Ximenes received them with cold civility; produced the testament of Ferdinand, by which he was appointed regent, together with the ratification of that deed by Charles. To both these they objected; and he endeavoured to establish their validity. As the conversation grew warm, he led them insensibly to a balcony, from which they had a view of a large body of troops under arms, and of a formidable train of artillery. "Behold (says he, pointing to these, and raising his voice) the powers which I have received from his Catholic majesty: With these I govern Castile; and with these I will govern it, till the king, your master and mine, takes possession of his kingdom!" A declaration so bold and haughty silenced them, and astonished their associates. They saw that he was prepared for his defence, and laid aside all thoughts of a general confederacy against his administration. At length, from the repeated intreaties of Ximenes, and the impatient murmurs of the Spanish ministry, Charles V. embarked, and landed in Spain, accompanied by his favourites. Ximenes was advancing to the coast to meet him, but at Bos Equillos was seized with a violent disorder, which his followers considered as the effects of poison. This accident obliging Ximenes to stop, he wrote to the king, and with his usual boldness advised him to dismiss all the strangers in his train, whose number and credit already gave offence to the Spaniards, and earnestly desired to have an interview with him, that he might inform him of the state of the nation, and the temper of his subjects. To prevent this, not only the Flemings, but the Spanish grandees, employed all their address to keep Charles at a distance from Aranda, the place to which the cardinal had removed. His advice was now slighted and despised, Ximenes, conscious of his own integrity and merit, expected a more grateful return from a prince to whom he delivered a kingdom more flourishing than it had been in any former age, and a more extensive authority than the most illustrious of his ancestors had ever possessed; and lamented the fate of his country, about to be ruined by the rapaciousness and insolence of foreign favourites. While his mind was agitated by these passions, he received a letter from the king; in which, after a few

cold

cold and formal expressions of regard, he was allowed to retire to his diocese; and he expired a few hours after reading it in 1517, in the 81st year of his age.

This famous cardinal ought not to be confounded with *Roderic* XIMENES, archbishop of Toledo, in the 13th century, who wrote a History of Spain in nine books; nor with several other Spanish writers of the name of *Ximenes*.

XIPHIAS, the SWORD-FISH; a genus of fishes belonging to the order of *apodes*. See ICHTHYOLOGY *Index*. This fish is common in the Mediterranean sea, especially in that part which separates Italy from Sicily, and which has been long celebrated for it: the promontory Pelorus, now Capo di Faro, was a place noted for the resort of the xiphias, and possibly the station of the speculatores, or the persons who watched and gave notice of the approach of the fish.

The ancient method of taking them is particularly described by Strabo, and agrees exactly with that practised by the moderns. A man ascends one of the cliffs that overhangs the sea: as soon as he spies the fish, he gives notice, either by his voice or by signs, of the course it takes. Another that is stationed in a boat, climbs up the mast, and on seeing the sword-fish, directs the rowers towards it. As soon as he thinks they are got within reach, he descends, and taking a spear in his hand, strikes it into the fish; which, after wearying itself with its agitation, is seized and drawn into the boat. It is much esteemed by the Sicilians, who buy it up eagerly, and at its first coming into season give for it about sixpence English per pound. The season lasts from May till August. The ancients used to cut this fish into pieces and salt it; whence it was called *Tomus Thurianus*, from Thurii, a town in the bay of Tarentum, where it was taken and cured.

The sword-fish is said to be very voracious, and that it is a great enemy to the tunny, which (according to Belon) are as much terrified at it as sheep are at the sight of a wolf. It is a great enemy to whales, and frequently destroys them.

XYLO-ALOES, or ALOE WOOD, in the *Materia Medica*, is the product of a tree growing in China and some of the Indian islands. See EXCÆCARIA.

This drug is distinguished into three sorts; the calambac or tambac, the common lignum aloes, and calambour.

The calambac, or finest aloes wood, called by authors *lignum aloes prestantissimum*, and by the Chinese *suk-kiang*, is the most resinous of all the woods we are acquainted with: it is of a light spongy texture, very porous, and its pores so filled up with a soft and fragrant resin, that the whole may be pressed and dented by the fingers like wax, or moulded about by chewing in the mouth in the manner of mastich. This kind, laid on the fire, melts in great part like resin, and burns away in a few moments with a bright flame and perfumed smell. Its scent, while in the mass, is very fragrant and agreeable; and its taste acrid and bitterish, but very aromatic and agreeable. It is so variable in its colour, that some have divided it into three kinds; the one variegated with black and purple; the second, with the same black, but with yellowish instead of purple; and the third, yellow alone like the yolk of an egg: this last is the least scented of the three. The variation, however, is owing to the trunk of the tree being itself of three different colours; and the heart of it is the valuable sort first described. The two following are supposed to be the outer parts of the trunk; though this seems doubtful, especially in regard to the last sort, from the circumstance mentioned of its being found in large logs entire, and sometimes only the *heart*, which, as above noticed, constitutes the calambac.

The *lignum aloes vulgare* is the second in value. This is of a more dense and compact texture, and consequently less resinous than the other; there is some of it, however, that is spongy, and has the holes filled up with the right resinous matter; and all of it, when good, has veins of the same resin in it. We meet with it in small fragments, which have been cut and split from larger: these are of a tolerably dense texture in the more solid pieces, and of a dusky brown colour, variegated with resinous black veins. It is in this state very heavy, and less fragrant than in those pieces which show a multitude of little holes, filled up with the same blackish matter that forms the veins in others. The woody part of these last pieces is somewhat darker than the other, and is not unfrequently purplish, or even blackish. The smell of the common aloe wood is very agreeable, but not so strongly perfumed as the former. Its taste is somewhat bitter and acrid, but very aromatic.

The calambour, called also *agallochum sylvestre*, and *lignum aloes mexicanum*, is light and friable, of a dusky and often mottled colour, between a dusky green black and a deep brown. Its smell is fragrant and agreeable, but much less sweet than that of either of the others; and its taste bitterish, but not so much acrid or aromatic as either of the two former. This is said to be met with very frequently, and in large logs; and these sometimes entire, sometimes only the heart of the tree. This is the aloe wood used by the cabinet-makers and inlayers.

This drug is esteemed a cordial taken inwardly; and is sometimes given in disorders of the stomach and bowels, and to destroy the worms. A very fragrant oil may be procured from it by distillation; which is recommended in paralytic cases from five to fifteen drops. It is at present, however, but little used; and would scarce be met with anywhere in the shops, but that it is an ingredient in some of the old compositions.

XYNOECIA, in Grecian antiquity, an anniversary feast observed by the Athenians in honour of Minerva, upon the sixteenth of Hecatombæon, to commemorate their leaving, by the persuasion of Theseus, their country seats, in which they lay dispersed here and there in Attica, and uniting together in one body.

XYSTARCHA, in antiquity, the master or director of the xystus. In the Greek gymnasium the xystarcha was the second officer, and the gymnasiarcha the first; the former was his lieutenant, and presided over the two xysti, and all exercises of the athletæ therein.

XYSTUS, among the Greeks, was a long portico, open or covered at the top, where the athletæ practised wrestling and running: the gladiators, who practised therein, were called *xystici*. Among the Romans, the xystus was only an alley, or double row of trees, meeting like an arbour, and forming a shade to walk under.

Y.

Y
Yard.

Y, or y, the 23d letter of our alphabet: its sound is formed by expressing the breath with a sudden expansion of the lips from that configuration by which we express the vowel *u*. It is one of the ambigenial letters, being a consonant in the beginning of words, and placed before all vowels, as in *yard*, *yield*, *young*, &c. but before no consonant. At the end of words it is a vowel, and is substituted for the sound of *i*, as in *try*, *descry*, &c. In the middle of words it is not used so frequently as *i* is, unless in words derived from the Greek, as in *chyle*, *empyreal*, &c. though it is admitted into the middle of some pure English words, as in *dying*, *flying*, &c. The Romans had no capital of this letter, but used the small one in the middle and last syllables of words, as in *coryambus*, *onyx*, *martyr*. Y is also a numeral, signifying 150, or, according to Baronius, 159; and with a dash a-top, as Ȳ, it signified 150,000.

YACHT, or YATCH, a vessel of state, usually employed to convey princes, ambassadors, or other great personages, from one kingdom to another.

As the principal design of a yacht is to accommodate the passengers, it is usually fitted with a variety of convenient apartments, with suitable furniture, according to the quality or number of the persons contained therein.

The royal yachts are commonly rigged as ketches, except the principal one reserved for the sovereign, which is equipped with three masts like a ship. They are in general elegantly furnished, and richly ornamented with sculpture; and always commanded by captains in his majesty's navy.

Besides these, there are many other yachts of a smaller kind, employed by the commissioners of the excise, navy, and customs; or used as pleasure-boats by private gentlemen.

YAMS. See DIOSCOREA, } BOTANY *Index*.
YAMBOO. See EUGENIA, } BOTANY *Index*.

YARD *of a* SHIP, a long piece of timber suspended upon the masts of a ship, to extend the sails to the wind. See MAST and SAIL.

All yards are either square or lateen; the former of which are suspended across the masts at right angles, and the latter obliquely.

The square yards are nearly of a cylindrical surface. They taper from the middle, which is called the *slings*, towards the extremities, which are termed the *yard-arms*; and the distance between the slings and the yard-arms on each side is by the artificers divided into quarters, which are distinguished into the first, second, third quarters, and yard arms. The middle quarters are formed into eight squares, and each of the end parts is figured like the frustum of a cone. All the yards of a ship are square except that of the mizen.

The proportions for the length of yards, according to the different classes of ships in the British navy, are as follows:

			Guns.
1000 : gun-deck : :	560 :	main-yard, fig. 1.	100
	559 :	Pl. CCCCLXVIII.	90 80
	570 :	*Note*, the figure	70
	576 :	represents the	60
	575 :	yard and sails of	50
	561 :	a ship of 74 guns.	44
1000 : main-yard : :	880 :	fore-yard.	100 90 80
	874 :		all the rest.

To apply this rule to practice, suppose the gun-deck 144 feet. The proportion for this length is, as 1000 is to 575, so is 144 to 83; which will be the length of the main-yard in feet, and so of all the rest.

			Guns.
1000 : main-yard : :	820 :	mizen-yard	100 90 80 60 44
	847 :		70
	840 :		24
1000 : main-yard : :	726 :	main topsail-yard	24
	720 :		all the rest.
1000 : fore yard : :	719 :	fore topsail-yard	70
	726 :		24
	715 :		all the rest.
1000 : main topsail-yard : :		main top gallant yard	all the rates.
1000 fore topsail yard : :	696 :	fore top gallant-yard	70
	690 :		all the rest.
1000 : fore-topsail yard : :	768 :	mizen topsail-yard.	70
	750 :		all the rest.

Cross jack and sprit-sail yards equal to the fore topsail-yard.

Sprit-topsail-yard equal to the fore top-gallant-yard.

The diameters of yards are in the following proportions to their length.

The main and fore yards five-sevenths of an inch to one yard. The topsail, cross-jack, and sprit-sail yards, nine-fourteenths of an inch to one yard. The top-gallant, mizen topsail, and sprit-sail topsail yards, eight-thirteenths of an inch to one yard.

The mizen-yard five ninths of an inch to one yard.

All studding-sail booms and yards half an inch to one yard in length.

The lifts of the main-yard are exhibited in the above figure by *g g*; the horses and their stirrups by *h i*; the reef-tackles and their pendents by *k*, *l*; and the braces and brace-pendents by *m*, *n*.

The lateen-yards evidently derive their names from having been peculiar to the ancient Romans. They are usually composed of several pieces fastened together by wooldings, which also serve as steps whereby the sailors climb to the peek or upper extremity, in order to furl or cast loose the sail.

The mizen-yard of a ship, and the main-yard of a bilander, are hung obliquely on the mast, almost in the same manner as the lateen-yard of a xebec, settee, or polacre.

YARD, a measure of length used in Britain and Spain, consisting of three feet, chiefly to measure cloth, stuffs, &c.

Yar-

Yard-arm ‖ Yawning.

Yard-Arm is that half of the yard that is on either side of the mast, when it lies athwart the ship.

Yards also denotes places belonging to the navy, where the ships of war, &c. are laid up in harbour.—There are belonging to his majesty's navy six great yards, viz. Chatham, Deptford, Woolwich, Portsmouth, Sheerness, and Plymouth; these yards are fitted with several docks, wharfs, launches, and graving places, for the building, repairing, and cleaning of his majesty's ships; and therein are lodged great quantities of timber, masts, planks, anchors, and other materials: there are also convenient store-houses in each yard, in which are laid up vast quantities of cables, rigging, sails, blocks, and all other sorts of stores needful for the royal navy.

YARE, among sailors, implies ready or quick: as be yare at the helm; that is, be quick, ready, and expeditious at the helm. It is sometimes also used for bright by seamen: as, to keep his arms yare; that is, to keep them clean and bright.

Yare, a river of Norfolk, which runs from west to east through that county, passing by Norwich, and falling into the German sea at Yarmouth.

YARMOUTH, a sea-port town of Norfolk, with a market on Wednesdays and Saturdays, and a fair on Friday and Saturday in Easter-week for petty chapmen. It is seated on the river Yare, where it falls into the sea; and is a place of great strength, both by art and nature, being almost surrounded with water; and there is a drawbridge over the river. It is esteemed the key of this coast, and is a clean handsome place, whose houses are well built, it being a considerable town for trade. It has one large church, and a neat chapel, and the steeple of St Nicholas is so high that it serves for a sea-mark. It is governed by a mayor. The harbour is a very fine one, though it is very dangerous for strangers in windy weather; and it has for its security a pretty strong fort. The inhabitants in 1811 amounted to 17,977. It is 27 miles east of Norwich, and 112 north-east of London. E. Long. 1. 55. N. Lat. 52. 45.

Yarmouth, a town of the isle of Wight, in Hampshire, with a market on Fridays, and one fair on July 25th for toys. It is seated on the western part of the island, on the sea shore, and is encompassed with water; for, not many years ago a channel was cut through the peninsula, over which there is a drawbridge, and it is defended by a strong castle on the quay. It is a handsome place, whose houses are chiefly built with stone, and covered with slate; and it sends two members to parliament. The market is now disused. W. Long. 1. 28. N. Lat. 50. 40.

YARN, wool or flax spun into thread, of which they weave cloth. See Cloth.

YARROW. See Achillæa, Botany *Index*.

YAWNING, an involuntary opening of the mouth, generally produced by weariness or an inclination to sleep. Yawning, according to Boerhaave, is performed by expanding at one and the same time all the muscles capable of spontaneous motion; by greatly extending the lungs; by drawing in gradually and slowly a large quantity of air; and gradually and slowly breathing it out, after it has been retained for some time and rarefied; and then restoring the muscles to their natural state. Hence the effect of yawning is to move, accelerate, and equally distribute all the humours through all the vessels of the body, and consequently to qualify the muscles and organs of sensation for their various functions.

Yawning, Year.

Sanctorius observes, that a great deal is insensibly discharged, when nature endeavours to get rid of the retained perspirable matter, by yawning and stretching of the limbs. To these a person is most inclined just after sleep, because a greater quantity going off by the pores of the skin than at other times, whensoever a person wakes, the increasing contraction that then happens closes a great deal of the perspirable matter in the cutaneous passages, which will continually give such irritations as excite yawning and stretching; and such motions, by shaking the membranes of the whole body, and shifting the contact of their fibres, and the inclosed matter, by degrees throw it off. Hence we see the reason why healthful strong people are most inclined to such motions, because they perspire most in time of sleep, and therefore have more of the perspirable matter to lodge in the pores, and greater irritations thereunto. The advantages of some little exercise just after waking in a morning are considerable, as it throws off all the perspirable matter that is ready for its exit out of the body. When yawning is troublesome, Hippocrates says that long deep respiration or drawing in the air at long intervals cures it.

YEAR, in *Astronomy* and *Chronology*. See Astronomy and Kalendar.

The ancient Roman year was the lunar year, which, as first settled by Romulus, consisted of only 10 months; viz. 1. March, containing 31 days. 2. April, 30. 3. May, 31. 4. June, 30. 5. Quintilis, 31. 6. Sextilis, 30. 7. September, 30. 8. October 31. 9. November, 30. 10. December, 30.—In all 304 days; which came short of the true lunar year by 50 days, and of the solar by 61 days. Numa Pompilius corrected this irregular constitution of the year, and composed two new months, January and February, of the days that were used to be added to the former year.

The ancient Egyptian year, called also the *year of Nabonassar*, on account of the epoch of Nabonassar, is the solar year of 365 days, divided into 12 months, of 30 days each, besides five intercalary days added at the end. The names, &c. of the months are as follows: 1. Thoth. 2. Paophi. 3. Athyr. 4. Chojac. 5. Tybi. 6. Mecheir. 7. Phamenoth. 8. Pharmuthi. 9. Pachon. 10. Pauni. 11. Epiphi. 12. Mesori; beside the *ημεραι επαγομεναι*.

The ancient Greek year was lunar; consisting of 12 months, which at first had 30 days a-piece, then alternately 30 and 29 days, computed from the first appearance of the new moon; with the addition of an embolismic month of 30 days, every 3d, 5th, 8th, 11th, 14th, 16th, and 19th year of a cycle of 19 years; in order to keep the new and full moons to the same terms or seasons of the year. Their year commenced with that new moon, the full moon of which comes next after the summer solstice. The order, &c. of their months was thus: 1. Εκατομβαιων, containing 29 days. 2. Μεταγειτνιων, 30. 3. Βοηδρομιων, 29. 4. Μαιμακτηριων, 30. 5. Πυανεψιων, 29. 6. Ποσιδεων, 30. 7. Γαμηλιων, 29. 8. Ανθεστηριων, 30. 9. Ελαφηβολιων, 30. 10. Μουνυχιων, 30. 11. Θαργηλιων, 29. 12. Σκιροφοριων, 30.

The ancient Jewish year is a lunar year, consisting commonly

Year. commonly of 11 months, which alternately contain 30 and 29 days. It was made to agree with the solar year, either by the adding of 11, and sometimes 12 days, at the end of the year, or by an embolismic month. The names and quantities of the months stand thus: 1. Nisan, or Abib, 30 days. 2. Jiar, or Zius, 29. 3. Siban, or Siwan, 30. 4. Thammuz, or Tammuz, 29. 5. Ab, 30. 6. Elul, 29. 7. Tisri, or Ethanim, 30. 8. Marchesvam, or Bul, 29. 9. Cisleu, 30. 10. Tebeth, 29. 11. Sabat, or Schebeth, 30. 12. Adar, in the embolismic year, 30. Adar, in the common year, was but 29. Note, in the defective year, Cisleu was only 29 days; and in the redundant year, Marchesvam was 30.

The Persian year is a solar year of about 365 days; consisting of 12 months of 30 days each, with five intercalary days added at the end.

The Arabic, Mahometan, and Turkish year, called also the *year of the Hegira*, is a lunar year, equal to 354 days eight hours and 48 minutes, and consists of 12 months, which contain alternately 30 and 29 days.

The Hindoo year differs from all these, and is indeed different in different provinces of India. The best account that we have of it is by Mr Cavendish, in the Phil. Trans. of the Royal Society of London for the year 1792. "Before I speak of the civil year of the Hindoos (says this eminent philosopher), it will be proper to say a few words of the astronomical year, by which it is regulated.

"The astronomical year begins at the instant when the sun comes to the first point of the Hindoo zodiac. In the year 1792, it began on April 9th, at 22h. 14′ after midnight of their first meridian, which is about 41′ of time west of Calcutta; but, according to Mr Gentil's account of the Indian astronomy, it began 3h. 24′ earlier. As this year, however, is longer than ours, its commencement falls continually later, in respect of the Julian year, by 50′ 26″ in four years. This year is divided into 12 months, each of which corresponds to the time of the sun's stay in some sign; so that they are of different lengths, and seldom begin at the beginning of a day.

"The civil day in all parts of India begins at sunrise, and is divided into 60 parts called *dandas*, which are again divided into 60 palas. In those parts of India in which the Benares almanac, or as it is there called *patras*, is used, the civil year is lunisolar, consisting of 12 lunar months, with an intercalary month inserted between them occasionally. It begins at the day after the new moon next before the beginning of the solar year. The lunar month is divided into 30 parts called *teethees*; these are not strictly of the same length, but are equal to the time in which the moon's true motion from the sun is 12°. From the new moon till the moon arrives at 12° distance from the sun is called the first *teethee*; from thence till it comes to 24°, is called the second *teethee*; and so on till the full moon, after which the teethees return in the same order as before.

"The civil day is constantly called by the number of that teethee which expires during the course of the day; and as the teethee is sometimes longer than one day, a day sometimes occurs in which no teethee ends. When this is the case, the day is called by the same number as the following day; so that two successive days go by the same name. It oftener happens, however, that two teethees end on the same day; in which case the number of the first of them gives name to the day, and there is no day called by the number of the last, so that a gap is made in the order of the days. In the latter part of the month the days are counted from the full moon, in the same manner as in the former part they are counted from the new moon; only the last day, or that on which the new moon happens, is called the 30th, instead of the 15th. It appears, therefore, that each half of the month constantly begins on the day after that on which the new or full moon falls; only sometimes the half month begins with the second day, the first being wanting.

"This manner of counting the days is sufficiently intricate; but that of counting the months is still more so.

"The civil year, as was before said, begins at the day after the new moon; and, moreover, in the years which have an intercalary month, this month begins at the day after the new moon; but notwithstanding this, the ordinary civil month begins at the day after the full moon. To make their method more intelligible, we will call the time from new moon to new moon the natural month. The civil month Visākha, the first in the Hindoo kalender, which extends from the 9th of our April to the 10th of May, begins at the day after that full moon which is nearest to the instant at which the sun enters Mesha, the first in order of the Indian signs, whether before or after; however, it is not always accurately the nearest.

"A consequence of this way of counting the months is, that the first half of Chitra, the last month in the Indian kalender, extending from March the 10th to April the 9th, falls in one year, and the latter half in the following year; and whenever the sun enters no sign during a natural month, this month is intercalary. The number of days in the month varies from 29 to 32. Indeed the Hindoo months, both solar and lunar, consist neither of a determinate number of days, nor are regulated by any cycle, but depend solely on the motions of the sun and moon; so that a Hindoo has no way of knowing what day of the month it is but by consulting his almanac; and what is more, the month ought sometimes to begin on different days, in different places, on account of the difference in latitude and longitude, not to mention the difference which may arise from errors in computation. This mode of computing time must be attended with many inconveniences; but in the transactions of civil life the Hindoos do not much regard it. A disagreement, however, in the computation of the teethee, which sometimes also happens, occasions no small perplexity; because by the teethees or lunar days are regulated most of their religious festivals. Every Brahmin in charge of a temple, or whose duty it is to announce the times for the observance of religious ceremonies, is therefore furnished with one of their almanacs; and if he be an astronomer, he makes such corrections in it as the difference of latitude and longitude renders necessary."

New YEAR's Gift. See GIFT.

YEAST, or YEST, a head or scum rising upon beer or ale while working or fermenting in the vat. See BREWING.

It is used for a leaven or ferment in the baking of bread, as serving to swell or puff it up very considerably in

Yeast. in a little time, and to make it much lighter, softer, and more delicate. See BAKING, BARM, and BREAD.

Mr Henry has published a method of preparing *artificial yeast*, by which good bread may be made without the assistance of any other ferment. The method is this: Boil flour and water together to the consistence of treacle, and when the mixture is cold saturate it with fixed air. Pour the mixture thus saturated into one or more large bottles or narrow-mouthed jars; cover it over loosely with paper, and upon that lay a slate or board with a weight to keep it steady. Place the vessel in a situation where the thermometer will stand from 70° to 80°, and stir up the mixture two or three times in 24 hours. In about two days such a degree of fermentation will have taken place, as to give the mixture the appearance of yeast. With the yeast in this state, and before it has acquired a thoroughly vinous smell, mix the quantity of flour intended for bread, in the proportion of six pounds of flour to a quart of yeast, and a sufficient portion of warm water. Knead them well together in a proper vessel, and covering it with a cloth, let the dough stand for 12 hours, or till it appears to be sufficiently fermented in the fore-mentioned degree of warmth. It is then to be formed into loaves and baked. Mr Henry adds, that perhaps the yeast would be more perfect, if a decoction of malt were used instead of simple water.

It has lately been discovered, that a decoction of malt alone, without any addition, will produce a yeast proper enough for the purpose of brewing. This discovery was made by Joseph Senyor, servant of the reverend Mr Mason of Aston near Rotheram; and he received for it a reward of 20l. from the Society for promoting Arts, Manufactures, and Commerce. The process is as follows: Procure three earthen or wooden vessels of different sizes and apertures, one capable of holding two quarts, the other three or four, and the third five or six: boil a quarter of a peck of malt for about eight or ten minutes in three pints of water; and when a quart is poured off from the grains, let it stand in the first or smaller vessel in a cool place till not quite cold, but retaining that degree of heat which the brewers usually find to be proper when they begin to work their liquor. Then remove the vessel into some warm situation near a fire, where the thermometer stands between 70 and 80 degrees Fahrenheit, and there let it remain till the fermentation begins, which will be plainly perceived within 30 hours: add then two quarts more of a like decoction of malt, when cool, as the first was; and mix the whole in the second or larger vessel, and stir it well in, which must be repeated in the usual way, as it rises in a common vat: then add a still greater quantity of the same decoction, to be worked in the largest vessel, which will produce yeast enough for a brewing of 40 gallons.

Common ale yeast may be kept fresh and fit for use several months by the following method: Put a quantity of it into a close canvas bag, and gently squeeze out the moisture in a screw-press till the remaining matter be as firm and stiff as clay. In this state it may be close packed up in a tight cask for securing it from the air; and will keep fresh, sound, and fit for use, for a long time. This is a secret that might be of great use to the brewers and distillers, who, though they employ very large quantities of yeast, seem to know no method of preserving it, or raising nurseries of it; for want of which they sustain a very considerable loss; whereas the brewers in Flanders make a very great advantage of supplying the malt distillers of Holland with yeast, which is rendered lasting and fit for carriage by this easy expedient.

Yell ‖ Yew.

YELL, one of the islands of Shetland, lying north-east from the Mainland, and divided from it by an arm of the sea, called *Yell-Sound*. By some it is thought to have been the *Thule* of the ancients. In the old descriptions it is said to be 20 miles long and 8 broad. It is very mountainous and full of moss; but there are pretty considerable pastures in which they feed a great many sheep; and it also affords plenty of peat. It has eight large harbours, which would not be thought despicable in other countries. Anciently it seems to have been pretty populous, since there are in it three churches, twenty chapels, and many brughs or Pictish forts.

YELLOW, one of the original colours of light.

YELLOW-Colour for House-painting. See COLOUR-*Making*.

Naples YELLOW, a beautiful colour much used by painters, formerly thought to be prepared from arsenic, but now discovered to have lead for its basis.

YELLOW-Hammer. See FRINGILLA, ORNITHOLOGY *Index*.

YELLOW-Fever. See MEDICINE, N° 168.

YEMEN, a province of Arabia, stretching along the Red sea and Indian ocean, and forming a part of the country once known by the name of Arabia Felix.

YEOMAN, the first or highest degree among the plebeians of England, next in order to the gentry.

The yeomen are properly freeholders, who having land of their own, live on good husbandry.

YEOMAN is also a title of office in the king's household, of a middle place or rank between an officer and a groom.

YEOMEN of the Guard were anciently 250 men of the best rank under gentry, and of larger stature than ordinary, each being required to be six feet high. At present there are but 100 yeomen in constant duty, and 70 more not in duty; and as any of the 100 dies, his place is supplied out of the 70. They go dressed after the manner of King Henry VIII.'s time. They formerly had diet as well as wages when in waiting; but this was taken off in the reign of Queen Anne.

YEST, or YEAST. See YEAST.

YEW. See TAXUS, BOTANY *Index*.

Yew trees are remarkable for their duration. There are now growing within 300 yards of the old Gothic ruins of Fountain's abbey, near Rippon, in Yorkshire, seven very large yew trees, commonly called the Seven Sisters, whose exact ages cannot be accurately ascertained, though tradition says that they were standing in the year 1088. It is said also, that when the great Fountain's abbey was building, which is 700 feet long, and was finished in 1283, the masons used to work their stones, during the hot summers, under the shade of these trees. The circumference of the Seven Sisters, when measured by a curious traveller, were of the following sizes:—the smallest tree, round its body, 5 yards 1 foot; fours others are from $5\frac{1}{2}$ to $7\frac{1}{2}$ yards; the sixth is $9\frac{2}{3}$ yards; and the seventh is 11 yards 1 foot 7 inches in circumference, being 2 yards 10 inches larger than the great

Yew & York.

great yew tree now growing in the churchyard at Gresford, in North Wales, which is 9 yards 9 inches. These trees are the largest and oldest in the British dominions.

YNCA, an appellation anciently given to the kings of Peru, and the princes of their blood; the word literally signifying lord, king, emperor, and royal blood.

YOAK, or YOKE, in *Agriculture*, a frame of wood fitted over the necks of oxen, whereby they are coupled together and harnessed to the plough.

Yoak of Land, anciently was the space which a yoke of oxen, that is, two oxen, may plough in one day.

YOLK, the yellow part in the middle of an egg (see EGG).

YONNE, a department in the central part of France, lying along both sides of the river Yonne. The soil is fertile, and produces grain of all kinds, hemp, legumes, fruits, and vines. Wine is a principal article of commerce in this department. Wood and pasturage also abound. The manufactures, which consist of woollens, cottons, hosiery, leather, paper, glass, ironwork, &c. are not of great importance. The extent of this department is 729,226 hectares, and the population in 1817 amounted to 325,994. Auxerre is the chief town.

YORK, in Latin *Eboracum*, the capital of Yorkshire in England. This city is so ancient that the origin of it is uncertain. In the time of the Romans a legion was stationed here, it being then the capital of the Brigantes; and here died the emperor Severus, and Flavius Valerius Constantius Chlorus, father of Constantine the Great. There was then also a temple of Bellona here, and no less than three military ways went from hence. In the time of the Saxons it was erected into an archbishopric by Pope Honorius, to which are now subject the bishoprics of Chester, Durham, Carlisle, and the isle of Man; though anciently 12 bishoprics in England, and all Scotland, were. A horn is still kept in the minster, by which Ulphius, one of the Saxon princes, bestowed all his lands and revenues upon the church.

This city suffered very much during the ravages of the Danes; but, after the Conquest, it began to flourish again. The cathedral, which cost a long time and a great deal of money in building, is a most stately Gothic pile. Its chapter-house is particularly admired for its painted glass, its fine marble stalls, its pillars of alabaster, and curious contrivance. In it is the following line in gold letters:

Ut Rosa, flos florum, sic est Domus ista Domorum.

The choir is remarkable for its fine carvings, particularly the statues of all the English monarchs; and the windows are exquisitely painted with the history of the Bible. The lanthorn steeple is 70 feet square, and 188 high, and the windows are 45. At the south end is a circular light, called the *marigold window* from the colour of its glass; and at the north end is a very large one, whose painting represents embroidery.

This city was formerly reckoned the second city in England; but though it stands upon more ground, it is inferior in trade, wealth, and population, to Manchester, Liverpool, and several other cities. The inhabitants amounted to 18,217 in 1811. It is situated in a fine plain, on both sides the Ouse, walled and divided into four wards, containing 28 parishes. It enjoys large privileges and immunities, conferred upon it by a succession of kings from Henry II. and its chief magistrate has the title of *lord mayor*, which is an honour peculiar to it and London. Richard II. made it a county of itself. The conservancy of most of the rivers of the county, within certain limits, belongs to the lord mayor and aldermen. The middle arch of the bridge here over the Ouse is thought to equal the Rialto at Venice in architecture, height, and breadth, the diameter being 81 feet, and the height 51. Though this city is 60 miles distant from the sea, yet ships of 70 tons burden come up the river to it. The town-house or guild-hall stands upon the bridge, and is superior in all respects to that of London. In the Popish times there were nine abbeys here, and a vast number of churches; but of the latter there are only 17 now. The steeple of that of Allhallows is reckoned the finest in England. The archbishop has a fine palace; and the assembly-room, designed by the earl of Burlington, is very noble. Here are plays, assemblies, concerts, and the like entertainments, at some house or other, almost every night in the week. In the old castle, built originally by William the Conqueror, and repaired in 1701, the assizes are kept. It serves also for the county-gaol, which is the neatest and pleasantest in England, with an area larger than that of the king's-bench, and it has a handsome chapel in it, with a good allowance for a preacher. This city has long given the title of *duke* to some branch of the royal family,

Yo... York.

The plenty and cheapness of provisions induces many persons of small fortune, or that would live frugally, to take up their abode here; and the venerable remains of Roman antiquities, and those of a later date, as abbeys, churches, and castles, procure this city a visit from every curious traveller. Many Roman altars, urns, coins, inscriptions, &c. have been found; and Saxon coins are still extant that have been struck here. The members, being two in number, for this city, have precedence of all others, except those of London, in the house of commons. An infirmary, after the manner of those of Bath, Bristol, &c. hath been erected in it; and a cotton manufacture established and brought to great perfection. Besides four weekly markets, it has a great many fairs; one, in particular, every other Thursday for cattle and sheep. W. Long. 1. 1. N. Lat. 53. 59.

YORKSHIRE, the largest county of England, bounded on the south by Derbyshire, Nottinghamshire, and Lincolnshire; on the north by Durham and Westmoreland; on the east by the German ocean; and on the west by Lancashire and a part of Cheshire.—It is upwards of 80 miles in length from east to west, nearly as much in breadth, and about 360 in circumference, containing, in the whole, 26 hundreds or wapentakes, 49 market-towns, 563 parishes, 242 vicarages, with many chapels of ease, and 2330 villages. Its area is computed by some at 4684 square miles, and its inhabitants in 1811 amounted to 973,113, of whom 305,150 lived in towns, and 667,963 in the country. It is divided into three parts or ridings, viz. the West, East, and North; so denominated from their situation, in respect of the city of York. Each of these is as large, if not larger, than any ordinary county. There are other divisions, as Richmondshire, Allertonshire, Howdenshire, Hallanshire, Craven, Cleveland, Marshland, Holderness, &c.

As the soil and face of the country vary greatly, so does

York. does the air. In the hilly parts the air is good, but the soil very indifferent; of the lower some are marshy, others drier, and the soil of both rich; but the air of the former is more foggy and unhealthy than that of the latter. The manufactures of this county are cutlery and hard-wares, particularly knives, bits, and spurs; but the principal are stockings and woollen cloth, with which it supplies in a great measure Germany and the North. As to the produce, it abounds in corn, cattle, horses, lead and iron, coal, wood, lime, liquorice, alum, jet, &c. It lies wholly in the northern circuit, and much the greater part of it in the diocese of York; that only which is called *Richmondshire* belonging to the diocese of Chester. The members it sends to parliament are 30; of which two are for the shire and 28 for the towns.

New-York, one of the United States of America, is bounded towards the south-east by the Atlantic ocean; east by Connecticut, Massachusets, and Vermont; north by the 45th degree of latitude, which divides it from Canada; north-westwardly by the river Iroquois or St Lawrence, and the lakes Ontario and Erie; south-west and south by Pennsylvania and New Jersey. The whose state contains about 44,000 square miles, equal to 28,160,000 acres.

The state, to speak generally, abounds with lakes, some of salt and others of fresh water. It is intersected by ridges of mountains running in a north-east and south-west direction. Beyond the Allegany mountains, however, the country is a dead level, of a fine rich soil, covered in its natural state, with maple, beech, birch, cherry, black-walnut, locust, hickory, and some mulberry trees. On the banks of Lake Erie, are a few chesnut and oak ridges. Hemlock swamps are interspersed thinly through the country. All the creeks that empty into Lake Erie have falls, which afford many excellent mill seats. East of the Allegany mountains, the country is broken into hills with rich intervening valleys. The hills are clothed thick with timber, and when cleared afford fine pasture; the valleys, when cultivated, produce wheat, hemp, flax, pease, grass, oats, Indian corn.

The principal rivers are the Hudson, and the Mohawk, which is a branch of the former. The Hudson is navigable for sloops 160 miles from its mouth, and by the Mohawk boats ascend about 70 miles farther. A canal is now in progress to extend the inland navigation from the head waters of the Mohawk to Lake Erie, a distance of 200 miles. In the north eastern ports, Lake Champlain affords a navigable communication for 100 miles; and the St Lawrence, with lakes Ontario and Erie, for many hundred miles more, on the north-western frontier.

Iron abounds in the state of New York, and lead is wrought at some places, but the other metals are scarce. Roofing slate, lime-stone, marble, and coal are found in some situations. Gypsum and salt (from springs) are abundant in the western parts. The mineral waters of Balston and Saratoga are celebrated for their medicinal virtues.

The wild animals are now becoming rare in this state. The wolf, formerly common, is seldom seen. The bears, which are still found in considerable numbers, often carry off the hogs from new settlements. The cougouar seldom appears; the deer, fox, marten, beaver, and squirrel are found occasionally. Snakes of a large size are met with in the uncultivated parts. York.

The population of this state in 1749 was estimated at 100,000; in 1800 it amounted to 586,050; and in 1810, to 959,049, including 15,017 slaves. At the last mentioned period New York was the second state in the union for population; but it is probably now the first.

The legislative power is vested in a senate and house of assembly. The latter is elected annually by ballot, by electors who must be freeholders to the value of fifty dollars, or residents renting tenements of five dollars yearly value. The senate is elected for four years, one fourth being renewed every year. The permanent number of senators is 32, of members of the lower house 150. The executive power resides in a governor elected for three years by the freeholders, with a council of four senators, chosen annually by the legislature. The judges, who are appointed by the governor and council, hold their offices during good behaviour till the age of sixty.

There is no state religion, but the clergymen of each persuasion are supported by the voluntary contributions of their congregations. The Presbyterians are the most numerous sect, the Episcopalians next. The Baptists, Methodists, Quakers, and Roman Catholics are also pretty numerous. In 1815, there were 2621 primary schools in the state, at which 140,720 scholars were educated. It is rare to meet with any person in this state who cannot read and write. There is also a considerable number of academies, and three colleges,—Columbia College founded in 1754, Union College founded in 1794; and Hamilton College in 1812. The number of scientific and humane societies is also considerable. Above seventy newspapers are printed in the state.

The manufactures of this state consist of iron, glass, gunpowder, woollens, linens and cottons, cordage, spirits, leather, hats, &c. Though several large works are established, about one third of the articles produced are made in families. The whole value of manufactures in 1810 was thirty-three millions of dollars; but during the war with England in 1814, the amount was supposed not to fall short of fifty millions. So rapid has been the accumulation of capital in this state, that the value of lands and houses, which was found by a fiscal survey in 1799 to be 100,380,706 dollars, amounted according to a new survey in 1814 to 269,370,900 dollars. The exports of this state, in 1817, amounted to 18,707,433 dollars; being one half greater than those of any other state in the union.

Though New York is the first commercial state in North America, the bulk of the inhabitants live by agriculture. They are generally industrious, sober, and well informed. There are still some small societies of Dutch and Germans, who preserve both the language and manners of their country. In general the inhabitants of this state are neither infected with the hypocritical austerity, pride, and selfishness of the New Englanders, nor with the lax morality and ostentatious habits of the people of the southern states. In times of difficulty they have generally held a moderate course.

New-York, a city of North America, capital of the state of the same name. It is situated at the south-west point.

York. point of an island, at the confluence of Hudson and East rivers, and is about four miles in circumference. The situation is both healthy and pleasant. Surrounded on all sides by water, it is refreshed by cool breezes in summer, and the air in winter is more temperate than in other places under the same parallel. York island is 15 miles in length, and hardly one in breadth. It is joined to the main by a bridge called King's bridge. The channels between Long and Staten islands, and between Long and York islands, are so narrow as to occasion an unusual rapidity of the tides, which is increased by the confluence of the waters of Hudson and East rivers. This rapidity, in general, prevents the obstruction of the channel by ice. There is no bason or bay for the reception of ships; but the road where they lie in East river is defended from the violence of the sea by the islands which interlock with each other; so that, except that of Rhode island, the harbour of New-York, which admits ships of any burden, is the best of the United States. The number of the inhabitants in 1817 was estimated at 120,000.

The most magnificent edifice in this city is *Federal Hall*, at the head of Broadstreet; in a gallery in front of which General Washington, attended by the senate and house of representatives, took his oath of office at the commencement of the operation of the federal constitution, 30th April, 1789. Near this building is another, appropriated to the American Museum and Academy of Fine Arts. There were about fifty churches and meeting-houses in the city in 1817, many of which are built and fitted up in a style of great elegance, and even splendour. The best private houses are built of brick painted red, and have a very neat and cleanly appearance. There is a theatre of great size, though not a fine building. The battery, which fronts the sea, forms one of the most beautiful walks of which any city can boast. Several of the principal streets being garnished with rows of trees, have an uncommonly gay and pleasing effect. In New York, as in many old towns in Britain, the entries to cellars project into the street, and injure both the beauty and the conveniency of the foot pavement. The street is also encumbered by large quantities of goods piled up at the outside of the shop doors; and great numbers of pigs are seen running about. Formerly the city suffered much from the want of water, but now it is conveyed in pipes to all the streets in abundance. Rents are high, even when a comparison is made with London. The natural harbour of New York is one of the best in America, and its trade is so great, that it amounts to nearly one-fifth of the whole foreign trade of the United States. It is probably at present the second trading city in Europe or America.

King's college was chiefly founded by the voluntary contributions of the inhabitants of the province, assisted by the general assembly, and the corporation of Trinity Church, and in the year 1754, obtained a royal charter. The building consists of an elegant stone edifice, three stories high, with four stair cases, 12 apartments in each, a chapel, hall, library, museum, anatomical theatre, and a school for experimental philosophy. It is situated on a dry gravelly soil, about 150 yards from the bank of Hudson's river, commanding a beautiful and extensive prospect. Since the revolution, the legislature passed an act constituting 21 gentlemen (of whom the governor and lieutenant-governor for the time being, are members *ex officiis*) a body corporate and politic by the name of "The Regents of the University of the State of New-York." They are entrusted with the care of literature in general, and have power to grant charters for erecting colleges and academies through the state. It is now denominated *Columbia college*. It consists of a faculty of arts, and one of physic, the first having a president and seven professors, and the second a dean, and the same number of professors.

The government of this city is at present in the hands of a mayor, aldermen, and common council; and the city is divided into seven wards, in each of which an alderman and assistant are annually chosen by the people. A court of session is held for the trial of criminal causes. There were eight banks in the city in 1814; and there is a great number of literary, scientific, and benevolent institutions. The shipping belonging to the port in 1815 amounted to 278,868 tons. New-York is 95 miles N. E. of Philadelphia, 197 N. E. of Baltimore, and 913 from Charleston. W. Long. 74° 9′ 45″. N. Lat. 40° 42′ 8″.

YOUNG, DR EDWARD, was the son of a clergyman of the same name, and was born about the year 1679. When sufficiently qualified, he was matriculated into All-Souls college, Oxford; and designing to follow the civil law, he took a degree in that profession. In this situation he wrote his poem called The Last Day, published in 1704; which coming from a layman gave universal satisfaction: this was soon after followed by another, entitled The Force of Religion, or Vanquished Love. These productions gained him a respectable acquaintance; he was intimate with Addison, and thus became one of the writers of the Spectator: but the turn of his mind leading him to the church, he took orders, was made one of the king's chaplains, and obtained the living of Welwyn in Hertfordshire, worth about 500l. per annum, but he never rose to higher preferment. For some years before the death of the late prince of Wales, Dr Young attended his court pretty constantly; but upon his decease all his hopes of church preferment vanished; however, upon the death of Dr Hales, he was taken into the service of the princess dowager of Wales, and succeeded him as her privy chaplain. When pretty far advanced in life, he married the lady Elizabeth Lee, daughter of the late earl of Litchfield. This lady was a widow, and had an amiable son and daughter, who both died young. What he felt for their loss, as well as for that of his wife, is finely expressed in his Night Thoughts, in which the young lady is characterised under the name of Narcissa; her brother by that of Philander; and his wife, though nameless, is frequently mentioned; and he thus, in an apostrophe to death, deplores the loss of all the three.

> Insatiate archer, could not once suffice!
> Thy shaft flew thrice, and thrice my peace was slain,
> And thrice ere thrice yon moon renew'd her horn.

He wrote three tragedies, The Revenge, Busiris, and The Brothers. His satires, called Love of Fame the universal Passion, are by many esteemed his principal performance; though Swift said the poet should have been

Young. been either more angry or more merry: they have been characterised as a string of epigrams written on one subject, that tire the reader before he gets through them. His Complaint, or Night Thoughts, exhibit him as a moral and melancholy poet, and are esteemed his masterpiece. They form a species of poetry peculiarly his own, and in which he has been unrivalled by all those who attempted to write in this manner. They were written under the recent pressure of his sorrow for the loss of his wife, daughter, and son-in-law; they are addressed to Lorenzo, a man of pleasure and the world, and who, as it is insinuated by some, is his own son, but then labouring under his father's displeasure. As a prose-writer, he arraigned the prevailing manners of his time, in a work called The Centaur not Fabulous; and when he was above 80 years of age, published Conjectures on Original Composition. He published some other pieces; and the whole of his works are collected in 4 and 5 vols 12mo. Dr Young's turn of mind was naturally solemn; and he usually, when at home in the country, spent many hours of the day walking in his own church-yard among the tombs. His conversation, his writings, had all a reference to the life after this; and this turn of disposition mixed itself even with his improvements in gardening. He had, for instance, an alcove with a bench, so painted, near his house, that at a distance it looked as a real one which the spectator was then approaching. Upon coming up near it, however, the deception was perceived, and this motto appeared, *Invisibilia non decipiunt*, "The things unseen do not deceive us." Yet, notwithstanding this gloominess of temper, he was fond of innocent sports and amusement: he instituted an assembly and a bowling-green in the parish of which he was rector, and often promoted the gaiety of the company in person. His wit was generally poignant, and ever levelled at those who testified any contempt for decency and religion. His epigram, spoken extempore on Voltaire, is well known; who happening in his company to ridicule Milton, and the allegorical personages of Death and Sin, Young thus addressed him:

Thou art so witty, profligate, and thin,
You seem a Milton with his Death and Sin.

Young ‖ Yunx. One Sunday, preaching in office at St James's, he found, that though he strove to make his audience attentive, he could not prevail. Upon which his pity for their folly got the better of all decorums, and he sat back in the pulpit and burst into a flood of tears. Towards the latter part of life he knew his own infirmities, and suffered himself to be in pupilage to his house-keeper; for he considered that, at a certain time of life, the second childhood of age demanded its wonted protection. His son, whose boyish follies were long obnoxious to paternal severity, was at last forgiven in his will; and our poet died regretted by all, having performed all that man could do to fill his post with dignity. His death happened in 1765.

YOUTH, that state of man in which he approaches towards his greatest perfection of body.

YPRES, a handsome, large, and populous town of the kingdom of the Netherlands, with a bishop's see. It has a considerable manufactory in cloth and serges, and every year in Lent there is a considerable fair. It is one of the barrier towns, but was besieged and taken by the French in 1744, and also in 1794. It is seated in a fertile plain on the river Ypre, in E. Long. 2. 48. N. Lat. 50. 51.

YTTRIA, one of the lately discovered earths. For an account of its properties and combinations, see CHEMISTRY, N° 1457.

Yttrio-Tantalite, a mineral substance containing the new earth yttria, and the new metal tantalium, which latter is found by Dr Wollaston to be identical with columbium.

YUCCA, ADAM'S NEEDLE, a genus of plants of the class hexandria. The species of this plant are all exceedingly curious in their growth, and are therefore much cultivated in gardens. The Indians make a kind of bread from the roots of this plant.

YULE, YOOL, or *Iul*. See IUL.

YUNX, a genus of birds of the order *picæ*. See ORNITHOLOGY *Index*.

Z.

Z. Z, or z, the 24th and last letter, and the 19th consonant of our alphabet; the sound of which is formed by a motion of the tongue from the palate downwards and upwards to it again, with a shutting and opening of the teeth at the same time. This letter has been reputed a double consonant, having the sound *ds*; but some think with very little reason: and, as if we thought otherwise, we often double it, as in *puzzle*, *muzzle*, &c. Among the ancients, Z was a numeral letter, signifying 2000; and with a dash added a-top, $\bar{Z}$ signified 2000 times 2000, or 4,000,000.

In abbreviations this letter formerly stood as a mark for several sorts of weights; sometimes it signified an ounce and a half; and very frequently it stood for half an ounce; sometimes for the eighth part of an ounce, or a dram troy weight; and it has in earlier times been used to express the third part of an ounce or eight scruples. ZZ were used by some of the ancient physicians to express myrrh, and at present they are often used to signify zinziber or ginger.

Z, Zaara. ZAARA, ZAPARA, SAHARA, or *the Desert*, a vast country of Africa, bounded on the north by Barbary, on the east by Fezzan and Cashna, on the south by Tombuctoo, and on the west by the Atlantic ocean. Zaara contains a variety of wandering nations, all proceeding from Arabs, Moors, and fugitive Portuguese, who took refuge there when the family of the Sherifs made themselves masters of the three kingdoms of Barbary.

bary. All these people bear indiscriminately the names of *Nars*, *Moors*, or *Arabs*. They are subdivided into various nations, of which the most considerable are the Mongearts, Trasars, and Bracnars. The Mongearts lead a wandering life, and live chiefly on the milk of their flocks, with a little barley-meal, and some dates. The poorer sort go naked, except the females, who commonly wrap a clout about their middle, and wear a kind of bonnet on their head; but the wealthier sort have a kind of loose gown, made of blue calico, with large sleeves, that is brought them from Negroland. When they move from one place to another for fresh pasture, water, or prey, most of them ride on camels, which have generally a sort of saddle between the bunch and the neck, with a string or strap run through their nostrils, which serves for a bridle; and instead of spurs they use a sharp bodkin. Their tents or huts are covered with a coarse stuff, made of camel's hair, and a kind of wool or moss that grows on the palm trees. These Arabs live here under the government of their sheiks or cheyks; as in Arabia, Egypt, and other places. The other two tribes are rather more civilized. They are all Mahometans.

ZABULON, in *Ancient Geography*, one of the twelve tribes; bounded on the north by the tribes of Asher and Naphthali; on the east by the sea of Galilee; on the south by the tribe of Issachar or the brook Cison, which ran between both; on the west by the Mediterranean; so that it touched two seas, or was bimarous.

ZABULON, in *Ancient Geography*, a very strong town in the tribe of that name, on the Mediterranean, sirnamed *of men*, near Ptolemais: its vicinity to which makes it probable that it was also Chabulon, unless either name is a faulty reading in Josephus; distant about 60 stadia from Ptolemais.

ZACYNTHUS, in *Ancient Geography*, an island to the south of Cephalenia 60 stadia, but nearer to Peloponnesus, in the Ionian sea, formerly subject to Ulysses, in compass above 160 stadia, woody and fruitful, with a considerable cognominal town and a port. The island lies over against Elis, having a colony of Achæans from Peloponnesus, over against the Corinthian gulf. Both island and town are now called *Zante*.

ZAFFRE, is the oxide of cobalt, employed for painting pottery ware and porcelain of a blue colour. The method of preparing it is as follows: The cobalt taken out of the mine is broken with hammers into pieces about the size of a hen's egg; and the stony involucrum, with such other heterogeneous matters as are distinguishable by the eye, are separated as much as possible. The chosen mineral is then pounded in stamping mills, and sifted through brass wire sieves. The lighter parts are washed off by water, and it is afterwards put into a large flat-bottomed arched furnace, resembling a baking oven, where the flame of the wood reverberates upon the ore; which is occasionally stirred and turned with long handled iron hooks or rakes; and the process is continued till it ceases to emit any fumes. The oven or furnace is terminated by a long horizontal gallery, which serves for a chimney; in which the arsenic, naturally mixed with the ore, sublimes. If the ore contains a little bismuth, as this semimetal is very fusible, it is collected at the bottom of the furnace. The cobalt remains in the state of a dark gray oxide, and is called *zaffre*. One hundred pounds of the cobalt ore lose 20 and even 30 per cent. during this operation, which is continued 4 or even 9 hours, according to the quality of the ore. The roasted ore being taken out from the furnace, such parts as are concreted into lumps are pounded and sifted afresh. Zaffre, in commerce, is never pure, being mixed with two or rather three parts of powdered flints. A proper quantity of the best sort of these, after being ignited in a furnace, is thrown into water to render it friable, and more easily reduced to powder; which, being sifted, is mixed with the zaffre, according to the before-mentioned dose; and the mixture is put into casks, after being moistened with water. This oxide, fused with three parts of sand and one of potash, forms a blue glass; which, when pounded, sifted, and afterwards ground in mills, included in large casks, forms *smalt*.

The blue of zaffre is the most solid and fixed of all the colours that can be employed in vitrification. It suffers no change from the most violent fire. It is successfully employed to give shades of blue to enamels, and to the crystal glasses made in imitation of some opaque and transparent precious stones, as the lapis lazuli, the turquois, the sapphire, and others of this kind.

ZALEUCUS, a famous legislator of the Locrians, and the disciple of Pythagoras, flourished 500 years, B. C. He made a law, by which he punished adulterers with the loss of both their eyes; and his son offending, was not absolved from this punishment: yet, to show the father as well as the just lawgiver, he put out his own right, and his son's left eye. This example of justice and severity made so strong an impression on the minds of his subjects, that no instance was found of the commission of that vice during the reign of that legislator. It is added, that Zaleucus forbade any wine being given to the sick on pain of death, unless it was prescribed by the physicians; and that he was so jealous of his laws, that he ordered, that whoever was desirous of changing them, should be obliged, when he made the proposal, to have a cord about his neck, in order that he might be immediately strangled, if those alterations were esteemed no better than the laws already established. Diodorus Siculus attributes the same thing to Charondas legislator of the Sybarites.

ZAMA, in *Ancient Geography*, a town of Chamane, a district of Cappadocia, of unknown situation.—Another Zama, of Mesopotamia, on the Saocoras, to the south of Nisibis.—A third, of Numidia, distant five days journey to the west of Carthage: it was the other royal residence of the kings of Numidia, hence called *Zama Regia*. It stood in a plain; was stronger by art than nature; richly supplied with every necessary; and abounding in men, and every weapon both of defence and annoyance.

The last of these is remarkable for the decisive battle fought betwen the two greatest commanders in the world, Hannibal the Carthaginian and Scipio Africanus. Of this engagement, the most important perhaps that ever was fought, Mr Hooke gives the following account.

"Scipio drew up his army after the Roman manner, except that he placed the cohorts of the Principes directly behind those of the Hastati, so as to leave sufficient space for the enemy's elephants to pass through from

Zama.

from front to rear. C. Lælius was posted on the left wing with the Italian horse, and Masinissa with his Numidians on the right. The intervals of the first line Scipio filled up with his Velites, or light-armed troops, ordering them, upon a signal given, to begin the battle; and, in case they were repulsed, or broke by the elephants, to run back through the lanes before mentioned, and continue on their flight till they were got behind the Triarii. Those that were wounded, or in danger of being overtaken, were to turn off to the right and left through the spaces between the lines, and that way escape to the rear.

"The army thus drawn up, Scipio went from rank to rank, urging his soldiers to consider the consequences of a defeat and the rewards of victory: on the one hand, certain death or slavery (for they had no town in Africa strong enough to protect them); on the other, not only a lasting superiority over Carthage, but the empire of the rest of the world.

"Hannibal ranged all his elephants, to the number of above 80, in one front. Behind these he placed his mercenaries, consisting of 12,000 men, Ligurians, Gauls, Baleares, and Mauritanians.

"The new levies of Carthaginians and other Africans, together with 4000 Macedonians, under a general named *Sopater*, composed the second line. And in the rear of all, at the distance of about a furlong, he posted his Italian troops, in whom he chiefly confided. The Carthaginian horse formed his right wing, the Numidians his left.

"He ordered their several leaders to exhort their troops not to be discouraged by their own weakness, but to place the hope of victory in him and his Italian army; and particularly directed the captains of the Carthaginians to represent to them what would be the fate of their wives and children if the event of this battle should not prove successful. The general himself, walking through the ranks of his Italian troops, called upon them to be mindful of the 17 campaigns in which they had been fellow-soldiers with him; and of that constant series of victories by which they had extinguished in the Romans all hope of ever being conquerors. He urged them to remember, above all, the battles of Trebia, Thrasymenus, and Cannæ; with any of which the approaching battle was in no wise to be compared, either with respect to the bravery or the number of the enemy. 'The Romans were yet unfoiled, and in the height of their strength, when you first met them in the field; nevertheless you vanquished them. The soldiers now before us are either the children of the vanquished, or the remains of those whom you have often put to flight in Italy. Maintain therefore your general's glory and your own, and establish to yourselves the name of invincible, by which you are become famous throughout the world.'

"When the Numidians of the two armies had skirmished a while, Hannibal ordered the managers of the elephants to drive them upon the enemy. Some of the beasts, frightened at the noise of the trumpets and other instruments of war which sounded on all sides, immediately ran back amongst the Numidians of the Carthaginian left wing, and put them into confusion; which Masinissa taking advantage of, entirely routed them. Great destruction was made of the Velites by the rest of the elephants, till these also being terrified, some of them ran through the void spaces of the Roman army which Scipio had left for that purpose; others falling in among the cavalry of the enemy's right wing, gave Lælius the same opportunity against the Carthaginian horse as had been given to Masinissa against the Numidian, and of which the Roman did not fail to make the same use. After this the infantry of the foremost lines joined battle. Hannibal's mercenaries had the advantage in the beginning of the conflict; but the Roman Hastati, followed and encouraged by the Principes, who exhorted them to fight manfully, and showed themselves ready to assist them, bravely sustained the attack, and at length gained ground upon the enemy. The mercenaries not being seasonably supported by their second line, and therefore thinking themselves betrayed, they in their retreat fell furiously upon the Africans; so that these, the Hastati coming up, were obliged to fight for some time both against their own mercenaries and the enemy. When the two Carthaginian lines had ceased their mutual rage, they joined their strength; and though now but a mere throng of men, broke the Hastati: but then the Principes advancing to the assistance of the latter, restored the battle; and most of the Africans and mercenaries were here cut off. Hannibal did not advance to their relief, the Roman Triarii not having yet engaged, and the Principes being still in good order; and lest the routed Africans and mercenaries should break the ranks of his Italian soldiers, he commanded these to present their spears at those who fled to them for protection, which obliged the runaways to move off to the right and left.

"The ground over which the Romans must march before they could attack Hannibal being strewed with heaps of dead bodies and weapons, and being slippery with blood, Scipio feared that the order of his battalions would be broke, should he pass it hastily. To avoid this mischief, he commanded the Hastati to give over the pursuit, and halt where they were, opposite to the enemy's centre: after which, having sent all his wounded to the rear, he advanced leisurely with the Principes and Triarii, and placed them on the wings of the Hastati. Then followed a sharp engagement, in which victory was long and eagerly disputed. It would seem that the Romans, though superior in number, were once upon the point of losing the day; for Polybius tells us, that Masinissa and Lælius came very seasonably, and as if sent from heaven, to their assistance. These generals being returned from the pursuit of the cavalry, fell suddenly upon the rear of Hannibal's men, most of whom were cut off in their ranks; and of those that fled, very few escaped the horse, the country all round being a plain.

"There died of the Carthaginians in the fight above 20,000, and almost the like number were taken prisoners. The loss on the side of the Romans amounted to about 2000 men. Hannibal escaped with a few horse to Adrumetum, having performed every thing in the engagement which could be expected from a great general. His army (says Polybius) could not have been more skilfully drawn up. For as the order of the Roman battalions makes it extremely difficult to break them, the Carthaginian wisely placed his elephants in the front, that they might put the enemy in confusion before the armies should engage. In his first line he placed the mercenaries; men bold and active, but not well

Zama ‖ Zapata.

well disciplined, that by their impetuosity he might give a check to the ardour of the Romans. The Africans and Carthaginians, whose courage he doubted, he posted in the middle between the mercenaries and his Italian soldiers, that they might be forced to fight, or at least that the Romans, by slaughtering them, might fatigue themselves and blunt their weapons. Last of all, he drew up the troops he had disciplined himself, and in whom he chiefly confided, at a good distance from the second line, that they might not be broken by the route of the Africans and mercenaries, and kept them in reserve for a vigorous attack upon a tired and weakened enemy."

ZANGUEBAR, a country in Africa, lying on the eastern coast, between three degrees of north latitude, and 18 south. It includes several petty kingdoms, in which the Portuguese have various settlements. The inhabitants, except those converted by the Portuguese, are all Mahometans or idolaters; and the latter much the more numerous. The names of the principal territories are *Mombaza*, *Lamon*, *Melinda*, *Quiola*, and *Mosambique*. The Portuguese have built several forts in Mombaza and Mosambique, and have settled several colonies there. They trade with the negroes for slaves, ivory, gold, ostrich-feathers, wax and drugs. The productions are much the same as in other parts of Africa between the tropics.

ZANONIA, a genus of plants of the class pentandria. See Botany *Index*.

ZANTE, an island of the Mediterranean, near the coast of the Morea, 19 miles south-east of the island of Cephalonia, belonging to the Ionian republic. It is about 24 miles in length and 12 in breadth, and very pleasant and fertile; but its principal riches consist in currants, with which it greatly abounds. They are cultivated in a very large plain, under the shelter of mountains on the shore of this island; for which reason the sun has greater power to bring them to perfect maturity. The town called *Zante* may contain near 20,000 inhabitants; the whole island contains about 40,000. The houses are low, on account of the frequent earthquakes, for scarce a year passes without one; however, they do no great damage. The natives speak both Greek and Italian. There are very few Roman Catholics among them; but they have a bishop as well as the Greeks. This place has no fortifications, but there is a fortress upon an eminence planted with cannon. In one part of this island is a place which shakes when trod upon like a quagmire; and a spring which throws out a great deal of bitumen, especially at the time of an earthquake. It serves instead of pitch to pay the bottoms of the ships, and about 100 barrels in a year are used for this purpose. There are about 50 villages in the island; but no other large town beside Zante. It is seated on the eastern side of the island, and has a good harbour. This and the other Ionian islands are now under the protection of Britain. E. Long. 21. 3. N. Lat. 37. 53.

ZANTHOXYLUM, the Toothache-tree, a genus of plants of the class of diœcia; and in the natural system arranged under the 46th order, *Hederaceæ*. See Botany *Index*.

ZAPATA, a kind of feast or ceremony held in Italy in the courts of certain princes, on St Nicholas's day; wherein people hide presents in the shoes or slippers of those they would do honour to, in such a manner as may surprise them on the morrow when they come to dress; being done in imitation of the practice of St Nicholas, who used in the night-time to throw purses of money in at the windows to marry poor maids withal.

Zapata ‖ Zea.

ZEA, Indian Corn; a genus of plants of the class monœcia. See Botany *Index*.—There is only one species, the *Mays*, maize. The Indians in New England, and many other parts of America, had no other vegetable but maize or Indian corn for making their bread.

They call it *weachin;* and in the United States of America there is a great proportion of the bread of the country made of this grain. In Italy and Germany also there is a species of maize which is the food of the poor inhabitants.

The ear of the maize yields a much greater quantity of grain than any of our corn ears. There are commonly about eight rows of grain in the ear, often more, if the ground be good. Each of these rows contains at least 30 grains, and each of these gives much more flour than a grain of any of our corn. The grains are usually either white or yellowish; but sometimes they are red, bluish, greenish, or olive-coloured, and sometimes striped and variegated. This sort of grain, though so essentially necessary to the natives of the place, is yet liable to many accidents. It does not ripen till the end of September; so that the rains often fall heavy upon it while on the stalk, and the birds in general peck it when it is soft and unripe. Nature has, to defend it from these accidents, covered it with a thick husk, which keeps off slight rains very well: but the birds if not frightened away, often eat through it, and devour a great quantity of the grain.

There are three or four varieties of maize in different parts of America. That of Virginia is very tall and robust, growing to seven or eight feet high; that of New England is shorter and lower. And the Indians farther up in the country have a yet smaller kind in common use. The stalk of the maize is jointed like the sugar-cane; it is very soft and juicy, and the juice is so sweet and saccharine, that a syrup, as sweet as that of sugar, has been often made of it; and things sweetened with it have been found not distinguishable from those done with sugar. It has not been tried yet whether it will crystallize into sugar; but in all probability it will.

The Americans plant this corn any time from the beginning of March to the beginning of June; but the best season is the middle of April. The savage Indians, who knew nothing of our account of months, used to guide themselves in the seed-time of this useful plant by the budding of some particular trees of that country, and by the coming up of a sort of fish into their rivers which they call the *aloofe*. These things were both so regular, that they were in no danger of mistaking the time.

The manner of planting maize is in rows, at equal distances, every way about five or six feet. They open the earth with a hoe, taking away the surface to three or four inches deep, and of the breadth of the hoe; they then throw in a little of the finer earth, so as to leave the hole four inches deep or thereabouts, and in each of these holes they place four or five grains at a little distance from one another. If two or three of these grow up, it is very well; some of them are usually destroyed either by the birds or other animals. When

When the young plants appear, they hoe up the weeds from time to time; and when the stalk gathers some strength, they raise the earth a little about it, and continue this at every hoeing till it begins to put forth the ears; then they enlarge the hill of earth, round the root, to the size of a hop-hill, and after this they leave it till the time of harvest, without any farther care. When they gather the ears, they either immediately strip off the corn, or else hang up the ears, tied in traces at distances from one another; for if they are laid near together, they will heat and rot, or else sprout and grow; but kept cool and separate, they will remain good all the winter. The best method is to thrash out the corn as soon as the harvest is over, to dry it well on mats in the sun, and then lay it up in holes of the ground, well lined with mats, grass, or the like, and afterwards covered at top with more earth. The most careful among the Indians use this method, and this sort of subterranean granary always proves good.

The uses of this plant among the Indians are very many. The great article is the making their bread of it; but besides this, the stalks, when cut up before they are too much dried, are an excellent winter food for cattle; but they usually leave them on the ground for the cattle to feed on. The husks about the ear are usually separated from the rest, and make a particular sort of fodder, not inferior to our hay. The Indian women have a way of slitting them into narrow parts, and they then weave them artificially into baskets and many other toys. The original way of eating the grain among the Indians was this: they boiled it whole in water till it swelled and became tender, and then they fed on it either alone, or ate it with their fish and venison instead of bread. After this, they found the way of boiling it into a sort of pudding, after bruising it in a mortar; but the way of reducing it to flour is the best of all. They do this by parching it carefully in the fire, without burning, and then beating it in mortars and sifting it. This flour they lay up in bags as their constant provision, and take it out with them when they go to war, eating it either dry or with water. The English have contrived, by mixing it into a stiff paste, either by itself or with rye or wheat-meal, fermenting it with leaven or yeast, and baking it in a hot oven, to make good bread of it. They have likewise found out a method of making good beer, either of the bread or by malting the grain.

ZEAL, passionate ardour for any person or cause. It is most frequently used to denote a strong and warm attachment to the distinguishing doctrines or worship of some particular sect of Christians. Thus we say, a zealous *Calvinist*, *Arminian*, or *Papist*; though we may likewise with the greatest propriety say of an upright and benevolent man, that he is zealous of *good works*.

ZEALAND, the chief of the Danish islands, is situated at the entrance of the Baltic sea, bounded by the Schaggerrac sea on the north; by the Sound, which separates it from Schonen, on the east; by the Baltic sea on the south; and by the strait called the *Great Belt*, which separates it from the island of Funen, on the west; being of a round figure, near 200 miles in circumference: the chief town is Copenhagen.

ZEALAND, is also a province of the United Netherlands, consisting of eight islands, which lie in the mouth of the river Scheldt, bounded by the province of Holland, from which they are separated by a narrow channel, on the north; by Brabant on the east; by Flanders, from which they are separated by one of the branches of the Scheldt, on the south; and by the German ocean on the west.

New ZEALAND, a country of Asia, in the South Pacific ocean, first discovered by Tasman, the Dutch navigator, in the year 1642, who gave it the name of *Staten Land*, though it has been generally distinguished in our maps and charts by the name of *New Zealand*, and was supposed to be part of a southern continent: but it is now known, from the late discoveries of Captain Cook who sailed round it, to consist of two large islands, divided from each other by a strait four or five leagues broad. They are situated between the latitudes of 34 and 48 degrees south, and between the longitudes of 166 and 180 degrees east from Greenwich. One of these islands is for the most part mountainous, rather barren, and but thinly inhabited; but the other is much more fertile, and of a better appearance. In the opinion of Sir Joseph Banks and Dr Solander, every kind of European fruits, grain, and plants, would flourish here in the utmost luxuriance. From the vegetables found here, it is supposed that the winters are milder than those in England, and the summers not hotter, though more equally warm; so that it is imagined, that if this country were settled by people from Europe, they would, with moderate industry, be soon supplied, not only with the necessaries, but the luxuries of life, in great abundance. Here are forests of vast extent, filled with very large timber trees; and near 400 plants were found here that had not been described by the naturalists. The inhabitants of New Zealand are stout and robust, and equal in stature to the largest Europeans. Their colour in general is brown, but in few deeper than that of the Spaniard who has been exposed to the sun, and in many not so deep; and both sexes have good features. Their dress is very uncouth, and they mark their bodies in a manner similar to the inhabitants of Otaheite, and which is called *tattowing*. Their principal weapons are lances, darts, and a kind of battle-axes; and they have generally shown themselves very hostile to the Europeans who have visited them.

ZEALOTS, an ancient sect of the Jews, so called from their pretended zeal for God's law and the honour of religion.

ZEBRA. See EQUUS, MAMMALIA *Index*.

ZEBU, a name given by M. de Buffon to the bos indicus of Linnæus. See MAMMALIA *Index*.

ZECHARIAH, a canonical book of the Old Testament. See SCRIPTURE, N° 80.

ZECHIN, or ZECCHINO. See SEQUIN.

ZEDOARY, in the *Materia Medica*. See KÆMPFERIA.

ZELL, a city of Germany in the circle of Lower Saxony, capital of the duchies of Zell and Lunenburg, situated at the confluence of the rivers Aller and Fuhse, 30 miles north of Hanover, and 40 south of Lunenburg. E. Long. 9. 58. N. Lat. 52. 40.

ZEMBLA, NOVA, a very large island lying in the Northern ocean, to the north of Russia, from which it is separated by the strait of Waigate. It has no inhabitants except wild beasts, particularly white foxes and bears. In 1595 a Dutch vessel was cast away on the coast, and the ship's company were obliged to winter here;

Zembla, Zemindar. here; but they did not see the sun from the fourth of November to the beginning of February, and had great difficulty to keep themselves from being frozen to death.

ZEMINDAR, in its original meaning, signifies a great landholder of Bengal; but it is now more strictly applicable to those who have their title constituted or confirmed by a patent or charter from government, by which they hold their lands or zemindaries upon certain conditions. It appears from history, that, in times prior to the irruption of the Mahomedans, the rajahs who held their residence at Delhy, and possessed the sovereignty of Hindostan, deputed officers to collect their revenues. The word *zemindar* is Persian, and that language can have had no currency in the countries of India, until it was introduced by the people of Persia. When the emperor Shehab-ul-Dien Ghory conquered the empire of Hindostan at the end of the 12th century, he left Sultan Cutub-ul-Dien to be his viceroy at Delhy, and administer the government of Hindostan. From that time the customs and practices of the Mahomedans began gradually to be established in India: their armies were sent into the countries of the reduced rajahs, under the command of omrahs, in order to preserve the conquest; and lands were allotted to them to defray the expence. From hence arose the system of Jaghiredarry in Hindostan. But when these Omrah Jaghiredars had established their own strength, several of them rebelled against the imperial authority, and aspired at the crown. Thus circumstanced, the emperors, in order to obviate these mischiefs, thought it would be more politic to commit the management of the country to the native Hindoos, who had most distinguished themselves by the readiness and constancy of their obedience to the sovereign power.

In pursuance of this plan, districts were allotted to numbers of them under a reasonable revenue (Jummah Monâsib), which they were required to pay in money to the governors of the provinces, deputed from the emperor. And in case any one of the omrahs or provincial governors should swerve from his allegiance, the zemindars of that country were to exert themselves in such a manner as should check rebellion, and restore good government. For this purpose, grants of zemindary were severally conferred upon such of the Hindoos as were obedient; describing their apportionment of the country; and every person who had received a grant under the authority of the crown was thereby fully invested with the functions of zemindar.

The functions of a zemindar are, 1st, The preservation and defence of their respective boundaries from traitors and insurgents. 2dly, The tranquillity of the subjects, the abundance of cultivators, and increase of his revenue. 3dly, The punishment of thieves and robbers, the prevention of crimes, and the destruction of highwaymen. The accomplishment of these objects is considered in the royal grant as the disharge of office to the sovereign; and on that account the word *office* (khidmut) is employed in the Dewanny Sunnud for a zemindary.

It was a rule in the times of the ancient emperors, that when any of the zemindars died, their effects and property were sequestrated by the government. After which, in consideration of the rights of long service, which is incumbent on sovereigns, and elevates the dignity of the employer, sunnuds for the office of zemindary were granted to the children of the deceased zemindar; and no other person was accepted, because the inhabitants could never feel for any stranger the attachment and affection which they naturally entertain for the family of their zemindar, and would have been afflicted if any other had been put over them. For this reason, the emperors, considering it as a means of conciliating the minds of the people, graciously fixed and confirmed the children of the deceased zemindar in the office of their fathers and grandfathers, by issuing new sunnuds to transfer the possession to them. By degrees zemindaries became truly heritable property, which, however, could be transferred by gift or sale from one family to another. They could likewise be forfeited to the sovereign, by the zemindar's deviating from his allegiance, neglecting to pay his tribute, or to discharge the duties of his station.

It is universally known, says Sir Charles Rous Boughton, that, when the three provinces of Bengal, Bahar, and Orissa, were ceded to the British East India Company, the country was distributed among the zemindars and talookdars or holders of land, who paid a stipulated revenue, by twelve instalments, to the sovereign power or its delegates. They assembled at the capital in the beginning of every Bengal year (commencing in April), in order to complete their final payments, and make up their annual accounts; to settle the discount to be charged upon their several remittances in various coins for the purpose of reducing them to one standard, or adjust their concerns with their bankers; to petition for remissions on account of storms, drought, inundation, disturbances, and such like; to make their representations of the state and occurrences of their districts: after all which they entered upon the collections of the new year; of which, however, they were not permitted to begin receiving the rents from their own farmers, till they had completely closed the accounts of the preceding year, so that they might not encroach upon the new rents, to make up the deficiency of the past. Our author proves, we think completely, the right of the zemindars to transfer their possessions, either by inheritance to their children, or, with the consent of the sovereign, to other families; and he argues strenuously and successfully against the bad policy, as well as injustice of interfering with those rights, as long as the zemindars discharge the duties of their several stations.

ZEND, or **ZENDAVESTA**, a book ascribed to Zoroaster, and containing his pretended revelations; which the ancient Magians and modern Persees, called also *Gaurs*, observe and reverence in the same manner as the Christians do the Bible, and the Mahometans the Koran, making it the sole rule both of their faith and manners. The word, it is said, originally signifies any instrument for kindling fire, and is applied to this book to denote its aptitude for kindling the flame of religion in the hearts of those who read it.

The Zend contains a reformed system of Magianism; teaching that there is a Supreme Being, eternal, self-existent, and independent, who created both light and darkness, out of which he made all other things; that these are in a state of conflict, which will continue till the end of the world; that then there shall be a general resurrection and judgment; and that just retribution shall

Zend ‖ Zeno.

shall be rendered unto men according to their works; that the angel of darkness with his followers shall be consigned to a place of everlasting darkness and punishment, and the angel of light with his disciples introduced into a state of everlasting light and happiness; after which light and darkness shall no more interfere with each other. The Zend also enjoins the constant maintenance of sacred fires and fire temples for religious worship; the distinction of clean and unclean beasts; the payment of tithes to priests, which are to be of one family or tribe; a multitude of washings and purifications, resembling those of the Jewish law; and a variety of rules and exhortations for the exercise of benevolence and charity.

In this book there are many passages evidently taken out of the Scriptures of the Old Testament, particularly out of the Psalms of David: The author represents Adam and Eve as the first parents of all mankind, gives in substance the same account of the creation and deluge with Moses, differing indeed with regard to the former, by converting the six days of the Mosaic account into six times, comprehending in the whole 365 days; and speaks also of Abraham, Joseph, Moses, and Solomon. Moreover, Dr Baumgarten asserts, that this work contains doctrines, opinions, and facts, actually borrowed from the Jews, Christians, and Mahometans; whence, and from other circumstances, he concludes that both the history and writings of this prophet were probably invented in the later ages, when the fire-worshippers under the Mahometan government thought fit to vindicate their religion from the suspicion of idolatry.

At whatever period the Zend may have been written, we are assured by Dr Hyde, that it is in the pure old Persian language, and in the character called *Peplavi*. Some parts of it contain the original text, and others Zoroaster's second thoughts subjoined, for explaining more fully his doctrine. These were occasioned by the opposition of adversaries, and unforeseen circumstances which occurred during the fabrication of the imposture. About 300 years ago, when the old Persian language had become antiquated and little understood, one of the destours or high-priests among the Persees composed the *Sadda*, which is a compendium in the vulgar or modern Persic tongue, of those parts of the Zend that relate to religion, or a kind of code of canons and precepts, drawn from the theological writings of Zoroaster, serving as an authoritative rule of faith and practice for his followers. This Sadda is written in a low kind of Persic verse, and as Dr Hyde informs us, it is *bonorum et malorum farrago*, having many good and pious things, and others very superstitious and trifling. See PERSEES and ZOROASTER.

ZENITH, in *Astronomy*, the vertical point, or a point in the heavens directly over our heads.

ZENO ELEATES, an eminent Grecian philosopher, was born at Elea about 504 years before Christ. He was a zealous friend of civil liberty, and is celebrated for his courageous and successful opposition to tyrants; but the inconsistency of the stories related by different writers concerning him in a great measure destroys their credit. He chose to reside in his small native city of Elea rather than at Athens, because it afforded freer scope to his independent and generous spirit, which could not easily submit to the restraints of authority. It is related, that he vindicated the warmth with which he resented reproach, by saying, "If I were indifferent to censure, I should also be indifferent to praise." The invention of the dialectic art has been improperly ascribed to Zeno; but there can be no doubt that this philosopher, and other metaphysical disputants in the Eleatic sect, employed much ingenuity and subtlety in exhibiting examples of most of the logical arts, which were afterwards reduced to rule by Aristotle and others.

Enfield's History of Philosophy.

Zeno

According to Aristotle, he taught, that nothing can be produced either from that which is similar or dissimilar; that there is only one being, God; who is eternal, homogeneous, and spherical, neither finite nor infinite, neither quiescent nor moveable; that there are many worlds; that there is in nature no vacuum; that all bodies are composed of four elements, heat and moisture, cold and dryness; and that the body of man is from the earth, and his soul an equal mixture of these four elements. He argued with great subtlety against the possibility of motion. If Seneca's account of this philosopher deserves credit, he reached the highest point of scepticism, and denied the real existence of external objects. The truth is, that after all that has been advanced by different writers, it is impossible to determine whether Zeno understood the term *one*, metaphysically, logically, or physically; or whether he admitted or denied a nature properly divine.

ZENO, the founder of the sect of the Stoics, was born about 300 years before Christ at Citium, in the island of Cyprus. This place having been originally peopled by a colony of Phœnicians, Zeno is sometimes called a Phœnician. His father was by profession a merchant, but discovering in the youth a strong propensity towards learning, he early devoted him to philosophy. In his mercantile capacity he had frequent occasion to visit Athens, where he purchased for his son several of the writings of the most eminent Socratic philosophers. These he read with great avidity; and when he was about 30 years of age, he determined to take a voyage to a city which was so celebrated both as a mart of trade and of science. If it be true, as some writers relate, that he brought with him a valuable cargo of Phœnician purple, which was lost by shipwreck upon the coast of Piræus, this circumstance will account for the facility with which he at first attached himself to a sect whose leading principle was the contempt of riches. Upon his first arrival in Athens, going accidentally into the shop of a bookseller, he took up a volume of the Commentaries of Xenophon; and after reading a few passages, was so much delighted with the work, and formed so high an idea of the author, that he asked the bookseller where he might meet with such men. Crates the Cynic philosopher happening at that instant to be passing by, the bookseller pointed to him, and said, "Follow that man." Zeno attended upon the instructions of Crates, and was so well pleased with his doctrine that he became one of his disciples. But though he admired the general principles of the Cynic school, he could not easily reconcile himself to their peculiar manners. Besides, his inquisitive turn of mind would not allow him to adopt that indifference to every scientific inquiry which was one of the characteristic distinctions of the sect. He therefore attended upon other masters, who professed to instruct their disciples in the nature and causes of things. When Crates, displeased at his following other philosophers, attempted to drag him by force out of the school of Stilpo, Zeno said

Zeno, Zenobia.

said to him, "You may seize my body, but Stilpo has laid hold of my mind." After continuing to attend upon the lectures of Stilpo several years, he passed over to other schools, particularly to those of Xenocrates and Diodorus Cronus. By the latter he was instructed in dialectics. He was so much delighted with this branch of study, that he presented to his master a large pecuniary gratuity, in return for his free communication of some of his ingenious subtleties. At last, after attending almost every other master, he offered himself as a disciple of Polemo. This philosopher appears to have been aware, that Zeno's intention in thus removing from one school to another, was to collect materials from various quarters for a new system of his own; for, when he came into Polemo's school, he said to him, "I am no stranger, Zeno, to your Phœnician arts; I perceive that your design is to creep slyly into my garden, and steal away my fruit." Polemo was not mistaken in his opinion. Having made himself master of the tenets of others, Zeno determined to become the founder of a new sect. The place which he made choice of for his school was a public portico, adorned with the pictures of Polygnotus, and other eminent painters. It was the most famous portico in Athens, and called, by way of eminence, Στοα, "the Porch." It was from this circumstance that the followers of Zeno were called *Stoics*.

In his person Zeno was tall and slender; his aspect was severe, and his brow contracted. His constitution was feeble, but he preserved his health by great abstemiousness. The supplies of his table consisted of figs, bread, and honey; notwithstanding which, he was frequently honoured with the company of great men. In public company, to avoid every appearance of an assuming temper, he commonly took the lowest place. Indeed so great was his modesty, that he seldom chose to mingle with a crowd, or wished for the company of more than two or three friends at once. He paid more attention to neatness and decorum in external appearance than the Cynic philosophers. In his dress indeed he was plain, and in all his expences frugal; but this is not to be imputed to avarice, but a contempt of external magnificence. He showed as much respect to the poor as to the rich; and conversed freely with persons of the meanest occupations. He had only one servant, or, according to Seneca, none.

Zeno lived to the extreme age of 98; and at last, in consequence of an accident, voluntarily put an end to his life. As he was walking out of his school he fell down, and in the fall broke one of his fingers; upon which he was so affected with a consciousness of infirmity, that, striking the earth, he said, "Why am I thus importuned? I obey thy summons;" and immediately went home and strangled himself. He died in the first year of the 129th Olympiad. The Athenians, at the request of Antigonus, erected a monument to his memory in the Ceramicum.

We ought not to confound the two Zenos already mentioned with

ZENO, a celebrated Epicurean philosopher, born at Sidon, who had Cicero and Pomponius Atticus for his disciples, and who wrote a book against the mathematics, which, as well as that of Possidonius's refutation of it, is lost; nor with several other Zenos mentioned in history.

ZENOBIA, queen of Palmyra. See PALMYRA.

ZEOLITE, a mineral substance. See MINERALOGY *Index*.

Zeolite, Zeuxis.

ZEPHANIAH, a canonical book of the Old Testament. See SCRIPTURE, N° 79.

ZEPHYR, the *West-Wind*, or that which blows from the cardinal point of the horizon opposite to the east.

ZEPHYRUS, one of the Pagan deities, was represented as the son of Aurora, and the lover of the nymph Chloris, according to the Greeks, or of Flora according to the Romans; and as presiding over the growth of fruits and flowers. He is described as giving a refreshing coolness to the air by his soft and agreeable breath, and as moderating the heat of summer by fanning the air with his silken wings. He is depictured under the form of a youth, with a very tender air, with wings resembling those of the butterfly, and with his head crowned with a variety of flowers. As the poets of Greece and Rome lived in a warm climate, they are lavish in their praise of this beneficent deity, and under his name describe the pleasure and advantage they received from the western breezes.

ZERDA. See CANIS, MAMMALIA *Index*.

ZERTA, the ZERTE, a fish caught in the rivers of Italy and some other places, of the figure of the chub, and called by authors *capito anodromus*, and the *blike*. It seldom grows to more than two pounds weight, and at times lives in rivers, at times in the sea; and is esteemed a very well tasted fish, especially a little before the season of its spawning. The zerte is that species of cyprinus described by Gesner and others under the name of *capito anodromus*.

ZEST, the woody thick skin quartering the kernel of a walnut; prescribed by some physicians, when dried and taken with white wine, as a remedy against the gravel.

ZEST is also used for a chip of orange or lemon peel; such as is usually squeezed into ale, wine, &c. to give it a flavour; or the fine oil which spurts out of that peel on squeezing it.

ZEUGMA, a figure in *Grammar*, whereby an adjective or verb which agrees with a nearer word, is also, by way of supplement, referred to another more remote.

ZEUS, a genus of fishes of the order of *thoracici*. See ICHTHYOLOGY *Index*.

ZEUXIS, a celebrated painter of antiquity, flourished about 400 years before Christ. He was born at Heraclea; but as there have been many cities of that name, it cannot be certainly determined which of them had the honour of his birth. Some learned men, however, conjecture, that it was the Heraclea near Crotona in Italy. He carried painting to a much higher degree of perfection than Apollodorus had left it; discovered the art of properly disposing of lights and shades, and particularly excelled in colouring. He amassed immense riches; and then resolved to sell no more of his pictures, but gave them away; saying very frankly, "That he could not set a price on them equal to their value." Before this time he made people pay for seeing them; and nobody was admitted to see his Helena without ready money, which occasioned the wags calling his picture *Helen the Courtezan*. It is not known whether this Helen of Zeuxis was the same with that which was at Rome in Pliny's time, or that which he painted for the inhabitants

inhabitants of Crotona to be hung up in the temple of Juno: this last he painted from five beautiful girls of that city, copying from each her greatest excellencies. Pliny observes, that this admirable painter, disputing for the prize of painting with Parrhasius, painted some grapes so naturally, that the birds flew down to peck them. Parrhasius, on the other hand, painted a curtain so very artfully, that Zeuxis, mistaking it for a real one that hid his rival's work, ordered the curtain to be drawn aside, to show what Parrhasius had done; but having found his mistake, he ingenuously confessed himself vanquished, since he had only imposed upon birds, while Parrhasius had deceived even a master of the art. Another time he painted a boy loaded with grapes; when the birds also flew to this picture, at which he was vexed; and confessed, that his work was not sufficiently finished, since, had he painted the boy as perfectly as the grapes, the birds would have been afraid of him. Archelaus, king of Macedon, made use of Zeuxis's pencil for the embellishment of his palace. One of this painter's finest pieces was a Hercules strangling some serpents in his cradle, in the presence of his affrighted mother: but he himself chiefly esteemed his Athleta, or Champion, under which he placed a Greek verse that afterwards became very famous, and in which he says, "That it was easier to criticise than to imitate the picture." He made a present of his Alcmena to the Agrigentines. Zeuxis did not value himself on speedily finishing his pictures; but knowing that Agatharchus gloried in his being able to paint with ease and in a little time, he said, "That for his part he, on the contrary, gloried in his slowness; and, if he was long in painting, it was because he painted for eternity." Verrius Flaccus says, that Zeuxis having painted an old woman, he laughed so very heartily at the sight of this picture, that he died: but as no other of the ancients has mentioned this particular, there is the greatest reason to believe it fabulous. Carlo Dati has composed in Italian the Life of Zeuxis, with those of Parrhasius, Apelles, and Protogenes. This work was printed at Florence in 1667.

ZICLAG, or ZIKLAG, in *Ancient Geography*, a town of the tribe of Simeon, on the borders of the Philistines (Joshua xv. and xix.), but in the hands of the Philistines till David's time (1 Sam. xxvii. and xxx.).

ZIMENT-WATER, COPPER-WATER, the name by which some have called water found in places where there are copper-mines, which is impregnated with particles of that metal.

The most famous spring of this kind is about a mile distant from Newsohl in Hungary, in the great copper-mine called by the Germans *Herrngrundt*. The water in this mine is found at different depths, and is received into basons, for the purpose of separating the copper from it: in some of these it is much more sated with this metal than in others, and will make the supposed change of iron into that metal much sooner. The most common pieces of iron used in the experiments are horse-shoes, nails, and the like; and they are found very little altered in shape, after the operation, except that their surfaces are more raised. The water appears greenish in the bason, where it stands; but if a glass of it be taken up, it looks clear as crystal; it has no smell, but a strong vitriolic astringent taste, insomuch that the lips and tongue are blistered and scorched upon tasting it.

ZIN, in *Ancient Geography*, a wilderness encompassing Idumea, at least on the south and west, as far as Palestine or Canaan; but according to Wells, on the east of Edom, to the north of Ezion-gaber.

ZINC, a metallic substance, formerly considered as one of the brittle metals; or, according to the distinction of the older chemists, a *semi-metal* or an imperfect metal, because it was found to be destitute of some of the properties of other metals which were considered as perfect. For an account of the properties and combinations of zinc, as they were then known, see CHEMISTRY *Index*; and for the history of its ores, see MINERALOGY *Index*.

But in the progress of chemical discovery it has been found that zinc is not a less perfect metal than others; for in the year 1805, it was announced that a patent was granted to Messrs Hobson and Sylvester of Sheffield for a method of manufacturing zinc. From their discovery it appears, that zinc raised to a temperature of between 210° and 300° of Fahrenheit, is not only very malleable, but may be passed through rollers, or drawn into wire. After the metal has been treated in this manner, it does not return to its former brittleness, but continues soft, flexible, and extensible, and may be applied to many uses for which this metal was before thought unfit *.

We must, however, notice, that a prior claim to the discovery of rendering zinc ductile and malleable, has been made by Mr Lowry, in favour of a Mr Sheffield of Somerstown. Twenty years before the time of Messrs Hobson and Sylvester's patent being announced, Mr Sheffield, in making an assay of some blende, was impatient to examine the metal, struck an ingot for the purpose of breaking it while it was yet hot, but was much surprised to find that instead of being brittle, and breaking with the usual fracture of zinc, it was extremely tough, and when he succeeded in breaking it, after many bendings backward and forward, it exhibited a steel-grained fibrous texture. At first he doubted of the metal being zinc, but he repeated the experiment on what he knew to be pure metal, and obtained the same result; and from this he concluded that zinc at a certain temperature is equally malleable and ductile with other metals. This he found to be the case by drawing it into wire, and laminating it between rollers, by which he produced plates not exceeding the $\frac{1}{100}$th of an inch, and possessing the strength and tenacity of silver †.

† *Phil. Mag.* xxiii. 282.

Since the time that our article CHEMISTRY was printed, the decomposition of potash, soda, the alkaline earths, and some other bodies which were formerly considered as simple, or were only conjectured from analogy to be compound, has been effected by Mr Davy; and as we were disposed to entertain hopes that something new might be added to the unexpected and brilliant discoveries of that celebrated chemist, we have deferred, till near the close of our work, giving any account of them. This is the reason that the fact was merely announced under the words POTASH and SODA, and a reference made to *Galvanic* TROUGH, under which it was intended to give a short description of the apparatus employed in the experiments which led to the discoveries alluded to. For the same reason we were induced to make a farther reference to this place, because zinc is one

Zinc. one of the metallic substances usually employed in the construction of galvanic apparatus. We shall therefore here employ a few pages, 1st, In a description of the improvements which have been made in the construction of galvanic apparatus; and, 2d, We shall lay before our readers a view of the discoveries in galvanic electricity since the treatises on CHEMISTRY and GALVANISM in this work were printed.

Galvanic Apparatus.—A very considerable improvement has been made on the construction of galvanic batteries, by which they are rendered, not only more convenient and manageable, but far more powerful. Under the article GALVANISM, we have described particularly the construction of the galvanic trough, and we have noticed that the soldering of the plates of zinc and copper employed for this purpose was attended with considerable difficulty. In the new method of construction the plates are not soldered together, but are merely connected by means of a metallic arc. In this way each pair of plates can be removed from the trough at pleasure, for the purpose of examining and cleaning them. The new apparatus is constructed precisely on the same principle as the *couronne de Tasses*, proposed by Volta, and described at p. 333 of GALVANISM. The trough employed in this apparatus is prepared in the same way as when the plates of zinc and copper soldered together were fixed in it by means of cement; but in place of the metallic plates, plates of glass, or some other non-conducting substance, are introduced and secured by cement, so that there shall be no communication between the different cells into which the liquid is introduced. The plates of zinc and copper connected by means of the metallic arc, at the distance of about half an inch, are placed in different cells, having a plate of glass between each pair of plates. Each cell then contains a plate of each of the metals, which are unconnected, excepting through the medium of the liquid which is to be the conductor of the electricity. It is scarcely necessary to mention, that the proper order of arrangement shall be observed, so that throughout the whole trough or battery there shall be a series of zinc, copper, and liquid.

Beside the conveniency and simplicity of this mode of constructing galvanic troughs, it possesses this farther advantage of being more powerful, because instead of one surface of the plates, as in the former construction of this apparatus, both surfaces are exposed to the action of electricity, and therefore the power is greatly increased. A farther improvement, it is said, has been made in constructing batteries of this kind, which consists in employing troughs of Wedgewood's ware, with partitions of the same material, instead of wooden troughs with partitions of glass. This improvement was first suggested by Dr Babington.

The following is the account of the construction of galvanic apparatus, with the view of ascertaining in what way the greatest effect might be produced, with the least waste of power and expence. The experiments which we are now to mention were made by Mr Children *. For this purpose a battery was constructed on the new method, with plates of copper and zinc, connected by leaden straps, soldered on the top of each pair of plates. Twenty pairs of plates were employed, and each plate was four feet high by two feet wide. The whole extent of surface exposed amounted to 92,160 square inches; the trough was made of wood, with wooden partitions, covered with cement, to resist the action of the acid employed. The battery was charged with a mixture of three parts of fuming nitrous, and one of sulphuric acid, diluted with thirty of water; the quantity employed was 120 gallons. With this apparatus the following experiments were made.

* Phil Trans. 1809, p. 32.

Exper. 1. Eighteen inches of platina wire, of one-thirtieth of an inch diameter, were completely fused in about twenty seconds. *Exper.* 2. Three feet of the same wire were heated to a bright red, visible by strong day-light. *Exper.* 3. Four feet of the same wire were rendered very hot, but not perceptibly red by day-light. *Exper.* 4. Charcoal burnt with intense brilliancy. *Exper.* 5. Ten inches of iron-wire of $\frac{1}{70}$th of an inch diameter, were barely fused; three feet of the same wire were not ignited. *Exper.* 6. No effect was produced on imperfect conductors. *Exper.* 7. The gold leaves of the electrometer were not affected. *Exper.* 8. When the cuticle was dry, no shock was given by the battery, and it was scarcely perceptible when the skin was wet.

To contrast the effects of this apparatus with another differing in the size and number of plates, the anther employed 200 pairs of plates, each about two inches square, placed in half pint pots of common queen's ware. The same liquid was employed, with the addition of a fresh portion of sulphuric acid, in the proportion of about a quarter of a pint to a gallon. The experiments with this apparatus gave the following results.

Exper. 1. Potash and barytes were readily decomposed. *Exper.* 2. The metallization of ammonia was produced with great facility. *Exper.* 3. Charcoal was vividly ignited. *Exper.* 4. The gold leaves of the electrometer diverged considerably. *Exper.* 5. After the battery was in action three hours, it gave a vivid spark; at the end of 24 hours it metallized ammonia; at the end of 41 hours it was nearly exhausted. From the results of these experiments, Mr Children concludes, that the theory of the mode of action of the voltaic battery proposed by Mr Davy is confirmed, namely, that the intensity increases with the number, and the quantity with the extent of the series. This is proved by the effects produced on the platina and iron wires, in the 1st and 5th experiments with the large battery, as well as by the experiments on imperfect conductors in the small apparatus; for as the platina wire is a perfect conductor, and not liable to oxidation, it allows the electricities to be freely transmitted, and from the immense quantity given out from a surface of such extent, they evolve, on their mutual annihilation, heat sufficient to raise the temperature of the platina to the point of fusion. But a very small portion of the electricity passes through the iron wire, in consequence of its easy oxidation, and the thin coat of oxide formed on its surface. This arises from the low state of the intensity of the electricity, as appears also from its want of power on the gold leaves of the electrometer. From the same deficient intensity, the decomposition of barytes could not be effected by the large battery, and the same battery exhibited a very weak action on imperfect conductors; but the small battery exerted great power on that class of bodies, and decomposed them readily, although its surface was 30 times less than the surface of the great battery; but the number

Zinc. ber of plates was nearly ten times greater. Another circumstance, of considerable importance in conducting experiments by means of the galvanic battery, is here noticed by the author; that the long continued action of the small battery was owing to the large capacity of the cells containing a proportional quantity of liquor. And beside this advantage he adds, that with very large combinations, a certain distance between each pair of plates is absolutely necessary to prevent spontaneous discharges, which are accompanied with vivid flashes of electric light. This happened to the author with a battery of 1250 four inch plates, constructed according to the new method. Mr Children has constructed a battery of 20 pairs of six feet high and $2\frac{1}{7}$ broad, and with this battery he ignited 6 feet of platina wire.

From the experiments and observations, some of which we have detailed, and for others we refer to the paper itself, the author concludes with the following remarks: "The absolute effect of a voltaic apparatus seems to be in the compound ratio of the number and size of the plates. The intensity of the electricity being as the former, the quantity given out as the latter, consequently regard must be had, in its construction, to the purposes for which it is designed. For experiments on perfect conductors, very large plates are to be preferred, a small number of which will probably be sufficient; but where the resistance of imperfect conductors is to be overcome, the combination must be great, but the size of the plates may be small: but if quantity and intensity be both required, then a large number of large plates will be necessary. For general purposes, four inches square will be found to be the most convenient size*." *Ibid.* 37.

Discoveries in Galvanism.—At the close of the article Galvanism, we noticed some experiments which were made about the beginning of the year 1805, which seemed to lead to the conclusion, that muriatic acid and soda were formed by means of galvanic electricity. In experiments on the decomposition of water, which was supposed to be in a state of the utmost purity, the appearance of muriatic acid and soda was adduced in support of this opinion. The accuracy of this conclusion, which seemed to be at variance with known facts, excited doubt, and probably led to the investigation which was undertaken by Mr Davy, and carried on with great ingenuity and address by the same philosopher, till it terminated in the brilliant discoveries, an account of which we are now to detail. Mr Davy's researches in galvanism, an account of which he laid before the Royal Society in a memoir entitled, *On some Chemical Agencies of Electricity*, may be considered as the first step in this train of investigation.

With the view of disproving the accuracy of the experiments in which the generation of acids and alkalies was supposed to have been effected by means of galvanism, Mr Davy employed agate cups, (fig. 1.), of a cylindrical form, and containing about one-fourth of a cubic inch each. The cups were boiled for some hours in distilled water, and a piece of white transparent amianthus, which had been treated in the same way, was made to connect them. They were then filled with distilled water, and exposed by means of two platina wires, to a current of electricity, from 150 pairs of plates of copper and zinc, four inches square. The liquid employed was a solution of alum. The action continued 48 hours, and the process was then examined. Paper tinged with litmus introduced into the tube con- Plate DLXXVIII. fig. 1.

taining the positive wire, was reddened; paper coloured by turmeric placed in the other tube, had its colour deepened; the acid matter produced a slight turbidity in a solution of nitrate of silver; the fluid from the negative tube retained the property of affecting the turmeric after being boiled, and indeed became more vivid as the quantity was diminished by evaporation. Carbonate of ammonia was added, and the whole being dried, and exposed to a strong heat, a minute quantity of white matter remained, which had all the properties of carbonate of soda. Zinc.

The same experiment was repeated with glass tubes, and the result was, that the quantity of alkali obtained was 20 times greater, but no traces of muriatic acid could be perceived. Mr Davy suspecting that the agate might contain a minute portion of saline matter, repeated the experiment four times. The quantity of alkaline matter diminished in every operation, and in the last process, although the battery had been kept in great activity for three days, the fluid possessed in a slight degree only the power of acting on paper tinged with turmeric; but its alkaline property was very sensible to litmus paper slightly reddened. The acid matter in the other tube was abundant; it had a sour taste, and produced no effect on solution of muriate of barytes, but left a black stain from a drop on a polished plate of silver. Thus it appeared to be extremely diluted nitrous acid.

For the purpose of making the experiment with greater accuracy, two hollow cones of pure gold (fig. 2.) Fig. 2. were employed, each containing about 25 grains of water. They were filled with distilled water, connected by moistened amianthus, as before, and exposed to the action of a battery of 100 pairs of plates of six inches square. The liquid used was a solution of alum, and diluted sulphuric acid. In ten minutes the water in the negative tube changed litmus paper to a slight blue, and the water in the positive tube produced a red tint. The process having continued for 14 hours, the acid was found to increase in quantity during the whole time, but the alkaline fluid in the other tube did not affect the tests more than in the first trial. The acid seemed to be the pure nitrous, with an excess of nitrous gas. The experiment was repeated, and the process carried on for three days, and similar results were obtained. From these experiments it was concluded, that the distilled water contained a minute portion of saline matter, but so minute indeed, that it was insensible to the most delicate chemical tests. This appeared to be the case by evaporating a quantity of the distilled water that was used very slowly, at a heat below 140° Fahrenheit, in a silver still. A quantity of solid matter equal to seven-tenths of a grain, of a saline but metallic taste, was obtained. It seemed to be a mixture of nitrate of soda and nitrate of lead. Mr Davy then employed some of the water collected in the second process of slow distillation, in another experiment with the gold tubes and connecting amianthus. At the end of two hours the water in the negative tube had no effect on turmeric paper; litmus, it could just be perceived, was changed; but by heating the water strongly for two or three minutes, it was deprived even of this power, and from this he supposes that it was owing to a small quantity of ammonia. A similar experiment was made with a portion of the same water in the agate tubes, and precisely the same results were obtained. From these

Zinc. experiments Mr Davy fairly concludes, that the fixed alkali is not generated during the process, but merely evolved, either from the solid materials employed, or some saline matter in the water.

Many experiments were made in vessels composed of different substances, with the water procured by slow distillation; and in almost every instance some fixed alkali appeared. When tubes of wax were employed, the alkaline matter was a mixture of soda and potash, and the acid matter, a mixture of sulphuric, muriatic, and nitric acids. A tube of resin afforded alkaline matter, which was principally potash. A cube of Carrara marble of about an inch, having an aperture in its centre, was placed in a platina crucible, which was filled as high as the upper surface of the cube, with the purified water. The aperture was filled with the same liquid, and the crucible was positively electrified by a powerful battery, and the negatively electrified wire introduced into the aperture. Fixed alkali and lime were obtained in this experiment; the quantity of alkali diminishing as the experiment was repeated, and after 11 processes, each continued for two or three hours, disappeared altogether. The quantity of lime-water obtained was uniform.

When 500 grains of this marble were analyzed, they afforded about three-fourths of a grain of fixed saline matter, having soda for its base. Suspecting that the Carrara marble might have been recently exposed to sea water, Mr Davy subjected to a similar experiment, a piece of granular marble from the mountains of Donnegal, and by means of negative electricity he obtained fixed alkali. Argillaceous schistus from Cornwall gave the same result, and serpentine and gray wacken both afforded soda.

In other experiments Mr Davy subjected other bodies to the action of the same power, with the view of effecting a decomposition. Thus, two cups of compact sulphate of lime, each containing about 14 grain measures of water, were connected by fibrous sulphate of lime moistened with pure water. The cups were filled with the same fluid, and they were introduced into the circuit of a galvanic battery with 100 pairs of plates of six inches. In five minutes the water in the positive cup became acid, while that in the opposite cup tinged tumeric. An hour after, a saturnine solution of lime was formed in the negative cup, and the other contained a solution of sulphuric acid of moderate strength.

Two cubical pieces of crystallized sulphate of strontites, of about an inch, with a hole drilled in each, capable of receiving eight grains of water, were plunged in pure water, in a platina crucible, and the level of the fluid was kept a few lines below the surface of the cubes. The holes in the earthy mineral were filled with pure water, and two platina wires were introduced into them. At the end of thirty hours the fluid in the cavity of the negative side precipitated solution of sulphate of potash, and sulphuric acid appeared in the other.

Two pieces of fluate of lime, having each a cavity, and connected by moist asbestus, were subjected to a similar experiment. The decomposition was slow; but in two days a solution of lime appeared in the one tube, and an acid in the other, which precipitated acetate of lead, and left a spot upon the glass, from which it was evaporated, so that it must have been fluoric acid.

Compact zeolite being prepared in the same way, and electrified in the same manner as the cube of Carrara marble, afforded soda and lime. Lepidolite, by similar treatment, gave potash; and an alkaline matter, which seemed to be a mixture of soda, potash and lime, was extracted from a piece of vitreous lava from Mount Etna.

The decomposition of saline bodies, which are soluble in water, was more rapid. A diluted solution of sulphate of potash introduced into the agate cups connected by amianthus moistened with pure water, being electrified by a battery with 50 pairs of plates, produced in four hours a weak solution of potash in the negative cup, and a solution of sulphuric acid in the positive cup. Similar phenomena were observed when sulphate of soda, nitrate of potash, nitrate of barytes, sulphate of ammonia, phosphate of soda, succinate, oxalate, and benzoate of ammonia and alum, were employed. The acids in a certain time collected in the tube containing the positive wire, and the alkalies and earths in the negative tube. Solutions of the muriatic salts, subjected to decomposition by the same processes, uniformly afforded oxymuriatic acid on the positive side.

Saturated saline solutions were most rapidly decomposed, but the smallest proportion was also acted on. Thus, if a piece of paper tinged with turmeric be plunged into pure water, in a proper circuit, in contact with the negative point, the minute quantity of saline compound contained in the paper, produces instantly a brown tint near its point of contact. Acid appears also from litmus paper at the positive surface.

Experiments were made with the view of ascertaining whether in these processes the separation of the constituent parts was complete, from the last portions of the compound. The following experiment shows that this is the case. "A very weak solution of sulphate of potash, containing 20 parts of water, and one part of saturated solution at 64°, was electrified in the two agate cups, by the power of 50 pairs of plates for three days; the connecting amianthus which had been moistened with pure water, was removed, washed with pure water, and again applied twice every day. By this precaution the presence of any neutral salt that might adhere to it, and disturb the results, was prevented. The alkali obtained in this process in the solution had the properties of pure potash, and when it had been saturated with nitric acid, it gave no turbidness by mixture with solution of muriate of barytes; the acid matter exposed to a strong heat, evaporated, without leaving any residuum."

Mr Davy then made experiments on the transfer of certain of the constituent parts of bodies, and also on the passage of acids, alkalies, and other substances, through various attracting chemical menstrua, by means of electricity, and in these experiments he obtained many curious and interesting results; but for an account of them, as well as of his observations on the different phenomena, and on the mode of decomposition and transition, we must refer to the memoir itself.

After the investigations in which Mr Davy had been occupied, and the singular and unexpected results which he obtained, he ventured to conclude, from the general principles on which the phenomena might be explained, that the new methods of proceeding would lead to a more intimate knowledge concerning the true elements of of bodies. Accordingly, in November 1807, he laid before the Royal Society a most interesting detail of an elaborate series of experiments on the decomposition of the alkalies.

Decomposition of the Alkalies.

In the first attempts that were made on the decomposition of potash, Mr Davy employed an aqueous solution, saturated at a common temperature. It was exposed to the action of a powerful galvanic battery, composed of 24 plates of copper and zinc of 12 inches square, 100 plates of six inches, and 150 plates of four inches square, charged with solutions of alum and nitrous acid. The action was very intense; a great deal of heat and violent effervescence were produced, but the water only of the solution was effected, and its hydrogen and oxygen were disengaged. Potash in the state of igneous fusion, in a spoon of platina, was next subjected to the action of a battery of 100 plates of six inches, highly charged. The spoon was connected with the positive side. In this experiment some brilliant phenomena were produced. The potash appeared to be a good conductor; and, while the communication was preserved, a most intense light was emitted from the negative wire, and a column of flame, seemingly owing to the developement of combustible matter, arose from the point of contact. When the order was reversed, and the platina spoon was connected with the negative side, a vivid and constant light appeared at the opposite point. There was no inflammation round it; but aeriform globules, which inflamed in the atmosphere, rose through the potash. The platina was considerably acted on.

Although potash, when perfectly dry, be a non-conductor, it acquires a conducting power by being slightly moistened. A small piece of pure potash exposed for a few seconds to the atmosphere, was placed on a disc of platina connected with the negative side of a battery of 250 plates of six and four inches, in a state of intense activity. A platina wire from the opposite side was brought in contact with the upper surface of the alkali. A vivid action soon took place. The potash fused at both points of electrisation; a violent effervescence appeared at the upper surface; but at the lower or negative surface no elastic fluid was emited, but small globules like quicksilver were produced, some of which burnt with explosion and bright flame as they were formed, and others remained and were only tarnished, and finally covered by a white film formed on their surfaces. These globules were the basis of potash. The same results were obtained, when gold and other metals, plumbago, or charcoal, were employed; and the effects were the same when the process was conducted in an exhausted receiver.

Mr Davy also obtained the same substance from potash, fused by means of a lamp, and placed in glass tubes confined by mercury, and furnished with hermetically inserted platina wires, to transmit the electricity; but the glass was rapidly dissolved by the action of the alkali, so that the process could not be long carried on.

In these experiments on potash, the combustible base was produced from the negative surface, and oxygen was evolved from the positive surface. The same effects invariably followed, when the experiment was conducted above mercury. The same thing was proved synthetically. The combustible substance obtained from the potash had its metallic lustre destroyed in the atmosphere, and a white crust formed upon it. This crust was found, upon examination, to be pure potash; but this was still farther confirmed by placing globules of the combustible matter in tubes containing common air, or oxygen gas, confined by mercury. An absorption of the oxygen took place, and a crust of alkali was formed upon the globule. When the combustible matter confined in given portions of oxygen, was strongly heated, a rapid combustion, with a brilliant white flame, was produced, and the metallic globules were converted into a white and solid mass, which was found to be pure potash.

To the combustible matter thus obtained from potash, Mr Davy gave the name of *potassium*. From its strong affinity for oxygen, it was extremely difficult to preserve it unchanged, for the purpose of examining its properties. The substance which he found to be least affected, is newly distilled naphtha. In this fluid potassium may be kept for many days nearly unaltered, and its physical properties may be examined in the atmosphere, when covered by a thin film of it.

Potassium, at 60° Fahrenheit, is in the form of small globules, which have the metallic lustre and general appearance of mercury; at 70° it becomes more fluid, and at 100°, different globules easily run into one. At 50° of Fahrenheit it is soft and malleable, and exhibits the lustre of polished silver. At 32° it becomes hard and brittle, and, when, broken, presents a crystallized texture. To reduce it to vapour, it requires a red heat; and in proper circumstances, it may be subjected to distillation, without change. It is a good conductor of heat, and a perfect conductor of electricity.

In the properties now mentioned, potassium approaches nearly to the metals; but it is very different in its specific gravity. In naphtha of the specific gravity of 861 it rose to the surface; and it did not sink in double distilled naphtha, the specific gravity of which was about .770. From these and other experiments, Mr Davy estimates the specific gravity of potassium at .6, so that it is the lightest fluid body known. In its solid form it is somewhat heavier; but, even in this state, when cooled to 40° Fahrenheit, it swims in double distilled naphtha.

With the view of ascertaining the proportions of the constituent parts of potash, Mr Davy made two experiments, by subjecting the metallic base to combustion in oxygen gas. In the first experiment, .12 of a grain of potassium were employed; the combustion was made upon platina, and was rapid and complete, and the basis appeared to be perfectly saturated. The result of this experiment indicates 86.7 of basis, and 13.3 of oxygen, in the 100 parts of potash. In another experiment, the result he obtained was 85.5 of basis, and 14.5 of oxygen. The mean of these two experiments is 86.1 of basis, and 13.9 of oxygen, in 100 parts of potash.

The results of the decomposition of water by the basis of the alkalies, which were more readily and perfectly obtained than those of their combustion, exhibited the proportion of base to be 84, and that of oxygen 16; but the mean of 86.1 of base, and 13.9 of oxygen, and 84 base and 16 oxygen, is 85 of potassium and 15 of oxygen, which may be taken as the proportions of the elements of potash.

Mr Davy's discoveries have been confirmed by the ingenious

Zinc.

genious experiments of Thenard and Gay-Lussac. These distinguished chemists have decomposed potash by a different process. They introduced iron filings into a bent gun barrel, which was placed across a furnace. A tube with a stopcock, containing a quantity of solid potash, is connected with one extremity of the gun barrel; to the other extremity there is attached a tube of safety, containing mercury, for the purpose of excluding the atmospheric air, and allowing any gaseous matter formed during the process to escape. The potash in the tube is to be kept cold by means of a freezing mixture, till that part of the barrel containing the iron filings has been raised to a white heat. The potash is then fused by applying heat, by means of a portable furnace; and it is allowed to pass through a small opening, to come in contact with the iron filings, where it is decomposed, the oxygen of the potash entering into combination with the iron, and the base passing on to the other extremity of the tube in a state of sublimation. At that extremity the metallic base is condensed by the application of excessive cold, and in this way the potassium may be obtained at less expence, and in greater quantity, than by means of galvanism. During this progress, hydrogen gas is evolved, which, it is supposed, is owing to the decomposition of the water contained in the alkali. The potassium thus obtained is in the form of brilliant laminæ, which adhere to the sides of the gun barrel. An alloy of the same metal with iron is also found in that part of the barrel containing the filings. Mr Davy has repeated this experiment, and he finds that the base obtained in this manner is heavier, and its melting point higher, than what is procured by means of galvanism. This, it is supposed, may arise from its being combined with a small proportion of iron. The metallic base of soda was obtained by a similar process.

But, according to the view which the French chemists have taken of these discoveries, and the results of their own experiments, they conclude, that the metallic substances derived from the alkalies are not simple, but are compounds of the several bases with hydrogen.

Another method of decomposing potash, and obtaining its base, which is still simpler, has been followed by Curaudau. In this process the decomposition is effected by charcoal. A mixture of carbonate of potash is made with flour or charcoal and linseed oil. This mixture is introduced into an iron or earthen tube or retort, and calcined, by gradually raising the heat, till a bluish light be seen in the inside of the vessel. Soon after an abundant evolution of vapour takes place, which is the base of the alkali, to be collected by introducing a clean iron rod, on which it condenses. Care must be taken to withdraw the rod before it is too hot, and to plunge it in oil of turpentine, under the surface of which the metallic crust on the rod may be separated. In this way a quantity of potassium may be procured. The base of soda is obtained by a similar process.

Fig. 3. Fig. 3. is a representation of the apparatus employed by the French chemists in decomposing potash. ABCE is the gun barrel laid across the furnace, with its apparatus; D is the furnace, and F is the pipe of the bellows.

Fig. 4. Fig. 4. is a section of the tube containing the potash.

But the chemical relations of potassium are not less extraordinary than its physical properties. It combines slowly with oxygen, and without flame, at all temperatures below that of its vaporization. At this point combustion takes place, with a brilliant white light, and intense heat. When it is heated slowly in a quantity of oxygen gas, which is not sufficient for its complete saturation, and at a temperature below that of inflammation, as for instance 400° of Fahrenheit, it changes to a red brown colour, and the solid form, consisting partly of potash, and partly of its base, is of a grayish colour. When exposed to water, or again heated in fresh quantities of air, the whole is converted into potash. When dry potash and potassium are fused together under proper circumstances, the base is deprived of its metallic splendour, and the two substances unite into a compound of a red brown colour when fluid, and of a dark gray when solid. This compound, when exposed to the air, soon absorbs its full proportion of oxygen, and is wholly converted into potash. The substance thus formed seems to be in a lower state of oxidation, so that it is to be considered as an oxide of potassium with a smaller proportion of oxygen.

When potassium is introduced into oxymuriatic acid gas, it burns spontaneously with a bright red light, and a white salt is formed, which is muriate of potash. When a globule of potassium is heated in hydrogen gas, at a degree below its point of vaporization, it seems to dissolve in it, for the globule is diminished in volume, and the gas explodes with alkaline fumes, and bright light, when brought into the air; but, by cooling, the potassium is wholly or principally deposited, for the gas is deprived of its property of spontaneous detonation.

When potassium is thrown into water, it decomposes it with great violence; an instantaneous explosion, with brilliant flame, is produced, and a solution of pure potash is obtained. In these experiments, a white ring of smoke, gradually extending as it rises in the air, is produced, similar to the phenomenon of the combustion of phosphorated hydrogen. When a globule of the basis of potash is placed upon ice, it instantly burns with a bright flame; part of the ice is melted, and in the cavity there is found a solution of potash.

By placing a globule of potassium upon moistened paper, tinged with turmeric, the moment that it comes in contact with the water, it burns, and, moving rapidly upon the paper, leaves behind it a deep reddish brown trace, thus demonstrating, in a very simple manner, the production of the alkali by the decomposition of water.

Potassium readily decomposes the small quantities of water contained in alcohol and ether, even in their purest state. As potash is insoluble in ether, when the base is thrown into it, oxygen is furnished to it, and hydrogen gas evolved, and, as the alkali is formed, the ether becomes white and turbid. It is observed, that the energy of action of potassium in ether and alcohol, is proportional to the quantity of water which they contain, and hydrogen and potash are always produced.

When potassium is thrown into solutions of the mineral acids, it inflames and burns on the surface, and when plunged, by proper means, beneath the surface enveloped in potash, surrounded by naphtha, it acts upon the oxygen with great intensity. In sulphuric acid, a white saline substance, covered with a yellow coating, which is supposed to be sulphate of potash surrounded with sulphur, and a gas, having the smell of sulphureous acid, and

Zinc.

and which is probably a mixture of that substance with hydrogen gas, are formed. When potassium is thrown into nitrous acid, nitrate of potash is formed, and nitrous gas is disengaged.

Potassium readily combines with phosphorus and sulphur. When pressed upon a piece of phosphorus, they both become fluid, enter into combustion, and produce phosphate of potash. When the experiment is made upon naphtha, no gaseous substance is given out; the compound has the appearance of a metallic phosphuret, is of the colour of lead, and has the lustre of polished lead. Exposed to the air at common temperatures, it combines slowly with oxygen, and is converted into phosphate of potash. When heated upon a plate of platina, it gives out fumes, but does not burn till it reaches the temperature of the rapid combustion of potassium.

When potassium is brought into contact with sulphur in fusion, in tubes filled with the vapour of naphtha, they combine rapidly, with the evolution of heat and light. A gray substance is thus formed, which has the appearance of artificial sulphuret of iron; if it be kept in fusion, it rapidly dissolves the glass. When this experiment is made in a glass tube, hermetically sealed, no gas is disengaged, if the tube be opened under mercury; but when it is made in a tube connected with a mercurial apparatus, a small quantity of sulphurated hydrogen is evolved. When the combination is effected in the atmosphere, a great inflammation takes place, and sulphuret of potash is formed, and by farther exposure to the air, it is at last converted into sulphate of potash.

When one part of potassium is added to eight or ten of mercury, in bulk, at 60° of Fahrenheit, they instantly unite, and form a substance like mercury in colour, but less coherent. When a globule is made to touch a globule of mercury about twice as large, they combine with considerable heat. The compound is fluid at the temperature of its formation, but, when cool, it becomes solid, with the appearance of silver. With the $\frac{1}{70}$th of potassium to the weight of mercury, the amalgam is hard and brittle; but with one part of potassium, and 70 of mercury, it is soft and malleable. Exposed to the air, these compounds absorb oxygen, and deliquescent potash is formed; and in a few minutes the mercury is revived. A globule of the amalgam, thrown into water, decomposes it rapidly with a hissing noise; potash is formed; pure hydrogen is disengaged, and the mercury remains free. This amalgam dissolves all the metals, and even acts on iron and platina.

When potassium is heated with gold, silver, or copper, in a close vessel of pure glass, a rapid action is produced, and the compounds thrown into water effect its decomposition; potash is formed, and the metals are revived. Potassium forms an alloy with fusible metal, which has a higher point of fusion than the fusible metal itself.

Potassium has little effect on colourless and recently distilled naphtha: but, in naptha, exposed to the air, it is soon oxidated, and an alkali which unites with the naphtha into a brown soap that collects round the globule, is formed. Potassium acts slowly on the concrete oils, as tallow, spermaceti, and wax, even when heated; coaly matter is deposited, a little gas is evolved, and a soap is formed. On the fluid fixed oils the effects are similar, but take place more slowly. With the assistance of heat, volatile oils are rapidly decomposed by potassium; gas is evolved, and charcoal deposited.

The metallic oxides, when heated in contact with potassium, are readily reduced. When a small quantity of oxide of iron was heated with it, to a temperature approaching its point of distillation, a vivid action took place. Alkali, in gray metallic particles, which effervesced in muriatic acid, appeared. The oxides of lead and tin were revived more rapidly, and with potassium in excess, an alloy was formed with the revived metal.

Potassium readily decomposes flint glass and green glass, by a gentle heat. The metallic oxides are reduced, and the alkali formed dissolves the glass. At a red heat, even the purest glass is acted on by potassium; the oxygen in the alkali of the glass seems to be divided between the potassium employed, and the potassium which is the base of the alkali in the glass, and thus effects an oxidation in the first degree.

Soda.—When pure soda was subjected in similar circumstances to the action of galvanism, similar results were obtained as from potash; but the decomposition required a more intense action in the battery, or it was necessary to have the alkali in thinner and smaller pieces. Potassium remained fluid at the temperature of the atmosphere, at the time of its production; but the base obtained from soda, which was fluid in the degree of heat of the alkali during its formation, became solid on cooling, and exhibited the lustre of silver. With a battery of 100 pairs of plates of six inches, in full activity, the decomposition of pieces of soda of about 15 to 20 grains in weight only could be effected; and it was necessary also that the distance between the wires should not exceed one-eighth or one-tenth of an inch. But when 250 pairs of plates were employed, highly charged for the decomposition of soda, the globules often burnt at the moment of their formation, and sometimes exploded and separated into smaller globules, which darted rapidly through the air, in a state of vivid combustion, producing a beautiful effect of continued jets of fire.

When the metallic base which is obtained from soda, and which Mr Davy has denominated *sodium*, was exposed to oxygen, it was converted into soda; and when this process was conducted by strongly heating the base in a given portion of oxygen, a rapid combustion with a brilliant white flame was produced, and the metallic globule was converted into a white solid mass, which was found to be soda. The oxygen gas was absorbed during the operation, and nothing was given out which affected the purity of the residual air.

The theory of the decomposition of the alkalies is stated by Mr Davy in the following words. "As in all decompositions of compound substances which I had previously examined, at the same time that combustible bases were developed at the negative surface in the electrical circuit, oxygen was produced, and evolved or carried into combination at the positive surface, it was reasonable to conclude, that this substance was generated in a similar manner by the electrical action of the alkali; and a number of experiments made above mercury, with the apparatus for excluding external air, proved that this was the case. When solid potash or soda, in its conducting state, was included in glass tubes, furnished with electrified platina wires, the new substances

were

Zinc.

were generated at the negative surfaces; the gas given out at the other surface proved, by the most delicate examination, to be pure oxygen; and, unless when excess of water was present, no gas was evolved from the negative surface.

For the purpose of determining the proportions of the elements of soda, Mr Davy made experiments similar to those by which he ascertained the proportions of the base and oxygen of potash. By subjecting sodium to combustion in oxygen gas, it appeared that 100 parts of soda are composed of 80 of metallic base, and 20 of oxygen; but the results of its oxidation by the decomposition of water, indicated the proportions to be 23 of oxygen, and 77 of base. By taking the mean proportions, obtained from the results of the two sets of experiments, the elements of soda may be estimated at 78.5 of metallic base, and 21.5 of oxygen.

Sodium, which remains solid at common temperatures, is white and opaque; and examined under a film of naphtha, has the lustre and appearance of silver. It is very malleable, and softer than common metallic substances. With a slight pressure it spreads into thin leaves, and a globule of one-tenth or one-twelfth of an inch in diameter, is easily spread over a surface of one-fourth of an inch; and different globules are easily made to adhere, and form one mass by strong pressure. This property of welding which belongs to iron and platina at a white heat only, is not diminished when sodium is cooled to 32° Fahrenheit.

Sodium, like potassium, is a conductor of electricity and heat, and small globules subjected to galvanism inflame and burn with bright explosions. Sodium sinks in naphtha of specific gravity .861; but by mixing perfectly about 12 parts of naphtha, and five of oil of sassafras, the sodium remains at rest in any part of the fluid. This makes its specific gravity = about .9348, water being taken as 1. The particles of sodium lose their cohesion at 120° Fahrenheit. It becomes quite fluid at 180°, so that it readily fuses under boiling naphtha. The temperature at which it is volatilized is not ascertained, but it remains fixed in a state of ignition at the point of fusion of plate glass.

The chemical relations of sodium are analogous to those of potassium, but with some characteristic differences. Exposed to the atmosphere, it is immediately tarnished, and is gradually covered with a white crust, which is pure soda. It combines slowly with oxygen, and without any luminous appearance at common temperatures. When heated, the combination is more rapid, but no light is emitted till it acquire a temperature near that of ignition. The flame in oxygen gas is white, and it sends forth bright sparks, producing a very beautiful effect; in common air, the colour of the light is like that of the combustion of charcoal, but brighter. When sodium was heated in hydrogen gas, it seemed to have no action on it.

Sodium burns vividly in oxymuriatic acid gas, giving out numerous sparks of a bright red colour; a saline matter is produced, which is muriate of soda. When sodium is thrown into water, it produces a violent effervescence with a loud hissing noise; it combines with the oxygen of the water to form soda, which is dissolved, and its hydrogen is disengaged. During the process there is no luminous appearance; but when sodium is thrown into hot water, a more violent decomposition takes place. A few scintillations are observed at the surface of the water, which is owing to small particles of the basis which are thrown out of the water, heated to such a degree as to burn in passing through the atmosphere. But when a globule of sodium is brought into contact with a small particle of water, or with moistened paper, the heat produced is usually sufficient for its combustion, as in this case there is no medium to carry off the heat rapidly.

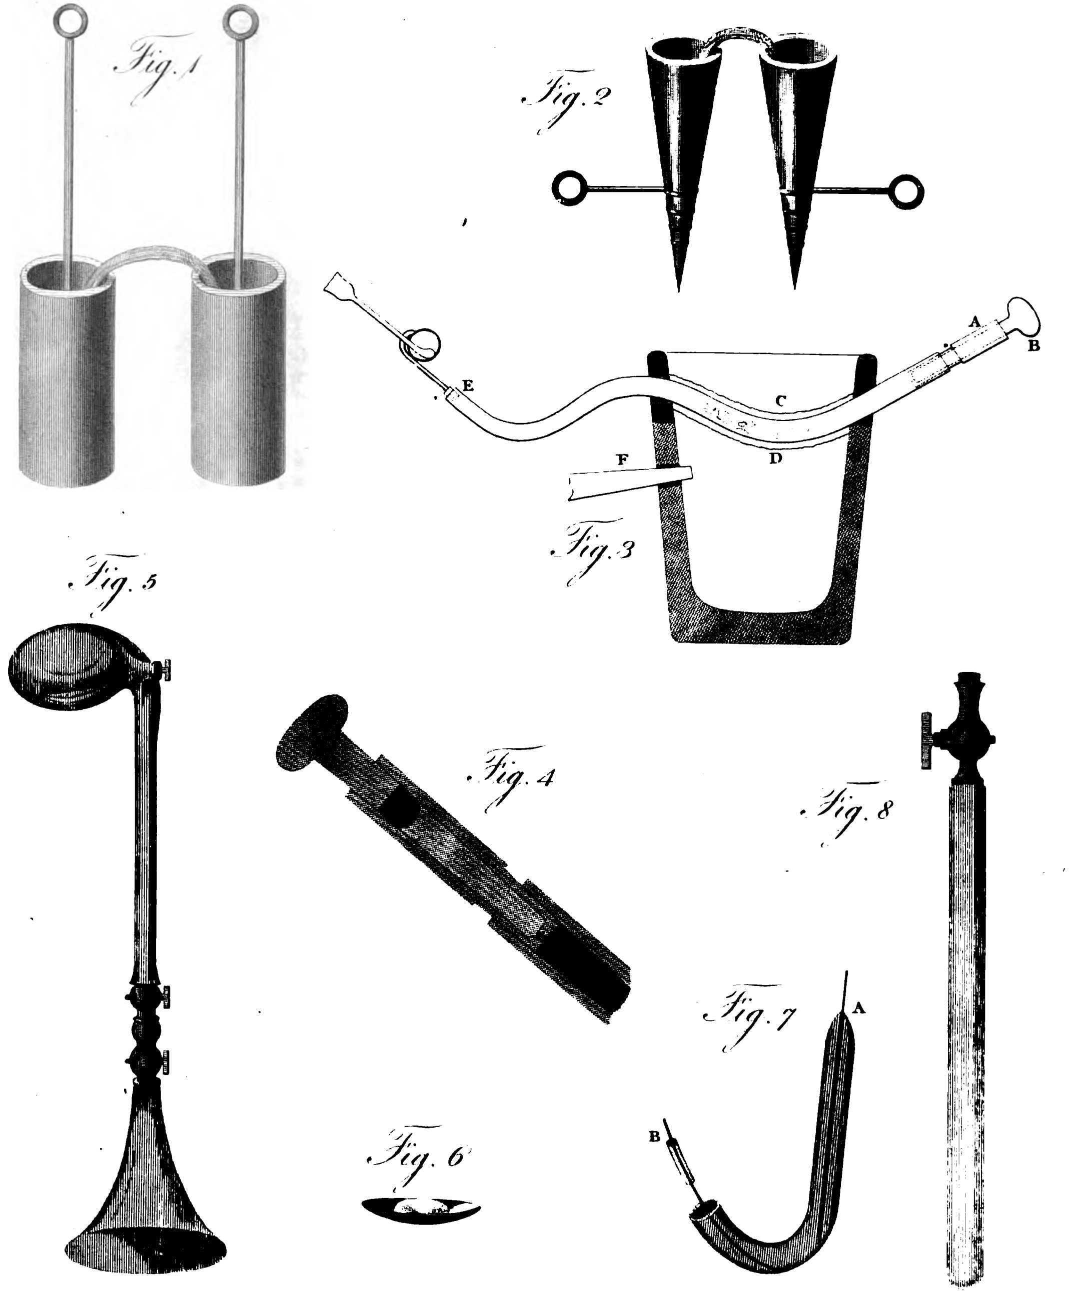
Sodium produces similar effects with potassium when brought into contact with alcohol and ether. It acts with great energy on the strong acids; with nitrous acid it produces a vivid inflammation, and with muriatic and sulphuric acids, great heat, but no light, is generated. The effects of sodium and potassium on the fixed and volatile oils, and naphtha, are quite analogous; but the appearances of the saponaceous compounds are somewhat different, the combinations with sodium being of a darker colour, and apparently less soluble.

Sodium also exhibits two degrees of combination with oxygen; the first is of a deep brown colour, which is fluid when produced, and becomes a dark gray solid on cooling. By attracting oxygen from the air, or by the decomposition of the water, it is converted into soda.

Sodium forms compounds with sulphur and phosphorus. In close vessels filled with the vapour of naphtha, it enters into combination with sulphur, giving out during the process a vivid light and heat, and often attended with explosion, from the vaporization of a portion of sulphur, and the disengagement of sulphurated hydrogen gas. The sulphuret of sodium is of a deep gray colour. In its combination with phosphorus, the compound obtained has the appearance of lead, and by exposure to the air, or by being subjected to combustion, the phosphuret of sodium is converted into phosphate of soda.

Sodium forms compounds with the metals. In the proportion of one-fortieth with mercury, a compound is obtained, which is of the colour of silver, and remains solid; the combination is accompanied with considerable heat. Sodium forms an alloy with tin, without producing any change of colour, and it has some action upon lead and gold when heated; but in its state of alloy it is soon converted into soda, by exposure to the air, or by the action of water, which it decomposes with disengagement of hydrogen. The amalgam of mercury and sodium seems to be capable of forming triple compounds with some other metals; and it would appear that iron and platina remain in combination with the mercury, after they are deprived of the sodium by exposure to the air. The same amalgam of sodium and mercury likewise forms combinations with sulphur; the triple compound thus obtained is of a dark gray colour.

Ammonia.—The chemical composition of ammonia has been many years considered as fully established; but in the course of Mr Davy's experiments on the decomposition of the fixed alkalies, it occurred to him that oxygen might also form one of the constituents of ammonia, and this he also proved by experiment. Charcoal carefully burnt, and deprived of moisture was ignited by a galvanic battery of 250 pairs of plates of six and four inches square, in a small quantity of pure ammoniacal gas, confined over mercury. A great expansion of the gaseous matter took place, and the white substance



Smith Sc. Clements Inn Strand

substance formed in the process collected on the sides of the glass tube. This matter effervesced in diluted muriatic acid, so that the product was probably carbonate of ammonia. A more decisive proof of ammonia containing oxygen as one of its elements, was obtained from another process. Very pure ammoniacal gas was passed over iron wire ignited in a platina tube, and two curved glass tubes were so arranged as to be inserted into a freezing mixture, and through one of these tubes the gas entered into the platina tube, to be conveyed through it by the other glass tube into an air-holder. The temperature of the air was 55°, and no sensible quantity of water was deposited in the cooled glass tube, which transmitted the unchanged ammonia. But after being exposed to heat, moisture was very perceptible, and the gas appeared in the air-holder densely clouded. This circumstance appeared to establish the formation of the water from the decomposition of ammonia during the process. But after the gas had been passed several times through the ignited tube, from one air-holder to the other, the iron wire was found superficially converted into oxide, and had increased in weight $\frac{44}{100}$ of a grain. About four-tenths of a grain of water were collected from the cooled glass tubes by means of filtrating paper, and 33.8 cubic inches of gas were expanded into 55.3 cubic inches, and by detonation with oxygen it was found, that the hydrogen gas in these was to the nitrogen or azote as 3.2 to 1 in bulk.

Ammonia was farther subjected to experiment by taking the electric spark in it. In experiments of this kind it was understood that it is resolved into hydrogen and azotic gases; but Mr Davy, found, after observing several variations in the results, that the weight of the two gases obtained was less by about one-eleventh than the weight of the ammonia employed. He ascribes this loss to the oxygen of the alkali, which had probably combined with the wires of platina employed in the experiment, and had thus disappeared. From these experiments he estimates the proportion of oxygen in ammonia at no less than 7 or 8 parts in 100; and as the gases evolved may contain more water than the gas decomposed, the proportion may even be larger. By thus considering ammonia as a triple compound of azote, hydrogen, and oxygen, the phenomena of its production and decomposition admit of an easy explanation. In all cases in which ammonia is formed, oxygen exists along with its other elements, in the substances from the decomposition of which it is obtained. In the decomposition of ammonia, on the other hand, the oxygen which forms one of its elements, may be abstracted by the substance employed in its decomposition, or it may enter into combination with portions of its hydrogen or azote.

But in the progress of investigating the nature of ammonia, to which the attention of chemical philosophers has been particularly directed, it appears that this alkali is analogous to the fixed alkalies in having a metallic base. The Swedish chemists Berzelius and Pontin, placed mercury negatively electrified in the galvanic circle, in contact with solution of ammonia. By this action the mercury increased in volume, and after an expansion of four or five times its former dimensions, it became a soft solid. From this amalgam exposed to the air, mercury and ammonia are reproduced, with the absorption of oxygen; and when the amalgam is put into water it forms ammonia, with the evolution of hydrogen, and the re-appearance of the mercury in its metallic state. Mr Davy repeated this experiment, and he found that to produce an amalgam, from 50 or 60 grains of mercury, in contact with a saturated solution of ammonia, required a considerable time, and that this amalgam changed considerably, even in the short period that was necessary for removing it from the solution. Conceiving that the de-oxidation and combination with mercury might be more easily effected in its nascent state, he placed 50 grains of mercury in a cavity in muriate of ammonia. The muriate slightly moistened was placed on a plate of platina, and connected with the positive side of a large galvanic battery. The mercury was made negative by means of a platina wire; a strong effervescence, with much heat, immediately took place; the globule of mercury in a few minutes enlarged to five times its former dimensions. It had the appearance of amalgam of zinc. Metallic crystallizations shot from it as a centre round the body of salt. They had an arborescent appearance, often became coloured at their points of contact with the muriate, and when the connection was broken, rapidly disappeared, while ammoniacal fumes were given out, and the mercury was reproduced. With a piece of carbonate of ammonia, similar phenomena were exhibited. The amalgam was formed very rapidly; but when the galvanic action was powerful in this last case, a black matter appeared in the cavity, which was probably carbone, from the decomposition of the carbonic acid.

Mr Davy considering the strong attraction of potassium and sodium for oxygen, was led to examine whether they produced any effect in the amalgamation of ammonia, independent of electricity. With this view he united small portions of potassium and sodium with mercury, and brought them into contact with moistened muriate of ammonia. An amalgam was formed, which rapidly increased to six or seven times its volume, and the compound seemed to contain a larger proportion of ammoniacal base than that obtained by electricity. It appears, too, that a portion of the metallic base employed to effect the de-oxidation always remained in combination with the compound, so that it was not a pure amalgam. The following are the properties of the amalgam from ammonia, obtained by means of galvanism.

When this amalgam is formed at the temperature of 70° or 80°, it is in the state of a soft solid, of the consistence of butter; at 32° it becomes firmer, and assumes a crystallized form, in which small facets appear, which seem to be cubical. The amalgam of potassium crystallizes in cubes, as beautiful, and in some cases as large, as those of bismuth. The specific gravity of the amalgam is less than three, water being one. When the amalgam is thrown into water, a quantity of hydrogen equal to half its bulk, is evolved, and the water becomes a weak solution of ammonia. The amalgam being confined in a given portion of air, the air increases in bulk, and the mercury is revived. Ammoniacal gas equal to $1\frac{1}{7}$ or $1\frac{1}{7}$ths of the volume of the amalgam, is produced, and oxygen equal to one-seventh or one-eighth of the ammonia, disappears. When the amalgam is thrown into muriatic acid gas, it becomes instantly coated with muriate of ammonia, and a small portion of hydrogen is evolved. In sulphuric acid it becomes

Zinc. becomes coated with sulphate of ammonia, and sulphur.

Mr Davy attempted, by various methods, to preserve the amalgam, in the hope of submitting it to distillation, for the purpose of obtaining the metallic base of the ammonia, which was united to the mercury, in a separate form. But as it is extremely difficult to free mercury, after being once moistened, entirely from water, he did not succeed in this attempt. In wiping the amalgam carefully with bibulous paper, part of the ammonia was regenerated, and in passing it through fine linen, with the view of separating the moisture, a complete decomposition was effected, and the mercury was revived.

The quantity of the base of ammonia combined with 60 grains of quicksilver, appears not to exceed $\frac{1}{200}$ of a grain, and the quantity of oxygen required for this is not more than $\frac{1}{1000}$ of a grain of water, which might be supplied by merely breathing upon the amalgam. Mr Davy made various other experiments, with the view of ascertaining the nature and properties of the amalgam of ammonia; but for an account of these we must refer to the paper itself. And he observes, that the more these properties are considered, the more extraordinary will they appear. Mercury, by combination with about $\frac{1}{12000}$ of its weight of new matter, becomes solid, and yet has its specific gravity reduced from 13.5 to less than 3, retaining at the same time its metallic characters, its colour, lustre, opacity, and conducting powers, undiminished. Can it then be conceived, Mr Davy asks, that a substance which forms with mercury so perfect an amalgam, should not be metallic in its own nature? This substance he denominates *ammonium*. On what then, it is farther asked, do the metallic properties of ammonium depend? Are hydrogen and nitrogen both metals in the gaseous state, at the usual temperature of the atmosphere; bodies of the same character, as zinc and mercury in the state of ignition? Or are these gases in their common form oxides which become metallized by de-oxidation? Or are they to be considered as simple bodies, not metallic in their own nature, but capable of composing a metal when deprived of oxygen, and becoming an alkali with the addition of oxygen?

In the farther prosecution of the experiments relative to the nature of ammonia, Mr Davy employed potassium. He brought ammonia into contact with about twice its weight of potassium at common temperatures; but excepting a slight diminution in the volume of the gas, and the metal losing its lustre and becoming white, no other effects were produced. The white crust when examined, proved to be potash, and a small portion of hydrogen was found in the ammonia, but not more than equal in volume to the metal. When the potassium was heated in the gas, by means of a spirit lamp applied to

Fig. 5. the bottom of the retort, (fig. 5.) the colour of the crust changed from white to bright azure, and gradually to bright blue, green, and dark olive. The crust and the metal then fused together. This process is attended with effervescence; and the crust passing off to the sides, exhibits the shining surface of the potassium. When heated a second time, it swells considerably, becomes porous, crystallized, and of a beautiful azure tint. A gas is evolved during this operation, which gives the same diminution by detonation with oxygen, as hydrogen, and ammonia disappears.

It has been observed that the proportion of ammonia which loses its elastic form, varies according as the gas employed contains more or less moisture. Thus, in ammonia saturated with water at 63° Fahrenheit, potassium caused the disappearance of twelve and a half cubical inches of ammonia; but in ammonia deprived of moisture, by exposure for two days to potash that had been ignited, the same quantity of potassium occasioned the disappearance of 16 cubical inches; but whatever were the degrees of moisture of the gas, the quantity of hydrogen generated always appeared equal for equal quantities of metal; and according to the French chemists, the proportions are stated to have been the same as would have resulted from the action of water upon potassium. But in Mr Davy's experiments, the proportions were rather less. In one, conducted with great care, eight grains of potassium generated, by their action upon water, eight and a half cubical inches of hydrogen gas; and eight grains of potassium from the same mass, by their operation upon ammonia, produced $8\frac{1}{8}$ cubical inches of hydrogen gas. This difference, although inconsiderable, Mr Davy found always to take place.

In Mr Davy's experiments on the action of potassium on ammonia, he employed retorts of plate glass. The potassium was fastened upon trays of platina or iron, which were introduced into the glass retorts furnished with stop-cocks. The retorts were exhausted by an air-pump, then filled with hydrogen, exhausted a second time, and afterwards filled with ammonia. (See fig. 5. and 6.). Fig. 5. and 6.

The following are the properties of the substance obtained from the action of ammonia on potassium. 1. It is crystallized, and presents irregular facets, which are extremely dark, and in colour and lustre not unlike the green oxide of iron; it is opaque when examined in large masses, but is semitransparent in thin films, and appears of a bright brown colour by transmitted light. 2. It is fusible at a heat a little above that of boiling water, and if heated much higher, emits globules of gas. 3. It appears to be considerably heavier than water, for it sinks rapidly in oil of sassafras. 4. It is a non-conductor of electricity. 5. When it is melted in oxygen gas, it burns with great vividness, emitting bright sparks. Oxygen is absorbed, nitrogen is emitted, and potash, which from its great fusibility seems to contain water, is formed. 6. When brought into contact with water, it acts upon it with much energy, produces heat, and often inflammation, and evolves ammonia. When thrown upon water, it disappears with a hissing noise, and globules from it often move in a state of ignition upon the surface of the water. It rapidly effervesces and deliquesces in air, but can be preserved under naphtha, in which, however, it softens slowly, and seems partially to dissolve. When it is plunged under water filling an inverted jar, by means of a proper tube, it instantly disappears with effervescence, and the non-absorbable elastic fluid liberated is found to be hydrogen gas.

It is found that the weight of this substance is greater than that of the potassium from which it is formed; and from this it is concluded, that part of the ammonia, or of its elements, enters into its composition. When this substance is decomposed by heat, nitrogen and hydrogen gases, with a portion of ammonia, are given out. It appears, however, that the production of the ammonia is is in proportion to the moisture admitted, and when the moisture is considerable, the whole product is ammonia. When this substance is exposed to heat, a matter remains, which even by increasing the heat, is no farther changed. On this residuum water acts violently, and with effervescence, from the evolution of hydrogen gas. Ammonia and potash are at the same time reproduced. Mr Davy's conclusion from these experiments is, that the substance formed by the action of ammonia on potassium is a compound of the latter with a small proportion of oxygen and nitrogen; and as it is found that the quantity of hydrogen given out during its formation is nearly equal to the hydrogen contained in the ammonia, it follows that neither hydrogen nor the ammonia itself can be supposed to enter into its composition.

In prosecuting this investigation, Mr Davy made various experiments, and whether the substance was acted on by water, exposed to the action of oxygen, or decomposed by heat, it was found, contrary to expectation, that the quantity of nitrogen evolved during its decomposition was much less than in proportion to the quantity of ammonia which had disappeared in its formation. In one experiment, in which the decomposition was effected by heat, the gaseous product was examined, and was found to be partly potash, and partly potassium; but it afforded no traces of ammonia, when acted on by water, which is a proof that it retained no nitrogen. In another experiment, 11 cubic inches of ammonia, or 2.05 grains, were decomposed by potassium. The product was 3.6 cubic inches of nitrogen, equal to 1.06 grain; 16 cubic inches of hydrogen, equal to .382 grain; and there was added to the potassium a quantity of oxygen equal to .6 grain. These products taken together amount to 2.04 grains, which is nearly equal to the quantity of ammonia employed; but this quantity of ammonia, if the proportions of its elements be estimated, from its decomposition by electricity, would have yielded 5.5 cubic inches of nitrogen, equal to 1.6 grain, and only 14 cubic inches equal to .33; and allowing the separation of oxygen in this process in water, it cannot be estimated at more than .11 or .12; and hence, if the analysis of ammonia by electricity come near to accuracy, there is in this process a considerable loss of nitrogen, and the production of oxygen and hydrogen.

How, says Mr Davy, can these extraordinary results be explained? The decomposition and composition of nitrogen seem proved, and one of its elements appears to be oxygen; but what is the other element? Is the gas that appears to possess the properties of hydrogen a new species of inflammable aeriform substance? Or has nitrogen a metallic basis, which alloys with the iron or platina? Or is water alike the ponderable matter of nitrogen, hydrogen, and oxygen? Or is nitrogen a compound of hydrogen, with a larger proportion of oxygen than exists in water? Of these important questions, Mr Davy adds, the two first seem the least likely to be answered in the affirmative, from the correspondence between the weight of the ammonia decomposed, and the products, supposing them to be known substances.

In concluding this subject, we must observe, that it still remains in a considerable degree of obscurity. It seems, however, to be ascertained, that the base of ammonia is of a metallic nature, which must be derived, either from the nitrogen or the hydrogen, or from both, or perhaps these substances are only different forms of combination of the elementary base. Or if nitrogen be supposed to be an oxide of hydrogen, then hydrogen in its gaseous form is either a metallic substance, or has a metallic base, which latter enters into combination with the mercury employed in the decomposition of ammonia.

Decomposition of the Earths.

From the results of the experiments on potash and soda, which Mr Davy obtained, he was led to entertain the strongest hopes of being able to effect the decomposition both of the alkaline and common earths; and the phenomena which took place in the first imperfect trials made upon these bodies countenanced the ideas, that had obtained since the earliest periods of chemistry, of their being metallic in their nature.

The earths, like the fixed alkalies, are non-conductors of electricity; but the fixed alkalies become conductors by fusion: the infusible nature of the earths, however, rendered it impossible to operate upon them in this state: the strong affinity of their bases for oxygen, made it unavailing, to act upon them in solution in water; and the only methods that proved successful, were those of operating upon them by electricity in some of their combinations, or of combining them at the moment of their decomposition by electricity in metallic alloys, so as to obtain evidences of their nature and properties. To render the experiments upon the earths satisfactory, a more powerful battery will be required, than Mr Davy has a prospect of seeing very soon constructed; he therefore prefers the imputation of having published unfinished labours, to that of having concealed any new facts.

Barytes, strontites, and lime, slightly moistened, were electrified by iron wires under naphtha, by the same methods, and with the same powers, as those employed for the decomposition of the fixed alkalies. In these cases gas was copiously evolved, which was inflammable; and the earths, where in contact with the negative metallic wires, became dark coloured, and exhibited small points, having a metallic lustre, which, when exposed to air, gradually became white: they became white likewise when plunged under water; and when examined in this experiment with a magnifier, a greenish powder seemed to separate from them, and small globules of gas were disengaged.

In these experiments there was great reason to believe that the earths had been decomposed; and that their bases had combined with the iron, so as to form alloys decomposable by the oxygen of the air or water; but the indistinctness of the effect, and the complicated circumstances required for producing it, were such as to compel Mr Davy to form other plans of operation.

Mr Davy bearing in mind the strong attraction of potassium for oxygen, was induced to try whether this body might not detach the oxygen from the earths, in the same manner as charcoal decomposes the common metallic oxides. He heated potassium in contact with dry pure lime, barytes, strontites, and magnesia, in tubes of plate-glass; but as he was obliged to use very small quantities, and as he could not raise the heat to ignition without fusing the glass, he obtained no good results in this manner.

Zinc. manner. The potassium appeared to act upon the earths and on the glass, and dark brown substances were obtained, which evolved gas from water; but no distinct metallic globules could be procured: from these, and other like circumstances, it seemed probable, that though potassium may partially deoxigenate the earths, yet its affinity for oxygen, at least at the temperature employed, is not sufficient to effect their decomposition. Mr Davy, having made mixtures of dry potash in excess and dry barytes, lime, strontites, and magnesia, brought them into fusion, and acted upon them in the galvanic circuit in the same manner as he employed for obtaining the metals of the alkalies. He expected that the potassium and the metals of the earths might be deoxigenated at the same time, and enter into combination in alloy.

In this way of operating, the results were more distinct than in the last: metallic substances appeared less fusible than potassium, which burned the instant after they had formed, and which by burning produced a mixture of potash and the earth employed. An attempt was made to form the metallic substances under naphtha, but without much success. To produce the result at all, required a charge by the action of nitric acid, which the state of the batteries would not often allow of; and the metal was generated only in very minute films, which could not be detached by fusion, and which were instantly destroyed by exposure to air.

Mr Davy had found in his researches upon potassium, that when a mixture of potash and the oxide of mercury, tin, or lead, was electrified in the galvanic circuit, the decomposition was very rapid, and an amalgam, or an alloy of potassium, was obtained; the attraction between the common metals and potassium apparently accelerating the separation of the oxygen. The idea that a similar kind of action might assist the decomposition of the alkaline earths, induced him to electrify mixtures of these bodies and the oxide of tin, of iron, of lead, of silver, and of mercury; and these operations were far more satisfactory than any of the others.

A mixture of two-thirds of barytes, and one-third of oxide of silver very slightly moistened, was electrified by iron wires; an effervescence took place at both points of contact, and a minute quantity of a substance, possessing the whiteness of silver, formed at the negative point. When the iron wire to which this substance adhered, was plunged into water containing a little alum in solution, gas was disengaged, which proved to be hydrogen; and white clouds, which were found to be sulphate of barytes, descended from the point of the wire.

A mixture of barytes and red oxide of mercury, in the same proportions was electrified in the same manner. A small mass of solid amalgam adhered to the negative wire, which evidently contained a substance, that produced barytes by exposure to the air, with the absorption of oxygen; and which occasioned the evolution of hydrogen from water, leaving pure mercury, and producing a solution of barytes.

Mixtures of lime, strontites, magnesia, and red oxide of mercury, treated in the same manner, gave similar amalgams, from which the alkaline earths were regenerated by the action of air or water, with like phenomena; but the quantities of metallic substances obtained were exceedingly minute; they appeared as mere superficial formations surrounding the point of the wire, nor did they increase after the first few minutes of electrization, even when the process was carried on for some hours.

These experiments were at first made when the batteries were in bad order; but were afterwards resumed with a new and much more powerful apparatus, constructed in the laboratory of the Royal Institution, and consisting of five hundred pairs of double plates of six inches square.

When Mr Davy attempted to obtain amalgams with this apparatus, the transmitting wires being of platina, of about $\frac{1}{70}$ of an inch diameter, the heat generated was so great as to burn both the mercury and basis of the amalgam at the moment of its formation; and when, by extending the surface of the conductors, this power of ignition was modified, yet still the amalgam was only procured in thin films, and globules sufficiently large to submit to distillation could not be procured. When the transmitting wires were of iron of the same thickness, the iron acquired the temperature of ignition, and combined with the bases of the earths in preference to the mercury; and metallic alloys of a dark gray colour were obtained, which acted on water with the evolution of hydrogen, and were converted into oxide of iron and alkaline earths.

While Mr Davy was engaged in these experiments, he received a letter from Professor Berzelius of Stockholm, who stated that in conjunction with Dr Pontin, he had succeeded in decomposing barytes and lime, by negatively electrifying mercury in contact with them, and that in this way he had obtained amalgams of the metals of these earths.

Mr Davy immediately repeated these operations with perfect success; a globule of mercury, electrified by the power of the battery of 500, weakly charged, was made to act upon a surface of slightly moistened barytes, fixed upon a plate of platina. The mercury gradually became less fluid, and after a few minutes was found covered with a white film of barytes, and when the amalgam was thrown into water, hydrogen was disengaged, the mercury remained free, and a solution of barytes was formed.

The result with lime, as these gentlemen had stated, was precisely analogous. Strontites and magnesia were decomposed in the same manner.

From strontites the expected result soon took place; but from magnesia, in the first trials, no amalgam could be procured. By continuing the process, however, for a longer time, and keeping the earth continually moist, at last a combination of the basis with mercury was obtained, which slowly produced magnesia by absorbing oxygen from the air, or by the action of water.

Mr Davy found that all these amalgams might be preserved for a considerable period under naphtha. In length of time, however, they became covered with a white crust under this fluid. In water, the amalgam of barytes was most rapidly decomposed; that of strontites and that of lime next in order: but the amalgam from magnesia, as might be expected from the weak affinity of the earth for water, very slowly changed. When a little sulphuric acid was added to the water, however, the evolution of hydrogen, and the production and solution of magnesia, were exceedingly rapid, and the mercury soon remained free.

Mr Davy believed, that one reason why magnesia was less easy to metallize, than the other alkaline earths, was

Zinc. was owing to its insolubility in water, which would prevent it from being presented in the nascent state, detached from its solution at the negative surface.

He then made the experiment, using moistened sulphate of magnesia instead of the pure earth; and the amalgam was much sooner obtained. Here the magnesia was attracted from the sulphuric acid, and probably deoxigenated and combined with the quicksilver at the same instant.

The amalgams of the other bases of the alkaline earths could be obtained in the same manner from their saline compounds: muriate and sulphate of lime, the muriate of strontites and barytes, and nitrate of barytes, were decomposed by the same means as the other earths. The earths, separated at the deoxigenating surface; these seemed instantly to undergo decomposition, and, seized upon by the mercury, were in some measure defended from the action of air, and from the contact of water, and preserved by their strong attraction for this metal.

In attempting to procure the metals of the alkaline earths, the latter were slightly moistened, and mixed with one-third of red oxide of mercury; the mixture was placed on a plate of platina; a cavity was made in the upper part of it to receive a globule of mercury, of from 50 to 60 grains in weight; the whole was covered by a film of naphtha, and the plate was made positive, and the mercury negative, by a proper communication with the battery of five hundred.

The amalgams obtained in this way were distilled in tubes of plate-glass, or in some cases in tubes of common glass. These tubes were bent in the middle, and the extremities were enlarged and rendered globular by blowing, so as to serve the purposes of a retort and receiver. The tube, after the amalgam had been introduced, was filled with naphtha, which was afterwards expelled, by boiling, through a small orifice in the end corresponding to the receiver, which was hermetically sealed when the tube contained nothing but the vapour of naphtha, and the amalgam. It was found immediately that the mercury rose pure by distillation from the amalgam, and it was very easy to separate a part of it; but to produce a complete decomposition was very difficult, as nearly a red heat was required for the purpose, and as at a red heat the bases of the earths instantly acted upon the glass, and became oxigenated. When the tube was large in proportion to the quantity of amalgam used, the vapour of the naphtha furnished oxygen sufficient to destroy part of the bases: and when a small tube was employed, it was difficult to heat the part used as a retort sufficient to drive off the whole of the mercury from the bases, without raising too highly the temperature of the part serving for the receiver, so as to burst the tube.

In consequence of these difficulties, in a multitude of trials, only a very few successful results were obtained; and in no case could our author be absolutely certain, that there was not a minute portion of mercury still in combination with the metals of the earths.

In the best result obtained from the distillation of the amalgam of barytes, the residuum appeared as a white metal, of the colour of silver. It was fixed at all common temperatures, but became fluid at a heat below redness, and did not rise in vapour when heated to redness, in a tube of plate-glass, but acted violently upon the glass, producing a black mass, which seemed to contain barytes, and a fixed alkaline basis, in the first degree of oxigenation. When exposed to air, it rapidly tarnished, and fell into a white powder, which was barytes. When this process was conducted in a small portion of air, the oxygen was absorbed and the nitrogen remained unaltered; when a portion of it was introduced into water, it acted upon it with great violence and sunk to the bottom, producing in it barytes; and hydrogen was generated. From the minuteness of the quantities obtained, neither its physical nor chemical qualities could be examined correctly. It sunk rapidly in water, and even in sulphuric acid, though surrounded by globules of hydrogen, equal to two or three times its volume; from which it seems probable, that it cannot be less than four or five times as heavy as water. It flattened by pressure, but required a considerable force to produce this effect.

The metals from strontites sunk in sulphuric acid, and exhibited the same characters as that from barytes, except in producing strontites by oxidation.

The metal from lime, Mr Davy has never been able to examine, either when exposed to air, or when under naphtha. In the case in which he was able to distil the quicksilver from it to the greatest extent, the tube unfortunately broke, while warm, and at the moment that the air entered, the metal, which had the colour and lustre of silver, instantly took fire, and burned with an intense white light into quicklime.

The metal from magnesia seemed to act upon the glass, even before the whole of the quicksilver was distilled from it. In an experiment in which the process was stopped before the mercury was entirely driven off, it appeared as a solid; having the same whiteness and lustre as the metals of the other earths. It sunk rapidly in water, though surrounded by globules of gas producing magnesia, and quickly changed in air, becoming covered with a white crust, and falling into a fine powder, which proved to be magnesia.

In several cases in which amalgams of the metals were obtained, containing only a small quantity of mercury, they were exposed to air on a delicate balance, and it was always found, that, during the conversion of metal into earth, there was a considerable increase of weight.

Mr Davy endeavoured to ascertain the proportions of oxygen and basis in barytes and strontites, by heating amalgams of them in tubes filled with oxygen, but without success. He satisfied himself, however, that when the metals of the earths were burned in a small quantity of air, they absorbed oxygen, gained weight in the process, and were in the highly caustic or unslaked state; for they produced strong heat by the contact of water, and did not effervesce during their solution in acids.

The evidence for the composition of the alkaline earths is then of the same kind as that for the composition of the common metallic oxides; and the principles of their decomposition are precisely similar, the inflammable matters in all cases separating at the negative surface in the galvanic circuit, and the oxygen at the positive surface.

Mr Davy has denominated the metals obtained from the alkaline earths, *barium*, *strontium*, *calcium*, and *magnium*.

In attempting the decomposition of the other earths, Mr

Zinc.

Mr Davy was less fortunate in obtaining distinct results; and he observes that the methods which have usually proved successful, as well as some others, failed. When alumina was subjected to the action of electricity, it was in a state of fusion with potash. In this process metallic globules were produced, but they consisted chiefly of the base of the alkali. Some appearances, however, shewed, that the alumina itself was decomposed; for when soda was employed, the metallic product obtained was less fusible than sodium itself, and when it was acted on by water, it produced soda and a white powder. When potash was fused with the alumina, and subjected to galvanic action, the metallic product decomposed water with great rapidity, and the solution obtained deposited alumina by the action of an acid. When potassium in the state of amalgam, with one-third of mercury, in contact with alumina, was negatively electrified under naphtha, and after the process had been continued for some time, the amalgam was added to water, a decomposition took place, and a solution was obtained, which produced a cloudiness on the addition of an acid; but all these results are to be considered as very imperfect evidence of the decomposition of alumina.

Mr Davy was still less successful in attempting the decomposition of silica, partly from its insolubility, and partly from its being scarcely, if at all, affected with electricity, when diffused in water, and placed in the galvanic circuit; but by following the same processes as in his experiments on alumina, some indications of decomposition appeared. When silica was fused with six parts of potash, and was placed in fusion in the galvanic circuit, metallic matter was obtained, from which, by exposure to the air, or by dropping it into water, a minute quantity of silica was reproduced. When potassium, amalgamated with one-third of mercury, and in contact with silica, was negatively electrified, he obtained a similar result; but in none of the experiments could the product obtained be considered as the pure base of the earth.

The earths of zirconia and glucina were also subjected to the action of galvanism, by processes similar to those which have now been described, and in both there were some indications of decomposition; but the results were not so perfect as to lead to any certain conclusion respecting their nature.

Decomposition of Sulphur and Phosphorus.

Sulphur.—Sulphur, which had formerly been considered as a simple substance, appears, from the experiments of some of the French chemists, and particularly those of Berthollet junior, to be a compound of sulphur and hydrogen. The latter chemist, in his experiments to investigate the nature of this substance, caused sulphur to pass through a coated glass tube, which was heated to whiteness; some indications of sulphurated hydrogen were obtained. He then formed metallic sulphurets, as of iron, copper, and mercury, and in these processes, which were performed in an earthen retort with great care, sulphurated hydrogen gas was also obtained. Water in the state of vapour being passed over sulphur in fusion, caused the evolution of sulphurated hydrogen; the water was not decomposed, for no trace of acid could be observed. It seemed only to have effected the disengagement of hydrogen from the sulphur.

Mr Davy, in the course of his experiments in galvanism, subjected sulphur to the action of that power. The sulphur which he employed was sublimed in a retort, filled with azotic gas, and it was kept hot till the commencement of the experiment. The reason of this preliminary process was, to avoid any uncertainty which might arise from water absorbed by the sulphur. The sulphur introduced into a curved tube, fig. 7. which was furnished with wires of platina A and B, the upper wire A being hermetically sealed into the end of the tube, was then placed in the galvanic circuit of a battery of 500 pairs of plates of six inches, in a state of great activity. A very intense action followed, accompanied by great heat and a brilliant light. The sulphur soon entered into ebullition, and gave out a great quantity of elastic fluid, a good deal of which was permanent. The sulphur itself assumed a deep red brown colour. The gas obtained was sulphurated hydrogen. In another experiment made on 200 grains of sulphur, the amount of sulphurated hydrogen obtained was equal to more than five times the volume of the sulphur. A considerable action was observed to have taken place on the wires of platina; and the sulphur, at its point of contact with the wires, reddened moist litmus paper. When sulphur and potassium are heated together, a very powerful action takes place. Sulphurated hydrogen is disengaged with very intense heat and light. From these experiments the conclusion seems fair and obvious, that hydrogen exists in sulphur, for a substance, as Mr Davy observes, which can be produced from it in such abundance, is not to be considered merely as an accidental ingredient.

But as it is admitted that sulphurated hydrogen contains oxygen, Mr Davy contends that oxygen is to be regarded as one of the constituents of sulphur. In this opinion he is supported by experiment. He heated potassium in sulphurated hydrogen gas, from which moisture had been as much as possible abstracted, by muriate of lime. The potassium took fire, and burnt with a brilliant flame. When four grains of potassium were heated in 20 cubic inches of gas, the quantity of gas diminished only about $2\frac{1}{2}$ cubic inches; but the properties of the gas were totally changed. A small portion only of it was absorbed by water, and the remainder was hydrogen, holding in solution a minute portion of sulphur. Some sulphur was observed on the sides of the retort, and a solid matter was formed, which on the surface was of a red colour, like sulphuret of potash, but internally dark gray, like sulphuret of potassium. By subjecting this substance to the action of muriatic acid, sulphurated hydrogen gas was obtained, but the proportion was less than would have been given out, had the potassium been in combination with pure combustible matter. From this Mr Davy concludes, that there is a principle in sulphurated hydrogen which is capable of destroying partially the inflammability of potassium, and of producing upon it all the effects of oxygen. As sulphurated hydrogen is obtained by heating sulphur strongly in hydrogen gas, Mr Davy introduced four grains of sulphur in a glass retort, containing about 20 cubical inches of hydrogen, and by means of a spirit lamp, he raised the heat nearly to redness. No perceptible change took place in the volume of the gas after the process. The sublimed sulphur was unchanged in its properties, and about three cubical inches of an elastic fluid, absorbable by water, reddening litmus, and having all the properties of sulphurated hydrogen gas, were formed. Supposing then sulphurated

Zinc.

sulphurated hydrogen to be constituted by sulphur dissolved in its unchanged state in hydrogen, and admit the existence of oxygen in this gas, its existence must likewise be allowed in sulphur. From these experiments Mr Davy thinks it not unreasonable to assume, that sulphur in its common state is a compound of small quantities of oxygen and hydrogen, with a large quantity of a base, which produces the acids of sulphur in combustion; and as this basis, it is added, possesses strong attractions for other bodies, it will probably be very difficult to obtain it in its uncombined state.

Sulphur combines readily with potassium, when brought into contact in tubes filled with the vapour of naphtha; heat and light are rapidly evolved during the combination, and a gray substance like artificial sulphuret of iron, is produced. The sulphurated hydrogen in small quantity is formed at the moment of combination, the hydrogen, of which, it is supposed, is derived from the sulphur. The sulphuret of potassium readily inflames, and when exposed to the air, it is gradually oxidated, and converted into sulphate of potash.

Sulphur also enters into combination with sodium, accompanied also with the evolution of heat and light. An explosion sometimes take place, which is owing to the volatilization of a portion of sulphur, and the disengagement of sulphurated hydrogen gas. The sulphuret of sodium is of a deep gray colour.

Phosphorus.—Mr Davy subjected phosphorus to similar experiments, and he found that the same analogies are applicable to this combustible. Common electrical sparks transmitted through phosphorus produces no evolution of permanent gas; but when acted upon by the same galvanic battery, and in the same circumstances as the sulphur, a considerable evolution of gas was effected, and the phosphorus became of a deep red brown colour. The gas was phosphorated hydrogen; and in an experiment continued for some hours, the quantity evolved was four times the volume of the phosphorus. The light by the galvanic spark was at first a brilliant yellow, and afterwards orange.

Three grains of potassium were heated in 16 cubical inches of phosphorated hydrogen. As the fusion was effected, the retort was filled with white fumes, and a reddish substance was deposited upon the upper part and sides; the heat was applied for some minutes, but no inflammation took place. When the retort cooled, the absorption was less than a cubical inch, the potassium externally was of a deep brown, and internally of a lead colour. The residual gas seemed to contain in solution a little phosphorus, but it had not the property of spontaneous inflammation. While the phosphuret was acted upon over mercury by a solution of muriatic acid, it gave out only $1\frac{1}{4}$ cubical inch of phosphorated hydrogen.

One grain of potassium, and one of phosphorus, were fused together. In combining, a very vivid light and intense ignition were produced; $\frac{1}{10}$ of a cubical inch of phosphorated hydrogen was evolved, and the phosphuret, with diluted muriatic acid over mercury, gave out $\frac{1}{10}$ of a cubical inch of phosphorated hydrogen. In another experiment with one grain of potassium, and three of phosphorus, nearly one-fourth of a cubical inch of phosphorated hydrogen was obtained; but the compound yielded by muriatic acid, only $\frac{1}{10}$ of a cubical inch.

From these experiments it is concluded, that phosphorated hydrogen contains a minute proportion of oxygen, and consequently that the same element enters into the composition of phosphorus. The deficiency of phosphorated hydrogen in the last experiment can only be referred to the supply of oxygen to the potassium from the phosphorus; and the quantity of phosphorated hydrogen produced in the experiment with equal parts of potassium and phosphorus, is much less than could be expected, if the potassium and phosphorus consisted merely of pure combustible matter.

Mr Davy also instituted a set of interesting experiments on the states of the carbonaceous principle in plumbago, charcoal, and the diamond, and the results of these are detailed in the same memoir; but for an account of them we must refer to the paper itself.

Decomposition of Boracic, Fluoric, and Muriatic acids.

The properties of boracic, fluoric, and muriatic acids, many of which are quite analogous to those of other acids whose elements have been discovered, have led chemists to conclude that oxygen is also the acidifying principle in the former; but the separate existence or nature of the base of these three acids was, till the late researches of galvanism were instituted, utterly unknown. The investigation of the nature of these substances has been prosecuted by Mr Davy, and some of the French chemists; and of their experiments we shall now give a very short account.

Boracic acid.—When boracic acid was moistened with water, and exposed between two surfaces of platina, and then subjected to the battery of 500 plates, an olive brown matter formed on the negative surface, and, increasing in thickness, appeared at last almost black. This substance was permanent in water, but it dissolved and effervesced in warm nitrous acid. Heated to redness on the platina, it burned slowly, and gave off white fumes, which reddened moistened litmus paper. A black mass remained, which through a magnifier appeared vitreous, and seemed to contain a fixed acid. The inference drawn from this experiment is, that the acid was decomposed, and again by the latter process reproduced.

When equal weights of potassium and boracic acid were heated together in a green glass tube, which had been exhausted, after being twice filled with hydrogen gas, an intense ignition, with vivid inflammation, where the potassium was in contact with the boracic acid, took place, even before the temperature approached near to a red heat. When the acid had been heated to whiteness, before being introduced into the tube, and powdered and used while yet warm, the quantity of gas which was hydrogen, given out in the operation, did not exceed twice the volume of the acid. In this mode of conducting the experiment, 12 or 14 grains of each of the two substances only could be employed, on account of the intense heat and consequent fusion of the glass tube with larger proportions. Mr Davy found in several experiments, in which he employed equal parts of acid and potassium, that a great proportion of the former remained undecomposed, and he ascertained that twenty grains of potassium had their inflammability destroyed by eight grains of boracic acid.

To collect the substances formed in the process, metallic tubes with stop-cocks, and exhausted, after being filled with hydrogen, were employed. With tubes of brass or copper, a dull red heat only, but with iron tubes, Zinc. tubes, a white heat was applied; and in all cases the acid was decomposed by the same results. The substance obtained from the iron tube was in some parts of a dark olive colour, and in others almost black. It did not effervesce with warm water, but was rapidly acted upon by it. The solutions obtained consisted of subborate of potash, and potash.

The following are the properties of the substance obtained in the decomposition of boracic acid by means of processes conducted in brass tubes, which afforded it in largest proportion. To this substance Mr Davy has given the name of *boracium*, which, as it is produced in the manner now described, is in the form of a pulverulent mass of the darkest shades of olive; it is opaque, very friable; the powder does not scratch glass, and is a non-conductor of electricity. Dried at 100° or 120°, it gives off moisture, by decreasing the temperature; and when heated in the atmosphere, takes fire at a temperature below the boiling point of olive oil, emitting a red light, and sparks like charcoal. When excluded from air, and subjected to a white heat in a platina tube, exhausted after being filled with hydrogen, it remains unchanged, excepting in becoming a little darker, and acquiring a greater specific gravity.

Boracium introduced into a retort filled with oxygen gas, and heated by a spirit lamp, throws off vivid scintillations like those of the combustion of the bark of charcoal, and the mass gives out a brilliant light. A sublimate appears, which is boracic acid; it becomes coated with a vitreous substance, which is also found to be the same acid. When this is washed off, the black residuum requires a greater heat, but it is also inflamed, and converted into boracic acid. When boracium is brought into contact with oxymuriatic acid gas, at common temperatures, it immediately takes fire, and burns with a brilliant white light, coating the inside of the vesssel with a white substance, which is boracic acid. Boracium heated to redness with hydrogen or nitrogen, became of a darker colour, and gave out a little moisture, but remained otherwise unchanged. Thrown into concentrated nitric acid, it rendered it bright red; nitrous gas was produced and absorbed, but no rapid solution took place till the acid was heated, when the boracium disappeared with effervescence and the evolution of nitrous gas, and the fluid yielded boracic acid. The action of boracium on sulphuric and muriatic acids was not remarkable. It combined with the fixed alkalies, both by fusion and aqueous solution, and formed pale olive-coloured compounds, which by muriatic acid were precipitated of a dark colour. When fused with sulphur, it dissolved slowly, and the sulphur became of an olive colour. Its action with phosphorus in the same circumstances was still feebler, but it communicated a shade of pale green.

From the experiments now detailed, it appears that boracium obtained by means of potassium, is different from any other known species of matter, and seems to be the same as that obtained from boracic acid by electricity. According to the result of experiments made by Mr Davy, boracic acid is composed of one part of boracium, and about 1.8 of oxygen; and supposing the dark residual substance to be an oxide, it consists of 4.7 of boracium, and 1.55 of oxygen.

For an account of the experiments of Gay Lussac and Thenard, in investigating the nature of boracic acid, see Jour. de Physique, tom. lxvii. or Nichol. Jour. xxiii. 260.

Fluoric acid.—According to the experiments of Mr Davy, potassium, when heated in fluoric acid gas, undergoes combustion, and a great absorption of the gas takes place. In other experiments, he found that when fluoric acid gas, procured in contact with glass, is introduced into a plate glass retort, exhausted after being filled with hydrogen gas, white fumes appear from the action of the potassium, which loses its splendour, and becomes coloured with a gray crust. The fumes are more copious when the bottom of the retort is gently heated. The volume of the gas examined at this time appears to be a little increased, with the addition of hydrogen; and when the temperature is raised nearly to the point of sublimation of the potassium, the metal rises through the crust, becomes first of a copper colour, and then inflames and burns with a brilliant red light. After this combustion, the fluoric acid is either wholly or partially destroyed, according as the quantity of potassium is great or small; and a mass of a chocolate colour is found in the bottom of the retort; the sides and the top are lined with a sublimate, which is partly chocolate, and partly of a yellow colour. When the residual gas is washed with water, mixed with oxygen gas, and exposed to the action of an electrical spark, it detonates, and affords a diminution in the same way as hydrogen gas.

In one experiment with 19 cubical inches of fluoric acid gas, and ten grains and a half of potassium, 14 cubical inches of the gas disappeared, and about two and a quarter of hydrogen gas were produced. The gas had not been artificially dried; little sublimate was produced, but the whole of the bottom of the retort was covered with a brown crust. When this mass was examined with a magnifier, it seemed to consist of different kinds of matter. It did not conduct electricity; it effervesced violently in water, with the evolution of an inflammable gas, which had somewhat of the odour of phosphorated hydrogen. Part of the mass heated in the air, burnt slowly, and was converted into a white saline matter. It also burnt with difficulty in heated oxygen gas, but it absorbed a portion that required nearly a red heat. The light emitted resembled that from the combustion of liver of sulphur. Chocolate-coloured particles were found floating in the water, acted on by a portion of the mass, and when the solid matter was separated by the filter, the fluid was found to contain fluate of potash and potash. The solid residuum was heated in a small glass retort filled with oxygen gas; it burnt before reaching a red heat, and became white. Oxygen was absorbed, and acid matter produced. The remainder had the properties of the substance formed from fluoric acid gas, holding siliceous earth in solution by the action of water.

"The decomposition of the fluoric acid, Mr Davy observes, by potassium, seems analogous to that of the acids of sulphur and phosphorus. In neither of these cases are the pure bases, or even the bases in their common form, evolved; but new compounds result, and in one case, sulphurets and sulphites, and in the other phosphurets and phosphites of potash, are generated."

In another experiment Mr Davy attempted the decomposition of fluoric acid gas, which was perfectly dry, and free from siliceous earth, by mixing 100 grs. of of dry boracic acid, and 200 grains of fluor spar. The mixture was introduced into the bottom of an iron tube, having a stop-cock and tube of safety attached. The tube was inserted horizontally in a forge, and 20 grains of potassium in an iron tray were placed in that part of it where the heat was only of a dull red. The bottom of the tube was raised to a white heat, and the acid, as it was generated, was acted upon by the heated potassium. The result obtained was a substance in some parts black, and in others of a dark brown colour. It did not effervesce with water, and when lixiviated, afforded a dark brown combustible mass which did not conduct electricity, and, when burnt in oxygen gas, afforded boracic and fluoric acids. This substance did not inflame spontaneously in oxymuriatic acid gas; but it effervesced violently, and dissolved in nitric acid. Mr Davy thinks that this substance is a compound of the olive-coloured oxide of boracium, and an oxide of the base of fluoric acid; but he had not examined its properties particularly.

Muriatic acid.—Many conjectures have been offered with regard to the nature and constitution of muriatic acid, and many attempts have been made to effect its decomposition. Mr Davy has extended his researches to this substance, and has prosecuted the investigation with his usual ardour. It is still, however, to be regretted, that his success has not been commensurate with his ingenuity and industry. Some have supposed, that the base of muriatic acid is hydrogen, while others contend that the base is a compound of hydrogen and nitrogen.

The result of Mr Davy's first experiments in this inquiry showed, that the water alone in combination with the muriatic acid is decomposed, and that this elastic fluid contains a larger proportion of water than is usually suspected; and from various experiments he concludes, that muriatic acid gas, in its common state, is combined with at least one-third of its weight of water. In the prosecution of his researches, therefore, his object was to obtain the muriatic acid free from water. With this view he heated dry muriate of lime, mixed both with phosphoric acid, and dry boracic acid, in tubes of porcelain and of iron, and employed the blast of an excellent forge; but by none of these methods was any gas obtained, till a little moisture was added to the mixture, and then muriatic acid was given out in such quantity as almost to produce explosions. In distilling the liquor of Libavius, or the fuming muriate of tin, which contains dry muriatic acid, with sulphur and with phosphorus, no separation of the acid took place; but with the addition of water, muriatic acid gas was evolved with great heat and violence. By distilling mixtures of corrosive sublimate and sulphur, and of calomel and sulphur in their common states, muriatic acid gas was evolved; but when these substances were dried by a gentle heat, the quantity of gas obtained was greatly diminished. Mr Davy, and also the French chemists, endeavoured to procure dry muriatic acid by the distillation of a mixture of calomel and phosphorus. The result obtained is considered as a compound of muriatic acid, phosphorus, and oxygen. In Mr Davy's experiments, the product was more copious when corrosive sublimate was employed. With the same view of procuring dry muriatic acid gas, he exposed phosphorus to the action of oxymuriatic acid gas, in the hope that in the oxidation of the phosphorus, the whole of the moisture would be absorbed; but the examination of the result showed, that no muriatic acid gas had been evolved during the process, so that the muriatic acid which had disappeared, must exist, either in the white sublimate which had collected in the top of the retort, or in a limpid fluid which had formed in its neck. When the sublimate was exposed to the air, it emitted fumes of muriatic acid, and when brought into contact with water, muriatic acid gas was evolved, and phosphoric and muriatic acids remained in solution in the water. Mr Davy regards this white sublimate as a combination of phosphoric and muriatic acids in their dry states. The limpid fluid was of a pale greenish yellow colour; it rapidly disappeared on exposure to the air, emitting dense white fumes, which had a strong smell, differing a little from that of muriatic acid. Mr Davy thinks that this is a compound of phosphoric and muriatic acids, both free from water.

Mr Davy made other experiments, for the purpose of procuring muriatic acid in its uncombined state, but with no better success. He then tried the effects of potassium introduced into the fluid generated by the action of phosphorus on corrosive sublimate; but such was the violent action of the substances operated upon, that the apparatus was generally destroyed, and he was thus precluded from examining the results. But for a particular detail of the experiments, we must refer to the memoir itself; and for the extended account of Mr Davy's investigations on this curious and interesting subject, of which we have given as comprehensive a view as our limits would permit, see CHEMISTRY, SUPPLEMENT.

ZINNIA, a genus of plants of the class *syngenesia*, and in the natural system arranged under the 49th order, *Compositæ*. See BOTANY *Index*.

ZINZENDORFF, NICHOLAS LEWIS, COUNT, was the noted founder of the German religious sect called *Moravians* or *Herrnhuters*, or, as they pretend, the restorer of that society. From his own narrative, it appears, that when he came of age in 1721, his thoughts were wholly bent on gathering together a little society of believers, among whom he might live, and who should entirely employ themselves in exercises of devotion under him. He accordingly purchased an estate at Bertholsdorff in Upper Lusatia, where, being joined by some followers, he gave the curacy of the village to a person of his own complexion; and Bertholsdorff soon became talked of for a new mode of piety. One Christian David, a carpenter, brought a few proselytes from Moravia: they began a new town about half a league from the village, where Count Zinzendorff fixed his residence among them, and whither great numbers of Moravians flocked and established themselves under his protection: so that in 1732 their number amounted to 600. An adjacent hill, called the *Huthberg*, gave occasion to these colonists to call their new settlement *Huth des Herrn*, and afterwards *Herrnhuth;* which may be interpreted "The guard or protection of the Lord:" and from this the whole sect have taken their name. The count spared neither pains nor art to propagate his opinions; he went himself all over Europe, and at least twice to America; and sent missionaries throughout the world. Count Zinzendorff died in 1760. Those who wish to know more of the Moravian tenets may consult Rimius's account

account of them, translated in 1753. See UNITED BRETHREN.

ZISCA, JOHN, a famous general of the forces of the Hussites, in the 15th century, was a gentleman educated at the court of Bohemia, in the reign of Wenceslaus. He entered very young into the army, and after distinguishing himself on several occasions, lost an eye in a battle, whence he was called *Zisca* or *One-eyed*. At length the Reformation, begun by John Huss, spreading through almost all Bohemia, Zisca placed himself at the head of the Hussites, and had soon under his command a body of 40,000 men. With this army he gained several victories over those of the Romish religion, who carried on a kind of crusade against them, and built a town in an advantageous situation, to which he gave the name of *Tabor;* whence the Hussites were afterwards called *Taborites*. Zisca lost his other eye by an arrow at the siege of the city of Rubi; but this did not prevent his continuing the war, his fighting battles, and gaining several great victories, among which was that of Ausig on the Elbe, in which 9000 of the enemy were left dead on the field. The emperor Sigismund, alarmed at his progress, caused very advantageous proposals to be offered to him; which he readily accepted, and set out to meet Sigismund, but died on the road. He ordered that his body should be left a prey to the birds and wild beasts; and that a drum should be made of his skin, being persuaded that the enemy would fly as soon as they heard the sound. It is added, that the Hussites executed his will; and that the news of this order made such an impression on the disturbed imaginations of the German Papists, that in many battles they actually fled at the beat of the drum with the utmost precipitation, leaving their baggage and artillery behind them.

ZINZIBER, or ZINGIBER. See AMOMUM, BOTANY and MATERIA MEDICA *Index*.

ZION, or SION, in *Ancient Geography*, a very famous mountain, standing on the north side of the city of Jerusalem, (Psal. xlviii. 2.); containing the upper city, built by King David; and where stood the royal palace, (Josephus. Psal. xlviii. 2.). A part of Zion, situated at its extremity, was called *Millo*, of or in the city of David, (2 Chron. xxxii. 5.). Modern travellers, who have been upon the spot, say, that Zion is the whole of the mountain, on which Jerusalem stands at this day, though not to the extent in which it anciently stood on the same mountain, as appears Psal. ix. 12. 15. lxv. 1. lxxxvii. 2. 3. Is. lxii. 1. It is swelled into several eminences or tops; as Moriah, Acra Bezetha, and Zion a particular eminence or mount, and Zion Proper, &c. encompassed on three sides, east, west, and south, with one continued very deep and steep valley; by means of which it was impregnable on these three sides, and always attacked and taken, according to Josephus, by the enemy on the north side, where Mount Zion became level, and the vales of Gihon and Jehoshaphat gradually lose themselves. This deep and steep valley incontestably constitutes the compass of the old Jerusalem on those three sides, as plainly appears to any person who has been upon the spot. Contrary to the opinion of former travellers, Dr Clarke thinks that the proper Mount Zion is an eminence entirely without the city on the south side; and in the valley between this and the city he places the holy sepulchre. That part of the valley which lay to the east was called *Jehoshaphat's*, having Mount Olivet lying beyond it; that to the south *Gehinnon;* and that to the west *Gihon*, from cognominal mountains lying beyond them. At the west end of Gihon, without the city, stood Golgotha or Calvary. Dr Clarke thinks that very little credit is due to the names given to the different places and objects by the monks. There is another *Zion*, the same with HERMON.

ZION, or *Zion College*. See LONDON, N° 76.

ZIPH, or SIPH, in *Ancient Geography*, the name of a wilderness or desert in the tribe of Judah, where David was fugitive; lying to the south-east of Hebron; so called from Ziph or Siph, a twofold town in this tribe; the one more to the south towards Idumea, on the confines of Eleutheropolis, (Jerome); the other eight miles to the east of Hebron, towards the Dead sea, inclining southwards, because near Mount Carmel. Here was a mountain, mentioned 1 Sam. xxiii. 14. in which David abode, said by Jerome to be rugged, dismal, and always overcast. *Ziphim, Ziphæi* or *Ziphenses*, the inhabitants of Ziph, ver. 19.

ZIRCHNITZER-SEE, otherwise called the *Lake of Czircknitz*, in Carniola, is about one German or four English miles in length, and half as much in breadth, contains three beautiful islands, and is encompassed at some distance with mountains and forests. But what is most remarkable is, that it disappears generally once a-year, about St John's or St James's day, running off through holes or pits in the bottom; sometimes it disappears twice or thrice a-year, and sometimes even in winter if the weather be dry. On the other hand, it has been known to continue two or three years without running off. Of the holes or pits, there are five much larger than the rest, each of which successively, when the water runs off, stands empty five days; so that the whole lake becomes dry in 25. As soon as the beginning of the ebb is observed, the fishing in the pits begins, which belongs to five seignories. The fish, which are carp, tench, pike, eels, and two other sorts called *schleien* and *ruten*, are caught by laying nets over the holes. Mr Keysler tells us, that upon the ringing of a bell at Zirknitz, when the waters begin to fall, the peasants, both men and women, run to the pools quite naked.

ZIRCON, a mineral substance containing a peculiar earth. See MINERALOGY *Index*.

ZIRCONIA, a peculiar earth. See CHEMISTRY *Index*.

ZIZANIA, a genus of plants of the class monœcia; and in the natural system arranged under the 4th order, *Gramina*. See BOTANY *Index*.

ZODIAC, a broad circle, whose middle is the ecliptic, and its extremes two circles parallel thereto, at such a distance from it as to bound or comprehend the excursions of the sun and planets, (see ASTRONOMY). It is a curious enough fact, that the solar division of the Indian zodiac is the same in substance with that of the Greeks, and yet that it has not been borrowed either from the Greeks or the Arabians. The identity, or at least striking similarity, of the division, is universally known; and M. Montucla has endeavoured to prove, that the Bramins received it from the Arabs. His opinion, we believe, has been very generally admitted; but in the second volume of the Asiatic Researches, the accomplished president Sir William Jones has proved unanswerably, that neither of those nations borrowed that division from the other; that it has been known among the

Zodiac ‖ Zoophytes.

the Hindoos from time immemorial; and that it was probably invented by the first progenitors of that race, whom he considers as the most ancient of mankind, before their dispersion. The question is not of importance sufficiently general, straitened as we are by the limits prescribed us, for our entering into the dispute; but we think it our duty to mention it, that our astronomical readers, if they think it worth their while, may have recourse to the original writers for further information.

ZOEGEA, a genus of plants of the class syngenesia. See BOTANY *Index*.

ZONE, in *Geography* and *Astronomy*, a division of the terraqueous globe with respect to the different degrees of heat found in the different parts thereof. The zones are denominated torrid, frigid, and temperate. The torrid zone is a band, surrounding the terraqueous globe, and terminated by the two tropics. Its breath is 46° 58′. The equator, running through the middle of it, divides it into two equal parts, each containing 23° 29′. The ancients imagined the torrid zone uninhabitable. The temperate zones are contained between the tropics and the polar circles. The breadth of each is 43° 2′. The frigid zones are segments of the surface of the earth, terminated, one by the antarctic, and the other by the arctic circle. The breadth of each is 46° 58′.

ZOOLOGY, is that part of natural history which relates to *animals*. See NATURAL HISTORY.

ZOOPHYTES. The name ZOOPHYTES, *Zoophyta* (i. e. *animal plants*, from ζωον, *animal* and φυτον, *plant*,) has been long appropriated to a numerous assemblage of marine or aqueous productions, which have puzzled the ingenuity of naturalists to ascertain their place in the chain of nature's works, and which have been alternately ranked among vegetable and animal, and sometimes even among mineral substances. At length, however, they seem, by general consent, to have been consigned over to the animal kingdom, and, with the addition of several tribes from the Linnæan orders of *Intestina*, *Mollusca* and *Infusoria*, have, by Cuvier and his colleagues of the French school, been elevated to the rank of a separate class. See HELMINTHOLOGY, N° 11.

In the Linnæan system, the zoophytes of earlier modern naturalists constitute the 4th order of the class VERMES, and as such have been enumerated under HELMINTHOLOGY; but as the circumscribed limits of that article did not admit of our describing or figuring many species, we shall now as far as possible supply that deficiency by selecting a few of the most curious or interesting species of the Linnæan zoophytes; and we shall take this opportunity of making a few observations on some of the genera to which they belong.

Tubipora Musica. Plate DLXXIX. Fig. 1. & 2.

Fig. 1. and 2. represent the TUBIPORA *musica*, *crimson tubipore*, or *organ coral*; one of the most elegant of these singular productions. This species is distinguished from its congeners by *having the tubes connected into fasciculæ* or *bundles, and separated from each other by transverse membranous partitions.* The whole mass consists of upright parallel tubes, rising over each other by stages, something like the cells of a honeycomb. These tubes vary in height from half an inch to an inch; and are from one-tenth to one-eighth of an inch in diameter. Examined internally, they appear to contain a smaller tube divided at certain distances by radiated partitions (see fig. 2.), by means of which the transverse *septa* sometimes communicate with each other. These transverse *septa* are of unequal heights. The colour of the mass is a deep purple, or a rich crimson. The size of the mass varies considerably; but specimens have been obtained of from a foot to three feet in diameter. It is found abundantly in the Pacific ocean, and on the shores of some of the islands in the Indian sea.

In its recent state it is covered with a mucous or gelatinous substance, which pervades the whole mass and enters within each tube. The inhabiting animal is not certainly ascertained, but seems to be allied to the *nereis* tribe.

Madrepora fungites. Fig. 3. & 4.

Figs. 3. and 4. exhibit two views of the MADREPORA *fungites*, or *mushroom madrepore*. This body so exactly resembles a mushroom that it has very commonly been regarded as that vegetable in a state of petrifaction; but recent observations seem to prove that it is formed by small animals like *medusæ*. The convex side of this madrepore is conical, sometimes obtusely pointed, and exhibits on its surface those stellated pores which form the distinguishing character of the genus, while the concave surface is divided into numerous radiated furrows so as to represent the *gills* of a mushroom. When first obtained, it is of a delicate white colour, especially on the concave part, but it soon acquires a brown or yellowish tinge. It is found of various sizes, from an inch to six inches in diameter. It is met with chiefly in the Indian ocean and Red Sea.

Isis hippuris. Fig. 5. & 6.

At fig. 5. is represented that elegant coral called by Linnæus ISIS *hippuris*, the *black and white jointed coral* of Ellis. The specific character of this coral is that it is *composed of white striated joints united by black junctures;* but that structure is not visible till after the coral has been freed from a whitish soft spongy part, with which the branches are covered in their natural state. See fig. 6. It is found chiefly in the Indian seas, and varies in height from a few inches to nearly two feet.

Antipathes myriophylla Plate DLXXX. Fig. 7. & 8.

Fig. 7. represents the ANTIPATHES *myriophylla, yarrow antipathes*, or *sea-yarrow*, of its natural size; while fig. 8. shews one of the pinnæ considerably magnified.

This is one of those zoophytes which in their habit and appearance almost exactly resemble some of the vegetable tribes, and hence have received the names of *sea-heath*, *sea-cypress*, *sea-fennel*, &c. From their colour they are usually denominated *black coral.* This species, though one of the smallest, is not the least elegant of the tribe. It consists of numerous branches, composed of very slender pinnæ arranged in no certain order. The whole coral is seldom above a foot in height, and rough on its outer surface. This also is a native of the Indian ocean, being found more especially on the coasts of the Molucca islands, and is sometimes met with in the Great South sea.

Gorgonia nobilis. Fig. 9. & 10.

Fig. 9. exhibits a specimen of *red coral*, the ISIS *nobilis* of Linné, and GORGONIA *nobilis* of later naturalists. This substance, though now nearly exploded from the *materia medica*, will still retain a place in our cabinets for its intrinsic beauty and elegant appearance; but when examined on its native beds, or soon after being fished up, it shews a very different surface from that under which we usually see it. Fig. 9. represents it as prepared for sale by being deprived of its fleshy animal *bark* or coating, but retaining the striated appearance which marks its specific character; but fig. 10. exhibits a piece of it in its natural state, with polypes extruded from the fleshy coat, and shewing still more distinctly at the extremities the streaks below.

Zoophytes.

Red coral is found in large beds or reefs in several parts of the Mediterranean sea, and coral fisheries are established on the coasts and near the islands. A fishery of this kind in the straits of Messina is minutely described by Spallanzani in his *Travels in the two Sicilies*, vol. iv. To tear the coral from the rocks, they make use of a machine composed of two beams tied across each other, and furnished with a leaden weight to sink them, and a quantity of loose hemp and several strong nets to entangle the branches of the coral. To this machine is attached a strong rope, which is held by the fishers, and serves both to direct the net and to draw it up when the coral is entangled. Several boats go in company, each containing eight men, and the fishery lasts from April to July. The quantity collected every year amounts on an average to twelve Sicilian quintals, each equal to 250 pounds Troy, and each pound usually sells for about four shillings and sixpence. They do not fish on the same bank oftener than once in ten years, as this time is deemed necessary for the coral to acquire its full size and vigour.

Gorgonia ceratophyta. Fig. 11.

Another beautiful species of gorgonia, the GORGONIA *ceratophyta*, is figured at fig. 11. This is distinguished by its *dichotomous flattish stem, and ascending branches.* The outer flesh is of a purplish colour, and the branches are furnished with two rows of scattered pores from which the polypi appear. It is found in the Mediterranean, and sometimes on the eastern coasts of America.

Alcyonium gorgonoides. Fig. 12.

Nearly allied to the gorgoniæ is the species of alcyonium represented at fig. 12. This is the ALCYONIUM *gorgonoides* of Gmelin. It is of a cinereous colour, of a sandy fleshy consistence, having radiated warty cellules. It is found on the northern coast of South America, especially near the island of Curaçoa.

The zoophytes which naturalists distinguish by the generic name alcyonium, sometimes form independent bodies of a rounded form, such as those called the *sea-orange, sea-fig*, &c.; or cover the surface of shells and other marine bodies like a kind of bark. Their internal part or base is friable, and, when dried, appears to be composed of fine fibres, which are either longitudinal, as in the present case, diverging, or circular. This base is covered with a soft crust, that in drying assumes a leathery consistence, and is pierced with numerous little cells inhabited by polypi. In some species these cells are dispersed over the whole surface of the coral, while in others they are confined to particular spots or tubercles. They are all inhabitants of the ocean, where they are usually fixed to rocks or other solid bodies.

Spongia tubulosa. Plate DLXXXI. Fig. 13.

In the article HELMINTHOLOGY we have sufficiently treated of the nature and properties of the sponges, and have there mentioned particularly the common or *officinal* sponge. At fig. 13. is represented a more curious species, the SP. *tubulosa* or *fistularis*, the *tubular* or *pipey sponge*. This consists of simple upright, attenuated, rigid tubes, tuberculated on the outer surface, which is of a black colour. It is found in the seas that wash the coasts of America.

Flustra arenosa. Fig. 14.

The *flustræ* are a tribe of insignificant zoophytes, which seem scarcely entitled to the rank which they hold in the animal creation. They are formed of a congeries of superficial cells, placed close together, like those of a honeycomb, but generally occupying only a single surface. Sometimes this substance forms a coating to some other marine body, at others it is unattached and forms a floating foliaceous mass or *mat*. The species represented at fig. 14. is one of the most curious, and is described by Ellis under the name of *English sea-mat*, called in the *Linnæan Transactions*, vol. v. FLUSTRA *arenosa*. It is composed of sandy particles agglutinated together with slime, and in shape resembles the fore part of a horse's hoof. It is very friable, and so thin as to be easily broken. These *flustræ* are found abundantly on the coast of Kent, and about Holy-head on the Welsh coast.

Sertularia setacea. Fig. 15. & 16.

Fig. 15. represents a specimen of SERTULARIA *setacea*, the *small sea-bristle coralline* of Ellis, of its natural size; and fig. 16. shews the same specimen considerably magnified. This species is distinguished by being *simply pinnated, with bent alternate pinnæ, furnished with very remote processes growing only on one side, and oblong axillary ovaries.* It is one of the smallest and most delicate of the tribe, seldom exceeding an inch and a half in height. It is very common, and is found on the British coasts.

None of the zoophytes bear a nearer resemblance to vegetables than the *sertulariæ*. Their creeping roots, their branched stem, and tufts of seeming flowers (the polypine processes) give them all the air of plants. Hence they were long considered as *sea-mosses*, and described by botanists under that name. See Ray's *Synopsis*, p. 38. and 39. When attentively examined, however, their animal nature will scarcely be disputed. Externally they are composed of a horny substance, perfectly transparent, and through this may be distinguished the animal substance traversing the centre of the stem and branches like the pith of a plant, and appearing externally as little knots or protuberances in the form of tentaculated polypes. These extraneous polypes are considered by Cuvier (*Tableau Elementaire*, p. 768.) not as distinct animals, but only as parts of the same animal which constitutes the sole inhabitant of the sertularia. These zoophytes adhere to rocks, shells, &c. by creeping roots, and appear to propagate by means of eggs. They are among the most common of this class of animated beings.

Pennatula phosphorea. Fig. 17. & 18.

The PENNATULÆ, or *Sea-pens*, constitute a very curious tribe of zoophytes, which are completely locomotive, and swim in the manner of fishes. They consist of an internal bone or rather horny substance, covered with a sensible fleshy coat. Their lower extremity is simple like the barrel of a quill, while the upper extremity is expanded into a flattened part, that is generally composed of pinnæ like the barbs of a quill, though it is sometimes merely a simple expanded mass furnished with polypine processes.

Fig. 17. represents one of the most common *sea-pens* properly so called, the PENNATULA *phosphorea, phosphorescent pennatula*, of its natural size. It has *a fleshy stem, a rough middle part, and imbricated pinnules.* The pinnæ are furnished on one side with lesser *pinnulæ*, at the extremities of which appear the polypes. See fig. 18. which shews one of the separate pinnæ, a little magnified. This species is of a fine red or light scarlet colour, and when alive exhibits a strong phosphorescent light, so as to render distinctly visible objects that are near it. It is pretty common on the coasts of Britain, and is sometimes taken in the fishermen's nets, or adhering to the baits.

For figures of two other Linnæan zoophytes, see Plate CCLIII. TUBULARIA *magnifica*, and HYDRA *viridis*,

CCLIII. Several of Cuvier's zoophytes are represented in Plates XXXIV. CCLI. and CCLII. and some of the *Infusoria* in Plates XXXV. and XXXVI.

ZOOTOMY, the art of dissecting animals or living creatures, being the same with anatomy. See ANATOMY.

ZORILLE, a species of weasel which inhabits Peru, and other parts of South America; and is said to be remarkable for its fetid odour.

ZOROASTER, or ZERDUSHT, a celebrated ancient philosopher, said to have been the reformer or the founder of the religion of the magi. It is wholly uncertain to how many eminent men the name of Zoroaster belonged. Some have maintained that there was but one Zoroaster, and that he was a Persian; others have said that there were six eminent founders of philosophy of this name. Ham the son of Noah, Moses, Osiris, Mithras, and others, both gods and men, have by different writers been asserted to have been the same with Zoroaster. Many different opinions have also been advanced concerning the time in which he flourished. Aristotle and Pliny fix his date at so remote a period as 6000 years before the death of Plato. According to Laertius, he flourished 600 years before the Trojan war; according to Suidas, 500. If, in the midst of so much uncertainty, any thing can be advanced with the appearance of probability, it seems to be this; that there was a Zoroaster, a Perso-Median, who flourished about the time of Darius Hystaspes; and that besides him there was another Zoroaster, who lived in a much more remote period among the Babylonians, and taught them astronomy. The Greek and Arabian writers are agreed concerning the existence of the Persian Zoroaster; and the ancients unanimously ascribe to a philosopher, whom they call *Zoroaster*, the origin of the Chaldean astronomy, which is certainly of much earlier date than the time of Hystaspes: it seems, therefore, necessary to suppose a Chaldean Zoroaster distinct from the Persian. Concerning this Zoroaster, however, nothing more is known, than that he flourished towards the beginning of the Babylonish empire, and was the father of the Chaldean astrology and magic. All the writings that have been ascribed to Zoroaster are unquestionably spurious.

ZOSTERA, a genus of plants of the class gynandria, and in the natural system arranged under the second order, *Piperitæ*. See BOTANY *Index*.

ZOSIMUS, an ancient historian who lived at the end of the fourth and beginning of the fifth century. There are six books of his history extant; in the first of which he runs over the Roman affairs in a very succinct manner from Augustus to Dioclesian; the other five are written more diffusely. Zosimus was a zealous Pagan; whence we find him frequently inveighing with great bitterness against the Christian princes, particularly against Constantine the Great, and the elder Theodosius. His history has been published with the Latin version of Leunclavius at Frankfort, 1590, with the other minor historians of Rome, in folio; and at Oxford in 8vo, 1679.

ZUG, a canton of Switzerland, bounded on the east and north by that of Zurich, on the south by Schweitz and Lucern, and on the west by the canton of Lucern and the Freye-Amt or Free Provinces. It is not above 12 miles either way; but very populous and fruitful, yielding wine, wheat, chesnuts, and other fruits, in its vales, and excellent pasture on its mountains. The inhabitants of this canton are staunch Roman Catholics. It lies in the diocese of Constance, and its government is democratical. There are two lakes in it abounding in fish, particularly large carps, pikes, and a species of trouts called *rotels;* as well as several woods full of game. Zug, which gives name to it, and is its capital, stands on the east side of a lake of the same name, about seven miles long, and is a strong neat town, containing a priory and two convents.

ZUILA, a town in the territory of Fezzan, in Africa, which stands on a space of about a mile in circuit, but was formerly of much greater extent. The environs are level, well supplied with water, and fertile, planted with groves of date-trees, and the inhabitants pay much attention to agriculture. N. Lat. 27. 29. E. Long. 16. 39.

ZUINGLIUS, ULRICUS, an able and zealous reformer, who laid the foundation of a separation from Rome in Switzerland, at the same time that Luther did the like in Saxony, was born at Wildehausen in 1487. While he officiated as preacher at Zurich, a Franciscan sent by Leo X. came to publish indulgences there; against which Zuinglius, after the example of Luther, declaimed powerfully. In the course of this opposition he started a new doctrine, which he called *Evangelical Truth;* and from the beginning of 1519 to 1523, he preached not only against indulgences, but against other articles of the Romish church. But though Zuinglius made no less progress than Luther, he conducted himself with more moderation and prudence; and wishing to have the concurrence of the civil powers, procured two assemblies to be called at Zurich: by the first, he was authorised to proceed as he had begun; and by the second, the outward worship and ceremonies of the church of Rome were abolished. During these transactions, Zuinglius published several books in defence of his doctrines; but treating of the eucharist, and prescribing a form of celebrating the Lord's Supper different from Luther, he was involved in violent disputes with the rest of his reforming brethren. Respecting the divine DECREES, the opinion of Zuinglius and his followers differed very little from that of the PELAGIANS: and instead of declaring with Calvin, that the church is a separate independent body, vested with the right of legislation for itself, Zuinglius ascribed to the civil magistrate an absolute and unbounded power in religious matters, allowing at the same time a certain subordination among the ministers of the church. This was abundantly agreeable to the magistrates of Zurich; but the rest of the Swiss cantons disallowing of their proceedings, other assemblies were called, and things tending to tumult, both sides had recourse to arms; when Zuinglius, who began as a preacher, died in arms as a soldier, in 1531. His works are in four volumes folio.

ZURICH, a canton of Switzerland, bounded to the north by Swabia and the canton of Schaffhausen; to the south by the town and territory of Rapperschweil and the cantons of Switz and Zug; to the east by the Thurgau, Toggenburg, and Utznach; and to the west by the free bailiages and county of Baden. It is about 60 miles from north to south, and 48 from east to west. With respect to its face, air, and soil, it is said to be an epitome of all Switzerland, as containing in it hills, valleys,

valleys, plains, corn-lands, vineyards, lakes, and rivers. Their wines have a tartness at first, but the longer they are kept the more agreeable they are. The other products are excellent fruits, corn, pasture, fine clay, chalk, several coloured earths, pit-coal, turf, and sulphur. There are also some mineral springs in the canton, and some lakes; Zurich is the most considerable, it is 24 miles long, and two broad. The reformation was introduced here by Zuinglius in the year 1517. This canton is the first in rank, and inferior only to that of Bern in extent, power, and wealth; in consequence of which, its representatives preside in the general diets, when held in any place belonging in common to the cantons; and the affairs relating to the whole confederacy are transacted in its offices. Its quota, for the defence of the several members of the confederacy, is 1400 men. Of one of the two armies raised on these occasions, it nominates one of the commanders in chief, as Lucern does the other. Its revenue is said to be about 150,000 crowns a-year; of which, one year with another, two thirds are expended in the charges of government, and the rest laid up in the treasury. It can bring 50,000 fighting men into the field at a very short warning.

ZURICH, the capital of a canton of the same name in Switzerland, stands in a pleasant country, near where the river Aa issues from the lake that takes its name from the town, 23 miles from Schaffhausen, and 114 from Geneva. After having been ruined by Attila the Hun, it is said to have been restored by Thuricus, son of Theodoric king of the Goths, from whom it took the name of *Thuricum*, corrupted afterwards into that of *Zurich*. It is fortified in the modern way, and has wide ditches, faced with free-stone. There are five arsenals in it, well stored with arms and artillery; an academy or college, having 15 professors; a museum, or chamber of rarities; a stately town-house, the pillars in the front of which are of black marble, streaked with white; and a town library. The sovereignty and administration of all affairs are lodged in the greater and lesser council, out of which are chosen the city-officers, as the councils are out of the 13 companies of burghers. There are several other councils or colleges, each of which has its particular department. Here are a great variety of silk, woollen, linen, cotton, and other manufactures; this being the place of the greatest trade in all Switzerland. The town is well supplied with provisions by and from its lake. The streets are neat, and houses well built, but not magnificent. In the town-library are several letters to Bullinger from Lady Jane Gray, daughter to the duke of Suffolk. In one of the arsenals is the figure of William Tell, dressed and armed in the ancient Swiss manner, with the cross-bow whence he shot the arrow that struck the apple off his child's head.

Both men and women are so fond of music, that there are few of them that cannot play on some instrument. If a burgher goes out of town, or a peasant enters it, without a sword, they are liable to be fined. No persons, whatever their rank or office may be, are exempted from the sumptuary laws. The burgomasters, who are the same as the advoyers at Bern, have the title of excellence. The hospitals here are neat and well endowed. The environs are pleasant and fruitful; for which it is not a little indebted to the lake. That part of it which is next Zurich is called the *Lower Lake*, and the other end the *Upper*. The cathedral, or great church here, is collegiate. The present city is said to owe its origin to a nunnery, founded by the emperor Lewis I. near where the ancient Tigurum stood. E. Long. 8. 30. N. Lat. 47. 20.

ZUTPHEN, a strong and considerable town of the province of Guelderland, in the kingdom of the Netherlands, and capital of a county of the same name. It has a magnificent church, and is surrounded with walls. It was taken by the French in 1672, who in 1674 delivered it up to the States-General. It is seated at the confluence of the rivers Berkel and Yessel, nine miles south-east of Deventer, and 55 east by south of Amsterdam. E. Long. 6. 0. N. Lat. 52. 10.

ZUYDER-ZEE, a great gulf or bay of the German ocean, which extends from south to north in the United Provinces, between Friesland, Over-Yessel, Guelderland, and Holland. It is so called from its situation towards the south. It is said that the Zuyder-zee was formerly a lake, and that the land is swallowed up which united North-Holland with Friesland.

ZYGOMA, a bone of the head, or rather an union or assemblage of two processes or eminences of bones. See *Bones of the Head*, under ANATOMY.

ZYGOMATICUS, a muscle of the head, arising from the *Os* ZYGOMA, whence its name, and terminating at the angle of the lips.

ZYGOPHYLLUM, BEAN-CAPER, a genus of plants of the class of decandria, and in the natural system arranged under the 14th order, *Gruinales*. See BOTANY *Index*.

ZYMOSIMETER (formed from ζυμωσις, *fermentation*, and μετρον, *measure*), an instrument proposed by Swammerdam, in his book *De Respiratione*, with which to measure the degree of fermentation occasioned by the mixture of different matters, and the degree of heat which those matters acquire in fermenting; the same instrument is employed to ascertain the heat or temperament of the blood of animals.

FINIS.
